The software described in this document is furnished under a license agreement. The software may be used or copied only under the terms of the license agreement. No part of this manual may be photocopied or reproduced in any form without prior written consent from The MathWorks, Inc.

FEDERAL ACQUISITION: This provision applies to all acquisitions of the Program and Documentation by, for, or through the federal government of the United States. By accepting delivery of the Program or Documentation, the government hereby agrees that this software or documentation qualifies as commercial computer software or commercial computer software documentation as such terms are used or defined in FAR 12.212, DFARS Part 227.72, and DFARS 252.227-7014. Accordingly, the terms and conditions of this Agreement and only those rights specified in this Agreement, shall pertain to and govern the use, modification, reproduction, release, performance, display, and disclosure of the Program and Documentation by the federal government (or other entity acquiring for or through the federal government) and shall supersede any conflicting contractual terms or conditions. If this License fails to meet the government’s needs or is inconsistent in any respect with federal procurement law, the government agrees to return the Program and Documentation, unused, to The MathWorks, Inc.

Trademarks
MATLAB and Simulink are registered trademarks of The MathWorks, Inc. See www.mathworks.com/trademarks for a list of additional trademarks. Other product or brand names may be trademarks or registered trademarks of their respective holders.

Patents
MathWorks products are protected by one or more U.S. patents. Please see www.mathworks.com/patents for more information.

| New for Version 6.0 (Release 2011a)                  |
| Revised for Version 6.1 (Release 2011b)              |
| Revised for Version 6.2 (Release 2012a)              |
| Revised for Version 6.3 (Release 2012b)              |
| Revised for Version 6.4 (Release 2013a)              |
| Revised for Version 6.5 (Release 2013b)              |
| Revised for Version 6.6 (Release 2014a)              |
| Revised for Version 6.7 (Release 2014b)              |
| Revised for Version 6.8 (Release 2015a)              |
| Revised for Version 6.9 (Release 2015b)              |
| Rereleased for Version 6.8.1 (Release 2015aSP1)      |
| Revised for Version 6.10 (Release 2016a)             |
| Revised for Version 6.11 (Release 2016b)             |
| Revised for Version 6.12 (Release 2017a)             |
| Revised for Version 6.13 (Release 2017b)             |
| Revised for Version 7.0 (Release 2018a)              |
Check Bug Reports for Issues and Fixes

Software is inherently complex and is not free of errors. The output of a code generator might contain bugs, some of which are not detected by a compiler. MathWorks reports critical known bugs brought to its attention on its Bug Report system at www.mathworks.com/support/bugreports/. Use the Saved Searches and Watched Bugs tool with the search phrase "Incorrect Code Generation" to obtain a report of known bugs that produce code that might compile and execute, but still produce wrong answers.

The bug reports are an integral part of the documentation for each release. Examine periodically all bug reports for a release, as such reports may identify inconsistencies between the actual behavior of a release you are using and the behavior described in this documentation.

In addition to reviewing bug reports, you should implement a verification and validation strategy to identify potential bugs in your design, code, and tools.
Model Architecture and Design

Modeling Environment for Embedded Coder

Design Models for Generated Embedded Code

Deployment .................................................. 1-2
Application Algorithms and Run-Time Environments . . . 1-2
Software Execution Framework for Generated Code . . . 1-3
Map Embedded System Architecture to Simulink Modeling
Environment .................................................. 1-5
Model Templates for Code Generation .................... 1-14

Model Single-Core, Single-Tasking Platform
Execution ........................................................ 1-16

Model Single-Core, Multitasking Platform Execution . . 1-21

Model Concurrent Execution for Symmetric Multicore
CPU Platforms .................................................. 1-26

Model Explicit Function Invocation with Atomic
Subsystems ....................................................... 1-34

Model Explicit Function Invocation with Function-Call
Subsystems ....................................................... 1-39

Modeling Patterns for AUTOSAR Runnables .............. 1-44
Generate Code and Executables for Individual Subsystems ........................................... 3-4
   Subsystem Build Limitations ......................................................... 3-6

Inline Subsystem Code ................................................................. 3-8
   Configure Subsystem to Inline Code .............................................. 3-8
   Exceptions to Inlining ................................................................. 3-9

Generate Subsystem Code as Separate Function and Files ........................................... 3-11

Optimize Code for Identical Nested Subsystems ................................................. 3-12

Code Generation of Constant Parameters ......................................................... 3-13

Referenced Models in Simulink Coder

Code Generation of Referenced Models ......................................................... 4-2

Generate Code for Referenced Models ......................................................... 4-4
   About Generating Code for Referenced Models ................................. 4-4
   Create and Configure the Subsystem .............................................. 4-4
   Convert Model to Use Model Referencing ........................................ 4-7
   Generate Model Reference Code for a GRT Target ............................. 4-10
   Work with Code Generation Folders .............................................. 4-12

Configure Referenced Models ............................................................... 4-14

Build Model Reference Targets ............................................................. 4-15
   Reduce Change Checking Time ...................................................... 4-15

Simulink Coder Model Referencing Requirements ........................................... 4-16
   Configuration Parameter Requirements ........................................... 4-16
   Configuration Parameters Changed During Code Generation ............... 4-19
   Naming Requirements ................................................................. 4-20
   Custom Target Requirements ....................................................... 4-20
Contents

Storage Classes for Signals Used with Model Blocks  4-21
  Storage Classes for Parameters Used with Model Blocks  4-21
  Signal Name Mismatches Across Model Reference Boundary  4-22

Inherited Sample Time for Referenced Models  4-25

Customize Library File Suffix and File Type  4-27

Simulink Coder Model Referencing Limitations  4-28
  Customization Limitations  4-28
  Data Logging Limitations  4-28
  State Initialization Limitation  4-29
  Reusability Limitations  4-29
  S-Function Limitations  4-30
  Simulink Tool Limitations  4-30
  Subsystem Limitations  4-30
  Target Limitations  4-30
  Other Limitations  4-31
  Configuration Parameters Changed During Accelerated Simulation and Code Generation  4-31

Combined Models in Simulink Coder

5

Combine Code Generated for Multiple Models  5-2
  Techniques  5-2
  Control Ownership of Data  5-3
  Combine Code Generated for Multiple Models or Multiple Instances of a Model  5-3

Code Reuse for Simulink Coder

6

What Is Code Reuse?  6-2
What Is Reentrant Code? ........................................... 6-4

Choose a Componentization Technique for Code Reuse .......................... 6-6

Simulink Function Blocks and Code Generation ........................ 6-8
Why Generate Code from Simulink Function Blocks and Function Callers? .......... 6-8
Implementation Options ........................................... 6-8
Choose a Modeling Pattern ........................................... 6-9
Specify Function Scope ........................................... 6-11
Decide Whether to Generate Export Function Code ........................ 6-11
Specify Function Code Interface Customizations ........................ 6-11
Requirements ........................................... 6-12
Limitations ........................................... 6-12
Generate and Call Reusable Function Code ................................ 6-13
Generate Code for a Simulink Function and Function Caller .......................... 6-20

Generate Reentrant Code from Top Models ........................... 6-24
Generate Reentrant, Multi-Instance Code ................................ 6-25
Share Data Between Instances ...................................... 6-28

Generate Reentrant Code from Simulink Function Blocks ......................... 6-30
Identify Requirements ........................................... 6-30
Create Model ........................................... 6-31
Configure Model and Model Elements ................................ 6-33
Generate and Inspect C Code ...................................... 6-35
Generate and Inspect C++ Code ...................................... 6-37
Limitations ........................................... 6-41

Generate Reentrant Code from Subsystems ................................ 6-42
Limitations ........................................... 6-43
Determine Why Subsystem Code Is Not Reused ........................ 6-45

Generate Reusable Code From Referenced Models .......................... 6-50
Considerations for Subsystems that Contain Referenced Models .................. 6-50
Code Reuse and Model Blocks with Root Inport or Outport Blocks ............... 6-50
Generate Reusable Code from Library Subsystems Shared Across Models .................................................. 6-53
  What Is a Reusable Library Subsystem? ................................. 6-53
  Reusable Library Subsystem Code Placement and Naming .................. 6-54
  Configure Reusable Library Subsystem ................................ 6-54
  Configure Models That Include Reusable Library Subsystems .......... 6-55
  Generate Reusable Code for Subsystems Shared Across Models ........ 6-55

Generate Reusable Code from Stateflow Atomic Subcharts .......................... 6-64
  Generate Reusable Code for Linked Atomic Subcharts ................. 6-64
  Generate Reusable Code for Unlinked Atomic Subcharts ................ 6-65
  Generate Reusable Code for Unit Testing ............................. 6-65

Generate Shared Utility Code .................................................. 6-70
  When to Generate Shared Utility Code ................................... 6-70
  Configure Naming of Generated Functions .............................. 6-70
  Control Placement of Shared Utility Code ............................... 6-71
  Control Placement of rtwtypes.h for Shared Utility Code ............... 6-72
  Avoid Duplicate Header Files for Exported Data ....................... 6-73
  Reduce Shared Utility Code Generation with Incremental Builds .......... 6-73
  Manage the Shared Utility Code Checksum ............................. 6-74

Generate Shared Utility Code for Fixed-Point Functions ......................... 6-80

Generate Shared Utility Code for Custom Data Types .......................... 6-82

Shared Constant Parameters for Code Reuse ............................... 6-84
  Suppress Shared Constants in the Generated Code ...................... 6-85
Save Base Workspace Definitions ......................... 8-24

Package a Protected Model ................................. 8-25

Specify Custom Obfuscator for Protected Model .......... 8-26

Define Callbacks for Protected Models .................. 8-28
  Creating Callbacks ...................................... 8-28
  Defining Callback Code .................................. 8-28
  Create a Protected Model with Callbacks ............... 8-29

Component Initialization, Reset, and Termination in Simulink Coder

9

Generate Code That Responds to Initialize, Reset, and Terminate Events ........................................... 9-2
  Generate Code for Initialize and Terminate Events ...... 9-2
  Generate Code for Reset Events .......................... 9-7
  Event Names and Code Aggregation ....................... 9-9
  Limitation ................................................ 9-12

Stateflow Blocks in Simulink Coder

10

Code Generation of Stateflow Blocks ...................... 10-2
  Comparison of Code Generation Methods ................ 10-2

Generate Reusable Code for Atomic Subcharts ............ 10-6
  How to Generate Reusable Code for Linked Atomic Subcharts .................................................. 10-6
  How to Generate Reusable Code for Unlinked Atomic Subcharts ................................................. 10-7

Generate Reusable Code for Unit Testing .................. 10-8
  Goal of the Tutorial ..................................... 10-8
  Convert a State to an Atomic Subchart .................. 10-9
Specify Code Generation Parameters .................. 10-10
Generate Code for Only the Atomic Subchart ........... 10-11

**Inline State Functions in Generated Code** ........... 10-14
  Inlined Generated Code for State Functions ........... 10-14
  How to Set the State Function Inline Option ........... 10-16
  Best Practices for Controlling State Function Inlining ........................................... 10-16

**Air-Fuel Ratio Control System with Stateflow Charts** ........... 10-17

---

**Block Authoring and Code Generation for Simulink Coder**

11

**S-Functions and Code Generation** ...................... 11-2
  Types of S-Functions ........................................ 11-3
  Files Required for Implementing Noninlined and Inlined S-Functions ........................................ 11-5
  Guidelines for Writing S-Functions that Support Code Generation ........................................ 11-6

**Import Calls to External Code into Generated Code with Legacy Code Tool** ...................... 11-7
  Legacy Code Tool and Code Generation ................. 11-7
  Generate Inlined S-Function Files for Code Generation ........................................ 11-8
  Apply Code Style Settings to Legacy Functions .... 11-9
  Address Dependencies on Files in Different Locations ........................................ 11-9
  Deploy S-Functions for Simulation and Code Generation ........................................ 11-10
  Integrate External C++ Object Methods ................ 11-11
  Integrate External C++ Objects ......................... 11-14
  Legacy Code Tool Examples ................................ 11-16

**External Code Integration Examples** ...................... 11-51
  Insert External C and C++ Code Into Stateflow Charts for Code Generation .......................... 11-51
IEC 61508 Standard ........................................ 12-9
   Apply Simulink and Embedded Coder to the IEC 61508 Standard .................................. 12-9
   Check for IEC 61508 Standard Compliance Using the Model Advisor .................................. 12-9
   Validate Traceability .................................. 12-9

Develop a Model that Complies with the IEC 61508 Standard ........................................... 12-11

IEC 62304 Standard ........................................ 12-14
   Apply Simulink and Embedded Coder to the IEC 62304 Standard ...................................... 12-14
   Check for IEC 62304 Standard Compliance Using the Model Advisor .................................. 12-14

ISO 26262 Standard ........................................ 12-15
   Apply Simulink and Embedded Coder to the ISO 26262 Standard ....................................... 12-15
   Check for ISO 26262 Standard Compliance Using the Model Advisor .................................. 12-15
   Validate Traceability .................................. 12-15

EN 50128 Standard ........................................... 12-17
   Apply Simulink and Embedded Coder to the EN 50128 Standard ........................................ 12-17
   Check for EN 50128 Standard Compliance Using the Model Advisor .................................. 12-17
   Validate Traceability .................................. 12-17

DO-178C Standard ............................................ 12-19
   Apply Simulink and Embedded Coder to the DO-178C Standard .......................................... 12-19
   Check for Standard Compliance Using the Model Advisor .................................................. 12-19
   Validate Traceability .................................. 12-19

  asynclib.tlc Support Library .......................... 18-56

Import Asynchronous Event Data for Simulation .......... 18-59
  Capabilities .......................................... 18-59
  Input Data Format ..................................... 18-59
  Example ............................................... 18-59

Asynchronous Support Limitations ......................... 18-63
  Asynchronous Task Priority ........................... 18-63
  Convert an Asynchronous Subsystem into a Model
    Reference ............................................ 18-63
Scheduling Considerations in Embedded Coder

Use Discrete and Continuous Time ........................................ 19-2
Support for Discrete and Continuous Time Blocks .............. 19-2
Support for Continuous Solvers ................................. 19-2
Support for Stop Time ........................................ 19-2

Optimize Multirate Multitasking Execution for RTOS Run-
Time Environments .......................................................... 19-4
Use rtmStepTask ......................................................... 19-4
Schedule Code for Real-time Model without an
RTOS ........................................................................ 19-4
Schedule Code for Multirate Multitasking on an
RTOS ........................................................................ 19-5
Suppress Redundant Scheduling Calls ......................... 19-5

Representing a Software Architecture by Creating
Code Generation Definitions

Define Storage Classes, Memory Sections, and Function
Templates for Software Architecture ............................... 20-2
Create Code Definitions for Use as Default Code
Generation Settings ..................................................... 20-2
Create Code Definitions to Override Default Settings .... 20-3
Avoid Maintaining Duplicate Definitions in Packages and
Dictionaries ................................................................. 20-3
Deploy Code Generation Definitions to Users .............. 20-3
Maintain Code Generation Definitions ......................... 20-4
Interact with Code Generation Definitions
Programmatically .......................................................... 20-5

Deploy Code Generation Definitions ............................ 20-6
Share Code Generation Definitions Between Multiple
Models and Users .......................................................... 20-6
Share Embedded Coder Dictionary Definition
Between Models ............................................................ 20-6
Migrate Definitions from Model File to Shared Data Dictionary ....................... 20-9
Definitions in Shared Dictionary Do Not Appear in Code Mapping Editor .............. 20-12
Make Shared Definitions in a Data Dictionary Available to New Models .................. 20-12
Use Data Dictionary to Store Code Definitions but Not Design Data .................... 20-13
Opening Code Perspective Generates Error .................................................. 20-13
Limitations for Definitions in a Simulink Data Dictionary .................................. 20-13

Conform to Software Architecture by Sharing and Copying Default Code Generation Settings Between Models ................................................................. 20-15
Tools to Copy and Share Settings ................................................................. 20-16
Techniques to Copy Settings ...................................................................... 20-18
Techniques to Share Settings ...................................................................... 20-19

Migrate Memory Section and Shared Utility Settings from Configuration Parameters to Code Mapping Editor ............................................................... 20-21
Effects of Migration ..................................................................................... 20-21
Considerations Before Migrating ............................................................... 20-22
Considerations After Migrating .................................................................... 20-23

Data, Function, and File Definition

Configuring Data and Functions in the Generated Code

Environment for Configuring Model Data and Functions for Code Generation ........... 21-2
Software Engineer: Configure Default Settings .............................................. 21-4
Software Engineer: Override Default Settings .............................................. 21-4
System Architect: Create Code Generation Definitions ...................................... 21-5
Configure Default Code Generation for Categories of Model Data and Functions ...................... 21-7
  Configure Default Data and Function Configurations in Model Editing Environment ............. 21-7
  Configure Default Code Generation for Data . . . . 21-8
  Configure Default Code Generation for Functions . . . 21-15
  Configure Default Data and Function Code Generation with Definitions Stored in Shared Data Dictionary . . . . 21-20
  Configure Default Data and Function Code Generation Programmatically .......................... 21-22
  Unresolved Storage Classes, Function Customization Templates, and Memory Sections ........ 21-31
  Elimination of Parameters and Other Internal Data by Optimizations ................................. 21-32
  Limitations ................................ 21-33

Data Representation in Simulink Coder

Configure Data Accessibility for Rapid Prototyping . . . 22-3
  Access Signal, State, and Parameter Data During Execution ............................................. 22-3
  Configure Data Accessibility ................................................................. 22-4
  Limitations ................................................................. 22-5

Access Signal, State, and Parameter Data During Execution .............................................. 22-7

Standard Data Structures in the Generated Code . . . 22-26
  Control Characteristics of Data Structures (Embedded Coder) ........................................ 22-27

Use the Real-Time Model Data Structure .................. 22-29

How Generated Code Exchanges Data with an Environment .................................................. 22-33
  Data Interfaces in the Generated Code .................................................. 22-33
  Configure Data Interface .................................................. 22-41
## Control Data and Function Interface in Generated Code

- Control Type Names, Field Names, and Variable Names of Standard I/O Structures (Embedded Coder) ........................................ 22-42
- Control Names of Generated Entry-Point Functions (Embedded Coder) .......................................................... 22-42
- Control Data Interface for Nonreentrant Code ....................... 22-43
- Control Data Interface for Reentrant Code ............................ 22-46
- Prevent Unintended Changes to the Interface ....................... 22-46
- Reduce Number of Arguments by Using Structures ................. 22-47
- Control Data Types of Arguments .................................... 22-48
- Promote Data Item to the Interface .................................... 22-48

## How Generated Code Stores Internal Signal, State, and Parameter Data

- Internal Data in the Generated Code ..................................... 22-51
- Local Variables in the Generated Code ................................ 22-61
- Appearance of Test Points in the Generated Code ................. 22-61
- Appearance of Workspace Variables in the Generated Code ........ 22-62
- Promote Internal Data to the Interface ............................... 22-63
- Control Default Representation of Internal Data (Embedded Coder) ........................................................ 22-65

## Choose a Storage Class for Controlling Data Representation in the Generated Code

- Specify File Names and Other Data Attributes With Storage Class (Embedded Coder) ............................................ 22-76
- Specify Default #include Syntax for Header Files That Declare Data (Embedded Coder) ........................................ 22-77
- Storage Class Limitations ................................................. 22-77

## Use Storage Classes in Reentrant, Multi-Instance Models and Components

- Directly Applied Storage Classes ..................................... 22-79
- Storage Classes Applied by Default ................................... 22-79

## Apply Storage Classes to Individual Signal, State, and Parameter Data Elements

- Apply Storage Classes to Data Items .................................. 22-81
- Built-In Storage Classes You Can Choose ............................ 22-85
- Decide Where to Store Storage Class Specification ............... 22-86
- Techniques to Apply Storage Classes Interactively ............... 22-87
Techniques to Apply Storage Classes
  programmatically ......................... 22-87
Parameter Object Configuration Quick
  Reference Diagram .......................... 22-89

Use Enumerated Data in Generated Code .............. 22-90
  Enumerated Data Types .................... 22-90
  Specify Integer Data Type for Enumeration ....... 22-90
  Customize Enumerated Data Type ............. 22-92
  Control Enumerated Type Implementation in Generated Code .................................. 22-96
  Type Casting for Enumerations ............... 22-98
  Enumerated Type Limitations ................ 22-99

Data Stores in Generated Code ..................... 22-100
  About Data Stores .......................... 22-100
  Generate Code for Data Store Memory Blocks ... 22-100
  Storage Classes for Data Store Memory Blocks .. 22-101
  Data Store Buffering in Generated Code ........ 22-103
  Data Stores Shared by Instances of a Reusable Model ........................................ 22-106
  Structures in Generated Code Using Data Stores ... 22-107

Specify Single-Precision Data Type for Embedded Application ........................................ 22-111
  Use single Data Type as Default for Underspecified Types .................................... 22-111

Tune Phase Parameter of Sine Wave Block During Code Execution ........................................ 22-115

Switch Between Output Waveforms During Code Execution for Waveform Generator Block .......... 22-117

Create Tunable Calibration Parameter in the Generated Code ............................................ 22-121
  Represent Block Parameter as Tunable Global Variable ........................................... 22-121
  Apply Storage Class When Block Parameter Refers to Numeric MATLAB Variable ............... 22-124
  Create Storage Class That Represents Calibration Parameters (Embedded Coder) ............... 22-125
Initialize Parameter Value From System Constant or Other Macro (Embedded Coder) ................... 22-129
Code Generation Impact of Storage Location for Parameter Objects ....................................... 22-130
Configure Accessibility of Signal Data ......................... 22-131
Programmatic Interfaces for Tuning Parameters ............ 22-131
Set Tunable Parameter Minimum and Maximum Values ...................................................... 22-132
Considerations for Other Modeling Goals .................. 22-132

Limitations for Block Parameter Tunability in the Generated Code ........................................ 22-135
  Tunable Expression Limitations ...................... 22-135
  Linear Block Parameter Tunability ................... 22-137
  Parameter Structures ..................................... 22-137

Code Generation of Parameter Objects With Expression Values ............................................. 22-139
  Considerations and Limitations ......................... 22-139
  Expression Preservation .................................. 22-140

Specify Instance-Specific Parameter Values for Reusable Referenced Model .............................. 22-142
  Pass Parameter Data to Referenced Model Entry-Point Functions as Arguments ..................... 22-142
  Control Data Types of Model Arguments and Argument Values ........................................... 22-153

Parameter Data Types in the Generated Code .............. 22-156
  Significance of Parameter Data Types .................. 22-156
  Typecasts Due to Parameter Data Type Mismatches ...................................................... 22-157
  Considerations for Other Modeling Patterns ........... 22-158

Generate Efficient Code by Specifying Data Types for Block Parameters .................................. 22-162
  Eliminate Unnecessary Typecasts and Shifts by Matching Data Types ................................... 22-162
  Reduce Memory Consumption by Storing Parameter Value in Small Data Type ............................ 22-166

Reuse Parameter Data in Different Data Type Contexts ...................................................... 22-173
Organize Data into Structures in Generated Code ........................................ 22-177
  Techniques to Create Structures ..................................................... 22-181
  Default Application of Structured Storage Class ............................... 22-182
  Direct Application of Structured Storage Class .................................. 22-183
  Nonvirtual Buses and Parameter Structures ....................................... 22-183
  Combine Techniques to Work Around Limitations ................................ 22-194
  Arrays of Structures ....................................................................... 22-194
  Structure Padding ........................................................................... 22-194
  Limitations ...................................................................................... 22-194

Switch Between Sets of Parameter Values During Simulation and Code Execution ..... 22-196

Design Data Interface by Configuring Inport and Outport Blocks ...................... 22-206

Generate Efficient Code for Bus Signals ................................................. 22-212
  Code Efficiency for Bus Signals ...................................................... 22-212
  Set Bus Diagnostics ....................................................................... 22-213
  Optimize Virtual and Nonvirtual Buses ............................................. 22-213

Control Signal and State Initialization in the Generated Code ....................... 22-216
  Signal and State Initialization in the Generated Code ......................... 22-216
  Generate Tunable Initial Conditions .................................................. 22-218
  Generate Tunable Initial Condition Structure for Bus Signal ................ 22-221

Initialization of Signal, State, and Parameter Data in the Generated Code .......... 22-228
  Static Initialization and Dynamic Initialization ................................. 22-228
  Real-World Ground Initialization Requiring Nonzero Bit Pattern ............. 22-229
  Initialization of Signal and State Data .............................................. 22-229
  Initialization of Parameter Data ..................................................... 22-231
  Data Initialization in the Generated Code ....................................... 22-232
  Modeling Goals .............................................................................. 22-237

Optimize Speed and Size of Signal Processing Algorithm by Using Fixed-Point Data ................................................................. 22-239
Optimize Generated Code Using Fixed-Point Data with Simulink®, Stateflow®, and MATLAB® ............................. 22-241

Declare Workspace Variables as Tunable Parameters Using the Model Parameter Configuration Dialog Box ................ 22-243
- Declare Existing Workspace Variables as Tunable Parameters .......................................................... 22-243
- Declare New Tunable Parameters .......................................................... 22-244
- Set Tunable Parameter Code Generation Options .............................................................................. 22-244
- Programmatically Declare Workspace Variables as Tunable Parameters ........................................ 22-245

Share Data Between Code Generated from Simulink, Stateflow, and MATLAB .............................................. 22-247

Data Definition and Declaration Management in Embedded Coder

Control Placement of Global Data Definitions and Declarations in Generated Files .............................. 23-2
- Organize Data to Support Component-Based, Team-Oriented Model Development ............................. 23-9
- Specify Default Placement .................................................................................................................... 23-11
- Override Default Placement for Individual Data Items ........................................................................ 23-12
- Prevent Name Clashes by Configuring Data Item as static .................................................................. 23-12
- Code Generation Impact of Storage Location for Parameter Objects .................................................. 23-13
- Specify Default #include Syntax for Data Header Files ..................................................................... 23-13

Establish Data Ownership in a System of Components ............................................................................. 23-15
## Data Types in Embedded Coder

### Control Data Type Names in Generated Code
- Control Names of Primitive Data Types .................. 24-2
- Control Names of Structure Types ......................... 24-11
- Generate Code That Reuses Data Types From External Code ......................................................... 24-11
- Create Data Type Alias in the Generated Code ........... 24-12
- Create a Named Fixed-Point Data Type in the Generated Code ......................................................... 24-17
- Rename Data Type Object .................................. 24-21
- Display Signal Data Types on Block Diagram ................. 24-21
- Limitations .................................................. 24-21

### Control File Placement of Custom Data Types .......... 24-23
- Data Scope and Header File ................................ 24-23
- Macro Guards ............................................... 24-25

### Replace and Rename Data Types to Conform to Coding Standards ............................................ 24-27
- Inspect External C Code .................................... 24-27
- Explore Example Model and Default Generated Code ................................................................. 24-27
- Reuse External Data Type Definitions ....................... 24-27
- Create Meaningful Data Type Aliases for Individual Data Items .................................................... 24-28
- Create Single Point of Definition for Primitive Types .... 24-29
- Permanently Store Data Type Objects ....................... 24-31
- Create and Maintain Objects Corresponding to Multiple C typedef Statements ................................ 24-32

### Exchange Structured and Enumerated Data Between Generated and External Code ...................... 24-34
- Inspect External Code ...................................... 24-34
- Create Simulink Model ...................................... 24-36
- Configure Generated Code to Write Output Data to Existing Structure Variable ................................ 24-38
- Configure Generated Code to Define Parameter Data ................................................................. 24-39
- Generate, Compile, and Inspect Code ...................... 24-40
- Replace Data Type Names Throughout Model .............. 24-41
Specify Boolean and Data Type Limit Identifiers .... 24-42
  Data Type Limit Identifiers .......................... 24-42
  Boolean Identifiers .................................... 24-43
  Boolean and Data Type Limit Identifier Header Files 24-43

Module Packaging Tool (MPT) Data Objects in Embedded Coder

25

MPT Data Object Properties .................................. 25-2
  Specify Persistence Level for Signals and Parameters ................................ 25-16
  Register mpt User Object Types ................. 25-19

Custom Storage Classes in Embedded Coder

26

Reuse Parameter Data from External Code in the Generated Code .......... 26-2

Import Parameter Data with Conditionally Compiled Dimension Length ............. 26-7

Access Structured Data Through a Pointer That External Code Defines ............. 26-12

Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements .................................................. 26-19
  Built-In Custom Storage Classes .............. 26-19
  Create Your Own Custom Storage Class ........ 26-19
  Techniques to Apply Custom Storage Classes
    Interactively ............................................ 26-19
  Techniques to Apply Custom Storage Classes
    Programmatically ...................................... 26-21
  Organize Parameter Data into a Structure by Using the Struct Custom Storage Class ................. 26-23
  Custom Storage Class Limitations ............... 26-25

  XCP External Mode Limitations ...................................................................................... 44-17

Customize XCP Slave Software .......................................................................................... 44-22
  External Mode Abstraction Layer .................................................................................... 44-23
  XCP Slave Protocol Layer ............................................................................................... 44-27
  XCP Slave Transport Layer ............................................................................................. 44-27
  XCP Platform Abstraction Layer ...................................................................................... 44-27

External Mode Simulation with TCP/IP or Serial Communication .................................... 44-36
  Create and Configure Model .......................................................................................... 44-36
  Build Target Executable ................................................................................................. 44-38
  Run Target Program ....................................................................................................... 44-40
  Tune Parameters ............................................................................................................ 44-44
  Control Memory Allocation for Communication Buffers in Target ............................... 44-46
  Pure Integer Code with External Mode .......................................................................... 44-46
  Control External Mode Simulation Through Editor Toolbar ........................................ 44-47
  Control External Mode Simulation Through External Mode Control Panel ................ 44-48
  Configure Host Monitoring of Target Program Signal Data .......................................... 44-52
Configure Host Archiving of Target Program
Signal Data ........................................ 44-60
Blocks and Subsystems Compatible with External Mode ............................................... 44-63
External Mode Mechanism for Downloading Tunable Parameters ..................................... 44-66
Choose Communication Protocol for Client and Server ................................................. 44-69
Use External Mode Programmatically ................................................................. 44-77
Animate Stateflow Charts in External Mode .............................................................. 44-84
TCP/IP and Serial External Mode Limitations .............................................................. 44-85
Create a Transport Layer for TCP/IP or Serial External Mode Communication .................. 44-90
Design of External Mode .................................................................................. 44-90
External Mode Communications Overview .................................................................. 44-93
External Mode Source Files .................................................................................. 44-94
Implement a Custom Transport Layer ..................................................................... 44-98

Logging in Simulink Coder

Log Program Execution Results ................................................................. 45-2
Log Data for Analysis .................................................................................. 45-2
Configure State, Time, and Output Logging ...................................................... 45-9
Log Data with Scope and To Workspace Blocks .................................................. 45-11
Log Data with To File Blocks ........................................................................ 45-11
Data Logging Differences Between Single- and Multitasking .................................. 45-12

Data Interchange Using the C API in Simulink Coder

Exchange Data Between Generated and External Code Using C API .......................... 46-2
Generated C API Files .................................................................................. 46-2
Generate C API Files ........................................ 46-3
Description of C API Files ............................ 46-5
Generate C API Data Definition File for Exchanging Data with a Target System ................................. 46-20
C API Limitations ........................................ 46-22

Use C API to Access Model Signals and States ........... 46-24
Use C API to Access Model Parameters .................... 46-30

**ASAP2 Data Measurement and Calibration in Simulink Coder**

47

Export ASAP2 File for Data Measurement and Calibration ........................................ 47-2
What You Should Know .................................. 47-3
Targets Supporting ASAP2 ................................ 47-3
Define ASAP2 Information ............................... 47-3
Generate an ASAP2 File ................................... 47-9
Structure of the ASAP2 File .............................. 47-12
Create a Host-Based ASAM-ASAP2 Data Definition File for Data Measurement and Calibration .............. 47-13

**Direct Memory Access to Generated Code for Simulink Coder**

48

Access Memory in Generated Code Using Global Data Map ...................................................... 48-2
Accelerate, Refine, and Test Hybrid Dynamic System on Host Computer by Using RSim System Target File . . . 49-2
  About Rapid Simulation ........................................ 49-2
  Rapid Simulation Advantage .................................... 49-2
  General Rapid Simulation Workflow .......................... 49-3
  Identify Rapid Simulation Requirements .................... 49-4
  Configure Imports to Provide Simulation Source Data ........................................ 49-6
  Configure and Build Model for Rapid Simulation ........ 49-6
  Set Up Rapid Simulation Input Data ......................... 49-8
  Scripts for Batch and Monte Carlo Simulations .......... 49-19
  Run Rapid Simulations ......................................... 49-19
  Tune Rapid Simulations Interactively During Rapid
    Simulation ...................................................... 49-30
  Rapid Simulation Target Limitations ....................... 49-33

Run Rapid Simulations Over Range of Parameter Values ........................................ 49-35

Run Batch Simulations Without Recompiling Generated Code ...................................... 49-43

Use MAT-Files to Feed Data to Inport Blocks for Rapid Simulations ................................ 49-51

Accelerate Simulation, Reuse Code, or Protect Intellectual Property by Using S-Function Target ..................................................... 49-59
  About the S-Function Target .................................... 49-59
  Create S-Function Blocks from a Subsystem ............... 49-63
  Tunable Parameters in Generated S-Functions ............. 49-67
  System Target File ............................................. 49-68
  Checksums and the S-Function Target ....................... 49-68
  Generated S-Function Compatibility ....................... 49-69
  S-Function Target Limitations ............................... 49-70
Generate Code That Dereferences Data from a Literal Memory Address ........................................... 52-21

**Deploy Generated Component Software to Application**

**Target Platforms** ................................................................. 52-31
Interface to an Example Real-Time Operating System (VxWorks®) ......................................................... 52-31
Multirate Modeling in Multitasking Mode (VxWorks® OS) ....................................................................... 52-33

**Export Code Generated from Model to External Application in Embedded Coder**

53

Control Generation of Function Interfaces .................. 53-2
Control Generation of C++ Class Interfaces .................. 53-4

**Code Replacement Customization for Simulink Models in Embedded Coder**

54

**What Is Code Replacement Customization?** ................. 54-3
Code Replacement Match and Replacement Process ........ 54-3
Code Replacement Customization Limitations ............... 54-4

**Code You Can Replace From Simulink Models** ............... 54-7
Math Functions – Simulink Support ......................... 54-7
Math Functions – Stateflow Support ......................... 54-14
Memory Functions ..................................................... 54-19
Nonfinite Functions .................................................. 54-20
Mutex and Semaphore Functions ......................... 54-20
Operators ............................................................ 54-21

**Develop a Code Replacement Library** ....................... 54-27
Quick Start Code Replacement Library Development - Simulink® .................................. 54-28

Identify Code Replacement Requirements ............ 54-39
  Mapping Information Requirements .................. 54-39
  Build Information Requirements ..................... 54-40
  Registration Information Requirements .............. 54-40

Prepare for Code Replacement Library Development ........................................... 54-42

Define Code Replacement Mappings .................. 54-43
  Choose an Approach for Defining Code Replacement Mappings ................................ 54-43
  Define Mappings Interactively with the Code Replacement Tool ............................... 54-44
  Define Mappings Programmatically .................... 54-47

Specify Build Information for Replacement Code ..... 54-61
  Build Information ...................................... 54-61
  Choose an Approach for Specifying Build Information ............................................. 54-61
  Specify Build Information Interactively with the Code Replacement Tool .................... 54-62
  Specify Build Information Programmatically ........ 54-64

Register Code Replacement Mappings ................. 54-70
  Choose an Approach for Creating the Registration File ........................................... 54-70
  Create Registration File Interactively with the Code Replacement Tool ....................... 54-71
  Create Registration File Programmatically ........ 54-73
  Register a Code Replacement Library ............... 54-75
  Register a Library that Includes Multiple Code Replacement Tables ......................... 54-76
  Registration Files That Define Code Replacement Library Hierarchies ......................... 54-76

Troubleshoot Code Replacement Library Registration .......................................... 54-78

Verify Code Replacements ............................... 54-79
  Code Replacement Hits and Misses ..................... 54-79
  Validate Table Definition File ........................ 54-80
Programmatic External Function Call Replacement Specification ........................................... 54-150

Replace MATLAB Functions Specified in MATLAB Function Blocks .................................... 54-153

Reserved Identifiers and Code Replacement ................................................................. 54-157

Performance

Optimizations for Generated Code in Simulink Coder

Increase Code Generation Speed .................................. 56-3
  Build a Model in Increments .................................. 56-3
  Build Large Model Reference Hierarchies in Parallel .... 56-3
  Minimize Memory Requirements During Code Generation .................................. 56-4
  Generate Only Code .............................................. 56-5
  No Creation of a Code Generation Report ..................... 56-5

Control Compiler Optimizations ................................. 56-6

Optimization Tools and Techniques .............................. 56-7
  Use the Model Advisor to Optimize a Model for Code Generation .................................. 56-7
  Design Tips for Optimizing Generated Code for Stateflow Objects .................................. 56-7
  Additional Optimization Techniques ............................ 56-8

Control Memory Allocation for Time Counters ............... 56-11

Execution Profiling for Generated Code ....................... 56-12
Optimize Generated Code by Combining Multiple for Constructs .................................. 56-15

Subnormal Number Performance .......................... 56-19
Simulation Time With and Without Subnormal Numbers ........................................ 56-20
Flush Subnormal Numbers to Zero .......................... 56-21

Remove Code From Floating-Point to Integer Conversions
That Wraps Out-of-Range Values .......................... 56-24
Example Model ............................................ 56-24
Generate Code Without Optimization .................. 56-25
Generate Code with Optimization ...................... 56-26

Remove Code That Maps NaN to Integer Zero ........ 56-27
Example Model ............................................ 56-27
Generate Code ............................................ 56-28
Generate Code with Optimization ...................... 56-29

Disable Nonfinite Checks or Inlining for Math Functions ........................................ 56-31

Minimize Computations and Storage for Intermediate Results at Block Outputs .................. 56-37
Expression Folding ...................................... 56-37
Example Model ............................................ 56-37
Generate Code ............................................ 56-38
Enable Optimization .................................... 56-38
Generate Code with Optimization ...................... 56-39

Inline Invariant Signals .................................. 56-40
Optimize Generated Code Using Inline Invariant Signals ........................................ 56-40

Inline Numeric Values of Block Parameters .......... 56-44

Configure Loop Unrolling Threshold ................. 56-50

Use memcpy Function to Optimize Generated Code for Vector Assignments ................. 56-53
Example Model ............................................ 56-54
Generate Code ............................................ 56-55
Generate Code with Optimization ...................... 56-55
Generate Target Optimizations Within Algorithm Code .......................... 56-57

Remove Code for Blocks That Have No Effect on Computational Results .................................. 56-59

Eliminate Dead Code Paths in Generated Code ............................................. 56-62

Floating-Point Multiplication to Handle a Net Slope Correction ...................... 56-65

Use Conditional Input Branch Execution ............................................. 56-68

Optimize Generated Code for Complex Signals ............................................. 56-74

Speed Up Linear Algebra in Code Generated from a MATLAB Function Block .................................. 56-77
   Specify LAPACK Library ............................................. 56-77
   Write LAPACK Callback Class ............................................. 56-77
   Generate LAPACK Calls by Specifying a LAPACK Callback Class ............................................. 56-78
   Locate LAPACK Library in Execution Environment ............................................. 56-79

Speed Up Fast Fourier Transforms in Code Generated from a MATLAB Function Block .................................. 56-81
   Install an FFTW Library ............................................. 56-81
   Write FFT Callback Class ............................................. 56-82
   Generate FFTW Calls by Specifying an FFT Callback Class ............................................. 56-83

Synchronize Multithreaded FFTW Planning in Code Generated from a MATLAB Function Block .................................. 56-85
   Prerequisites ............................................. 56-85
   Create a Model with a MATLAB Function Block That Calls an FFT Function ............................................. 56-86
   Write Supporting C Code ............................................. 56-86
   Create an FFT Library Callback Class ............................................. 56-87
   Configure Code Generation Parameters and Build the Model ............................................. 56-88

Control Memory Allocation for Variable-Size Arrays in a MATLAB Function Block .................................. 56-90
   Provide Upper Bounds for Variable-Size Arrays ............................................. 56-90
Disable Dynamic Memory Allocation for MATLAB Function Blocks .................................. 56-91
Modify the Dynamic Memory Allocation Threshold ........................................ 56-91

Optimize Memory Usage for Time Counters .................. 56-93

Optimize Generated Code Using Boolean Data for Logical Signals ............................................. 56-100

Reduce Memory Usage for Boolean and State Configuration Variables .............................. 56-103

Customize Stack Space Allocation ................................. 56-104

Optimize Generated Code Using memset Function ........................................ 56-106

Vector Operation Optimization .................................................... 56-110

Enable and Reuse Local Block Outputs in Generated Code ........................................ 56-113
  Example Model ................................................................. 56-113
  Generate Code Without Optimization ................................ 56-114
  Enable Local Block Outputs and Generate Code ........................ 56-114
  Reuse Local Block Outputs and Generate Code ....................... 56-115

Configuration in Embedded Coder

57

Set Hardware Implementation Parameters ......................... 57-2

Data Copy Reduction in Embedded Coder

58

Optimize Global Variable Usage ........................................ 58-2
  Use Global to Hold Temporary Results ............................... 58-2
  Minimize Global Data Access ........................................ 58-7
Reuse Global Block Outputs in the Generated Code  
Virtualized Output Ports Optimization  
Specify Buffer Reuse by Using Simulink.Signal Objects  
Specify Buffer Reuse for MATLAB Function Blocks in a Path  
Example Model  
Generate Code with Optimization  
Remove Data Copies by Reordering Block Operations in the Generated Code  
Example Model  
Generate Code without Optimization  
Generate Code with Optimization  
Data Copy Reduction for Data Store Read and Data Store Write Blocks  
Reduce Data Copies for Bus Assignment Blocks  
Example Model  
Generate Code Without Optimization  
Generate Code with Optimization  
Optimize Generated Code by Using Signal Labels to Guide Buffer Reuse  
Example Model  
Generate Code Without Optimization  
Generate Code with Optimization  
Using Label-Based Reuse Versus Reusable Custom Storage Classes  
Execution Speed in Embedded Coder  
Reduce Memory Usage for Signals  
lxxv
Remove Initialization Code .................................. 59-4
  Remove Zero Initialization Code for Internal Data ...... 59-4
  Remove Initialization Code for Root-Level Inports and
  Outports Set to Zero .................................... 59-6
  Additional Information ................................... 59-9

Simplify Multiply Operations in Array Indexing .......... 59-10
  Example Model ......................................... 59-10
  Generate Code ......................................... 59-11
  Generate Code with Optimization ....................... 59-11

Replace boolean with Specific Integer Data Type ....... 59-14
  Example Model ......................................... 59-14
  Generate Code That Contains the Default boolean Data
  Type ...................................................... 59-15
  Generate Code That Contains the Target boolean Data
  Type ...................................................... 59-16

Remove Code That Guards Against Division Exceptions for
Integers and Fixed-Point Data .............................. 59-19

Division Arithmetic Exceptions in Generated Code .... 59-23
  Division by Zero ........................................ 59-23
  INT_MIN/-1 ............................................. 59-23
  Other Factors Affecting Generated Code of Division
  Operations .............................................. 59-24

Optimize Generated Code by Consolidating Redundant If-
Else Statements ........................................... 59-25

Optimize Generated Code for Fixed-Point Data
Operations .................................................. 59-30

Optimize Generated Code By Developing and Using Code
Replacement Libraries - Simulink® ........................ 59-33

Improve Execution Efficiency by Reordering Block
Operations in the Generated Code ......................... 59-65
Memory Usage in Embedded Coder

Optimize Generated Code Using Minimum and Maximum Values ........................................ 60-2
  Configure Your Model .................................. 60-2
  Optimize Generated Code Using Specified Minimum and Maximum Values ......................... 60-3
  Limitations ........................................... 60-7

Flat Structures for Reusable Subsystem Parameters .......................................................... 60-9

Reduce Global Variables in Nonreusable Subsystem Functions ............................................ 60-13
  Generate void-void Function ......................... 60-13
  Generate Function with Arguments .................... 60-14

Optimize Generated Code By Packing Boolean Data Into Bitfields ....................................... 60-16

Optimize Generated Code By Passing Reusable Subsystem Outputs as Individual Arguments .......... 60-20

Convert Data Copies to Pointer Assignments ................................................................. 60-25

Reuse Buffers of Different Sizes and Dimensions ............................................................... 60-30

Remove Reset and Disable Functions from the Generated Code .......................................... 60-37
  Example Model ........................................ 60-37
  Generate Code ......................................... 60-38
  Enable Optimization ................................... 60-39

Code Execution Profiling in Embedded Coder

Code Execution Profiling with SIL and PIL ................................................................. 61-2
  Configure Code Execution Profiling .................... 61-3

lxxvii
### Profiling for Atomic Subsystems and Model Reference Hierarchies
- View and Compare Code Execution Times ........................................ 61-7

Design Models for Generated Embedded Code Deployment

When using Embedded Coder to generate code for an embedded system architecture, it is important to design your Simulink models with code generation in mind from the very beginning of the design process. Think about relevant design factors and issues such as:

In this section...
“Application Algorithms and Run-Time Environments” on page 1-2
“Software Execution Framework for Generated Code” on page 1-3
“Map Embedded System Architecture to Simulink Modeling Environment” on page 1-5
“Model Templates for Code Generation” on page 1-14

Application Algorithms and Run-Time Environments

Use Simulink to design models that represent application algorithms and run-time environments from which you intend to generate deployable code. Depending on your application, you might deploy code to an execution environment that consists of a combination of:

<table>
<thead>
<tr>
<th>Execution Environment Components</th>
<th>Choices</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hardware</td>
<td>• Development computer</td>
</tr>
<tr>
<td></td>
<td>• Rapid-prototyping board</td>
</tr>
<tr>
<td></td>
<td>• Microprocessor</td>
</tr>
<tr>
<td></td>
<td>• Microcontroller</td>
</tr>
<tr>
<td></td>
<td>• FPGA</td>
</tr>
<tr>
<td></td>
<td>• ASIC</td>
</tr>
<tr>
<td>Cores</td>
<td>• Single</td>
</tr>
<tr>
<td></td>
<td>• Multiple</td>
</tr>
<tr>
<td>Operating system</td>
<td>• General-purpose</td>
</tr>
<tr>
<td></td>
<td>• Real-time</td>
</tr>
<tr>
<td></td>
<td>• None (bare metal)</td>
</tr>
</tbody>
</table>
As you design models to generate C or C++ code for rapid prototyping or production deployment, keep in mind the execution environment. Generate code that meets implementation requirements and avoids potential design rework. As the preceding table reflects, the execution environment for code that you generate can range from relatively simple to complex. For example, a simple case is code that you generate from a single, single-tasking model that runs on a single-core microprocessor. A complex case is code that generate from a model partitioned to run as a distributed system on a multicore microprocessor and an FPGA.

**Software Execution Framework for Generated Code**

Part of an application execution environment is the software execution framework that is responsible for scheduling and running the generated code. That software can preexist, as in the case of an operating system and its scheduler, or you can code the software manually. The level of complexity varies depending on which of the following modeling and code generation scenarios applies:

- Generate code from a single top model, which represents the algorithms intended to run in the execution environment.
- Generate code from a model, which represents part of an overall algorithm. You can mix the generated code with code written manually and code generated from other sources or releases of MathWorks® products.

**Single Top Model**

For a single top model, the software execution framework is responsible for running generated code the same way that Simulink simulates the model. Functions in the
generated code are highly coordinated and optimized because Simulink is aware of dependencies. The framework interfaces with code generated for the top model only. Code generated for a top model handles interfacing with code for referenced Model blocks.

Consider the following example, where a single top model is mapped to tasks that run on a single-core CPU.

For this system, you map model clock rates to tasks that run on the hardware. You can choose for Simulink to map the rates implicitly or you can map them explicitly in your model. You can model latency effects resulting from how you map rates in a model to single-tasking or multitasking execution environments. Simulink schedules the tasks properly based on rates in the model and data dependencies between tasks. The code generator implements the same dependencies in the code that it generates. The software execution framework invokes generated entry-point functions at rates based on system timers and interrupts. The generated code executes in the same manner that Simulink simulates the model, and contains code dedicated to communicating data between functions running at different rates.

**Multiple Top-Level Models**

When you generate code from multiple top models separately and mix that code with code acquired in other ways, the execution environment of the application takes on more software execution framework responsibility. For this modeling scenario, you generate code for standalone, atomic reusable components.
With this scenario, Simulink is not aware of model dependencies. Functions in code generated from the different models are minimally coordinated and optimized. For example, the models might share generated utility functions. Potential optimizations that cross model boundaries are not possible. You must design the software execution framework taking into account dependencies between units of code, including execution order. For an application that requires concurrent execution across multiple cores, you must consider data latency effects across the cores.

The code generator helps you address software execution framework challenges, such as sharing global data and avoiding identifier conflicts. The code generated for a each model handles the interfacing for referenced Model blocks.

**Map Embedded System Architecture to Simulink Modeling Environment**

When mapping an embedded system architecture to the Simulink modeling environment, think about the model design.

<table>
<thead>
<tr>
<th>“Modeling Algorithms” on page 1-6</th>
<th>Given initial state and input, a set of tasks or instructions that efficiently produce the results that you want.</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Modeling Interfaces” on page 1-7</td>
<td>Mechanisms that enable algorithm components to communicate and exchange information across component boundaries.</td>
</tr>
<tr>
<td>“Modeling Systems” on page 1-9</td>
<td>Collection of algorithm components that achieve a higher-level, domain-specific goal or result. Components often share resources.</td>
</tr>
</tbody>
</table>
Consider the following questions regarding an embedded system architecture with corresponding modeling capabilities and links to related information. Use the information as a guide for mapping your architecture details to the Simulink modeling environment. Designing a model architecture with your specific embedded system architecture in mind can help you avoid rework and future conversion and maintenance costs.

Model Templates for Code Generation

The code generator provides a set of built-in templates to use as a starting point to create models for common application designs. Use the templates to create models that are preconfigured to generate code for rapid-prototyping or embedded system applications.

<table>
<thead>
<tr>
<th>Template</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Code Generation System</td>
<td>Basic model consisting of an Inport block and Output block.</td>
</tr>
<tr>
<td>Exported functions</td>
<td>Model for generating code from function-call subsystems. You can export each function-call subsystem separately by right-clicking a subsystem, selecting C/C++ Code &gt; Export Functions, and clicking Build.</td>
</tr>
<tr>
<td>Fixed-step, multirate</td>
<td>Fixed-step model that uses multiple rates and consists of Inport blocks, an Outport block, and a Sum block. The model is configured to use a fixed-step discrete solver and to use two rates with Periodic sample time constraint set to Unconstrained and the Treat each discrete rate as a separate task option selected. Simulink inserts a Rate Transition block to handle the two sample rates.</td>
</tr>
<tr>
<td>Fixed-step, single rate</td>
<td>Fixed-step model that uses a single rate and consists of Inport blocks, an Outport block, and a Sum block. The model is configured to use a fixed-step discrete solver.</td>
</tr>
</tbody>
</table>

To create a model from a template:

1. On the MATLAB® home tab, click Simulink.
2. In the Simulink start page, expand Embedded Coder.
3. Select a template.
4. Click Create. A new model that uses the template contents and settings appears in the Simulink Editor window.

For more information, for example to create and use a template as a reference design, see “Create a Template from a Model” (Simulink).

Model Single-Core, Single-Tasking Platform Execution

This example shows a model designed and configured for embedded system code generation intended to execute on a single-core, single-tasking platform. The application algorithm is captured in a single model hierarchy, making it possible to use Simulink® time-based, single-task scheduling to simulate the model and execute the generated code.

Periodic Multirate Model Set Up for Single-Tasking Execution

Open the example model rtwdemo_multirate_singletasking. The model is configured to display color-coded sample times with annotations. To see them, after opening the model, update the diagram by pressing Ctrl+D. To display the legend, press Ctrl+J.
Sample times for Inport blocks In1_1s and In2_2s are set to 1 and 2 seconds, respectively.

To provide clean partitioning of rates, sample times for subsystems SS1 and SS2 are set to 1.
Relevant Model Configuration Parameter Settings

- **Solver > Type** set to **Fixed-step**.
- **Solver > Solver** set to **discrete (no continuous states)**.
- **Solver > Treat each discrete rate as a separate task** cleared.

Scheduling

Simulink® simulates the model based on the model configuration. Code generated from the model implements the same execution semantics. Simulink propagates and uses the Inport block sample times to order block execution based on a single-core, single-tasking execution platform.

For this model, the sample time legend shows an implicit rate grouping. Red represents the fastest discrete rate. Green represents the second fastest discrete rate.

The generated code schedules subrates in the model. In this example, the rate for Inport block **In2_2s**, the green rate, is a subrate. The generated code properly transfers data between tasks running at the different rates.

Benefits of implicit rate grouping:

- Simulink does not impose architectural constraints on the model.
- Your execution framework does not require details about underlying function scheduling and data transfers between rates. Therefore, the model interface requirements are simplified. The execution framework uses generated interface code to write input, call the model step function, and read output.
- The code generator optimizes code across rates based on single-tasking execution semantics.

Your execution framework can communicate with external devices for reading and writing model input. For example, model external devices by using Simulink S-Function blocks. Generate code for those blocks with the rest of the algorithm.

Generate Code and Report

Generate code and a code generation report. The example model generates a report.

Review Generated Code

From the code generation report, review the generated code.
• ert_main.c is an example main program (execution framework) for the model. This code controls model code execution by calling the entry-point function rtwdemo_multirate_singletasking_step. Use this file as a starting point for coding your execution framework.

• rtwdemo_multirate_singletasking.c contains entry points for the code that implements the model algorithm. This file includes the rate scheduling code.

• rtwdemo_multirate_singletasking.h declares model data structures and a public interface to the model entry points and data structures.

• rtwtypes.h defines data types, structures, and macros that the generated code requires.

**Code Interface**

Open and review the Code Interface Report. Use the information in that report to write the interface code for your execution framework:

1. Include the generated header file by adding directive 
   `#include rtwdemo_multirate_singletasking.h`.

2. Write input data to the generated code for model Inport blocks.

3. Call the generated entry-point functions.

4. Read data from the generated code for model Outport blocks.

**Input ports:**

• rtu.In1_1s of data type real_T with dimension of 1

• rtu.In2_2s of data type real_T with dimension of 1

**Entry-point functions:**

• Initialization entry-point function, `void rtwdemo_multirate_singletasking_initialize(void)` At startup, call this function once.

• Output and update entry-point (step) function, `void rtwdemo_multirate_singletasking_step(void)` Call this function periodically at the fastest rate in the model. For this model, call the function every second. To achieve real-time execution, attach this function to a timer.

**Output ports:**
• `rtY.Out1` of data type `real_T` with dimension of 1
• `rtY.Out2` of data type `real_T` with dimension of 1

• “Customize Code Organization and Format” on page 39-56
Model Single-Core, Multitasking Platform Execution

Use Simulink® time-based, multitask scheduling to simulate and generate code for an application algorithm captured in a single model hierarchy. The model is designed and configured for an embedded system intended to execute on a single-core, multitasking platform. The model simulates and the generated code executes based on the model configuration and a rate monotonic scheduling algorithm.

**Periodic Multirate Model Set Up for Multitasking Execution**

Open the example model `rtwdemo_multirate_multitasking`. The model is configured to display color-coded sample times with annotations. To see them, after opening the model, update the diagram by pressing `Ctrl+D`. To display the legend, press `Ctrl+J`. 
- Sample times for Inport blocks In1_1s and In2_2s are set to 1 and 2 seconds, respectively.
- To provide a clear partitioning of rates, sample times for subsystems SS1 and SS2 are set to 1.
• The Rate Transition block models an explicit rate transition. Alternatively, instruct Simulink to insert Rate Transition blocks for you by selecting model configuration parameter **Solver > Automatically handle rate transition for data transfer.**

**Relevant Model Configuration Parameter Settings**

- **Solver > Type** set to **Fixed-step**.
- **Solver > Solver** set to **discrete (no continuous states)**.
- **Solver > Treat each discrete rate as a separate task** selected.

**Scheduling**

Simulink® simulates the model based on the model configuration. Code that this model generates implements the same execution semantics. Simulink propagates and uses the Inport block sample times to order block execution based on a single-core, multitasking execution platform.

For this model, the sample time legend shows an implicit rate grouping. Red represents the fastest discrete rate. Green represents the second fastest discrete rate. Yellow represents the mixture of the two rates.

The generated code schedules subrates in the model. In this example, the rate for Inport block **In2_2s**, the green rate, is a subrate. The generated code properly transfers data between tasks that run at the different rates.

**Benefits of implicit rate grouping:**

- Simulink does not impose architectural constraints on the model. Create a model without imposing software architecture constraints within the model.
- Your execution framework does not require details about underlying function scheduling and data transfers between rates. Therefore, the model interface requirements are simplified. The execution framework uses generated interface code to write input, call the model step function, and read output.
- The code generator optimizes code across rates based on multitasking execution semantics.

Simulink enforces data transfer constraints to achieve rate monotonic scheduling:

- Data transfers occur between a single read task and a single write task.
- When data transfers between two tasks, only one task can preempt the other task.
• For periodic tasks, a task with a faster rate has a higher priority than a task with a slower rate. In addition, a task with the faster rate, preempts a task with a slower rate.
• Tasks run on a single processor.
• Time slicing, use of a defined time period during which a task can run in a preemptive multitasking system, is not allowed.
• Processes do not crash or restart, especially during data transfers between tasks.
• Read and write operations on byte-sized variables are atomic.

Your execution framework communicates with external devices for reading and writing model input. For example, model external devices by using Simulink S-Function blocks. Generate code for those blocks with the rest of the algorithm.

Generate Code and Report

Generate code and a code generation report. The example model generates a report.

Review Generated Code

From the code generation report, review the generated code.

• ert_main.c is an example main program (execution framework) for the model. This code controls model code execution by calling the entry-point functions rtwdemo_multirate_multitasking_step0 and rtwdemo_multirate_multitasking_step1. Use this file as a starting point for coding your execution framework.
• rtwdemo_multirate_multitasking.c contains entry points for the code that implements the model algorithm. This file includes the rate scheduling code.
• rtwdemo_multirate_multitasking.h declares model data structures and a public interface to the model entry points and data structures.
• rtwtypes.h defines data types, structures, and macros that the generated code requires.

Code Interface

Open and review the Code Interface Report. Use the information in that report to write the interface code for your execution framework:

1. Include the generated header file by adding directive 
#include rtwdemo_multirate_singletasking.h.
2 Write input data to the generated code for model Inport blocks.
3 Call the generated entry-point functions.
4 Read data from the generated code for model Outport blocks.

Input ports:
• rtU.In1_1s of data type real_T with dimension of 1
• rtU.In2_2s of data type real_T with dimension of 1

Entry-point functions:
• Initialization entry-point function, void
  rtwdemo_multirate_multitasking_initialize(void). At startup, call this
  function once.
• Output and update entry-point (step) function, void
  rtwdemo_multirate_multitasking_step0(void). Call this function periodically
  at the fastest rate in the model. For this model, call the function every second. To
  achieve real-time execution, attach this function to a timer.
• Output and update entry-point function, void
  rtwdemo_multirate_multitasking_step1(void). Call this function periodically
  at the second fastest rate in the model. For this model, call the function every two
  seconds. To achieve real-time execution, attach this function to a timer.

Output ports:
• rtY.Out1 of data type real_T with dimension of 1
• rtY.Out2 of data type real_T with dimension of 1

• “Customize Code Organization and Format” on page 39-56
Model Concurrent Execution for Symmetric Multicore CPU Platforms

Use Simulink® time-based, multitask scheduling to simulate and generate code for an application algorithm captured in a single model hierarchy. The model is designed and configured for an embedded system intended to execute on a symmetric multicore, multitasking platform.

**Periodic Multirate Model Set Up for Multitasking Concurrent Execution**

Open the example model rtwdemo_concurrent_execution. The model is configured to display color-coded sample times with annotations. To see them, after opening the model, update the diagram by pressing Ctrl+D. To display the legend, press Ctrl+J.
Simulink supports simulating concurrent task execution by assigning partitions of a model to tasks that you designate to run concurrently on multicore hardware. Use an implicit or explicit approach to designating partitions.

Simulink implicit partitioning:

- Partitions the model based on sample times specified in the model.
- Assigns a task to each sample rate and designates that the tasks run concurrently.
- Controls the granularity of partitions. For example, you cannot split a sample rate into multiple tasks.
• Does not impose modeling constraints.
• Provides ready-to-use hardware solutions, such as solutions that the Simulink® Real-Time™ product produces.
• Is not relevant to standalone production code generation due to the lack of control over partition granularity.

Explicit partitioning:
• Use Model and Subsystem blocks to partition the model.
• Create an arbitrary number of tasks.
• Simulink assigns each partition to a task.
• Simulink imposes modeling constraints.
• Control the granularity of partitions.
• Split a sample rate into multiple tasks.
• Assign partitions to different processor cores.
• Is for standalone production code generation due to the level of control you have over granularity of partitions.

This example shows explicit partitioning.

Consider the following periodic multirate model that is set up for multitasking execution.
• Sample times for Inport blocks In1_1s and In2_2s are set to 1 and 2 seconds, respectively.
• To provide a clear partitioning of rates, sample times for models SS1 and SS2 are set to 1.
• The Rate Transition block explicitly models a rate transition.

To support concurrent execution of tasks in a multicore run-time environment, the preceding model was modified:

• The Integrator block is in a Model block configured with a fixed-step discrete solver and a step size of two seconds.
• Subsystems SS1 and SS2 were converted to Model blocks configured with a fixed-step discrete solver and a step size of one second.
• The Sum block is in a Model block configured with a fixed-step discrete solver and a step size of one second. Another option for the Sum block is to place it in SS1 or SS2 and compute its value coincident with the Model block. For concurrent execution of tasks, only connection blocks, Model blocks, and Subsystem blocks can be at the root level of a model.
• The Rate Transition block was removed.

**Relevant Model Configuration Parameter Settings**

- **Solver > Type** set to Fixed-step.
- **Solver > Solver** set to discrete (no continuous states).
- **Solver > Treat each discrete rate as a separate task** selected.
- **Solver > Automatically handle rate transition for data transfer** selected. Necessary because Rate Transition block was removed.
- **Solver > Allow tasks to execute concurrently on target** selected.

**Concurrent Execution Parameter Settings**

Open the Concurrent Execution dialog box by clicking **Configure Tasks** on the Configuration Parameters **Solver** pane. Selecting **Allow tasks to execute concurrently on target** enables the **Configure Tasks** button.

When selected, the **Enable explicit model partitioning for concurrent behavior** parameter enables concurrent execution options for the top-level model.

Click **Tasks and Mapping** to review the tasks and mapping.
Simulink creates a default mapping for each partition (Model block) by assigning each partition to a separate task. Simulink designates that each partition executes concurrently and simulates latency effects that data communication between processor cores imposes. This dialog box displays a mapping consisting of partitions spread across two independent periodic triggers: SS1, SS2, and Sum mapped to periodic trigger 1 and Integrator mapped to periodic trigger 2.

**Scheduling**

Simulink® simulates the model based on the model configuration. Code generated from the model implements the same execution semantics. Simulink propagates and uses the
Inport block sample times to order block execution based on a multicore, multitasking execution platform.

For this model, the sample time legend shows an implicit rate grouping. Red represents the fastest discrete rate. Green represents the second fastest discrete rate.

The generated code schedules subrates in the model. In this example, the rate for Inport block `In2_2s`, the green rate, is a subrate. The generated code properly transfers data between the rates.

Benefits of implicit Simulink rate grouping:

- Simulink does not impose architectural constraints on the model. Create a model without imposing software architecture constraints within it.
- Your execution framework does not require details about underlying function scheduling and data transfers between rates. Therefore, model interface requirements are simplified. The execution framework uses generated interface code to write input, call the model step function, and read output.
- The code generator optimizes code across rates, based on multitasking execution semantics.

Simulink enforces data transfer constraints:

- Data transfers occur between a single read task and a single write task.
- Tasks run on a single processor.
- Processes do not stop or restart, especially during data transfers between tasks.
- Read and write operations on byte-sized variables are atomic.

Your execution framework can communicate with external devices for reading and writing model input. For example, model external devices by using Simulink S-Function blocks. Generate code for those blocks with the rest of the algorithm.

**Generate Code and Report**

Generate code and a code generation report. The example model generates a report.

**Review Generated Code**

From the code generation report, review the generated code.
- `ert_main.c` is an example main program (execution framework) for the model. This code controls model code execution by indirectly calling entry-point functions `PeriodicTrigger1_OneSecond_step`, `PeriodicTrigger1_TwoSecond_step`, and `PeriodicTrigger2_OneSecond_step` with the function `rtwdemo_concurrent_execution_step`. Use this file as a starting point for coding your execution framework.

- `rtwdemo_concurrent_execution.c` contains entry points for the code that implements the model algorithm. This file includes the rate and task scheduling code.

- `rtwdemo_concurrent_execution.h` declares model data structures and a public interface to the model entry points and data structures.

- `model_reference_types.h` contains type definitions for timing bridges. These type definitions are generated for a model reference target or a model containing Model blocks.

- `rtw_windows.h` declares mutex and semaphore function prototypes that the generated code uses for concurrent execution on Microsoft® Windows® platforms.

- `rtwtypes.h` defines data types, structures, and macros that the generated code requires.

**Code Interface**

Open and review the Code Interface Report. Use the information in that report to write the interface code for your execution framework:

1. Include the generated header file by adding directive `#include rtwdemo_concurrent_execution.h`.
2. Write input data to the generated code for model Inport blocks.
3. Call the generated entry-point functions.
4. Read data from the generated code for model Outport blocks.

**Input ports:**
- `In1_1s` of data type `real_T` with dimension of 1
- `In2_2s` of data type `real_T` with dimension of 1

**Entry-point functions:**
- Initialization entry-point function, `void rtwdemo_concurrent_execution_initialize(void)`. At startup, call this function once.
• Output and update entry-point (step) function, void 
  PeriodicTrigger1_OneSecond_step(void). Call this function periodically for one of two tasks that require scheduling at the fastest rate in the model. For this model, call the function every second.

• Output and update entry-point function, void 
  PeriodicTrigger1_TwoSecond_step(void). Call this function periodically at the second fastest rate in the model. For this model, call the function every two seconds.

• Output and update entry-point function, void 
  PeriodicTrigger2_OneSecond_step(void). Call this function periodically for the second task that requires scheduling at the fastest rate in the model. For this model, call the function every second.

To achieve real-time execution, define a task or thread for each entry-point step function. Trigger execution of each function based on a timer that has the same rate as the given function. The operating system schedules the tasks across cores dynamically or based on your mapping of tasks to cores.

Output ports:

- Out1_1s of data type real_T with dimension 1
- Out2_1s of data type real_T with dimension 1

Model Explicit Function Invocation with Atomic Subsystems

Deploy embedded system code from Simulink® models by partitioning a model into multiple atomic subsystems that you build separately.

Atomic Subsystem Model

Open the example model rtwdemo_explicitinvocation_atomicsubsy. The model is configured to display color-coded sample times with annotations. To see them, after opening the model, update the diagram by pressing Ctrl+D. To display the legend, press Ctrl+J.
This model partitions an algorithm into two atomic subsystems: Rate1s and Rate2s. Subsystem Rate1s is configured with a sample time of 1 second. Subsystem Rate2s is configured with a sample time of 2 seconds.

**Relevant Model Configuration Parameter Settings**

- **Solver > Type** set to Fixed-step.
- **Solver > Solver** set to discrete (no continuous states).
• **Solver > Treat each discrete rate as a separate task** cleared.

**Scheduling**

Simulink® simulates the model based on the model configuration. Simulink propagates and uses the Inport block sample times to order block execution based on a single-core, single-tasking execution platform.

For this example, the sample time legend shows implicit rate grouping. Red represents the fastest discrete rate. Green represents the second fastest discrete rate.

Based on ratemonotonic scheduling, your application code (execution framework) must transfer data between subsystems Rate2s and Rate1s at a frequency of 2 seconds with the priority of 1 second. That is, the generated function transfers data in the 1 second task every other time prior to executing code for subsystem Rate1s.

Your execution framework must schedule the generated function code and handle the data transfers between them. This is an advantage for multirate models because the generated code assumes no scheduling or data transfer semantics. However, the execution framework must handle data transfers explicitly.

**Generate Code and Report**

Generate a single callable function for each subsystem without connections between them. Multiple ways are available to generate code for a subsystem, including from the subsystem context menu. For example, right-click a subsystem block and click **C/C++ Code > Build This Subsystem**. In the Build code for Subsystem dialog box, click **Build**.

The example model generates a report.

**Review Generated Code**

From the code generation report, review the generated code.

- **ert_main.c** is an example main program (execution framework) for the subsystem. This code controls model code execution by calling entry-point function Rate1s_step or Rate2s_step. Use this file as a starting point for coding your execution framework.
- **Rate1s.c** and **Rate2s.c** contain entry points for the code that implements subsystem Rate1s and Rate2s, respectively. This file includes the rate and task scheduling code.
• Rate1s.h and Rate2s.h declare model data structures and a public interface to subsystem entry points and data structures.
• rtwtypes.h defines data types, structures, and macros that the generated code requires.

**Code Interface**

Open and review the Code Interface Report. Use the information in that report to write the interface code for your execution framework:

1. Include the generated header file by adding directive #include rtwdemo_explicitinvocation_atomicssusys.h.
2. Write input data to the generated code for model Inport blocks.
3. Call the generated entry-point functions.
4. Read data from the generated code for model Outport blocks.

Input ports, Rate1s:
• rtU.In1 of type real_T with dimension of 1
• rtU.In2 of type real_T with dimension of 1

Entry-point functions, Rate1s:
• Initialize entry-point function, void Rate1s_initialize(void). At startup, call this function once.
• Output and update entry-point (step) function, void Rate1s_step(void). Call this function periodically, every second.
• Termination function, void Rate1s_terminate(void). Call this function once from your shutdown code.

Output ports, Rate1s:
• rtY.Out1 of type real_T with dimension of 1
• rtY.Out2 of type real_T with dimension of 1

Input ports, Rate2s:
• rtU.In1 of type real_T with dimension of 1

Entry-point functions, Rate2s:
• Initialize entry-point function, `void Rate2s_initialize(void)`. Call this function once at startup.
• Output and update entry-point (step), `void Rate2s_step(void)`. Call this function periodically, every 2 seconds.
• Termination function, `void Rate2s_terminate(void)`. Call this function once from your shutdown code.

Output ports, Rate2s:
• `rtY.Out1` of type `real_T` with dimension of 1

Model Explicit Function Invocation with Function-Call Subsystems

Deploy embedded system code from Simulink® models by partitioning a model into function-call subsystems that you build separately.

**Function-Call Subsystem Model**

Open the example model rtwdemo_explicitinvocation_funccallsys. The model is configured to display color-coded sample times with annotations. To see them, after opening the model, update the diagram by pressing Ctrl+D. To display the legend, press Ctrl+J.
This model partitions an algorithm into three function-call subsystems: Rate1s, Rate2s, and DataBuffer. Use function-call subsystems to model multirate systems explicitly.

Subsystems Rate1s and DataBuffer use a sample time of 1 second. Subsystem Rate2s uses a sample time of 2 seconds.

This model design is referred to as export function modeling. Simulink constrains the model to function-call subsystems at the root level. The driving Inport block specifies the function name.
Relevant Model Configuration Parameter Settings

- **Solver > Type** set to Fixed-step.
- **Solver > Solver** set to discrete (no continuous states).
- **Solver > Treat each discrete rate as a separate task** selected. Simulink applies multitasking execution because the model uses multiple sample rates.

**Scheduling**

Simulink® simulates the model based on the model configuration. Simulink propagates and uses the Inport block sample times to order block execution based on a single-core, multitasking execution platform.

In the sample time legend, red identifies the fastest discrete rate. Magenta identifies rates inherited from exported functions, indicating their execution is outside the context of Simulink scheduling.

Your execution framework must schedule the generated function code and transfer data between functions.

Your execution framework needs to schedule the generated function code and handle data transfers between functions. The generated code is simple and you control the order of execution.

**Generate Code and Report**

Generate code and a code generation report. The example model generates a report.

**Review Generated Code**

From the code generation report, review the generated code.

- *ert_main.c* is an example main program (execution framework) for the model. This code shows how to call the exported functions. The code also shows how to initialize, execute, and terminate the generated code.
- *rtwdemo_explicitinvocation_funcallsubsys.c* calls the initialization function and exported functions for subsystems Rate1s, Rate2s, and DataBuffer.
- *rtwdemo_explicitinvocation_funcallsubsys.h* declares model data structures and a public interface to the exported entry point functions and data structures.
• `rtwtypes.h` defines data types, structures, and macros that the generated code requires.

**Code Interface**

Open and review the Code Interface Report. Use the information in that report to write the interface code for your execution framework:

1. Include the generated header files by adding directives `#include Rate1s.h`, `#include DataBuffer.h`, and `#include Rate2s.h`.
2. Write input data to the generated code for model Inport blocks.
3. Call the generated entry-point functions.
4. Read data from the generated code for model Outport blocks.

Input ports:

- `rtU.In1_1s` of type `real_T` with dimension of 1
- `rtU.In2_2s` of type `real_T` with dimension of 1

Entry-point functions:

- Initialize entry-point function, `void rtwdemo_explicitinvocation_funccallsubsys_initialize(void)`. At startup, call this function once.
- Exported function, `void CallEvery1s(void)`. Call this function as needed.
- Exported function, `void CallEvery1s(void)`. Call this function as needed.
- Exported function, `void CallEvery2sAt1sPriority(void)`. Call this function as needed.

Output ports:

- `rtY.Out1` of type `real_T` with dimension of 1
- `rtY.Out2` of type `real_T` with dimension of 1

**More About**

Modeling Patterns for AUTOSAR Runnables

Use Simulink® models, subsystems, and functions to model AUTOSAR atomic software components and their runnable entities (runnables).

Prerequisites

The Embedded Coder Support Package for AUTOSAR Standard is required for generating C code and arxml descriptions for AUTOSAR software components.

• Install the AUTOSAR Standard Support Package
• “Support Package Installation” (MATLAB)

Multiple Periodic Runnables Configured for Multitasking

Open the example model rtwdemo_autosar_swc. The model shows the implementation of an AUTOSAR atomic software component (ASWC). Two periodic runnables, Runnable_1s and Runnable_2s, are modeled with multiple sample rates: 1 second (In1_1s) and 2 seconds (In2_2s). To maximize execution efficiency, the model is configured for multitasking.

The model includes an Initialize Function block, which initializes the integrator in Runnable_2s to a value of 1.

To display color-coded sample rates with annotations and a legend, select Display > Sample Time > Colors.
Relevant Model Configuration Parameter Settings

- **Solver > Type** set to Fixed-step.
- **Solver > Solver** set to discrete (no continuous states).
- **Solver > Fixed-step size (fundamental sample time)** set to auto.
- **Solver > Treat each discrete rate as a separate task** selected.

**Scheduling**

In the model window, enable sample time color-coding by selecting **Display > Sample Time > Colors**. The sample time legend shows the implicit rate grouping. Red represents the fastest discrete rate. Green represents the second fastest discrete rate. Yellow represents the mixture of the two rates.
Because the model has multiple rates and the Solver parameter **Treat each discrete rate as a separate task** is selected, the model simulates in multitasking mode. The model handles the rate transition for In2_2s explicitly with the Rate Transition block.

The Rate Transition block parameter **Ensure deterministic data transfer** is cleared to facilitate integration into an AUTOSAR Runtime Environment (RTE).

The generated code for the model schedules subrates in the model. In this example, the rate for Inport block In2_2s, the green rate, is a subrate. The generated code properly transfers data between tasks that run at the different rates.

**Generate Code and Report**

Generate code and a code generation report. The example model generates a report.

Generated code complies with AUTOSAR so that you can schedule the code with the AUTOSAR RTE.

**Review Generated Code**

In the code generation report, review the generated code.

- **rtwdemo_autosar_swc.c** contains entry points for the code that implements the model algorithm. This file includes the rate scheduling code.
- **rtwdemo_autosar_swc.h** declares model data structures and a public interface to the model entry points and data structures.
- **rtwdemo_autosar_swc_private.h** contains local define constants and local data required by the model and subsystems.
- **rtwdemo_autosar_swc_types.h** provides forward declarations for the real-time model data structure and the parameters data structure.
- **rtwtypes.h** defines data types, structures, and macros that the generated code requires.
- **rtwdemo_autosar_swc_component.arxml**, **rtwdemo_autosar_swc_datatype.arxml**, **rtwdemo_autosar_swc_implementation.arxml**, and **rtwdemo_autosar_swc_interface.arxml** contain elements and objects that represent AUTOSAR software components, ports, interfaces, data types, and packages. You integrate arxml files into an AUTOSAR RTE. You can import arxml files into the Simulink environment by using the AUTOSAR arxml importer tool.
• Compiler.h, Platform_Types.h, Rte_ASWC.h, Rte_Type.h, and Std_Types.h contain stub implementations of AUTOSAR RTE functions. Use these files to test the generated code in Simulink, for example, in software-in-the-loop (SIL) or processor-in-the-loop (PIL) simulations of the component under test.

**Code Interface**

Open and review the Code Interface Report. This information is captured in the arxml files. The RTE generator uses the arxml descriptions to interface the code into an AUTOSAR RTE.

**Input ports:**

- Require port, interface: sender-receiver of type real-T of 1 dimension
- Require port, interface: sender-receiver of type real-T of 1 dimension

**Entry-point functions:**

- Initialization entry-point function, void Runnable_Initialize(void). At startup, call this function once.
- Output and update entry-point function, void Runnable_1s(void). Call this function periodically at the fastest rate in the model. For this model, call the function every second. To achieve real-time execution, attach this function to a timer.
- Output and update entry-point function, void Runnable_2s(void). Call this function periodically at the second fastest rate in the model. For this model, call the function every 2 seconds. To achieve real-time execution, attach this function to a timer.

**Output ports:**

- Provide port, interface: sender-receiver of type real-T of 1 dimension
- Provide port, interface: sender-receiver of type real-T of 1 dimension

**Multiple Runnables Configured as Periodic-Rate Runnable and Asynchronous Function-Call Runnable**

Open the example model rtwdemo_autosar_swcfncalls. The model shows the implementation of an AUTOSAR atomic software component (ASWC). The model uses an asynchronous function-call runnable, Runnable_Trigger, which is triggered by an external event. The model also includes a periodic rate-based runnable, Runnable_1s. The Rate Transition blocks represent inter-runnable variables (IRVs).
Use this approach to model the JMAAB complex control model type beta architecture. In JMAAB type beta modeling, at the top level of a control model, you place function layers above scheduling layers.

The model includes an Initialize Function block, which initializes the unit delay in Runnable_1s to a value of 0.

To display color-coded sample rates with annotations and a legend, select **Display > Sample Time > Colors**.
• **Solver > Type** set to Fixed-step.
• **Solver > Solver** set to discrete (no continuous states).
• **Solver > Fixed-step size (fundamental sample time)** set to 1.
• **Solver > Treat each discrete rate as a separate task** cleared.

**Scheduling**

In the model window, enable sample time color-coding by selecting **Display > Sample Time > Colors**. The sample time legend shows the implicit rate grouping. Red represents the discrete rate. Magenta represents the asynchronous function trigger. Yellow represents the mixture of two rates.

The asynchronous trigger runnable runs at asynchronous rates (the **Sample time type** parameter of the function-call subsystem Trigger block is set to |triggered|) while the periodic rate runnable runs at the specified discrete rate. The generated code manages the rates by using single-tasking assumptions. For models with one discrete rate, the code generator does not produce scheduling code because there is only a single rate to execute. Use this technique for a single-rate application when you have one periodic runnable.

The model handles transitions between the asynchronous and discrete rates of the connected runnables with the two Rate Transition blocks. The Rate Transition block parameter **Ensure deterministic data transfer** is cleared to facilitate integration into an AUTOSAR Runtime Environment (RTE).

**Generate Code and Report**

Generate code and a code generation report. The example model generates a report.

Generated code complies with AUTOSAR so that you can schedule the code with the AUTOSAR RTE.

**Review Generated Code**

In the code generation report, review the generated code.

• **rtwdemo_autosar_swc_fcncalls.c** contains entry points for the code that implements the model algorithm. This file includes the rate scheduling code.
• **rtwdemo_autosar_swc_fcncalls.h** declares model data structures and a public interface to the model entry points and data structures.
- `rtwdemo_autosar_swc_fcncalls_private.h` contains local define constants and local data required by the model and subsystems.
- `rtwdemo_autosar_swc_fcncalls_types.h` provides forward declarations for the real-time model data structure and the parameters data structure.
- `rtwtypes.h` defines data types, structures, and macros that the generated code requires.
- `rtwdemo_autosar_swc_fcncalls_component.arxml`, `rtwdemo_autosar_swc_fcncalls_datatype.arxml`, `rtwdemo_autosar_swc_fcncalls_implementation.arxml`, and `rtwdemo_autosar_swc_fcncalls_interface.arxml` contain elements and objects that represent AUTOSAR software components, ports, interfaces, data types, and packages. You integrate `arxml` files into an AUTOSAR RTE. You can import `arxml` files into the Simulink environment by using the AUTOSAR `arxml` importer tool.
- `Compiler.h`, `Platform_Types.h`, `Rte_ASWC.h`, `Rte_Type.h`, and `Std_Types.h` contain stub implementations of AUTOSAR RTE functions. Use these files to test the generated code in Simulink, for example, in software-in-the-loop (SIL) or processor-in-the-loop (PIL) simulations of the component under test.

### Code Interface

Open and review the Code Interface Report. This information is captured in the `arxml` files. The RTE generator uses the `arxml` descriptions to interface the code into an AUTOSAR RTE.

**Input port:**
- Require port, interface: sender-receiver of type `real-T` of 1 dimension

**Entry-point functions:**
- Initialization entry-point function, `void Runnable_Initialize(void)`. At startup, call this function once.
- Simulink function, `void Runnable_1s(void)`. Call this function periodically at the fastest rate in the model. For this model, call the function every second. To achieve real-time execution, attach this function to a timer.
- Exported function, `void Runnable_Trigger(void)`. Call this function at any time from an external trigger.

**Output port:**
• Provide port, interface: sender-receiver of type real-T of 1 dimension

**Multiple Runnables Configured As Function-Call Subsystem and Simulink Function**

Open the example model `rtwdemo_autosar_swc_slfcns`. The model shows the implementation of an AUTOSAR atomic software component (ASWC). The model includes one periodic rate runnable, `Runnable_1s`, that uses a function-call subsystem, SS1. The model also includes a Simulink function, `readData`, to provide a value (CurVal) to clients that request it.

The model includes an Initialize Function block, which initializes the unit delay in subsystem `RollingCounter` to a value of 0.

To display color-coded sample rates with annotations and a legend, select **Display > Sample Time > Colors**.
Use function-call subsystems:

- When it is difficult or not possible to specify system events in a Simulink model.
- To achieve complex multirate scheduling of runnables. Model each rate as a separate function-call subsystem.
Relevant Model Configuration Parameter Settings

- **Solver > Type** set to Fixed-step.
- **Solver > Solver** set to discrete (no continuous states).
- **Solver > Fixed-step size (fundamental sample time)** set to 1.
- **Solver > Treat each discrete rate as a separate task** selected.

Scheduling

In the model window, enable sample time color-coding by clicking **Display > Sample Time > Colors**. The sample time legend shows the implicit rate grouping. Red identifies the discrete rate. Magenta identifies rates inherited from exported functions, indicating their execution is outside the context of Simulink scheduling.

Your execution framework must schedule the generated function code and handle data transfers between functions.

Generate Code and Report

Generate code and a code generation report. The example model generates a report.

The code generator:

- Produces an AUTOSAR runnable for the function-call subsystem at the root level of the model.
- Implements signal connections between runnables as AUTOSAR inter-runnable variables (IRVs).

Generated code complies with AUTOSAR so that you can schedule the code with the AUTOSAR Runtime Environment (RTE).

Review Generated Code

In the code generation report, review the generated code.

- `rtwdemo_autosar_swc_slfcns.c` contains entry points for the code that implements the model algorithm. This file includes the rate scheduling code.
- `rtwdemo_autosar_swc_slfcns.h` declares model data structures and a public interface to the model entry points and data structures.
- `rtwdemo_autosar_swc_slfcns_private.h` contains local define constants and local data required by the model and subsystems.
rtwdemo_autosar_swc_slfcns_types.h provides forward declarations for the real-time model data structure and the parameters data structure.
readData.c contains code for the Simulink function.
readData_private.h contains local define constants and local data required by the function.
readData.h declares data structures and a public interface for calling the function.
rtwtypes.h defines data types, structures, and macros that the generated code requires.
rtwdemo_autosar_swc_slfcns_component.arxml, rtwdemo_autosar_swc_slfcns_datatype.arxml, rtwdemo_autosar_swc_slfcns_implementation.arxml, and rtwdemo_autosar_swc_slfcns_interface.arxml contain elements and objects that represent AUTOSAR software components, ports, interfaces, data types, and packages. You integrate arxml files into an AUTOSAR RTE. You can import arxml files into the Simulink environment by using the AUTOSAR arxml importer tool.
Compiler.h, Platform_Types.h, Rte_ASWC.h, Rte_Type.h, and Std_Types.h contain stub implementations of AUTOSAR RTE functions. Use these files to test the generated code in Simulink, for example, in software-in-the-loop (SIL) or processor-in-the-loop (PIL) simulations of the component under test.

**Code Interface**

Open and review the Code Interface Report. This information is captured in the arxml files. The RTE generator uses the arxml descriptions to interface the code into an AUTOSAR RTE.

Input ports:
- Require port, interface: sender-receiver of type uint16-T of 1 dimension
- Require port, interface: sender-receiver of type real-T of 1 dimension

Entry-point functions:
- Initialization entry-point function, void Runnable_Init(void). At startup, call this function once.
- Exported function, void Runnable_1s(void). Call this function periodically, every second.
• Simulink function, `Std_ReturnType readData(real_T Data[2])`. Call this function at any time.

Output ports:
• Provide port, interface: sender-receiver of type `uint16-T` of 1 dimension

Configure a Model for Code Generation

Model configuration parameters determine the method for generating the code and the resulting format.

1. Open `rtwdemo_throttlecntrl` and save a copy as `throttlecntrl` in a writable location on your MATLAB path.

   **Note** This model uses Stateflow® software.

2. Open the Configuration Parameters dialog box **Solver** pane. To generate code for a model, you must configure the model to use a fixed-step solver. For this example, set the parameters as noted in the following table.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Setting</th>
<th>Effect on Generated Code</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Fixed-step</td>
<td>Maintains a constant (fixed) step size, which is required for code generation</td>
</tr>
<tr>
<td>Solver</td>
<td>discrete (no continuous states)</td>
<td>Applies a fixed-step integration technique for computing the state derivative of the model</td>
</tr>
<tr>
<td>Fixed-step size</td>
<td>.001</td>
<td>Sets the base rate; must be the lowest common multiple of all rates in the system</td>
</tr>
</tbody>
</table>

3. Open the **Code Generation** pane and make sure that **System target file** is set to `grt.tlc`. 
The GRT (Generic Real-Time Target) configuration requires a fixed-step solver. However, the rsim.tlc system target file supports variable step code generation.

The system target file (STF) defines a target, which is an environment for generating and building code for execution on a certain hardware or operating system platform. For example, one property of a target is code format. The grt configuration requires a fixed step solver and the rsim.tlc supports variable step code generation.

4 Open the Code Generation > Custom Code pane, and under Include list of additional, select Include directories. In the Include directories text field, enter:

"$matlabroot$\toolbox\rtw\rtw\demos\EmbeddedCoderOverview\"

This directory includes files that are required to build an executable for the model.

5 Apply your changes and close the dialog box.
Blocks and Products Supported for C Code Generation

In this section...

“Related Products” on page 2-4
“Simulink Built-In Blocks That Support Code Generation” on page 2-7
“Simulink Block Data Type Support Table” on page 2-30
“Block Set Support for Code Generation” on page 2-30

As you construct a model, to prevent issues later in the development process, determine whether the Simulink Coder and Embedded Coder code generators support the products and blocks that you want to use.

Related Products

The following table summarizes MathWorks products that extend and complement Simulink Coder software. For information about these products and how code generation supports them, refer to their product documentation at www.mathworks.com.

Simulink Built-In Blocks That Support Code Generation

The following tables summarize code generator support for Simulink blocks. There is a table for each block library. For more detail, including data types each block supports, in the MATLAB Command Window, type `showblockdatatypetable`, or consult the block reference pages. For some blocks, the generated code might rely on `memcpy` or `memset` (`string.h`).

Simulink Block Data Type Support Table

The Simulink Block Data Type Support table summarizes characteristics of blocks in the Simulink and Fixed-Point Designer block libraries, including whether or not they are recommended for use in production code generation. To view this table, in the MATLAB Command Window, type `showblockdatatypetable`, or consult the block reference pages.

Block Set Support for Code Generation

Several products that include blocks are available for you to consider for code generation. However, before using the blocks for one of these products, consult the documentation for that product to confirm which blocks support code generation.

## Data Propagation

The first stage of code generation is compilation of the block diagram. This stage is analogous to that of a C or C++ program. The compiler carries out type checking and preprocessing. Similarly, the Simulink engine verifies that input/output data types of block ports are consistent, line widths between blocks are of expected thickness, and the sample times of connecting blocks are consistent.

The Simulink engine propagates data from one block to the next along signal lines. The data propagated consists of:

- Data type
- Line widths
- Sample times

You can verify what data types a Simulink block supports by typing `showblockdatatypetable` at the MATLAB prompt, or (from the Help browser) clicking the command above.

The Simulink engine typically derives signal attributes from a source block. For example, the Inport block’s parameters dialog box specifies the signal attributes for the block.
In this example, the Inport block has a port width of 3, a sample time of .01 seconds, the data type is double, and the signal is complex.

This figure shows the propagation of the signal attributes associated with the Inport block through a simple block diagram.
In this example, the Gain and Outport blocks inherit the attributes specified for the Inport block.

**Sample Time Propagation**

Inherited sample times in source blocks (for example, a root inport) can sometimes lead to unexpected and unintended sample time assignments. Since a block may specify an inherited sample time, information available at the outset is often insufficient to compile a block diagram completely.

In such cases, the Simulink engine propagates the known or assigned sample times to those blocks that have inherited sample times but that have not yet been assigned a sample time. Thus, the engine continues to fill in the blanks (the unknown sample times) until sample times have been assigned to as many blocks as possible. Blocks that still do not have a sample time are assigned a default sample time.

For a completely deterministic model (one where no sample times are set using the above rules), you should explicitly specify the sample times of your source blocks. Source blocks include root inport blocks and blocks without input ports. You do not have to set subsystem input port sample times. You might want to do so, however, when creating modular systems.

An unconnected input implicitly connects to ground. For ground blocks and ground connections, the sample time is always constant (\(\text{inf}\)).

All blocks have an inherited sample time (\(T_s = -1\)). They are assigned a sample time of \((T_f - T_i)/50\).

**Blocks Whose Outputs Have Constant Values**

When you display sample time colors, by default, Constant blocks appear magenta in color to indicate that the block outputs have constant values during simulation. Downstream blocks whose output values are also constant during simulation, such as Gain blocks, similarly appear magenta if they use an inherited sample time. The code generated for these blocks depends in part on the tunability of the block parameters.

If you set **Configuration Parameters > Optimization > Default parameter behavior** to **Inlined**, the block parameters are not tunable in the generated code. Because the block outputs are constant, the code generator eliminates the block code due to constant folding. If the code generator cannot fold the code, or if you select settings to disable constant folding, the block code appears in the model initialization function. The
generated code is more efficient because it does not compute the outputs of these blocks during execution.

However, if you configure a block or model so that the block parameters appear in the generated code as tunable variables, the code generator represents the blocks in a different way. Block parameters are tunable if, for example:

- You set Default parameter behavior to Tunable. By default, numeric block parameters appear as tunable fields of a global parameter structure.
- You use a tunable parameter, such as a Simulink.Parameter object that uses a storage class other than Auto, as the value of one or more numeric block parameters. These block parameters are tunable regardless of the setting that you choose for Default parameter behavior.

If a block parameter is tunable, the generated code must compute the block outputs during execution. Therefore, the block code appears in the model step function. If the model uses multiple discrete rates, the block code appears in the output function for the fastest downstream rate that uses the block outputs.

**Latches for Subsystem Blocks**

When an Inport block is the signal source for a triggered or function-call subsystem, you can use latch options to preserve input values while the subsystem executes. The Inport block latch options include:

<table>
<thead>
<tr>
<th>For</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>Triggered subsystems</td>
<td>Latch input by delaying outside signal</td>
</tr>
<tr>
<td>Function-call subsystems</td>
<td>Latch input for feedback signals of function-call subsystem outputs</td>
</tr>
</tbody>
</table>

When you use **Latch input for feedback signals of function-call subsystem outputs** for a function-call subsystem, the code generator

- Preserves latches in generated code regardless of optimizations that might be set
- Places the code for latches at the start of a subsystem's output/update function

For more information on these options, see the block description of Inport.
**Block Execution Order**

Once the Simulink engine compiles the block diagram, it creates a `model.rtw` file (analogous to an object file generated from a C or C++ file). The `model.rtw` file contains the connection information of the model, as well as the signal attributes. Thus, the timing engine in can determine when blocks with different rates should be executed.

You cannot override this execution order by directly calling a block (in handwritten code) in a model. For example, in the next figure the `disconnected_trigger` model on the left has its trigger port connected to ground, which can lead to the blocks inheriting a constant sample time. Calling the trigger function, `f()`, directly from user code does not work. Instead, you should use a function-call generator to specify the rate at which `f()` should be executed, as shown in the `connected_trigger` model on the right.

Instead of the function-call generator, you could use another block that can drive the trigger port. Then, you should call the model's main entry point to execute the trigger function.

For multirate models, a common use of the code generator is to generate code for individual models separately and then manually code the I/O between the generated code modules. This approach places the burden of data consistency between models on the developer of the models. Another approach is to let Simulink and the code generator maintain data consistency between rates and generate multirate code for use in a multitasking environment. The Rate Transition block is able to interface periodic and asynchronous signals. For a description of the Simulink Coder block libraries, see 2-35.
“Asynchronous Events” (Simulink Coder). For more information on multirate code generation, see “Modeling for Multitasking Execution” (Simulink Coder).

**Algebraic Loops**

Algebraic loops are circular dependencies between variables. This prevents the straightforward direct computation of their values. For example, in the case of a system of equations

- \( x = y + 2 \)
- \( y = -x \)

the values of \( x \) and \( y \) cannot be directly computed.

To solve this, either repeatedly try potential solutions for \( x \) and \( y \) (in an intelligent manner, for example, using gradient based search) or “solve” the system of equations. In the previous example, solving the system into an explicit form leads to

- \( 2x = 2 \)
- \( y = -x \)
- \( x = 1 \)
- \( y = -1 \)

An algebraic loop exists whenever the output of a block having direct feedthrough (such as Gain, Sum, Product, and Transfer Fcn) is fed back as an input to the same block. The Simulink engine is often able to solve models that contain algebraic loops, such as the next diagram.
The code generator does not produce code that solves algebraic loops. This restriction includes models that use Algebraic Constraint blocks in feedback paths. However, the Simulink engine can often eliminate algebraic loops that arise, by grouping equations in certain ways in models that contain them. It does this by separating the update and output functions to avoid circular dependencies. For details, see “Algebraic Loops” (Simulink).

**Algebraic Loops in Triggered Subsystems**

While the Simulink engine can minimize algebraic loops involving atomic and enabled subsystems, a special consideration applies to some triggered subsystems. An example for which code can be generated is shown in the following model and triggered subsystem.

The default Simulink behavior is to combine output and update methods for the subsystem, which creates an apparent algebraic loop, even though the Unit Delay block in the subsystem has no direct feedthrough.

You can allow the Simulink engine to solve the problem by splitting the output and update methods of triggered and enabled-triggered subsystems when feasible. If you want the code generator to take advantage of this feature, select the **Minimize algebraic loop occurrences** check box in the Subsystem Parameters dialog box. Select this option to avoid algebraic loop warnings in triggered subsystems involved in loops.

**Note** If you check this box, the generated code for the subsystem might contain split output and update methods, even if the subsystem is not actually involved in a loop. Also, if a direct feedthrough block (such as a Gain block) is connected to the inport in the above.
triggered subsystem, the Simulink engine cannot solve the problem, and the code generator is unable to generate code.

A similar **Minimize algebraic loop occurrences** option appears on the **Model Referencing** pane of the Configuration Parameters dialog box. Selecting it enables the Simulink Coder software to generate code for models containing Model blocks that are involved in algebraic loops.
Modeling Guidelines for Blocks

Code generation modeling guidelines include recommended model settings, block usage, and block parameters. When you develop models for code generation, use these guidelines.

For more information, see “Modeling Guidelines” (Simulink).

Control Generation of Subsystem Functions

What is a Subsystem Function?

A subsystem function is function code that the code generator produces for a subsystem in a model. The function interface and how the code generator packages the code depends on whether the subsystem is a virtual or atomic (nonvirtual) subsystem and how you configure the subsystem block parameters. For more information, see Subsystem, Atomic Subsystem, Nonvirtual Subsystem, CodeReuse Subsystem.

Options for Controlling Generation of Subsystem Function Code

You can design and configure a model in a way that controls how the code generator produces code from subsystems.

Subsystem Function Dependence

Code generated from subsystems can be completely independent of code generated for a model. When generating code for a subsystem, the code can reference global data structures of the model, even if the subsystem function code is in a separate file. Each
subsystem code file contains include directives and comments describing the dependencies. The code generator checks for cyclic file dependencies and warns about them at build time. For descriptions of how the code generator packages code, see “Manage Build Process File Dependencies” (Simulink Coder).

To generate subsystem function code that is independent of the code generated for the parent model, place the subsystem in a library and configure it as a reusable subsystem, as explained in “Generate Reusable Code from Library Subsystems Shared Across Models” on page 6-53.

Related Examples

• “Modeling Guidelines for Subsystems” on page 2-40
Generate Code and Executables for Individual Subsystems

You can generate code and build an executable for a subsystem within a model. The code generation and build process uses the code generation and build parameters of the root model.

1. In the Configuration Parameters dialog box, set up the code generation and build parameters, similar to setting up the code generation for a model.

2. Right-click the Subsystem block. From the context menu, select **C/C++ Code > Build This Subsystem** from the context menu.

   Alternatively, in the current model, click a subsystem and then from the **Code** menu, select **C/C++ Code > Build Selected Subsystem**.

   **Note** When you select **Build This Subsystem**, if the model is operating in external mode, the build process automatically turns off external mode for the duration of the build. The code generator restores external mode upon completion of the build process.

3. The **Build code for Subsystem** window displays a list of the subsystem parameters. The upper pane displays the name, class, and storage class of each variable (or data object) that is referenced as a block parameter in the subsystem. When you select a parameter in the upper pane, the lower pane shows the blocks that reference the parameter and the parent system of each block.

   The **Storage Class** column contains a menu for each row. The menu options set the storage class or inline the parameter. To declare a parameter to be tunable, set the **Storage Class** to a value other than **Inlined**.
For more information on tunable and inlined parameters and storage classes, see “Create Tunable Calibration Parameter in the Generated Code” on page 22-121.

4 After selecting tunable parameters, **Build** to initiate the code generation and build process.

5 The build process displays status messages in the MATLAB Command Window. When the build is complete, the generated executable is in your working folder. The name of the generated executable is `subsystem.exe` (on PC platforms) or `subsystem` (on The Open Group UNIX® platforms). `subsystem` is the name of the source subsystem block.

The generated code is in a build subfolder, named `subsystem_target_rtw`. `subsystem` is the name of the source subsystem block and `target` is the name of the target configuration.

When you generate code for a subsystem, you can generate an S-function by selecting **Code > C/C++ Code > Generate S-Function**, or you right-click the subsystem block and select **C/C++ Code > Build This Subsystem** from the context menu. For more information on S-functions, see “Generate S-Function from Subsystem” (Simulink Coder).
Subsystem Build Limitations

The following limitations apply to building subsystems:

- Subsystem build does not support a subsystem that has a function-call trigger input or a function-call output.

- When you right-click a subsystem block and select **C/C++ Code > Build This Subsystem** from the context menu to build a subsystem that includes an Outport block for which the **Data type** parameter specifies a bus object, you must address errors that result from setting signal labels. To configure the software to display these errors, in the Configuration Parameters dialog box for the parent model, on the **Diagnostics > Connectivity** pane, set the **Signal label mismatch** parameter to **error**.

- When a subsystem is in a triggered or function-call subsystem, the right-click build process might fail if the subsystem code is not sample-time independent. To find out whether a subsystem is sample-time independent:
  
  1. Copy all blocks in the subsystem to an empty model.
  2. In the Configuration Parameters dialog box, on the **Solver** pane, set:
     
     a. **Type** to **Fixed-step**.
     b. **Periodic sample time constraint** to **Ensure sample time independent**.
     c. Click **Apply**.
  3. Update the model. If the model is sample-time dependent, Simulink generates an error in the process of updating the diagram.

- When you use the right-click build process for a subsystem, the code generator attempts to use the subsystem name for generated code files. In some cases, there can be a conflict with the name that you specify when you set, for example, **File name options** to **Use function name** or **Function name options** to **Use subsystem name**. You see an error:

  The subsystem 'model/subsys'
  is trying to generate code to an reserved file (subsys) for
  the model 'subsys'...

  To resolve the error, modify one of the conflicting file names so that the names are unique.
In a subsystem build warning, the subsystem block path hyperlink that is created references a temporary model block path instead of the actual model block path. In the Diagnostic Viewer, clicking the subsystem hyperlink does not take you to the block. In the Command Window, you see a message:

```plaintext
... No system or file called 'subsystemName' found. ...
```
**Inline Subsystem Code**

You can configure a nonvirtual subsystem to inline the subsystem code with the model code. In the Subsystem Parameters dialog box, setting the **Function packaging** parameter to **Auto** or **Inline** inlines the generated code of the subsystem.

The **Auto** option is the default. When there is only one instance of a subsystem in the model, the **Auto** option inlines the subsystem code. When multiple instances of a subsystem exist, the **Auto** option results in a single copy of the function (as a reusable function). For function-call subsystems with multiple callers, the subsystem code is generated as if you specified **Nonreusable function**.

To inline subsystem code, select **Inline**. The **Inline** option explicitly directs the code generator to inline the subsystem unconditionally.

**Configure Subsystem to Inline Code**

To configure your subsystem for inlining:

1. Right-click the Subsystem block. From the context menu, select **Block Parameters (Subsystem)**.
2. In the Subsystem Parameters dialog box, if the subsystem is virtual, select **Treat as atomic unit**. This option makes the subsystem nonvirtual. On the **Code Generation** tab, the **Function packaging** option is now available.

   If the system is already nonvirtual, the **Function packaging** option is already selected.

3. Click the **Code Generation** tab and select **Auto** or **Inline** from the **Function packaging** parameter.
4 Click **Apply** and close the dialog box.

The border of the subsystem thickens, indicating that it is nonvirtual.

When you generate code from your model, the code generator inlines subsystem code within `model.c` or `model.cpp` (or in its parent system's source file). You can identify this code by system/block identification tags, such as:

```c
/* Atomic SubSystem Block: <Root>/AtomicSubsys1 */
```

**Exceptions to Inlining**

There are certain cases in which the code generator does not inline a nonvirtual subsystem, even though the **Inline** option is selected.

- If the subsystem is a function-call subsystem that is called by a noninlined S-function, the **Inline** option is ignored. Noninlined S-functions make calls by using function pointers. Therefore, the function-call subsystem must generate a function with all arguments present.
• In a feedback loop involving function-call subsystems, the code generator forces one of the subsystems to be generated as a function instead of inlining it. Based on the order in which the subsystems are sorted internally, the software selects the subsystem to be generated as a function.

• If a subsystem is called from an S-function block that sets the option \texttt{SS\_OPTION\_FORCE\_NONINLINED\_FCNCALL} to \texttt{TRUE}, it is not inlined. When user-defined Async Interrupt blocks or Task Sync blocks are present, this result might occur. Such blocks must be generated as functions. These blocks are located in the \texttt{vxlib1} block library and use the \texttt{SS\_OPTION\_FORCE\_NONINLINED\_FCNCALL} option. This library demonstrates integration with an example RTOS (VxWorks®).\textsuperscript{1}

\textbf{Note} You can use the blocks in the \texttt{vxlib1} (Simulink Coder) library (Async Interrupt and Task Sync) for simulation and code generation. These blocks provide starting point examples to help you develop custom blocks for your target environment.

\textsuperscript{1} VxWorks is a registered trademark of Wind River® Systems, Inc.
Generate Subsystem Code as Separate Function and Files

To generate a separate subsystem function and a separate file for a subsystem in a model:

1   Right-click a Subsystem block. From the context menu, select **Block Parameters (Subsystem)**.

2   In the Subsystem Parameters dialog box, if the subsystem is virtual, select **Treat as atomic unit**. On the **Code Generation** tab, the **Function packaging** parameter is now available.

3   Click the **Code Generation** tab and select **Nonreusable function** from the **Function packaging** parameter. The **Nonreusable function** option enables two parameters:
   - The “Function name options” (Simulink) parameter controls the naming of the generated function.
   - The “File name options” (Simulink) parameter controls the naming of the generated file.

4   Set the **Function name options** parameter.

5   Set the **File name options** parameter to a value other than **Auto**. If you are generating a reusable function for your subsystem, see “Generate Reentrant Code from Subsystems” on page 6-42 or “Generate Reusable Code from Library Subsystems Shared Across Models” on page 6-53.

6   Click **Apply** and close the dialog box.
Optimize Code for Identical Nested Subsystems

The **Function packaging** parameter *Auto* option can optimize code in situations in which identical subsystems contain other identical subsystems, by both reusing and inlining generated code. Suppose a model, such as the one shown in “Reuse of Identical Nested Subsystems” on page 3-12, contains identical subsystems A1 and A2. A1 contains subsystem B1, and A2 contains subsystem B2, which are identical. In such cases, the *Auto* option causes one function to be generated which is called for both A1 and A2. This function contains one piece of inlined code to execute B1 and B2. This optimization generates less code which improves execution speed.

### Special Case Optimization:
When B1=B2 and A1=A2, selecting the *Auto* option inlines code for B within code for function A

![Diagram of Reuse of Identical Nested Subsystems](image)

**Reuse of Identical Nested Subsystems**
The code generator attempts to generate constant parameters to the shared utilities folder first. If constant parameters are not generated to the shared utilities folder, they are defined in the top model in a global constant parameter structure. The declaration of the structure, `ConstParam_model`, is in `model.h`:

```c
/* Constant parameters (auto storage) */
typedef struct {
    /* Expression: [1 2 3 4 5 6 7]
       * Referenced by: '<Root>/Constant'
    */
    real_T Constant_Value[7];

    /* Expression: [7 6 5 4 3 2 1]
       * Referenced by: '<Root>/Gain'
    */
    real_T Gain_Gain[7];
} ConstParam_model;
```

The definition of the constant parameters, `model_constP`, is in:

```c
/* Constant parameters (auto storage) */
const ConstParam_model model_ConstP = {
    /* Expression: [1 2 3 4 5 6 7]
       * Referenced by: '<Root>/Constant'
    */
    { 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0 },

    /* Expression: [7 6 5 4 3 2 1]
       * Referenced by: '<Root>/Gain'
    */
    { 7.0, 6.0, 5.0, 4.0, 3.0, 2.0, 1.0 }
};
```

The `model_constP` is passed as an argument to referenced models.

Code Generation of Referenced Models

This section describes model referencing considerations that apply specifically to code generation by the Simulink Coder. This section assumes that you understand referenced models and related terminology and requirements, as described in “Overview of Model Referencing” (Simulink) and associated topics.

When generating code for a referenced model hierarchy, the code generator produces a stand-alone executable for the top model, and a library module called a model reference target for each referenced model. When the code executes, the top executable invokes the model reference targets to compute the referenced model outputs. Model reference targets are sometimes called Simulink Coder targets.

Be careful not to confuse a model reference target (Simulink Coder target) with other types of targets:

- Target hardware — A platform for which the Simulink Coder software generates code
- System target — A file that tells the Simulink Coder software how to generate code for particular purpose
- Rapid Simulation target (RSim) — A system target file supplied with the Simulink Coder product
- Simulation target — A MEX-file that implements a referenced model that executes with Simulink Accelerator™ software

The code generator places the code for the top model of a hierarchy in the code generation folder (Simulink) and places the code for referenced models in an slprj folder in the code generation folder (Simulink). Subfolders in slprj provide separate places for different types of files. For folder information, see “Manage Build Process Folders” (Simulink Coder).

By default, the product uses incremental code generation. When generating code, it compares structural checksums of referenced model files with the generated code files to determine whether to regenerate model reference targets. To control when rebuilds occur, use the configuration parameter Model Referencing > Rebuild. For details, see “Rebuild” (Simulink).

In addition to incremental code generation, the Simulink Coder software uses incremental loading. The code for a referenced model is not loaded into memory until the code for its parent model executes and needs the outputs of the referenced model. The product then
loads the referenced model target and executes. Once loaded, the target remains in memory until it is no longer used.

Most code generation considerations are the same whether or not a model includes referenced models: the code generator handles the details automatically insofar as possible. This chapter describes topics that you may need to consider when generating code for a model reference hierarchy.

If you have a Embedded Coder license, custom targets must declare themselves to be model reference compliant if they need to support Model blocks. For more information, see “Support Model Referencing” on page 74-84.
Generate Code for Referenced Models

In this section...

"About Generating Code for Referenced Models“ on page 4-4
"Create and Configure the Subsystem“ on page 4-4
"Convert Model to Use Model Referencing“ on page 4-7
"Generate Model Reference Code for a GRT Target“ on page 4-10
"Work with Code Generation Folders“ on page 4-12

About Generating Code for Referenced Models

To generate code for referenced models, you

1. Create a subsystem in an existing model.
2. Convert the subsystem to a referenced model (Model block).
3. Call the referenced model from the top model.
4. Generate code for the top model and referenced model.
5. Explore the generated code and the code generation folder.

You can accomplish some of these tasks automatically with a function called Simulink.Subsystem.convertToModelReference.

Create and Configure the Subsystem

In the first part of this example, you define a subsystem for the vdp example model, set configuration parameters for the model, and use the Simulink.Subsystem.convertToModelReference function to convert it into two new models — the top model (vdptop) and a referenced model vdpmultRM containing a subsystem you created (vdpmult).

1. In the MATLAB Command Window, create a new working folder wherever you want to work and cd into it:

   mkdir mrexample
   cd mrexexample

2. Open the vdp example model by typing:
Drag a box around the three blocks outlined in blue below:

Choose **Create Subsystem from Selection** from the **Diagram > Subsystem & Model Reference** menu.

A subsystem block replaces the selected blocks.

If the new subsystem block is not where you want it, move it to a preferred location.

Rename the block `vdpmult`.

Right-click the `vdpmult` block and select **Block Parameters (Subsystem)**.

The **Function Block Parameters** dialog box appears.

In the **Function Block Parameters** dialog box, select **Treat as atomic unit**, then click **OK**.

The border of the `vdpmult` subsystem thickens to indicate that it is now atomic. An atomic subsystem executes as a unit relative to the parent model: subsystem block execution does not interleave with parent block execution. This property makes it possible to extract subsystems for use as stand-alone models and as functions in generated code.
The block diagram should now appear as follows:

You must set several properties before you can extract a subsystem for use as a referenced model. To set the properties,

1. Open Model Explorer by selecting **Model Explorer** from the model's View menu.
2. In the **Model Hierarchy** pane, click the symbol preceding the model name to reveal its components.
3. Click **Configuration (Active)** in the left pane.
4. In the center pane, select **Solver**.
5. In the right pane, under **Solver selection** change the **Type** to Fixed-step, then click **Apply**. You must use fixed-step solvers when generating code, although referenced models can use different solvers than top models.
6. In the center pane, select **Diagnostics**. In the right pane, select the **Data Validity** tab. In the **Signals** area, set **Signal resolution** to Explicit only. Alternatively, if you do not want to use Simulink.Signal objects, set **Signal resolution** to None.
7. Click **Apply**.

The model now has the properties that model referencing requires.
In the center pane, click **Model Referencing**. In the right pane, set **Rebuild** to **If any changes in known dependencies detected**. Click **Apply**. This setting prevents code regeneration when it is not required.

In the vdp model window, choose **File > Save as**. Save the model as **vdptop** in your working folder. Leave the model open.

### Convert Model to Use Model Referencing

In this portion of the example, you use the conversion function `Simulink.SubSystem.convertToModelReference` to extract the subsystem `vdpmult` from `vdptop` and convert `vdpmult` into a referenced model named `vdpmultRM`. To see the complete syntax of the conversion function, type at the MATLAB prompt:

```
help Simulink.SubSystem.convertToModelReference
```

For additional information, type:

```
doc Simulink.SubSystem.convertToModelReference
```

If you want to see an example of `Simulink.SubSystem.convertToModelReference` before using it yourself, type:

```
sldemo_mdlref_conversion
```

Simulink also provides a menu command, **Subsystem & Model Reference > Convert Subsystem to > Referenced Model**, that you can use to convert a subsystem to a referenced model. The command calls `Simulink.SubSystem.convertToModelReference` with default arguments. For more information, see “Convert a Subsystem to a Referenced Model” (Simulink).

### Extract the Subsystem to a Referenced Model

To use `Simulink.SubSystem.convertToModelReference` to extract `vdpmult` and convert it to a referenced model, type:

```
Simulink.SubSystem.convertToModelReference... ('vdptop/vdpmult', 'vdpmultRM',... 'ReplaceSubsystem', true, 'BuildTarget', 'Sim')
```

This command:

1. Extracts the subsystem `vdpmult` from `vdptop`. 
2 Converts the extracted subsystem to a separate model named vdpmultRM and saves the model to the working folder.

3 In vdptop, replaces the extracted subsystem with a Model block that references vdpmultRM.

4 Creates a simulation target for vdptop and vdpmultRM.

The converter prints progress messages and terminates with

\[
\text{ans} = 1
\]

The parent model vdptop now looks like this:

Note the changes in the appearance of the block vdpmult. These changes indicate that it is now a Model block rather than a subsystem. As a Model block, it does not have contents of its own: the previous contents now exist in the referenced model vdpmultRM, whose name appears at the top of the Model block. Widen the Model block to expose the complete name of the referenced model.

If the parent model vdptop had been closed at the time of conversion, the converter would have opened it. Extracting a subsystem to a referenced model does not automatically create or change a saved copy of the parent model. To preserve the changes to the parent model, save vdptop.

Right-click the Model block vdpmultRM and choose Open to open the referenced model. The model looks like this:
Files Created and Changed by the Converter

The files in your working folder now consist of the following (not in this order).

<table>
<thead>
<tr>
<th>File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>vdptop</code> model file</td>
<td>Top model that contains a Model block where the <code>vdpmult</code> subsystem was</td>
</tr>
<tr>
<td><code>vdpmultRM</code> model file</td>
<td>Referenced model created for the <code>vdpmult</code> subsystem</td>
</tr>
<tr>
<td><code>vdpmultRM_msf.mexw64</code></td>
<td>Static library file (Microsoft® Windows platforms only). The file extension is system-dependent and may differ. This file executes when the <code>vdptop</code> model calls the Model block <code>vdpmult</code>. When called, <code>vdpmult</code> in turn calls the referenced model <code>vdpmultRM</code>.</td>
</tr>
<tr>
<td><code>/slprj</code></td>
<td>Folder for generated model reference code</td>
</tr>
</tbody>
</table>

Code for model reference simulation targets is placed in the `slprj/sim` subfolder. Generated code for GRT, ERT, and other Simulink Coder targets is placed in `slprj` subfolders named for those targets. You will inspect some model reference code later in this example. For more information on code generation folders, see “Work with Code Generation Folders” on page 4-12.

**Run the Converted Model**

Open the Scope block in `vdptop` if it is not visible. In the `vdptop` window, click the **Run** tool or choose **Run** from the **Simulation** menu. The model calls the `vdpmultRM_msf` simulation target to simulate. The output looks like this:
Generate Model Reference Code for a GRT Target

The function `Simulink.SubSystem.convertToModelReference` created the model and the simulation target files for the referenced model `vdpmultRM`. In this part of the example, you generate code for that model and the `vdptop` model, and run the executable you create:

1. Verify that you are still working in the `mrexample` folder.
2. If the model `vdptop` is not open, open it. Make sure it is the active window.
3. Open Model Explorer by selecting Model Explorer from the model's View menu.
4. In the Model Hierarchy pane, click the symbol preceding the `vdptop` model to reveal its components.
5. Click Configuration (Active) in the left pane.
6. In the center pane, select Data Import/Export.
7. In the pane, select Time and Output and clear Data stores. Click Apply.

These settings instruct the model `vdptop` (and later its executable) to log time and output data to MAT-files for each time step.

8. Generate GRT code (the default) and an executable for the top model and the referenced model. For example, in the model, press Ctrl+B.
The Simulink Coder build process generates and compiles code. The current folder now contains a new file and a new folder:

<table>
<thead>
<tr>
<th>File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>vdptop.exe</td>
<td>The executable created by the build process</td>
</tr>
<tr>
<td>vdptop_grt_rtw/</td>
<td>The build folder, containing generated code for the top model</td>
</tr>
</tbody>
</table>

The build process also generated GRT code for the referenced model and placed it in the slprj folder.

To view a model's generated code in Model Explorer, the model must be open. To use the Model Explorer to inspect the newly created build folder, vdptop_grt_rtw:

1. Open Model Explorer by selecting Model Explorer from the model's View menu.
2. In the Model Hierarchy pane, click the symbol preceding the model name to reveal its components.
3. Click the symbol preceding Code for vdptop to reveal its components.
4. Directly under Code for vdptop, click This Model.

A list of generated code files for vdptop appears in the Contents pane:

- rtmodel.h
- vdptop.c
- vdptop.h
- vdptop.mk
- vdptop_private.h
- vdptop_types.h

You can browse code by selecting a file of interest in the Contents pane.

To open a file in a text editor, click a filename, and then click the hyperlink that appears in the gray area at the top of the Document pane. The figure below illustrates viewing code for vdptop.c, in a text editor. Your code may differ.
To view the generated code in the HTML code generation report, see “Generate a Code Generation Report” (Simulink Coder).

**Work with Code Generation Folders**

Model reference code is generated in your code generation folder (Simulink) and simulation target code is generated in your simulation cache folder (Simulink). Because of this process, there are constraints on:

- When and where model reference targets are built.
- How the model reference targets are accessed.

The models referenced by Model blocks can be stored anywhere on the MATLAB path. A given top model can include models stored on different file systems or in different folders. The same is not true for the simulation targets and generated code derived from these models. Under most circumstances, to allow code reuse, models referenced by a given top model must be set up to simulate and generate model reference target code in a single code generation folder.

This means that, if you reference the same model from several top models, each stored in a different folder, you must choose one of these approaches:

- Always work with the same code generation folder and be sure that the models are on your path.
• Allow separate code generation folders, simulation targets, and Simulink Coder targets to be generated in each folder in which you work.

The second approach requires maintenance of several instances of the model reference code and it is possible for generated code to become redundant. For example, when you make changes to the referenced model. Therefore, to minimize code regeneration of referenced models, choose a specific code generation folder for all sessions.

Configure Referenced Models

Minimize occurrences of algebraic loops by selecting the **Minimize algebraic loop occurrences** parameter on the **Model Reference** pane. The setting of this option affects only generation of code from the model. For information on how this option affects code generation, see “Configure Run-Time Environment Options” (Simulink Coder). For more information about direct feed through, see “Algebraic Loops” (Simulink).

Use the **Integer rounding mode** parameter on your model’s blocks to simulate the rounding behavior of the C compiler that you intend to use to compile code generated from the model. This setting appears on the **Signal Attributes** pane of the parameter dialog boxes of blocks that can perform signed integer arithmetic, such as the Product and n-D Lookup Table blocks.

For most blocks, the value of **Integer rounding mode** completely defines rounding behavior. For blocks that support fixed-point data and the Simplest rounding mode, the value of **Signed integer division rounds to** also affects rounding. For details, see “Precision” (Fixed-Point Designer).

When models contain Model blocks, all models that they reference must be configured to use identical hardware settings. For information on the **Model Referencing** pane options, see “Model Configuration Parameters: Model Referencing” (Simulink) and “Set Configuration Parameters for Model Referencing” (Simulink).

**Note** There are some configuration parameter setting limitations for code generation. See “Simulink Coder Model Referencing Limitations” (Simulink Coder).
Build Model Reference Targets

By default, the Simulink engine rebuilds simulation targets before the Simulink Coder software generates model reference targets. You can change the rebuild criteria or specify when the engine rebuilds targets. For more information, see “Rebuild” (Simulink).

The Simulink Coder software generates a model reference target directly from the Simulink model. The product automatically generates or regenerates model reference targets, for example, when they require an update.

You can command the Simulink and Simulink Coder products to generate a simulation target for an Accelerator mode referenced model, and a model reference target for a referenced model, by executing the `slbuild` command with arguments in the MATLAB Command Window.

The Simulink Coder software generates only one model reference target for all instances of a referenced model. See “Generate Reentrant Code from Subsystems” (Simulink Coder) for details.

Reduce Change Checking Time

You can reduce the time that the Simulink and Simulink Coder products spend checking whether simulation targets and model reference targets need to be rebuilt by setting configuration parameter values as follows:

- In the top model, consider setting the model configuration parameter `Model Referencing > Rebuild` to `If any changes in known dependencies detected`. (See “Rebuild” (Simulink).)
- In all referenced models throughout the hierarchy, set the configuration parameter `Diagnostics > Data Validity > Signal resolution` to `Explicit only` or `None`. (See “Signal resolution” (Simulink).)

These parameter values exist in a referenced model's configuration set, not in the individual Model block. Setting either value for an instance of a referenced model, sets it for all instances of that model.
Simulink Coder Model Referencing Requirements

A model reference hierarchy must satisfy various Simulink Coder requirements, as described in this section. In addition to these requirements, a model referencing hierarchy to be processed by the Simulink Coder software must satisfy:

- The Simulink requirements listed in:
  - “Configuration Requirements for All Referenced Model Simulation” (Simulink)
  - “Define Referenced Model Inputs and Outputs” (Simulink)
- The Simulink limitations listed in “Signal Limitations” (Simulink)
- The Simulink Coder limitations listed in “Simulink Coder Model Referencing Limitations” on page 4-28

Configuration Parameter Requirements

A referenced model uses a configuration set in the same way a top model does, as described in “Manage a Configuration Set” (Simulink). By default, every model in a hierarchy has its own configuration set, which it uses in the same way that it would if the model executed independently.

Because each model can have its own configuration set, configuration parameter values can be different in different models. Furthermore, some parameter values are intrinsically incompatible with model referencing. The response of the Simulink Coder software to an inconsistent or unusable configuration parameter depends on the parameter:

- Where an inconsistency has no significance, the product ignores or resolves the inconsistency without posting a warning.
- Where a nontrivial and possibly acceptable solution exists, the product resolves the conflict silently; resolves it with a warning; or generates an error.
- If an acceptable resolution is not possible, the product generates an error. You must then change parameter values to eliminate the problem.

When a model reference hierarchy contains many referenced models that have incompatible parameter values, or a changed parameter value must propagate to many referenced models, manually eliminating all configuration parameter incompatibilities can be tedious. You can control or eliminate such overhead by using configuration references to assign an externally-stored configuration set to multiple models. See “Manage a Configuration Reference” (Simulink) for details.
The following tables list configuration parameters that can cause problems if set in certain ways, or if set differently in a referenced model than in a parent model. Where possible, the Simulink Coder software resolves violations of these requirements automatically, but most cases require changes to the parameters in some or all models.

### Configuration Parameters Changed During Code Generation

For referenced models, if these **Configuration Parameters** > **Code Generation** > **Symbols** parameters have settings that do not contain a $R$ token (which represents the name of the reference model), code generation prepends the $R$ token to the identifier format:

- **Global variables** (CustomSymbolStrGlobalVar)
- **Global types** (CustomSymbolStrType)
- **Subsystem methods** (CustomSymbolStrFcn)
- **Constant macros** (CustomSymbolStrMacro)

You can use the Model Advisor to identify models in a model referencing hierarchy for which code generation changes configuration parameter settings.

1. In the Simulink Editor, select **Analysis** > **Model Advisor**.
2. Select **By Task**.
3. Run the **Check code generation identifier formats used for model reference** check.

If a script that operates on generated code uses identifier formats that code generation changes, then update the script to use the updated identifier format (which includes an appended $R$ token).

For more information about identifiers, see “Identifier Format Control” on page 39-22.
Naming Requirements

Within a model that uses model referencing, names of the constituent models cannot collide. When you generate code from a model that uses model referencing, the Maximum identifier length parameter must be large enough to accommodate the root model name and the name-mangling text. A code generation error occurs if Maximum identifier length is not large enough.

When a name conflict occurs between a symbol within the scope of a higher-level model and a symbol within the scope of a referenced model, the symbol from the referenced model is preserved. Name mangling is performed on the symbol from the higher-level model.

Embedded Coder Naming Requirements

The Embedded Coder product lets you control the formatting of generated symbols in much greater detail. When generating code with an ERT target from a model that uses model referencing:

- The $R token must be included in the Identifier format control parameter specifications (in addition to the $M token) except for Shared utilities identifier format.
- The Maximum identifier length must be large enough to accommodate full expansions of the $R and $M tokens.

See “Model Configuration Parameters: Code Generation Symbols” (Simulink Coder) for more information.

Custom Target Requirements

If you have an Embedded Coder license, a custom target must meet various requirements to support model referencing. For details, see “Support Model Referencing” on page 74-84.
Storage Classes for Signals Used with Model Blocks

Models containing Model blocks can use signals of storage class Auto without restriction. However, when you declare signals to be global, you must be aware of how the signal data will be handled.

A global signal is a signal with a storage class other than Auto:

- ExportedGlobal
- ImportedExtern
- ImportedExternPointer
- Custom

The above are distinct from signals that use the storage class Model default when you set the default storage class of the corresponding data category to Default in the Code Mapping Editor, which are treated as test points with Auto storage class.

Global signals are declared, defined, and used as follows:

- An extern declaration is generated by all models that use a given global signal.
  As a result, if a signal crosses a Model block boundary, the top model and the referenced model both generate extern declarations for the signal.
- For an exported signal, the top model is responsible for defining (allocating memory for) the signal, whether or not the top model itself uses the signal.
- Global signals used by a referenced model are accessed directly (as global memory). They are not passed as arguments to the functions that are generated for the referenced models.

Custom storage classes also follow the above rules. However, certain custom storage classes are not currently supported for use with model reference. For details, see “Storage Class Limitations” (Simulink Coder).

Storage Classes for Parameters Used with Model Blocks

Storage classes are supported for both simulation and code generation, and all except Auto are tunable. The supported storage classes thus include

- Model default
• ExportedGlobal
• ImportedExtern
• ImportedExternPointer
• Custom

Note the following restrictions on parameters in referenced models:

• Tunable parameters are not supported for noninlined S-functions.
• Tunable parameters set using the Model Parameter Configuration dialog box are ignored.

Note the following considerations concerning how global tunable parameters are declared, defined, and used in code generated for targets:

• A global tunable parameter is a parameter in the base workspace with a storage class other than Auto.
• An extern declaration is generated by all models that use a given parameter.
• If a parameter is exported, the top model is responsible for defining (allocating memory for) the parameter (whether it uses the parameter or not).
• Global parameters are accessed directly (as global memory). They are not passed as arguments to the functions that are generated for the referenced models.
• In a referenced model that sets the default storage class for a category of parameter data to Default in the Code Mapping Editor, symbols for Model default parameters are generated using unstructured variables (rtP_xxx) instead of being written into the model_P structure. This is so that each referenced model can be compiled independently.

Certain custom storage classes for parameters are not currently supported for model reference. For details, see “Storage Class Limitations” (Simulink Coder).

Parameters used as Model block arguments must be defined in the referenced model’s workspace. For details, see “Parameterize Instances of a Reusable Referenced Model” (Simulink).

**Signal Name Mismatches Across Model Reference Boundary**

Within a parent model, the name and storage class for a signal entering or leaving a Model block might not match those of the signal attached to the root inport or outport.
within that referenced model. Because referenced models are compiled independently without regard to a parent model, they cannot adapt to the possible variations in how parent models label and store signals.

The Simulink Coder software accepts all cases where input and output signals in a referenced model have Auto storage class. When such signals are test pointed or are global, as described above, certain restrictions apply. The following table describes how mismatches in signal labels and storage classes between parent and referenced models are handled:

### Relationships of Signals and Storage Classes Across Model Reference Boundary

<table>
<thead>
<tr>
<th>Referenced Model</th>
<th>Parent Model</th>
<th>Signal Passing Method</th>
<th>Signal Mismatch Checking</th>
</tr>
</thead>
<tbody>
<tr>
<td>Auto</td>
<td>Any storage class</td>
<td>Function argument</td>
<td>None</td>
</tr>
<tr>
<td>Model default (when Code Mapping Editor specifies Default storage class) or resolved to Signal Object</td>
<td>Any storage class</td>
<td>Function argument</td>
<td><strong>Signal label mismatch</strong></td>
</tr>
<tr>
<td>Global</td>
<td>Auto or Model default (when Code Mapping Editor specifies Default storage class)</td>
<td>Global variable</td>
<td><strong>Signal label mismatch</strong></td>
</tr>
<tr>
<td>Global</td>
<td>Global</td>
<td>Global variable</td>
<td>Labels and storage classes must be identical (else error)</td>
</tr>
</tbody>
</table>

To summarize, the following signal resolution rules apply to code generation:

- If the storage class of a root input or output signal in a referenced model is Auto (or is Model default when you set the storage class of the corresponding data category to Default in the Code Mapping Editor), the signal is passed as a function argument.

- When such a signal is Model default or resolves to a Simulink.Signal object, the **Signal label mismatch** diagnostic is applied.

- If a root input or output signal in a referenced model is global, it is communicated by using direct memory access (global variable). In addition,
• If the corresponding signal in the parent model is also global, the names and storage classes must match exactly.
• If the corresponding signal in the parent model is not global, the **Signal label mismatch** diagnostic is applied.

You can set the **Signal label mismatch** diagnostic to **error**, **warning**, or **none** in the **Diagnostics > Connectivity** pane of the Configuration Parameters dialog box.

Inherited Sample Time for Referenced Models

For information about Model block sample time inheritance, see “Inherit Sample Times for Model Referencing” (Simulink). In generated code, you can control inheriting sample time by using `ssSetModelReferenceSampleTimeInheritanceRule` in different ways:

- An S-function that precludes inheritance: If the sample time is used in the S-function's run-time algorithm, then the S-function precludes a model from inheriting a sample time. For example, consider the following `mdlOutputs` code:

  ```c
  static void mdlOutputs(SimStruct *S, int_T tid)
  {
    const real_T *u = (const real_T*) ssGetInputPortSignal(S,0);
    real_T       *y = ssGetOutputPortSignal(S,0);
    y[0] = ssGetSampleTime(S,tid) * u[0];
  }
  ```

  This `mdlOutputs` code uses the sample time in its algorithm, and the S-function therefore should specify

  ```c
  ssSetModelReferenceSampleTimeInheritanceRule(S, DISALLOW_SAMPLE_TIME_INHERITANCE);
  ```

- An S-function that does not preclude Inheritance: If the sample time is only used for determining whether the S-function has a sample hit, then it does not preclude the model from inheriting a sample time. For example, consider the `mdlOutputs` code from the S-function example `sfun_multirate.c`:

  ```c
  static void mdlOutputs(SimStruct *S, int_T tid)
  {
    InputRealPtrsType enablePtrs;
    int               *enabled = ssGetIWork(S);
    
    if (ssGetInputPortSampleTime
        (S,ENABLE_IPORT)==CONTINUOUS_SAMPLE_TIME 
        && ssGetInputPortOffsetTime(S,ENABLE_IPORT)==0.0) {
      if (ssIsMajorTimeStep(S) 
          && ssIsContinuousTask(S,tid)) {
        enablePtrs = ssGetInputPortRealSignalPtrs(S,ENABLE_IPORT);
        *enabled = (*enablePtrs[0] > 0.0);
      }
    } else {
  ```
int enableTid =
ssGetInputPortSampleTimeIndex(S, ENABLE_IPORT);
if (ssIsSampleHit(S, enableTid, tid)) {
    enablePtrs =
    ssGetInputPortRealSignalPtrs(S, ENABLE_IPORT);
    *enabled = (*enablePtrs[0] > 0.0);
}

if (*enabled) {
    InputRealPtrsType uPtrs  =
    ssGetInputPortRealSignalPtrs(S, SIGNAL_IPORT);
    real_T            signal = *uPtrs[0];
    int               i;

    for (i = 0; i < NOUTPUTS; i++) {
        if (ssIsSampleHit(S, ssGetOutputPortSampleTimeIndex(S, i), tid)) {
            real_T *y = ssGetOutputPortRealSignal(S, i);
            *y = signal;
        }
    }
} /* end mdlOutputs */

The above code uses the sample times of the block, but only for determining whether there is a hit. Therefore, this S-function should set

ssSetModelReferenceSampleTimeInheritanceRule (S, USE_DEFAULT_FOR_DISCRETE_INHERITANCE);
Customize Library File Suffix and File Type

You can control the library file suffix and file type extension that the Simulink Coder code generator uses to name generated model reference libraries. Use the model configuration parameter TargetLibSuffix to specify the scheme for the suffix and extension. The scheme must include a period (.). If you do not set this parameter, the Simulink Coder software names the libraries as follows:

- On Windows systems, *model_rtwlib.lib*
- On UNIX or Linux® systems, *model_rtwlib.a*

The TargetLibSuffix parameter does not apply for model builds that use the toolchain approach. For more information, see “Identify Library File Type for Toolchain Approach” (Simulink Coder).
Simulink Coder Model Referencing Limitations

The following Simulink Coder limitations apply to model referencing. In addition to these limitations, a model reference hierarchy used for code generation must satisfy:

- The Simulink requirements listed in:
  - “Configuration Requirements for All Referenced Model Simulation” (Simulink)
  - “Define Referenced Model Inputs and Outputs” (Simulink)
- The Simulink limitations listed in “Model Referencing Limitations” (Simulink).
- The Simulink Coder requirements applicable to the code generation target, as listed in “Configuration Parameter Requirements” on page 4-16.

Customization Limitations

- The code generator ignores custom code settings in the Configuration Parameters dialog box and custom code blocks when generating code for a referenced model.
- Data type replacement is not supported for simulation target code generation of referenced models.
- Simulation targets do not include Stateflow target custom code.
- If you have an Embedded Coder license, some restrictions exist on grouped custom storage classes in referenced models. For details, see “Storage Class Limitations” (Simulink Coder).

Data Logging Limitations

- To Workspace blocks, Scope blocks, and all types of runtime display, such as the display of port values and signal values, are ignored when the Simulink Coder software generates code for a referenced model. The resulting code is the same as if the constructs did not exist.
- Code generated for referenced models cannot log data to MAT-files. If data logging is enabled for a referenced model, the Simulink Coder software disables the option before code generation and re-enables it afterwards.
- If you log states for a model that contains referenced models, the ordering of the states in the output is determined by block sorted order, and might not match between simulation output and generated code MAT-file logging output.
State Initialization Limitation

When a top model uses the Data Import/Export > Initial state parameter in the Configuration Parameters dialog box to specify initial conditions, the Simulink Coder software does not initialize the discrete states of the referenced models during code generation.

Reusability Limitations

If a referenced model used for code generation has any of the following properties, the model must specify the configuration parameter Model Referencing > Total number of instances allowed per top model as One, and no other instances of the model can exist in the hierarchy. If you do not set the parameter to One, or more than one instance of the model exists in the hierarchy, an error occurs. The properties are:

- The model references another model which has been set to single instance
- The model contains a state or signal with non-auto storage class
- The model uses any of the following Stateflow constructs:
  - Machine-parented data
  - Machine-parented events
  - Stateflow graphical functions
- The model contains a subsystem that is marked as function
- The model contains an S-function that is:
  - Inlined but has not set the option SS_OPTION_WORKS_WITH_CODE_REUSE
  - Not inlined
- The model contains a function-call subsystem that:
  - Has been forced by the Simulink engine to be a function
  - Is called by a wide signal

For more information about Total number of instances allowed per top model, see “Total number of instances allowed per top model” (Simulink).
S-Function Limitations

- If a referenced model contains an S-function that should be inlined using a Target Language Compiler file, the S-function must use the `ssSetOptions` macro to set the `SS_OPTION_USE_TLC_WITH_ACCELERATOR` option in its `mdlInitializeSizes` method. The simulation target will not inline the S-function unless this flag is set.
- A referenced model cannot use noninlined S-functions generated by the Simulink Coder software.
- The Simulink Coder S-function target does not support model referencing.

For additional information, see “Use S-Functions with Referenced Models” (Simulink).

Simulink Tool Limitations

- Simulink tools that require access to a model's internal data or configuration (including the Model Coverage tool, the Simulink Report Generator product, the Simulink debugger, and the Simulink profiler) have no effect on code generated by the Simulink Coder software for a referenced model, or on the execution of that code. Specifications made and actions taken by such tools are ignored and effectively do not exist.

Subsystem Limitations

- If a subsystem contains Model blocks, you cannot build a subsystem module by right-clicking the subsystem (or by using `Code > C/C++ Code > Build Selected Subsystem`) unless the model is configured to use an ERT target.
- If you generate code for an atomic subsystem as a reusable function, inputs or outputs that connect the subsystem to a referenced model might prevent code reuse, as described in “Generate Reentrant Code from Subsystems” (Simulink Coder).

Target Limitations

- The Simulink Coder S-function target does not support model referencing.
Other Limitations

- Errors or unexpected behavior can occur if a Model block is part of a cycle, the Model block is a direct feedthrough block, and an algebraic loop results. For details, see “Algebraic Loops” (Simulink).
- The **External mode** option is not supported. If it is enabled, it is ignored during code generation.
- When a model contains a trigger or enable port, you cannot generate standalone Simulink Coder code or PIL code.

Configuration Parameters Changed During Accelerated Simulation and Code Generation

During model referencing simulation in accelerator and rapid accelerator mode, Simulink temporarily sets several **Configuration Parameters > Diagnostics > Data Validity** parameter settings to None, if they are set to Warning or Error. You can use the Model Advisor to check for parameters that change. For details, see “Accelerated Simulation and Code Generation Changes Settings” (Simulink).

If the **Configuration Parameters > Code Generation > Symbols** parameters hold identifier information about the name of a referenced model and do not use a $R token, code generation prepends the $R token to the name of the model. You can use the Model Advisor to check for changed model names. See “Configuration Parameters Changed During Code Generation” (Simulink Coder).
Combined Models in Simulink Coder
Combine Code Generated for Multiple Models

Techniques

Techniques that you can use to combine code, which the code generator produces for multiple models or multiple instances of a model, into one executable program include:

- Referenced models. See “Overview of Model Referencing” (Simulink) and “Generate Code for Referenced Models” on page 4-4.
- If you have Embedded Coder software, interface the code for multiple models to a common harness program. From the harness program, call the entry-point functions generated for each model. The `ert.tlc` system target file has restrictions, relating to embedded processing, that could be incompatible with your application.
- Generate reusable, multi-instance code that is reentrant. See “Combine Code Generated for Multiple Models or Multiple Instances of a Model” on page 5-3.

The S-function system target (`rtwfcn.tlc`) does not support combining code generated for multiple models.

Consider using model referencing to combine models for simulation and code generation. Model referencing helps with:

- Symbol naming consistency
- Required scheduling of the overall algorithm
- Model configuration consistency

If you combine code generated for different models (that is, without using referenced models), consider:

- Data is global. Symbol (name) clashes can result.
- Configuration parameter settings for the models must match, including settings such as hardware word sizes.
- Reuse and sharing of code can be suboptimal (for example, duplicate code for shared utility functions, scheduling, and solvers).
- Scheduling can be more complex (for example, models can have periodic sample times that are not multiples of each other, making scheduling from a common timer interrupt more complicated)
• For plant models that use continuous time and state, the continuous time signals connecting models are not handled by a single solver like continuous time signals within a model. This can lead to subtle numeric differences.

Control Ownership of Data

If you have Embedded Coder software, you can specify an owner for individual data items such as signals, parameters, and states. The owner of a data item generates the definition (memory allocation and initialization) for the data item. For example, if you apply a custom storage class to a Simulink.Signal object so that it appears as a global variable in the generated code, specify one of the combined models as the owner of the object. The code generated for that model defines the variable.

If you use model referencing, you can modularize the generated code and establish clear ownership of data when you work in a team.

If you do not use model referencing, you can prevent generation of duplicate definitions for a data item. For example, suppose you store a Simulink.Parameter object in the base workspace and apply the storage class ExportedGlobal. If you generate code from two separate models that use the object, each model generates a definition for the corresponding global variable. Instead, you can specify an owner for the object so that only the owner generates a definition.

To specify an owner for a data item:

1  Apply a custom storage class to the data item. See “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 26-19.
2  Configure the owner of the data item by specifying the Owner custom attribute.
3  Select the model configuration parameter Use owner from data object for data definition placement.

For more information about controlling ownership and file placement of data definitions and declarations, see “Control Placement of Global Data Definitions and Declarations in Generated Files” on page 23-2.

Combine Code Generated for Multiple Models or Multiple Instances of a Model

For each model for which you are combining code, generate the code.
1. Set the system target file to a GRT- or ERT-based system target file. The system target file for the models you combine, must be the same.

2. If you intend to have multiple instances of that model in the application, set the model configuration parameter Code Generation > Interface > Code interface packaging to Reusable function. If you specified an ERT-based system target file, optionally, you can set the model configuration parameter Use dynamic memory allocation for model initialization, depending on whether you want to statically or dynamically allocate the memory for each instance of the model.

3. Generate source code. The code generator includes an allocation function in the generated file model.c. The allocation function dynamically allocates model data for each instance of the model.

After generating source code for each model:

1. Compile the code for each model that you are combining.
2. Combine the makefiles generated for the models into one makefile.
3. Create a combined simulation engine by modifying a main program, such as rt_malloc_main.c. The main program initializes and calls the code generated for each model.
4. Run the makefile. The makefile links the object files and the main program into an executable program.

**Share Data Across Models**

Use unidirectional signal connections between models. This affects the order in which models are called. For example, if you use an output signal from modelA as input to modelB, the modelA output computation should be called first.

**Timing Issues**

When combining code generated for multiple models or multiple instances of a model:

- Configure the models with the same solver mode (single-tasking or multitasking).
- If the models use continuous states, configure the models with the same solver.

If the base rates for the models differ, the main program (such as rt_malloc_main.c) must set up the timer interrupt to occur at the greatest common divisor rate of the models. The main program calls each model at a time interval.
Data Logging and External Mode Support

A multiple-model program can log data to separate MAT-files for each model.

Only one of the models in a multiple-model program can use external mode.
Code Reuse for Simulink Coder
What Is Code Reuse?

Code reuse is a programming technique that reduces time and resources to develop software. When you develop code for reuse, the code serves multiple purposes. The technique involves modularization, which enables multiple individuals to develop code for various system components independently and in parallel. The technique also simplifies software distribution.

A software library is an example of code reuse. A library can contain code for several functions, each having specific behavior. To use a library, you need to know only the interface, which is the specification for calling the library functions.

Reusable code can be reentrant. You can invoke, interrupt, and reinvoke reentrant code. Reentrant code resides in shared memory. Instances of data associated with each use of the code are unique and preserved. Multiple calls to a reusable, reentrant function, for example, can access the function code with each call maintaining a unique data set.

Applications of code reuse include:

- Team-based development.
- Switching between implementations of a function.
- Intellectual property protection.
- Overriding library behavior with a custom implementation.
- Implementing a library that is based on standard library functions.
- Unit testing.
- Performance improvement.

The code generator supports code reuse and reentrancy. You can use key Simulink componentization techniques to partition a model into design components that you simulate, generate code for, and verify independently. You can save individual components as subsystems, libraries, referenced models, or combinations of these elements from which you can generate code. For example, the code generator produces reusable function code from library subsystems and export-function models.

More About

- “What Is Reentrant Code?” on page 6-4
- “Choose a Componentization Technique for Code Reuse” on page 6-6
**What Is Reentrant Code?**

Reentrant (multi-instance) code is a reusable routine that multiple programs can invoke, interrupt, and reinvoke simultaneously. When you want to reuse code, but associate each instance of the shared code with unique, preserved data, use reentrant code. For example, consider this figure that shows four instances of function `sensor_read`. Although the function algorithm is the same in each case, the data associated with each instance varies and is relative to the sensor position.

To make generated code for a model component reentrant, you configure the component such that model entry-point functions receive root-level input and output data as arguments. How you configure the component depends on the modeling style or technique that you apply.

Simulink Function Blocks and Code Generation

Why Generate Code from Simulink Function Blocks and Function Callers?

Simulink Function blocks provide a mechanism for generating C or C++ code for modeling components that represent shared resources. You define the logic as a resource in a Simulink Function block, which separates the function interface (name and arguments) from the implementation of the logic. Function callers (Function Caller blocks, MATLAB Function blocks, and Stateflow charts) can then reuse the function logic at different levels of the model hierarchy.

Simulink Function blocks provide an alternative to reusable subsystems. For example, a consideration for using a Simulink Function block instead of a subsystem block is that a Simulink Function block shares states between function callers. The code generator produces one function. If the Simulink Function block contains blocks that have states, such as a delay or memory, the states persistent between function callers. The order of the function calls is an important consideration.

Reusable functions that the code generator produces from subsystems do not share states. The code generator produces one function for multiple instances of the subsystem as an optimization. If that subsystem contains blocks that have states, the code generator produces one function, but passes a different state variable to each instance. The instances do not share states.

Other uses of Simulink Function blocks and callers include:

- Nesting calls to a function.
- Calling a function defined in one modeling component from another modeling component.
- Generating functions that are globally accessible or scoped.
- Producing code for a client and server application.

Implementation Options

Choose how to implement Simulink functions and function callers based on your code generation requirements. Considerations include:
• How you represent a function and function callers in a model
• Scope of a function
• Whether to export a function from a model (requires Embedded Coder)
• Function code interface customizations (requires Embedded Coder)
• Code generation requirements
• Code generation limitations

Choose a Modeling Pattern

This table shows C code for a function that multiplies an input value times two and a Simulink Function block that can represent that function in a Simulink model.

<table>
<thead>
<tr>
<th>Function Definition</th>
<th>Modeling Element</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>codegen-folder/subsystem.c</code></td>
<td>Simulink Function block</td>
</tr>
<tr>
<td>#include &quot;timestwo_sf.h&quot;</td>
<td></td>
</tr>
<tr>
<td>#include &quot;ex_slfunc_comp_sf.h&quot;</td>
<td></td>
</tr>
<tr>
<td>#include &quot;ex_slfunc_comp_sf_private.h&quot;</td>
<td></td>
</tr>
<tr>
<td><code>void timestwo_sf(real_T rtu_x, real_T *rty_y)</code></td>
<td></td>
</tr>
<tr>
<td>{</td>
<td></td>
</tr>
<tr>
<td>*rty_y = 2.0 * rtu_x;</td>
<td></td>
</tr>
<tr>
<td>}</td>
<td></td>
</tr>
</tbody>
</table>

A Simulink function caller invokes a function defined with a Simulink Function block. From anywhere in a model or chart hierarchy, you can call a function defined with a Simulink Function block by using one of these modeling elements:
<table>
<thead>
<tr>
<th>Function Call</th>
<th>Modeling Element</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>codegen-folder/model.c</strong>&lt;br&gt;void ex_slfunc_comp_sf_step(void)&lt;br&gt;{&lt;br&gt;    real_T rtb FunctionCaller1;&lt;br&gt;    timestwo_sf(ex_slfunc_comp_sf_U.In1, &amp;rtb FunctionCaller1);&lt;br&gt;    ex_slfunc_comp_sf_Y.Out1 = rtb FunctionCaller1;&lt;br}&gt;</td>
<td>Function Caller block</td>
</tr>
<tr>
<td><strong>codegen-folder/model.c</strong>&lt;br&gt;void ex_slfunc_comp_gf_step(void)&lt;br&gt;{&lt;br&gt;    real_T rtb y1_l;&lt;br&gt;    timestwo_gf(ex_slfunc_comp_gf_U.In4, &amp;rtb y1_l);&lt;br&gt;    ex_slfunc_comp_gf_Y.Out4 = rtb y1_l;&lt;br}&gt;</td>
<td>Stateflow chart transition</td>
</tr>
<tr>
<td><strong>codegen-folder/model.c</strong>&lt;br&gt;void ex_slfunc_comp_mf_step(void)&lt;br&gt;{&lt;br&gt;    real_T rtb y;&lt;br&gt;    timestwo_mf(ex_slfunc_comp_mf_U.In3, &amp;rtb y);&lt;br&gt;    ex_slfunc_comp_mf_Y.Out3 = rtb y;&lt;br}&gt;</td>
<td>MATLAB Function block</td>
</tr>
</tbody>
</table>

For more information about modeling choices, see “Simulink Functions” (Simulink).
Specify Function Scope

A function that you define with a Simulink Function block can be global or scoped.

- Global---The code generator places code for a global function in source and header files that are separate from model code files (for example, function.c and function.h). The separate files make the function code available for sharing between function callers.
- Scoped---The code generator places code for a scoped function in model code files (model.c and model.h). To call a scoped function in the context of a model, the function caller must be at the same level as the function in the model hierarchy, or one or more levels below.

To create a library of functions that are accessible from anywhere in the generated model code, set up each function as a scoped Simulink Function block. Place each scoped function within a virtual subsystem at the root level of a model.

For more information, see and “Scoped and Global Simulink Function Blocks” (Simulink).

Decide Whether to Generate Export Function Code

Although you can use Simulink Function blocks in a single top-model design, function code is more reusable when you generate it as standalone, atomic components. You do that by designing the functions in the context of export-function models.

For information, see “Generate Component Source Code for Export to External Code Base” on page 42-52 and “Export-Function Models” (Simulink).

Specify Function Code Interface Customizations

With Embedded Coder, simplify integration of generated code with external code by customizing generated function code interfaces for Simulink Function and Function Caller blocks. You can customize the function interfaces for:

- Global Simulink Function blocks
- Scoped Simulink Function blocks that are at the root level of a model

For more information, see “Customize Generated Function Interfaces for Simulink Function and Function Caller Blocks” on page 29-24.
Requirements

• Within a model hierarchy, function names are unique. If the code generator finds multiple functions with the same name, it issues an error. Change the name of one of the functions and delete the slprj folder.

• The signature (for example, the arguments and argument data types) for a function and function callers must match.
  • If the code generator finds the function first and the signature of a function caller does not match, the code generator issues an error. Change the function caller signature to match the signature of the Simulink Function block or delete the slprj folder.
  • If the code generator finds a function caller first and the signature of the function does not match, the code generator issues a warning message. Change the signature of the function or function caller so that the signatures match.

• In a Simulink Function block definition, do not define input and output signals for Argument Inport and Argument Outport blocks with a storage class.

• Do not specify Argument Inport and Argument Outport blocks as test points.

• If you specify the data type of input and output signals for Argument Inport and Argument Outport blocks as a Simulink.IntEnumType, Simulink.AliasType, or Simulink.Bus, set the DataScope property to Imported or Exported.

• A function interface and function callers must agree in data type, complexity, dimension, and number of arguments.

Limitations

• To generate code from a model that includes scoped Simulink functions, the model must be an export-function model. The code generator does not support rate-based models that include scoped Simulink functions.

• You can use a Simulink Function block to define a scoped function in a referenced model. However, you cannot generate code for an export-function model that uses a Function Caller block in an atomic subsystem to invoke that function.

• You can invoke a C++ function that the code generator produces from a Simulink Function block with code generated from a Stateflow chart. Due to current scope limitations for generated C++ functions, you must invoke those functions with code generated from a Function Caller block.

• Simulink functions and function callers do not honor the MaxStackSize parameter.
• Code generation for a C++ class interface supports scoped Simulink functions only.

**Generate and Call Reusable Function Code**

This example shows how to use the Simulink Function and Function Caller blocks to generate reusable function code. The code generator produces a global function, which complies with code requirements so that existing external code can call the function and a local function. The code generator also produces calls to global and local functions. The call to the global function shows that the global function is reused (shared).

Code requirements for the global function are:

• Function names start with prefix `func_`.
• Names of input arguments are of the form `x_n`, where `n` is a unique integer value.
• Names of output arguments are of the form `y_n`, where `n` is a unique integer value.
• Input and output arguments are integers (`int`) and are passed by reference. The native integer size of the target hardware is 32 bits.

You create a function that calls the generated reusable function code. Then, you construct and configure a model to match the code requirements.

Some of the features used in this example, such as data type aliasing and replacement, require Embedded Coder software.

**Inspect External Code That Calls Reusable Function**

In your code generation root folder, create the files `call_times2.h` and `call_times2.c`. If you prefer, you can copy the files from `matlabroot\help\toolbox\ecoder\examples`.

`call_times2.h`

typedef int my_int;

call_times2.c

#include "call_times2.h"

void call_times2(void)
{
    int times2result;
func_times2(x1, &y1);

printf('Times 2 Value:', y1);
}

This C code calls reusable function func_times2. The function multiplies an integer input value x1 by 2 and returns the result as y1.

**Create Model**

Open the example model ex_slfunc_comp, which is available in the folder matlabroot\help\toolbox\ecoder\examples. The model includes two Simulink functions modeled as Simulink Function blocks, func_times2 and func_times3, and a call to each function. As indicated in the model, the visibility of the Simulink Function block for func_times2 is set to global. That visibility setting makes the function code accessible to other code, including external code that you want to integrate with the generated code. The visibility for func_times3 is set to scoped.

If you configure the model with the GRT system target file or the ERT system target file with **File packaging format** set to Modular, the code generator produces function code for the model.

For more information, see “Generate Code for a Simulink Function and Function Caller” on page 6-20.
Configure Generated Code to Reuse Custom Data Type

The example assumes that the generated code runs on target hardware with a native integer size of 32 bits. The external code represents integers with data type `my_int`, which is an alias of `int`. Configure the code generator to use `my_int` in place of the data type that the code generator uses by default, which is `int32_T`.

1. Create a Simulink.AliasType object to represent the custom data type `my_int`.

   ```
   my_int = Simulink.AliasType
   my_int =
   
   AliasType with properties:
   
   Description: ''
   DataScope: 'Auto'
   HeaderFile: ''
   BaseType: 'double'
   ```

2. Set the alias type properties. Enter a description, set the scope to `Imported`, specify the header file that includes the type definition, and associate the alias type with the Simulink base type `int32`.

   ```
   my_int.Description='Custom 32-bit int representation';
   my_int.DataScope='Imported';
   my_int.HeaderFile='call_times2.h';
   my_int.BaseType='int32';
   ```

   ```
   my_int
   
   AliasType with properties:
   
   Description: 'Custom 32-bit int representation'
   DataScope: 'Imported'
   HeaderFile: 'call_times2.h'
   BaseType: 'int32'
   ```

3. Configure the code generator to replace instances of type `int32_T` with `my_int`. In the Configuration Parameters dialog box, open the **Code GenerationData Type Replacement** pane.

   - Select **Replace data type names in the generated code**.
   - In the **Data type names** table, enter `my_int` for the replacement name for `int32`.
Configure Reusable, Global Function

For external code to call a global function, configure the corresponding Simulink Function block to have global visibility and an interface that matches what is expected by the external callers.

1. Open the block that represents the \texttt{times2} function.

2. Configure the function name and visibility by setting Trigger Port block parameters. For example, the code requirements specify that the function name start with the prefix \texttt{func_}.
   - Set \textbf{Function name} to \texttt{func\_times2}.
   - Set \textbf{Function visibility} to \texttt{global}.

3. Configure the function input and output arguments by setting Argument Inport and Argument Outport block parameters. For example, the code requirements specify that argument names be of the form $x_n$ and $y_n$. The requirements also specify that arguments be type \texttt{my\_int}.
   - On the \textbf{Main} tab, set \textbf{Argument name} to $x_1$ (input) and $y_1$ (output).
   - On the \textbf{Signal Attributes} tab, set \textbf{Data type} to \texttt{int32}. With the data type replacement that you specified previously, \texttt{int32} appears in the generated code as \texttt{myint}.

4. Configure the Simulink Function block code interface. At the top level of the model, right-click the global function \texttt{func\_times2}. From the menu, select \textbf{C/C++ Code} \textbf{Configure C/C++ Function Interface}.
   - Set \textbf{C/C++ function name} to \texttt{func\_times2}.
   - Set \textbf{C/C++ return argument} to \texttt{void}.
   - Set \textbf{C/C++ Identifier Name} for argument $x_1$ to $x_1$. 

6-16
• Set **C/C++ Identifier Name** for argument y1 to y1.

If the dialog box lists output argument y1 before input argument x1, reorder the arguments by dragging the row for x1 above the row for y1.

**Configure Local Function**

Configure a Simulink Function block that represents a local function with scoped visibility. Based on code requirements, you might also have to configure the function name, input and output argument names and types, and the function interface.

1. Open the block that represents the times3 function.
2. Configure the function name and visibility by setting Trigger Port block parameters. For example, the code requirements specify that the function name start with the prefix `func_`.
   - Set **Function name** to `func_times3`.
   - Set **Function visibility** to `scoped`.
3. Configure the function input and output arguments by setting Argument Inport and Argument Outport block parameters. For example, the code requirements specify that argument names be of the form `xn` and `yn`. The requirements also specify that arguments be type `my_int`.
   - On the **Main** tab, set **Argument name** to `x1` (input) and `y1` (output).
   - On the **Signal Attributes** tab, set **Data type** to `int32`. With the data type replacement that you specified previously, `int32` appears in the generated code as `my_int`.
4. Configure the Simulink Function block code interface. At the top level of the model, right-click the scoped function `func_times3`. From the menu, select **C/C++ CodeConfigure C/C++ Function Interface**. In this case, the code generator controls naming the function and arguments. The function name combines the name of the root model and the function name that you specify for the trigger port of the Simulink Function block. In this example, the name is `ex_slfnc_comp_func_times3`.

   You can set **C/C++ return argument** to the argument name that you specify for the Argument Outport block or `void`. For this example, set it to `void`.

   For arguments, the code generator prepends `rtu_` (input) or `rty_` (output) to the argument name that you specify for the Argument Inport block.
If the dialog box lists output argument \( y_1 \) before input argument \( x_1 \), reorder the arguments by dragging the row for \( x_1 \) above the row for \( y_1 \).

**Configure Function Callers**

For each function caller, configure Function Caller block parameters:

- Set **Function prototype** to \( y_1 = \text{func\_times2}(x_1) \).
- Set **Input argument specifications** to \( \text{int32}(1) \).
- Set **Output argument specifications** to \( \text{int32}(1) \).

**Generate and Inspect Code**

Generate code for the model.

- **Global function code**

  Source code for the global, reusable function `func\_times2` is in the build folder in subsystem file, `func\_times2.c`.

  ```c
  #include "func\_times2.h"
  
  /* Include model header file for global data */
  #include "ex\_slfunc\_comp.h"
  #include "ex\_slfunc\_comp\_private.h"
  
  void func\_times2(my\_int x1, my\_int *y1)
  {
    *y1 = x1 << 1;
  }
  
  ```

- **Local function code**

  The code generator places the definition for the local (scoped) function `func\_times3` in file build folder in file `ex\_slfunc\_comp.c`.

  ```c
  void ex\_slfunc\_comp\_func\_times3(my\_int rtu\_x1, my\_int *rtu\_y1)
  {
    *rtu\_y1 = 3 * rtu\_x1;
  }
  ```

- **Calls to generated functions**

  The model execution (step) function, in model file `ex\_slfunc\_comp.c`, calls the two Simulink functions: global function `func\_times2` and local function `func\_times3`. 

6-18
ex_slfunc_comp_func_times3. The name ex_slfunc_comp_func_times3 reflects the scope of the local function by combining the name of the model and the name of the function.

void ex_slfunc_comp_step(void)
{
    my_int rtb_FunctionCaller2;
    func_times2(ex_slfunc_comp_U.In1, &rtb_FunctionCaller2);
    ex_slfunc_comp_Y.Out1 = rtb_FunctionCaller2;
    ex_slfunc_comp_func_times3(ex_slfunc_comp_U.In2, &rtb_FunctionCaller2);
    ex_slfunc_comp_Y.Out2 = rtb_functionCaller2;
    
• Entry-point declaration for local function

The model header file ex_slfunc_comp.h includes an extern declaration for function ex_slfunc_comp_func_times3. That statement declares the function entry point.

extern void ex_slfunc_comp_func_times3(my_int rtu_x1, my_int *rty_y1);

• Include statements for global function

The model header file ex_slfunc_comp.h lists include statements for the global function func_times2.

#include "func_times2_private.h"
#include "func_times2.h"

• Local macros and data for global function

The subsystem header file func_times2_private.h defines macros and includes header files that declare data and functions for the global function, func_times2.

#ifndef RTW_HEADER_func_times2_private_h_
#define RTW_HEADER_func_times2_private_h_
#ifndef ex_slfunc_comp_COMMON_INCLUDES_
#define ex_slfunc_comp_COMMON_INCLUDES_
#include "rtwtypes.h"
#endif
#endif

• Entry-point declaration for global function
The shared header file `func_times2.h`, in the shared utilities folder `slprj/stf/_sharedutils`, lists shared type includes for `rtwtypes.h`. The file also includes an `extern` declaration for the global function, `func_times2`. That statement declares the function entry point.

```c
#ifndef RTW_HEADER_func_times2_
#define RTW_HEADER_func_times2_

#include "rtwtypes.h"

extern void func_times2(my_int rtu_x1, my_int *rtu_y1);

#endif
```

### Generate Code for a Simulink Function and Function Caller

This example shows how to generate C code for Simulink Function and Function Caller blocks and displays the relevant generated code.

Open the example model `rtwdemo_export_functions`. The model uses Stateflow software, but this example reviews only the code generated from the referenced models.
Generate Code for Function Definition

1. To view the contents of the subsystem, double-click rtwdemo_functions. The Simulink Function block is the f3 subsystem defined as \( y = f_3(u) \).

2. Generate code.

The code generator creates rtwdemo_functions.c. This file contains the function definition and function initialization code.

- Initialization code for function f3:
  
  ```c
  void f3_Init(void)
  {
    rtDWork.Delay_DSTATE = 1;
  }
  ```

- Code for function f3:
  
  ```c
  void f3(real_T rtu_u, real_T *rty_y)
  {
  ```
rtY.TicToc10 = rtDWork.Delay_DSTATE;
rtDWork.Delay_DSTATE = (int8_T)(int32_T)-(int32_T)rtY.TicToc10;
adder_h(rtB.Subtract, rtU.U2, rtu_u, rtB.FunctionCaller);
    *rty_y = rtB.FunctionCaller;
}

void adder_h(real_T rtu_u1,
    real_T rtu_u2,
    real_T rtu_u3,
    real_T *rty_y)
{
    *rty_y = (rtu_u1 + rtu_u2) + rtu_u3;
}

- The shared header file f3.h contains the entry point declaration for function f3.

#include "rtwtypes.h"
extern void f3(real_T rtu_u, real_T *rty_y);

**Generate Code for Function Caller**

1. In the rtwdemo_export_functions model, double-click rtwdemo_caller to view the contents of the caller subsystem.

2. Generate code.

The code generator creates the files rtwdemo_caller.h and rtwdemo_caller.c in the folder rtwdemo_caller_ert_rtw.

rtwdemo_caller.h includes the shared header file, f3.h, which contains the function entry-point declaration.

rtwdemo_caller.c calls function f3.

```c
void rtwdemo_caller_t_10tic(const real_T *rtu_u,
    real_T *rty_y)
{
    f3(*rtu_u, rty_y);
}
```

Generate Reentrant Code from Top Models

By default, for top models, the code generator produces code that is not reentrant. Entry-point functions have a void-void interface. Code communicates with other code by sharing access to global data structures that reside in shared memory.

For applications that can benefit from reuse and require that each use or instance of the code maintains its own unique data, configure a model such that the code generator produces reentrant code. To generate reentrant code, set the model configuration parameter “Code interface packaging” (Simulink Coder) to Reusable function. If you are using Embedded Coder and generating C++ code, alternatively, you can set the parameter to C++ class. In both cases, the code generator:

- Packages model data, such as block I/O, DWork vectors, and parameters, in the real-time model data structure (rtModel).
- Passes the real-time model data structure as an input argument, by reference, to generated model entry-point functions.
- Passes root-level input and output arguments to generated model entry-point functions as individual arguments.
- Allocates memory for model data structures statically.
- Exports the real-time model data structure in the generated header file model.h.

Apply additional diagnostic and code generation control by setting these model configuration parameters:

- To select the severity level for diagnostic messages that the code generator displays when a model does not meet requirements for multi-instance code, set parameter “Multi-instance code error diagnostic” (Simulink Coder) to None, Warning, or Error.
- To control how the generated code passes root-level model input and output to the reusable execution (step) function (requires Embedded Coder), set parameter “Pass root-level I/O as” (Simulink Coder) to Individual arguments, Structure reference, or Part of model data structure.
- To reduce memory usage by omitting the error status field from the real-time model data structure (requires Embedded Coder), set parameter Remove error status field in real-time model data structure to On.
- To include a function in the generated file model.c that uses malloc to dynamically allocate memory for model data structures (requires Embedded Coder), set parameter Use dynamic memory allocation for model initialization to On.
Generate Reentrant, Multi-Instance Code

This example shows you how to configure a model for reentrant, multi-instance code generation. Multiple programs can use reentrant code simultaneously. When you configure a model for reentrancy, the execution (step) entry-point function uses root-level input and output arguments instead of global data structures. After examining the configuration settings, generate and review the generated code.

Open the Model

Open the model `rtwdemo_reusable`. The model contains two root Inport blocks and a root Outport block.

```matlab
model='rtwdemo_reusable';
open_system(model);
```

In your working folder, create a temporary folder for generating and reviewing the code.

```matlab
currentDir=pwd;
 [~, cgDir] = rtwdemodir();
```

Examine Relevant Model Configuration Settings

1. Open the Model Configuration Parameters dialog box.

2. System target file is set to `ert.tlc`. Although you can generate reentrant code for a model configured with the System target file set to `grt.tlc`, ERT and ERT-based system target files provide more control over how the code passes root-level I/O.

3. Open the Code Generation > Interface pane and explore relevant parameter settings.
• **Code interface packaging** is set to **Reusable function**. This parameter setting instructs the code generator to produce reusable, multi-instance code.

• The **Reusable function** parameter setting also displays the **Multi-instance code error diagnostic** parameter. That parameter is set to **Error**, indicating that the code generator abort if the model violates requirements for generating multi-instance code.

• **Pass root-level I/O as** is set to **Part of model data structure**. This setting packages root-level model input and output into the real-time model data structure (`rtModel`), which is an optimized data structure that replaces `SimStruct` as the top-level data structure for a model.

• **Remove error status field in real-time model data structure** is selected. This parameter setting reduces memory usage by omitting the error status field from the generated real-time model data structure.

**Generate and Review Code**

```matlab
rtwbuild(model);

### Starting build procedure for model: rtwdemo_reusable
### Successful completion of build procedure for model: rtwdemo_reusable
```

From the code generation report, review the generated code.

• **ert_main.c** is an example main program (execution framework) for the model. This code controls model code execution by calling the entry-point function `rtwdemo_reusable_step`. Use this file as a starting point for coding your execution framework.

• **rtwdemo_reusable.c** contains entry points for the code that implements the model algorithm. This file includes the rate scheduling code.

• **rtwdemo_reusable.h** declare model data structures and a public interface to the model entry points and data structures.

• **rtwtypes.h** defines data types, structures, and macros that the generated code requires.

Open and review the Code Interface Report. Use the information in that report to write the interface code for your execution framework.

1. Include the generated header file by adding directive `#include rtwdemo_reusable.h`.

2. Write input data to the generated code for model Inport blocks.
3. Call the generated entry-point functions.

4. Read data from the generated code for the model Outport block.

Input ports:
- `<Root>/In1` of data `real_T` with dimension of 1
- `<Root>/In2` of data `real_T` with dimension of 1

Entry-point functions:
- Initialization entry-point function, `void rtwdemo_reusable_initialize(RT_MODEL *const rtM)`. At startup, call this function once.
- Output and update (step) entry-point function, `void rtwdemo_reusable_step(RT_MODEL *const rtM)`. Call this function periodically at the fastest rate in the model. For this model, call the function every second. To achieve real-time execution, attach this function to a timer.

Output port:
- `<Root>/Out1` of data type `real_T` with dimension of 1

Examine the `rtwdemo_reusable_step` function code in `rtwdemo_reusable.c`.

```c
/* Model step function */
void rtwdemo_reusable_step(RT_MODEL *const rtM)
{
    Parameters *rtP = ((Parameters *) rtM->defaultParam);
    D_Work *rtDWork = ((D_Work *) rtM->dwork);
    ExternalInputs *rtU = (ExternalInputs *) rtM->inputs;
    ExternalOutputs *rtY = (ExternalOutputs *) rtM->outputs;

    /* Outport: '<Root>/Out1' incorporates:
     * UnitDelay: '<Root>/Delay'
    */
    rtY->Out1 = rtDWork->Delay_DSTATE;

    /* Gain: '<Root>/Gain' incorporates:
    * Inport: '<Root>/In1'
    */
```

6-27
The code generator passes model data to the `rtwdemo_reusable_step` function as part of the real-time model data structure. Try different settings for the **Code interface packaging** and **Pass root-level I/O** parameters and regenerate code. Observe how the function signature for the `rtwdemo_reusable_step` function changes.

Close the model and the code generation report.

```matlab
bdclose(model);
rtwdemoclean;
cd(currentDir);
```

### Share Data Between Instances

When your code calls a reentrant model entry-point function multiple times, each call represents an instance of the model. By default, the code generator generates code that assumes each instance reads from and writes to a separate copy of the signals, block states, and parameters in the model.

- To share a piece of parameter data between the instances (for example, to share a setpoint for a reusable PID control algorithm), use a parameter object, such as `Simulink.Parameter`, and apply a storage class other than `Auto` or, if you set the default storage class for the corresponding category of parameter data to `Default` (the default setting) in the Code Mapping Editor, `Model default`. The parameter object appears in the code as a global symbol, such as a global variable, that the function accesses directly. For more information, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder).

- To share a piece of nonparameter data between the instances, for example, to share a fault indication or an accumulator, use a data store. You can configure the data store to appear in the code as a global symbol, such as a global variable, that the function accesses directly. Create a global data store by using a `Simulink.Signal` object or use a Data Store Memory block and select the **Share across model instances** parameter. For more information, see “Model Global Data by Creating Data Stores” (Simulink) and Data Store Memory.

- “Use Storage Classes in Reentrant, Multi-Instance Models and Components” (Simulink Coder)
Generate Reentrant Code from Simulink Function Blocks

If you are using Embedded Coder, you can generate reusable, reentrant code by representing an algorithm as a scoped Simulink Function block. Examples of when to generate reentrant code from Simulink Function blocks are when a function shares state between function callers within a model or for client/server applications. You can generate code that is highly modularized by using multiple instances of a shared Simulink Function block in an export-function model. The code generator produces function code and associates each use or call to the function with instance-specific data. The scope of the function depends on whether you place the function at the root level of model or in a subsystem.

The code generator produces reentrant function code when you configure a:

- Top model with model configuration parameter “Code interface packaging” (Simulink Coder) set to Reusable function or C++ class (C++ only).
- Referenced model with “Total number of instances allowed per top model” (Simulink) set to Multiple.

Call a function represented by a scoped Simulink Function block from one level above, at the same level, or from a level below the level of the function definition. You can scope a function in an atomic or nonvirtual subsystem, but function call accessibility is limited to the same level or below of the hierarchy. The function name does not have to be unique.

Identify Requirements

Before and while you design your model, consider:

- How many instances of each function are required?
- Do you need to restrict call sites for a function to the model containing the function definition?
- Do you need for a function to interface with signals in the local environment, but keep those signals hidden from callers?
- Do functions need to communicate directly with each other?
- Do functions need to connect to external I/O?
- Do you need to log function output?
Create Model

Use the example model component `rtwdemo_comp` to see how to use Simulink Function blocks to generate reentrant C code. Use example model `rtwdemo_comp_cpp` if you prefer to generate C++ code. Open the model and examine the model hierarchy.

The top level of the model includes a function-call subsystem and two instances of a referenced model.

The referenced model, `rtwdemo_func_dinteg`, consists of a Simulink Function block that defines function `multiinstfunc` and subsystem `subsys_calc`.

The subsystem consists of a Simulink Function block. This use of a Simulink Function block shows how you can limit the scope of the function that the block defines to the model that contains the subsystem. The code generator produces function code for
func_calc and associates each call to the function with instance-specific data. The data includes states, such as data stored in memory.

The Simulink Function block that defines function multiinstfunc uses a Function Caller block to invoke function func_calc. That Simulink Function block also shows that it can interface to signals in the local environment of the block through Inport and Outport blocks (see “Simulink Functions in a Simulink Model” (Simulink)).

At the top level of model rtwdemo_comp, the function-call subsystem uses Function Caller blocks to invoke the two instances of function multiinstfunc. The code generator produces function code and associates each call with instance-specific data.
Configure Model and Model Elements

Configure Simulink Function Blocks

Configure the Simulink Function blocks by setting parameters for the function Trigger Port block. For the code generator to produce reentrant code from Simulink Function blocks:

- Configure block instances with the same function name.
- Set Function visibility to scoped.

In the example, the function name for the Simulink Function blocks in the two instances of the referenced model $\text{rtwdemo\_func\_dinteg}$ is specified as multiinstfunc.

Configure Function Caller Blocks

Configure the Function Caller blocks. For each of the blocks, set the Function prototype block parameter. Start typing a prototype. For example, type $y$. Prototype options, based on function definitions in the model, appear in a selection list. Select the prototype that is appropriate for each function call.
For this example, the prototypes are configured as follows:

- In the function-call subsystem, the prototypes for the function callers are configured as
  \( y = \text{Instance1.multiinstfunc}(u) \) and \( y = \text{Instance2.multiinstfunc}(u) \). The `Instance\text{en}` prefix identifies each function invocation uniquely and associates the invocation with its own data set.

- The function caller in function `multiinstfunc` is configured with the prototype \( y = \text{subsys_calc.func_calc}(u) \). The prefix `subsys_calc` identifies the subsystem that contains the function definition.

For the example, the input and output argument specifications and sample time retain default settings.

**Subsystem Configuration**

No configuration changes are required for the subsystem in the example model. When you include a Simulink Function block in a subsystem, the code generator

- Scopes the function to the model that includes the subsystem.
- Treats the subsystem as an atomic unit.

**Configure Referenced Model**

Configure the referenced model that includes a Simulink Function block:

- In the Block Parameters dialog box, set **Model name** to the referenced model file name. For this example, the model name is `rtwdemo_func_dinteg.slx`.
- Set **Number of model instances allowed** to Multiple.
- To generate a C++ class interface for the reference model, set **Language** to C++ and **Code interface packaging** to C++ class.

Optionally, you can configure custom prototypes for the initialize and execution (step) model-entry point functions. Custom prototypes can minimize changes to existing external code that you integrate with the generated code. The example uses the default function prototypes. See “Customize Generated Function Interfaces for Simulink Function and Function Caller Blocks” on page 29-24.

**Configure Top Model**

Configure the top model for a model component. If you want the model component (that is, the top model) to be reusable, set **Code interface packaging** to Reusable.
Generate Reentrant Code from Simulink Function Blocks

function. If you are generating C++ code, you can set this parameter to C++ class. In either case, also:

• Set **Multi-instance code error diagnostic** to Error.
• Set **Pass root-level I/O as** to Part of model data structure.

Optionally, you can configure custom prototypes for the initialize and execution (step) model-entry point functions. Custom prototypes can minimize changes to existing external code that you integrate with the generated code. Also see “Customize Generated Function Interfaces for Simulink Function and Function Caller Blocks” on page 29-24.

**Generate and Inspect C Code**

Generate C code for the model.

• Function code for multi-instance Simulink Function block

When you place a scoped Simulink Function block in a referenced model that you use multiple times in another model, the code generator places the function code in the `model.c` file for the referenced model. For this example, the code generator places function code for `multiinstfunc` in `slprj/ert/rtwdemo_func_dinteg/rtwdemo_func_dinteg.c`.

```c
real_T rtwdemo_func_dinteg_multiinstfunc(RT_MODEL_rtwdemo_func_dinteg_T * const rtwdemo_func_dinteg_M, const real_T rtu_u)
{
    real_T rtb_TmpLatchAtInOutport1;
    real_T rtb_TmpLatchAtIn2Outport1;
    real_T rty_y_0;
    rtb_TmpLatchAtInOutport1 =
        *rtwdemo_func_dinteg_M->rtwdemo_func_dintegrtextInport.rtu_In1;
    rtb_TmpLatchAtIn2Outport1 =
        *rtwdemo_func_dinteg_M->rtwdemo_func_dintegrtextInport.rtu_In2;
    *rtwdemo_func_dinteg_M->rtwdemo_func_dintegrtextOutport.rty_Out2 = 2.0 *
        rtb_TmpLatchAtIn2Outport1;
    rtwdemo_func_dinteg_func_calc(rtwdemo_func_dinteg_M, rtb_TmpLatchAtIn2Outport1,
        rtwdemo_func_dinteg_M->rtwdemo_func_dintegrtextOutport.rty_Out1);
    rty_y_0 = rtwdemo_func_dinteg_M->dwork.DiscreteIntegrator_DSTATE;
    rtwdemo_func_dinteg_M->dwork.DiscreteIntegrator_DSTATE += 0.1 * rtu_u;
    return rty_y_0;
}
```
• Function code for a Simulink Function block defined in a subsystem

The code generator places the function code for a Simulink Function block that you define in a subsystem in the `model.c` file for the model that contains the subsystem. For this example, the code generator places the function code for `func_calc` in `slprj/ert/rtwdemo_func_dinteg/rtwdemo_func_dinteg.c`.

```c
void rtwdemo_func_dinteg_func_calc(RT_MODEL_rtwdemo_func_dinteg_T * const rtwdemo_func_dinteg_M, real_T rtu_u, real_T *rty_y)
{
    rtwdemo_func_dinteg_M->dwork.calcMem =
        rtwdemo_func_dinteg_M->dwork.UnitDelay_DSTATE;

    *rty_y = rtwdemo_func_dinteg_M->dwork.UnitDelay_DSTATE;

    rtwdemo_func_dinteg_M->dwork.UnitDelay_DSTATE = rtu_u * 0.07;
}
```

• Self-referential structure that stores multi-instance data for reusable functions

The code generator uses the real-time model (RT_MODEL) data structure as a self-referential structure to store the multi-instance data associated with a reusable function. The code generator defines the structure in `slprj/ert/rtwdemo_func_dinteg/rtwdemo_func_dinteg.h`.

```c
typedef struct rtwdemo_func_dinteg_tag_RTM RT_MODEL_rtwdemo_func_dinteg_T;
```

• Initialization code for multi-instance referenced model

For each instance of a referenced model that includes the same scoped Simulink Function block, the code generator produces initialization and startup function code. A single copy of the initialization code is defined in `slprj/ert/rtwdemo_func_dinteg/rtwdemo_func_dinteg.c`.

```c
void rtwdemo_func_dinteg_Start(RT_MODEL_rtwdemo_func_dinteg_T *const rtwdemo_func_dinteg_M, const real_T *rtu_In1, const real_T *rtu_In2, real_T *rty_Out2, real_T *rty_Out1)
{
    rtwdemo_func_dinteg_M->rtwdemo_func_dintegrtextInport.rtu_In1 = rtu_In1;
    rtwdemo_func_dinteg_M->rtwdemo_func_dintegrtextInport.rtu_In2 = rtu_In2;
    rtwdemo_func_dinteg_M->rtwdemo_func_dintegrtextOutport.rty_Out2 = rty_Out2;
    rtwdemo_func_dinteg_M->rtwdemo_func_dintegrtextOutport.rty_Out1 = rty_Out1;
}
```

```c
void rtwdemo_func_dinteg_initialize(const char_T **rt_errorStatus,
    RT_MODEL_rtwdemo_func_dinteg_T *const rtwdemo_func_dinteg_M)
{
    rtSetErrorStatusPointer(rtwdemo_func_dinteg_M, rt_errorStatus);
}
```
The initialization code is called for each instance of a referenced model that contains the same Simulink Function block. That code is in file `rtwdemo_comp.c` in the build folder.

```c
rtwdemo_func_dinteg_initialize(rtmGetErrorStatusPointer(rtwdemo_comp_M),
    (&(rtwdemo_comp_M->Instance1)));
rtwdemo_func_dinteg_initialize(rtmGetErrorStatusPointer(rtwdemo_comp_M),
    (&(rtwdemo_comp_M->Instance2)));
rtwdemo_func_dinteg_Start((&(rtwdemo_comp_M->Instance1)), &rtU->In2, &rtU->In3,
    &rtY->Out2, &rtY->Out3);
rtwdemo_func_dinteg_Start((&(rtwdemo_comp_M->Instance2)), &rtU->In4, &rtU->In5,
    &rtY->Out4, &rtY->Out5);
```

- **Top model entry-point function declarations**

  The model header file `rtwdemo_comp.h` includes `extern` declarations for top model initialize, terminate, and execution (run) entry-point functions.

```c
extern void rtwdemo_comp_initialize(RT_MODEL_rtwdemo_comp_T *const rtwdemo_comp_M);
extern void Run(RT_MODEL_rtwdemo_comp_T *const rtwdemo_comp_M);
```

- **Reference model entry-point function declarations**

  Header file `slprj/ert/rtwdemo_func_dinteg/rtwdemo_func_dinteg.h` includes `extern` declarations for reference model entry-point functions.

```c
extern void rtwdemo_func_dinteg_initialize(const char_T **rt_errorStatus,
    RT_MODEL_rtwdemo_func_dinteg_T *const rtwdemo_func_dinteg_M);
extern real_T rtwdemo_func_dinteg_multiinstfunc(RT_MODEL_rtwdemo_func_dinteg_T *
    const rtwdemo_func_dinteg_M, const real_T rtu_u);
extern void rtwdemo_func_dinteg_Start(RT_MODEL_rtwdemo_func_dinteg_T *const rtwdemo_func_dinteg_S,
    const real_T *rtu_In1, const real_T *rtu_In2, real_T *
    rtY_Out2, real_T *rtY_Out1);
```

### Generate and Inspect C++ Code

Generate C++ code for the model.

- **Function code for multi-instance Simulink Function block**

  When you place a scoped Simulink Function block in a referenced model that you use multiple times in another model, the code generator places the function code in the
model.cpp file for the referenced model. For this example, the code generator places function code for multiinstfunc in slprj/ert/rtwdemo_func_dinteg/rtwdemo_func_dinteg_cpp.cpp.

```cpp
real_T rtwdemo_func_dintegModelClass::multiinstfunc(const real_T rtu_u)
{
    real_T rtb_TmpLatchAtInOutport1;
    real_T rtb_TmpLatchAtIn2Outport1;
    real_T rty_y_0;

    rtb_TmpLatchAtInOutport1 = *rtwdemo_func_dinteg_cprtrtu_In1;
    rtb_TmpLatchAtIn2Outport1 = *rtwdemo_func_dinteg_cprtrtu_In2;
    *rtwdemo_func_dinteg_crttrty_Out2 = 2.0 * rtb_TmpLatchAtInOutport1;
    rtwdemo_func_dinteg_c_func_calc(rtb_TmpLatchAtIn2Outport1,
                                rtwdemo_func_dinteg_crttrty_Out1);

    rty_y_0 = rtwdemo_func_dinteg_cpprtDW.DiscreteIntegrator_DSTATE;

    rtwdemo_func_dinteg_cpprtDW.DiscreteIntegrator_DSTATE += 0.1 * rtu_u;
    return rty_y_0;
}
```

- Function code for a Simulink Function block defined in a subsystem

The code generator places the function code for a Simulink Function block that you define in a subsystem in model.cpp for the model that contains the subsystem. For this example, the code generator places the function code for func_calc in slprj/ert/rtwdemo_func_dinteg/rtwdemo_func_dinteg_cpp.cpp.

```cpp
void rtwdemo_func_dintegModelClass::rtwdemo_func_dinteg_c_func_calc(real_T rtu_u,
    real_T *rty_y)
{
    rtwdemo_func_dinteg_cpprtDW.calcMem =
        rtwdemo_func_dinteg_cpprtDW.UnitDelay_DSTATE;

    *rty_y = rtwdemo_func_dinteg_cpprtDW.UnitDelay_DSTATE;
    rtwdemo_func_dinteg_cpprtDW.UnitDelay_DSTATE = rtu_u * 0.07;
}
```

- Self-referential structure that stores multi-instance data for reusable functions

The code generator uses the real-time model (RT_MODEL) data structure as a self-referential structure to store the multi-instance data associated with a Reusable function. The code generator defines the structure in slprj/ert/rtwdemo_func_dinteg/rtwdemo_func_dinteg_cpp.h.

```cpp
typedef struct rtwdemo_func_dinteg_cpp_tag_RTM rtwdemo_func_dinteg_cp_RT_MODEL;
```
• Initialization code for multi-instance referenced model

For each instance of a referenced model that includes the same scoped Simulink Function block, the code generator produces initialization and startup function code. A single copy of the initialization code is defined in slprj/ert/rtwdemo_func_dinteg/rtwdemo_func_dinteg_cpp.cpp.

```cpp
void rtwdemo_func_dintegModelClass::start(real_T *rtu_In1, real_T *rtu_In2,
    real_T *rty_Out2, real_T *rty_Out1)
{
    rtwdemo_func_dinteg_cprtrtu_In1 = rtu_In1;
    rtwdemo_func_dinteg_cprtrtu_In2 = rtu_In2;
    rtwdemo_func_dinteg_crtrty_Out2 = rty_Out2;
    rtwdemo_func_dinteg_crtrty_Out1 = rty_Out1;
}
```

The initialization code is called for each instance of a referenced model that contains the same Simulink Function block. That code is in file rtwdemo_comp_cpp.cpp in the build folder.

```cpp
Instance1MDLOBJ0.initializeRTM();
Instance1MDLOBJ0.setErrorStatusPointer(rtmGetErrorStatusPointer((&rtM)));
Instance1MDLOBJ0.initialize();
Instance2MDLOBJ1.initializeRTM();
Instance2MDLOBJ1.setErrorStatusPointer(rtmGetErrorStatusPointer((&rtM)));
Instance1MDLOBJ0.start(&rtU.In2, &rtU.In3, &rtY.Out2, &rtY.Out3);
Instance2MDLOBJ1.start(&rtwU.In4, &rtwU.In5, &rtY.Out4, &rtY.Out5);
```

• Top model class declaration

The model header file rtwdemo_comp_cpp.h includes the class declaration for the top model.

```cpp
class rtwdemo_compModelClass {
    public:
```
ExtU rtU;
ExtY rtY;

void initialize();
void Run();
rtwdemo_compModelClass();
-rtwdemo_compModelClass();

RT_MODEL * getRTM();

private:
RT_MODEL rtM;

rtwdemo_func_dintegModelClass Instance1MDLOBJ0;
rtwdemo_func_dintegModelClass Instance2MDLOBJ1;

• Reference model class declaration

Header file slprj/ert/rtwdemo_func_dinteg/rtwdemo_func_dinteg_cpp.h includes the class declaration for the reference model.

class rtwdemo_func_dintegModelClass {
public:
    real_T multiinstfunc(const real_T rtu_u);

    void start(real_T *rtu_In1, real_T *rtu_In2, real_T *rty_Out2, real_T *rty_Out1);

    rtwdemo_func_dintegModelClass();

    -rtwdemo_func_dintegModelClass();

    rtwdemo_func_dinteg_cp_RT_MODEL * getRTM();

    void initializeRTM();

    void setErrorStatusPointer(const char_T **rt_errorStatus);

private:
    rtwdemo_func_dinteg_cpp_DW rtwdemo_func_dinteg_cpprtDW;

    const real_T *rtwdemo_func_dinteg_cprtrtu_In1;
    const real_T *rtwdemo_func_dinteg_cprtrtu_In2;
    real_T *rtwdemo_func_dinteg_crrttrty_Out2;
    real_T *rtwdemo_func_dinteg_crrttrty_Out1;

    rtwdemo_func_dinteg_cp_RT_MODEL rtwdemo_func_dinteg_cpprtM;
void rtwdemo_func_dinteg_c_func_calc(real_T rtu_u, real_T *rty_y);
);

Limitations

These code generation limitations apply to export-function models that include multiple instances of a Simulink Function block.

- You must set the model configuration parameter `Pass root-level I/O as to Part of model data structure`.
- Generated code is compatible with single-threaded execution only. To avoid race conditions for shared signal data, invoke instances of the function code from the same execution thread.
- You cannot:
  - Generate code if the export-function model includes model variants.
  - Call the generated code from a Stateflow chart.
  - Enable the external mode data exchange interface.

Generate Reentrant Code from Subsystems

You can reduce the amount of code that the code generator produces for identical atomic subsystems by configuring the subsystems as reusable functions that pass data as arguments (for example, \texttt{rtB\_\*} for block input and output, \texttt{rtDW\_\*} for continuous states, and \texttt{rtP\_\*} for parameters). By default, the code generator produces subsystem code that communicates with other code by sharing access to global data structures that reside in shared memory. By passing data as arguments, the code can be reentrant. Each instance of the code maintains its own unique data.

To configure subsystems for reusability and reentrancy, configure mask and block parameters of the identical subsystems the same way. The code generator performs a checksum to determine whether subsystems are identical and whether the code is reusable. If the code is reusable, the code generator produces a single instance of reusable, reentrant function code.

To configure the subsystem block parameters:

1. If a subsystem is virtual, select “Treat as atomic unit” (Simulink) to enable function packaging parameters.

2. On the Code Generation tab, set “Function packaging” (Simulink) to Reusable function. The code generator produces a separate function with arguments for each subsystem. Selecting Reusable function also enables additional parameters that you can use to control the names of the function and file that the code generator produces for the subsystem code.

3. Set “Function name options” (Simulink). To generate reusable, reentrant code, specify the same setting for identical subsystems.
   - To let the code generator determine the function name, select Auto.
   - To use the subsystem name or, for a library block, the name of the library block, select Use subsystem name.
   - To display the “Function name” (Simulink) parameter and enter a unique, valid C/C++ function name, select User specified.

If there are multiple instances of an identical subsystem within a model reference hierarchy, select Auto.

If you are using Embedded Coder, you can use identifier format controls. See “Identifier Format Control” on page 39-22.
4  Set “File name options” (Simulink). To generate reusable, reentrant code, specify the same setting for identical subsystems.

- To let the code generator determine file naming select Auto.
- To use the subsystem name or, for a library block, the name of the library block select Use subsystem name.
- To use the function name, as specified by Function name options select Use function name.
- To display the “File name (no extension)” (Simulink) parameter and enter a file name, excluding the extension (for example, .c or .cpp) select User specified.

Other considerations:

- If there are multiple instances of an identical subsystem within a model reference hierarchy, select Auto.
- If the code generator does not generate a separate file for a subsystem, the function code is placed in the file generated from the subsystem's parent system. If the parent is the model itself, the code generator places the function code in `model.c` or `model.cpp`.
- If your generated code is under source control, specify a value other than Auto. This specification prevents the generated file name from changing when you modify and rebuild the model.
- If you select Use subsystem name, the code generator mangles the subsystem file name if the model contains Model blocks, or if a model reference target is being generated for the model. In these situations, the code generator uses the file name `modelsubsystem.c`.

If subsystem A has mask parameter b and K and subsystem B has mask parameters c and K, code reuse is not possible. The code generator produces separate functions for subsystems A and B. If you set block parameters for subsystems A and B differently, code reuse is not possible.

**Limitations**

- The code generator uses a checksum to determine whether subsystems are identical and reusable. Subsystem code is not reused if:
• In blocks and data objects, you use symbols to specify dimensions.
• A port has different sample times, data types, complexity, frame status, or dimensions across subsystems.
• The output of a subsystem is marked as a global signal.
• Subsystems contain identical blocks with different names or parameter settings.
• The output of a subsystem is connected to a Merge block, and the output of the Merge block is configured with a custom storage class that is implemented in the C code as nonaddressable memory (for example, BitField).
• The input of a subsystem is nonscalar and is configured with a custom storage class that is implemented in the C code as nonaddressable memory.
• A masked subsystem has a parameter that is nonscalar and is configured with a custom storage class that is implemented in the C code as nonaddressable memory.
• A function-call subsystem uses mask parameters when you set the model configuration parameter “Default parameter behavior” (Simulink Coder) to Tunable. To reuse the masked function-call subsystem, place it inside a new atomic subsystem without a mask. Then move the Trigger block from the masked subsystem into the atomic subsystem.
• A block in a subsystem uses a partially tunable expression. Some partially tunable expressions disable code reuse.

Partially tunable expressions are expressions that contain one or more tunable variables and an expression that is not tunable. For example, suppose that you create the tunable variable \( K \) with value 15.23 and the tunable variable \( P \) with value \([5;7;9]\). The expression \( K+P' \) is a partially tunable expression because the expression \( P' \) is not tunable. For more information about tunable expression limitations, see “Tunable Expression Limitations” (Simulink Coder).

• For subsystems that contain S-function blocks that are reusable, the blocks must meet the requirements listed in “S-Functions That Support Code Reuse” on page 11-105.
• If you select Reusable function, and the code generator determines that you cannot reuse the code for a subsystem, it generates a separate function that is not reused. The code generation report might show that the separate function is reusable, even if only one subsystem uses it. If you prefer that the code generator inline subsystem code in such cases (rather than deployed as functions), set “Function packaging” (Simulink) to Auto.
• If a reusable subsystem uses a shared local data store and you configure default mapping for model data elements, leave the default storage class mapping for category Shared local data stores set to Default.
Determine Why Subsystem Code Is Not Reused

Due to the limitations described in “Generate Reentrant Code from Subsystems” (Simulink Coder), the code generator might not reuse generated code as you expect. To determine why code generated for a subsystem is not reused:

1 Review the Subsystems section of the code generation report.
2 Compare subsystem checksum data.

Review Subsystems Section of HTML Code Generation Report

If the code generator does not generate code for a subsystem as reusable code, and you configured the subsystem as reusable, examine the Subsystems section of the code generation report (see “Generate a Code Generation Report” (Simulink Coder)). The Subsystems section contains:

• A table that summarizes how nonvirtual subsystems were converted to generated code.
• Diagnostic information that describes why subsystems were not generated as reusable code.

The Subsystems section also maps noninlined subsystems in the model to functions or reused functions in the generated code. For an example, open and build the rtwdemo_atomic model.

Compare Subsystem Checksum Data

You can determine why subsystem code is not reused by comparing subsystem checksum data. The code generator determines whether subsystems are identical by comparing subsystem checksums, as noted in “Limitations” (Simulink Coder). For subsystem reuse across referenced models, this procedure might not flag every difference.

Consider the model, rtwdemo_ssreuse. SS1 and SS2 are instances of the same subsystem. In both instances the subsystem parameter Function packaging is set to Reusable function.
Use the method `Simulink.SubSystem.getChecksum` to get the checksum for a subsystem. Review the results to determine why code is not reused.

1. Open the model `rtwdemo_ssreuse`. Save a copy of the model in a folder where you have write access.

2. Associate the subsystems `SS1` and `SS2` with `gcb`. For each of the subsystems, in the model window, select the subsystem. While the subsystem is selected, in the Command Window, enter:

   ```matlab
   SS1 = gcb;
   SS2 = gcb;
   ```

3. Use the method `Simulink.SubSystem.getChecksum` to get the checksum for each subsystem. This method returns two output values: the checksum value and details on the input used to compute the checksum.

   ```matlab
   [chksum1, chksum1_details] = Simulink.SubSystem.getChecksum(SS1);
   [chksum2, chksum2_details] = Simulink.SubSystem.getChecksum(SS2);
   ```

4. Compare the two checksum values. The values should be equal based on the subsystem configurations.

   ```matlab
   isequal(chksum1, chksum2)
   ans =
   1
   ```

5. To use `Simulink.SubSystem.getChecksum` to determine why the checksums of two subsystems differ, change the data type mode of the output port of `SS1` so that it differs from that of `SS2`. 
a Look under the mask of SS1. Right-click the subsystem. In the context menu, select **MaskLook Under Mask**.

b In the block diagram of the subsystem, double-click the Lookup Table block to open the Subsystem Parameters dialog box.

c Click **Data Types**.

d Select **Saturate on integer overflow** and click **OK**.

6 Get the checksum for SS1. Compare the checksums for the two subsystems. This time, the checksums are not equal.

   \[
   \text{[chksum1, chksum1_details]} = ... \\
   \text{Simulink.SubSystem.getChecksum(SS1);} \\
   \text{isequal(chksum1, chksum2)} \\
   \text{ans = 0}
   \]

7 After you determine that the checksums are different, find out why. The Simulink engine uses information, such as signal data types, some block parameter values, and block connectivity information, to compute the checksums. To determine why checksums are different, compare the data that computes the checksum values. You can get this information from the second value returned by Simulink.SubSystem.getChecksum, which is a structure array with four fields.

   Look at the structure **chksum1_details**.

   \[
   \text{chksum1_details} = \\
   \text{chksum1_details =} \\
   \text{ContentsChecksum: [1x1 struct]} \\
   \text{InterfaceChecksum: [1x1 struct]} \\
   \text{ContentsChecksumItems: [287x1 struct]} \\
   \text{InterfaceChecksumItems: [53x1 struct]}
   \]

   **ContentsChecksum** and **InterfaceChecksum** are component checksums of the subsystem checksum. The remaining two fields, **ContentsChecksumItems** and **InterfaceChecksumItems**, contain the checksum details.

8 Determine whether a difference exists in the subsystem contents, interface, or both. For example:

   \[
   \text{isequal(chksum1_details.ContentsChecksum.Value, ...} \\
   \text{chksum2_details.ContentsChecksum.Value)} \\
   \text{ans = 0}
   \]
isequal(chksum1_details.InterfaceChecksum.Value,...
        chksum2_details.InterfaceChecksum.Value)
ans =
    1

In this case, differences exist in the content.

9 Write a script like this script to find the differences.

```matlab
idxForCDiffs=[];
for idx = 1:length(chksum1_details.ContentsChecksumItems)
    if (~strcmp(chksum1_details.ContentsChecksumItems(idx).Identifier, ...
        chksum2_details.ContentsChecksumItems(idx).Identifier))
        disp(['Identifiers different for contents item ', num2str(idx)]);
        idxForCDiffs=[idxForCDiffs, idx];
    end
    if (ischar(chksum1_details.ContentsChecksumItems(idx).Value))
        if (~strcmp(chksum1_details.ContentsChecksumItems(idx).Value, ...
            chksum2_details.ContentsChecksumItems(idx).Value))
            disp(['Character vector values different for contents item ', num2str(idx)]);
            idxForCDiffs=[idxForCDiffs, idx];
        end
    end
    if (isnumeric(chksum1_details.ContentsChecksumItems(idx).Value))
        if (chksum1_details.ContentsChecksumItems(idx).Value ~= ...
            chksum2_details.ContentsChecksumItems(idx).Value)
            disp(['Numeric values different for contents item ', num2str(idx)]);
            idxForCDiffs=[idxForCDiffs, idx];
        end
    end
end
```

10 Run the script. The example assumes that you named the script check_details.

```matlab
check_details
```

Character vector values different for contents item 202

The results indicate that differences exist for index item 202 in the subsystem contents.

11 Use the returned index values to get the handle, identifier, and value details for each difference found.

```matlab
chksum1_details.ContentsChecksumItems(202)
```

ans =

```matlab
    Handle: 'rtwdemo_ssreuse/SS1/Lookup Table'
    Identifier: 'SaturateOnIntegerOverflow'
    Value: 'on'
```

The details identify the Lookup Table block parameter **Saturate on integer overflow** as the focus for debugging a subsystem reuse issue.

Generate Reusable Code From Referenced Models

Considerations for Subsystems that Contain Referenced Models

You can generate reusable code for subsystems that contain referenced models by using the same procedures and options described in “Control Generation of Subsystem Functions” on page 3-2. However, consider these restrictions:

- A top model that uses single-tasking mode and includes a referenced model that uses multi-tasking mode executes for blocks with different rates that are not connected. However, you get an error if the blocks with different rates are connected by a Rate Transition block (inserted manually or by Simulink).
- S-functions that you generate with the Embedded Coder Code > C/C++ Code > Generate S-function menu option do not support subsystems that contain a continuous sample time.
- The S-function system target file is not supported.
- The code generator ignores tunable parameters settings that you configure from the Model Parameter Configuration dialog box. To configure parameters to be tunable, define them as Simulink parameter objects in the base workspace.
- The code generator inlines parameters that are not tunable in the generated code and S-function.

**Note** If you select the S-function system target file, the subsystem block menu options C/C++ Code > Build This System and Code > C/C++ Code > Build Selected Subsystem behave like Code > C/C++ Code > Generate S-Function (see “Generate S-Function from Subsystem” on page 11-62).

Code Reuse and Model Blocks with Root Inport or Outport Blocks

A reusable subsystem function with input or output connected to the root Inport or Outport block of a referenced model can affect code reuse. This can prevent you from reusing atomic subsystems in a reference model context the same way you might reuse the subsystems in a standalone model.

For example, consider this subsystem:
Suppose that you make the following changes to the subsystem block parameters:

- Select “Treat as atomic unit” (Simulink).
- On the **Code Generation** tab, set “Function packaging” (Simulink) to **Reusable function**.

Then, suppose you create this model, which includes three instances of the preceding subsystem.

With the model configuration parameter “Default parameter behavior” (Simulink Coder) set to **Inlined**, the code generator optimizes the code by generating one copy of the function for the reused subsystem.

```c
void reuse_subsys1_Subsystem(real_T rtu_In1, B_Subsystem_reuse_subsys1_T *localB)
{
  localB->Gain = 3.0 * rtu_In1;
}
```

If you move the three subsystems into a Model block, you must modify your model and model configuration.

1. Add a Signal Conversion block or a Bias block between Subsystem3 and the Outport block. If the subsystem has a Merge block with initial conditions, do not add a Signal Conversion block. Instead, add a Bias block to obtain a reusable function.

2. Select the model configuration parameter “Pass fixed-size scalar root inputs by value for code generation” (Simulink).

The result is a single reusable function:
void reuse_subsys1_Subsystem(real_T rtu_In1, B_Subsystem_reuse_subsys1_T *localB)
{
  localB->Gain = 3.0 * rtu_In1;
}

• “Generate Reusable Code from Library Subsystems Shared Across Models”
  (Simulink Coder)
Generate Reusable Code from Library Subsystems Shared Across Models

What Is a Reusable Library Subsystem?

A reusable library subsystem is a subsystem included in a library that is configured for reuse. You must define a subsystem in a library and configure it for reuse to reuse the subsystem across models.

To reuse common functionality, you can include multiple instances of a subsystem:

• Within a single model, which is a top model or part of model reference hierarchy
• Across multiple referenced models in a model reference hierarchy
• Across multiple top models that contain Model blocks
• Across multiple top models that do not include Model blocks

The code generator uses checksums to determine reusability. There are cases when the code generator cannot reuse subsystem code.

For incremental code generation, if the reusable library subsystem changes, a rebuild of itself and its parents occurs. During the build, if a matching function is not found, a new instance of the reusable function is generated into the shared utilities folder. If a different matching function is found from previous builds, that function is used, and a new reusable function is not emitted.

For subsequent builds, unused files are not replaced or deleted from your folder. During development of a model, when many obsolete shared functions exist in the shared utilities folder, you can delete the folder and regenerate the code. If all instances of a reusable library subsystem are removed from a model reference hierarchy and you regenerate the code, the obsolete shared functions remain in the shared utilities folder until you delete them.

If a model changes such that the change might cause different generated code for the subsystem, a new reusable function is generated. For example, model configuration parameters that modify code comments might cause different generated code for the subsystem even if the reusable library subsystem did not change.
Reusable Library Subsystem Code Placement and Naming

The generated code of a reusable library subsystem is independent of the generated code of the model. Code for the reusable library subsystem is generated to the shared utility folder, `slprj/target/_sharedutils`, instead of the model reference hierarchy folders. The generated code for the supporting types, which are generated to the `.h` file, are also in the shared utilities folder.

For unique naming, reusable function names have a checksum appended to the reusable library subsystem name. For example, the code and files for a subsystem, `SS1`, which links to a reusable library subsystem, `RLS`, might be:

- Function name: `RLS_mgdjlngd`
- File name: `RLS_mgdjlnnd.c` and `RLS_mgdjlnnd.h`

Configure Reusable Library Subsystem

Set the Subsystem parameters as listed here:

- Select **Treat as an atomic unit**.
- On the **Code Generation** tab:
  - Set **Function packaging** to **Reusable function**.
  - Set **Function name options** and **File name options** to **Auto**, **Use subsystem name**, or **User specified**.

In a model reference hierarchy, if an instance of the reusable library subsystem is in the top model, then on the **Model Referencing** pane of the Configuration Parameters dialog box, you must select the **Pass fixed-size scalar root input by value for code generation** parameter. If you do not select the parameter, a separate shared function is generated for the reusable library subsystem instance in the top model, and a reusable function is generated for instances in the referenced models.

If a reusable library subsystem is connected to the root outport, reuse does not happen with identical subsystems that are not connected to the root outport. However, you can set **Pass reusable system outputs as** to **Individual arguments** on the **Optimizations** pane to make sure that reuse occurs between these subsystems. This parameter requires an Embedded Coder license.
For more information on creating a library, see “Libraries” (Simulink). For an example of creating a reusable library subsystem, see “Generate Reusable Code for Subsystems Shared Across Models” (Simulink Coder).

Configure Models That Include Reusable Library Subsystems

For a model to use a reusable library subsystem, you must configure the model differently depending on whether the model is a reference model or top model. If the subsystem is in a referenced model hierarchy, set the configuration parameter, “Shared code placement” (Simulink Coder) to Auto. Otherwise, for each model that uses the subsystem, set the model configuration parameter **Shared code placement** to **Shared location**.

If a reusable library subsystem uses a shared local data store and you configure default mapping for model data elements, leave the default storage class mapping for category **Shared local data stores** set to **Default**.

Generate Reusable Code for Subsystems Shared Across Models

This example shows how to configure a reusable library subsystem and generate a reusable function for a subsystem shared across referenced models. The result is reusable code for the subsystem, which is generated to the shared utility folder (`slprj/target/_sharedutils`).

- “Create a reusable library subsystem.” on page 6-55
- “Create the example model.” on page 6-58
- “Set configuration parameters of the top model.” on page 6-60
- “Create and propagate a configuration reference.” on page 6-60
- “Generate and view the code.” on page 6-61

Create a reusable library subsystem.

1 In the Simulink Editor, select **File > New > Library**. Open `rtwdemo_ssreuse` to copy and paste subsystem `SS1` into the Library Editor. This action loads the variables for `SS1` into the base workspace. Rename the subsystem block to `RLS`. 
2 Click the Subsystem block and press **Ctrl+U** to view the contents of subsystem **RLS**.
To configure the subsystem, in the Library editor, right-click RLS. In the context menu, select **Block Parameters(Subsystem)**. In the Subsystem Parameters dialog box, choose the following options:

- Select **Treat as an atomic unit**.
- On the **Code Generation** tab:
  - Set **Function packaging** to Reusable function.
  - Set **Function name options** to User specified and verify that the Function name is set to myfun.
  - Set **File name options** to Auto.

Click **Apply** and **OK**.
5  Save the reusable library subsystem as `ssreuselib`, which creates a file, `ssreuselib.slx`.

**Create the example model.**

1  Create a model which includes one instance of RLS from `ssreuselib`. Name this subsystem SS1. Add another subsystem and name it SS2. Name the model `ex_model1`.

![Diagram](image)

2  Create another model which includes one instance of RLS from `ssreuselib`. Name this subsystem SS1. Add another subsystem and name it SS3. Name the model `ex_model2`.
Create a top model with two model blocks that reference `ex_model1` and `ex_model2`. Save the top model as `ex_mdlref_ssreuse`.
Set configuration parameters of the top model.

1. With model `ex.mdlref_ssreuse` open in the Simulink Editor, select **Simulation > Model Configuration Parameters** to open the Configuration Parameters dialog box.
2. On the **Solver** pane, specify the **Type** as **Fixed-step**.
3. On the **Model Referencing** pane, select **Pass fixed-size scalar root inputs by value for code generation**.
4. On the **Code Generation > Report** pane, select **Create code generation report** and **Open report automatically**.
5. On the **Code Generation > Interface** pane, set the “Shared code placement” (Simulink Coder) to **Shared location**.
6. On the **Code Generation > Symbols** pane, set the **Maximum identifier length** to 256. This step is optional.
7. Click **Apply** and **OK**.

Create and propagate a configuration reference.

1. In the Simulink Editor, select **View > Model Explorer** to open the Model Explorer. In the left navigation column of the Model Explorer, expand the `ex.mdlref_ssreuse` node.
2 Right-click **Configuration** and select **Convert to Configuration Reference**.

3 In the Convert Active Configuration to Reference dialog box, click **OK**. This action converts the model configuration set to a configuration reference, `Simulink.ConfigSetRef`, and creates the configuration reference object, `configSetObj`, in the base workspace.

4 In the left navigation column, right-click **Reference (Active)** and select **Propagate to Referenced Models**.

5 In the Configuration Reference Propagation to Referenced Models dialog box, select the referenced models in the list. Click **Propagate**.

Now, the top model and referenced models use the same configuration reference, **Reference (Active)**, which points to a model configuration reference object, `configSetObj`, in the base workspace. When you save your model, you also need to export the `configSetObj` to a MAT-file.

**Generate and view the code.**

1 To generate code, in the Simulink Editor, press **Ctrl+B**. After the code is generated, the code generation report opens.

2 To view the code generation report for a referenced model, in the left navigation pane, in the **Referenced Models** section, select **ex_model1**. The code generation report displays the generated files for **ex_model1**.

3 In the left navigation pane, expand the **Shared files**. The code generator uses the reusable library subsystem name. The code for subsystem **SS1** is in **myfun.c** and **myfun.h**.
Click **Back** and navigate to the `ex_model2` code generation report. `ex_model2` uses the same source code, `myfun.c` and `myfun.h`, as the code for `ex_model1`. Your subsystem function and file names will be different.

Generate Reusable Code from Stateflow Atomic Subcharts

Generate Reusable Code for Linked Atomic Subcharts

To specify code generation parameters for linked atomic subcharts from the same library:

1. Open the library model that contains your atomic subchart.
2. Unlock the library.
3. Right-click the library chart and select Block Parameters.
4. In the dialog box, specify the following parameters:
   a. On the Main tab, select Treat as atomic unit.
   b. On the Code Generation tab, set Function packaging to Reusable function.
   c. Set File name options to User specified.
   d. For File name, enter the name of the file with no extension.
   e. Click OK to apply the changes.

5. (OPTIONAL) Customize the generated function names for atomic subcharts:
   a. Open the Model Configuration Parameters dialog box.
   c. Navigate to the Code Generation > Symbols pane.
   d. For Subsystem methods, specify the format of the function names using a combination of the following tokens:
      - $R — root model name
      - $F — type of interface function for the atomic subchart
      - $N — block name
      - $H — subsystem index
      - $M — name-mangling text
   e. Click OK to apply the changes.

When you generate code for your model, a separate file stores the code for linked atomic subcharts from the same library.
Generate Reusable Code for Unlinked Atomic Subcharts

To specify code generation parameters for an unlinked atomic subchart:

1. In your chart, right-click the atomic subchart and select Properties.
2. In the dialog box, specify the following parameters:
   a. Set Code generation function packaging to Reusable function.
   b. Set Code generation file name options to User specified.
   c. For Code generation file name, enter the name of the file with no extension.
   d. Click OK to apply the changes.
3. (OPTIONAL) Customize the generated function names for atomic subcharts:
   a. Open the Model Configuration Parameters dialog box.
   c. Navigate to the Code Generation > Symbols pane.
   d. For Subsystem methods, specify the format of the function names using a combination of the following tokens:
      • $R — root model name
      • $F — type of interface function for the atomic subchart
      • $N — block name
      • $H — subsystem index
      • $M — name-mangling text
   e. Click OK to apply the changes.

When you generate code for your model, a separate file stores the code for the atomic subchart. For more information, see “Generate Reusable Code for Unit Testing” on page 10-8.

Generate Reusable Code for Unit Testing

Convert a State to an Atomic Subchart

To convert state A to an atomic subchart, right-click the state and select Group & Subchart > Atomic Subchart. State A changes to an atomic subchart:
Set Up a Standalone C File for the Atomic Subchart

1. Open the properties dialog box for A.
2. Set Code generation function packaging to Reusable function.
4. For Code generation file name, enter saturator as the name of the file.
5. Click OK.

Set Up the Code Generation Report

1. Open the Model Configuration Parameters dialog box.
2. In the Code Generation pane, set System target file to ert.tlc.
   This step automatically selects Open report automatically and Code-to-model.
4. Select Model-to-code.
5. Click Apply.
Customize the Generated Function Names

1. In the Model Configuration Parameters dialog box, go to the **Code Generation > Symbols** pane.

2. Set **Subsystem methods** to the format scheme `$R$N$M$F`, where:
   - `$R$` is the root model name.
   - `$N$` is the block name.
   - `$M$` is the mangle token.
   - `$F$` is the type of interface function for the atomic subchart.

   For more information, see “Subsystem methods” (Simulink Coder).

3. Click **Apply**.

Generate Code for Only the Atomic Subchart

To generate code for your model, press **Ctrl+B**. In the code generation report that appears, you see a separate file that contains the generated code for the atomic subchart.

To inspect the code for `saturator.c`, click the hyperlink in the report to see the following code:
Code Reuse for Simulink Coder
Line 28 shows that the during function generated for the atomic subchart has the name `ex_reuse_states_A_during`. This name follows the format scheme $R$N$M$F specified for **Subsystem methods**:

- $R$ is the root model name, `ex_reuse_states`.
- $N$ is the block name, `A`.
- $M$ is the mangle token, which is empty.
- $F$ is the type of interface function for the atomic subchart, `during`.

**Note** The line numbers shown can differ from the numbers that appear in your code generation report.

Generate Shared Utility Code

When to Generate Shared Utility Code

Blocks in a model can require common functionality to implement their algorithms. Consider modularizing this functionality into standalone support or helper functions. This approach can be more efficient than inlining the code for the functionality for each block instance. To decide about using a library or a shared utility, consider:

- Packaging functions that can have multiple callers into a library when the functions are defined statically. That is, before you use the code generator to produce code for your model, the function source code exists in a file.
- Packaging functions that can have multiple callers as shared utilities (produced during code generation) when the functions cannot be defined statically. For example, several model- and block-specific properties specify which functions are used and their behavior. Also, these properties determine type definitions (for example, typedef) in shared utility header files. The number of possible combinations of properties that determine unique behavior make it impractical to define statically the possible function files before code generation.

Configure Naming of Generated Functions

Configure a default naming rule for generated shared utility functions by using one of these methods.

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>A new model or an existing model for which you have mapped default customization settings by using the <strong>Code Mapping Editor</strong> or code default mapping programming interface</td>
<td>In the <strong>Embedded Coder Dictionary</strong>, define a function customization template that specifies a custom function naming rule. Then, in the <strong>Code Mapping Editor</strong> or by using the code default mapping programming interface, map the <strong>Shared utility</strong> function category to that template. For more information, see “Configure Default Code Generation for Categories of Model Data and Functions” on page 21-7.</td>
</tr>
</tbody>
</table>
A model created in a release earlier than R2018a and that has not been configured with the **Code Mapping Editor** or default mapping programming interface

Set the model configuration parameter **Shared utilities identifier format** (CustomSymbolsStrUtil) to a custom function naming rule. For more information, see “Identifier Format Control” on page 39-22.

Once you use the **Code Mapping Editor** or default mapping programming interface to configure a model, setting the **Shared utilities identifier format** parameter has no effect.

The naming rule for shared utility functions must include the conditional checksum token $C$. To customize the length of the checksum that the code generator produces, use the **Shared checksum length** (SharedChecksumLength) parameter. Increasing the length of the checksum reduces the probability of clashes.

This example shows the customization of shared utility function names.

1. Open the example model `rtwdemo_crlmath`.
2. Set model configuration parameter **Shared code placement** to **Shared location**.
3. Set parameter **Shared utilities identifier format** as `mymodel_$N$C`. You can customize this format with any string. However, you must include token $C$.
4. Set parameter **Shared checksum length** to 5.
5. Generate code and a code generation report.
6. In the left navigation pane of the report, review the list generated files for shared utilities under **Shared files**.

### Control Placement of Shared Utility Code

Control placement of shared utility code with the model configuration parameter **Shared code placement**. The default option value is **Auto**. For this setting, the code generator places required code for fixed-point and other utilities in the `model.c` file, the `model.cpp` file, or a separate file in the build folder (for example, `vdp_grt_rtw`) if a model does not contain existing shared utility code or one of these blocks:

- Model blocks
- Simulink Function blocks
- Function Caller blocks
- Calls to Simulink Functions from Stateflow or MATLAB Function blocks
- Stateflow graphical functions when you select the **Export Chart Level Functions** parameter

If a model contains one or more of the preceding blocks, the code generator creates and uses a shared utilities folder within `slprj`. The naming convention for shared utility folders is `slprj/target/_sharedutils`. `target` is `sim` for simulations with Model blocks or the name of the system target file for code generation.

```
slprj/sim/_sharedutils   % folder used with simulation
slprj/grt/_sharedutils   % folder used with grt.tlc STF
slprj/ert/_sharedutils   % folder used with ert.tlc STF
slprj/mytarget/_sharedutils % folder used with mytarget.tlc STF
```

To force a model build to use the `slprj` folder for shared utility generation, even when the current model does not contain existing shared utility code or one of the preceding blocks, set parameter **Shared code placement** to **Shared location**. The code generator places utilities under the `slprj` folder rather than in the normal build folder. This setting is useful when you are manually combining code from several models, because it prevents symbol collisions between the models.

**Control Placement of rtwtypes.h for Shared Utility Code**

The generated `rtwtypes.h` header file provides fundamental type definitions, `#define` statements, and enumerations. For more information, see “rtwtypes.h” on page 36-50.

Control placement of `rtwtypes.h` file by selecting whether the build process uses the shared utilities folder. If the model build uses a shared utilities folder, the build process places `rtwtypes.h` in `slprj/target/_sharedutils`. Otherwise, the software places `rtwtypes.h` in `model_target_rtw`.

Adding a model to a model hierarchy or changing an existing model in the hierarchy can result in updates to the shared `rtwtypes.h` file during code generation. If updates occur, recompile and, depending on your development process, reverify previously generated code. To minimize updates to the `rtwtypes.h` file, make the following changes in the Configuration Parameters dialog box:

- Select **Support: complex numbers** even if the model does not currently use complex data types. Selecting this parameter protects against a future requirement to add support for complex data types when integrating code.
• Clear the **Support non-inlined S-functions** parameter. If you use noninlined S-functions in the model, this option generates an error.

• Clear the **Classic call interface** parameter. This parameter setting disables use of the GRT system target file.

### Avoid Duplicate Header Files for Exported Data

Exported header files appear in the shared utility folder when:

• You control the file placement of declarations for signals, parameters, and states by defining and applying storage classes.

• The code generator places utility code in a shared location.

For example, you can specify a header file for a piece of data through:

• A storage class that you define in the **Embedded Coder Dictionary** and map to categories of model data in the **Code Mapping Editor**.

• The **Code Generation** tab in a Signal Properties dialog box.

• The **HeaderFile** property of a data object. Data objects are objects of the classes `Simulink.Signal` and `Simulink.Parameter`.

If you want the declaration to appear in the file `model.h`, it is a best practice to leave the header file name unspecified. By default, the code generator places data declarations in `model.h`.

If you specify `model.h` as the header file name, and if the code generator places utility code in a shared location, you cannot generate code from the model. The code generator cannot create the file `model.h` in both the model build folder and the shared utility folder.

### Reduce Shared Utility Code Generation with Incremental Builds

You can specify that the model build generates C source files in a shared utilities folder. See “Generate Shared Utility Code“ (Simulink Coder). These files include C source files that contain function definitions and header files that contain macro definitions. For this discussion, the term functions means functions and macros.

Blocks within the same model and blocks in different models can use a shared function when you use model reference or when you build multiple standalone models from the
same start build folder. The code generator produces the code for a given function only once for the block that first triggers code generation. As the product determines the requirement to generate function code for subsequent blocks, it performs a file existence check. If the file exists, the model build does not regenerate the function. The shared utility code mechanism requires that a given function and file name represent the same functional behavior regardless of which block or model generates the function. To satisfy this requirement:

• Model properties that determine function behavior contribute to the shared utility checksum or determine the function and file name.
• Block properties that determine the function behavior also determine the function and file name.

During compilation, makefile rules for the shared utilities folder select compilation of only new C files and incrementally archive the object file into the shared utility library, rtwshared.lib, or rtwshared.a. Incremental compilation also occurs.

Manage the Shared Utility Code Checksum

When you set the model configuration parameter Shared code placement to Shared location or when the model contains Model blocks, the code generator places shared code in the shared utilities folder. The build process generates a shared utilities checksum of the code generation configuration for the shared code.

During subsequent code generation, if the checksum file slprj/target/_sharedutils/checksummap.mat exists relative to the current folder, the code generator reads that file. The code generator verifies that the current model that you are building has configuration properties that match the checksum of properties from the shared utility model. If mismatches occur between the properties defined in checksummap.mat and the current model properties, you see an error. Use the error message to manage the checksum (for example, diagnose and resolve the configuration issues with the current model).

For more information, see “Reduce Shared Utility Code Generation with Incremental Builds” (Simulink Coder).

• “View the Shared Utility Checksum Hash Table” on page 6-75
• “Relate the Shared Utility Checksum to Configuration Parameters” on page 6-76
**View the Shared Utility Checksum Hash Table**

It is helpful to view the property values that contribute to the checksum. This example uses the `rtwdemo_lct_start_term.slx` model. To load the `checksum.mat` file into MATLAB and view the `targetInfoStruct` that defines the checksum-related properties:

1. Open the `rtwdemo_lct_start_term.slx` model. In the Command Window, type:
   ```matlab
   rtwdemo_lct_start_term
   ```
2. Create and move to a new working folder.
   ```matlab
   mkdir C:\Temp\demo
   cd C:\Temp\demo
   ```
3. Save a copy of the model in the folder.
4. Build the model. This model is already set up to produce shared utilities.
5. Move to the `_sharedutils` folder created by the build process.
   ```matlab
   cd C:\Temp\demo\slprj\grt\_sharedutils
   ```
6. Load the `checksummap.mat` file into MATLAB.
   ```matlab
   load checksummap
   ```
7. Display the contents of `hashTbl.targetInfoStruct` and examine the checksum-related property values.
   ```matlab
   hashTbl.targetInfoStruct
   ```

For this example, the Command Window displays `hashTbl.targetInfoStruct` for the shared utilities that you generated from the model:

```matlab
ShiftRightIntArith: 'on'
ProdShiftRightIntArith: 'on'
Endianness: 'LittleEndian'
ProdEndianness: 'LittleEndian'
wordlengths: '8,16,32,32,64,32,64,64,64,64'
Prodwordlengths: '8,16,32,32,64,32,64,64,64,64'
TargetWordSize: '64'
ProdWordSize: '64'
TargetHWDeviceType: 'Custom Processor->MATLAB Host Computer'
ProdHWDeviceType: 'Intel->x86-64 (Windows64)'
TargetIntDivRoundTo: 'Zero'
ProdIntDivRoundTo: 'Zero'
tmfName: ''
toolchainName: ''
computer: 'PCWIN64'
UseDivisionForNetSlopeComputation: 'off'
PurelyIntegerCode: 'off'
PortableWordSizes: 'off'
SupportNonInlinedSFcns: ''
```
Relate the Shared Utility Checksum to Configuration Parameters

Examine the targetInfoStruct hash table from the shared utility model. Some key-value pairs relate directly to a model property. Other pairs relate to groups of properties.

The following table describes the key-value pairs.

<table>
<thead>
<tr>
<th>Key Names</th>

Generate Shared Utility Code for Fixed-Point Functions

An important set of generated functions that the model build places in the shared utility folder are the fixed-point support functions. Based on model and block properties, there are many possible versions of fixed-point utilities functions that make it impractical to provide a complete set as static files. Generating only the required fixed-point utility functions during the code generation process is an efficient alternative.

The shared utility checksum mechanism makes sure that several critical properties are identical for models that use the shared utilities. For the fixed-point functions, there are additional properties that determine function behavior. The mechanism codes these properties into the functions and file names to maintain requirements. The additional properties include:

<table>
<thead>
<tr>
<th>Category</th>
<th>Function/Property</th>
</tr>
</thead>
<tbody>
<tr>
<td>Block properties</td>
<td>• Fixed-point operation that the block performs</td>
</tr>
<tr>
<td></td>
<td>• Fixed-point data type and scaling (Slope, Bias) of function inputs and outputs</td>
</tr>
<tr>
<td></td>
<td>• Overflow handling mode (Saturation, Wrap)</td>
</tr>
<tr>
<td></td>
<td>• Rounding Mode (Floor, Ceil, Zero)</td>
</tr>
<tr>
<td>Model properties</td>
<td>get_param(bdroot, 'NoFixptDivByZeroProtection')</td>
</tr>
</tbody>
</table>

The property-based naming convention for the fixed-point utilities is as follows:

```
operation + [zero protection] + output data type + output bits + [input1 data] + input1 bits + [input2 data type + input2 bits] + [shift direction] + [saturate mode] + [round mode]
```

The file names shown are examples of generated fixed-point utility files. The function or macro names in the file are identical to the file name without the extension.

```
FIX2FIX_U12_U16.c
FIX2FIX_S9_S9_SR99.c
ACCUM_POS_S30_S30.h
MUL_S30_S30_S16.h
div_nzp_s16s32_floor.c
div_s32_sat_floor.c
```

For these examples, the table shows how the respective fields correspond.

The ACCUM_POS example uses the output variable as one of the input variables. So, the file and macro name only contain the output and second input.
The second div example has identical data type and bits for both inputs and the output. So, the file and function name only include the output.

<table>
<thead>
<tr>

- “Cross-Release Shared Utility Code Reuse” (Simulink Coder)
Generate Shared Utility Code for Custom Data Types

By default, if a model employs a custom data type (such as a Simulink.AliasType object or an enumeration class), the code generator places the corresponding type definition (typedef) in the model_types.h file. When you generate code from multiple models, each model duplicates the type definition. These duplicate definitions can prevent you from compiling the bodies of generated code together.

However, you can configure the code generator to place a single type definition in a header file in the _sharedutils folder. Then, when you generate code from a model, if the type definition already exists in the _sharedutils folder, the code generator does not duplicate the definition, but instead reuses it through inclusion (#include).

Through this mechanism, you can share:

- Simulink data type objects that you instantiate from the classes Simulink.AliasType, Simulink.Bus, and Simulink.NumericType. For basic information about creating and using these objects, see “Control Data Type Names in Generated Code” on page 24-2 and Simulink.Bus.

- Enumerations that you define, for example, by authoring an enum class in a script file or by using the function Simulink.defineIntEnumType. For basic information about defining enumerations in Simulink, see “Use Enumerated Data in Simulink Models” (Simulink).

To share a custom data type across multiple models:

1. Define the data type. For example, create the Simulink.AliasType object.
2. Set data scope and header file properties to specific values that enable sharing.
   
   For a data type object, set the DataScope property to 'Exported' and, optionally, specify the header file name through the HeaderFile property.
   
   For an enumeration that you define as an enum class in a script file, implement the getDataScope method (with return value 'Exported') and, optionally, implement the getHeaderFile method.
   
   For an enumeration that you define by using the Simulink.defineIntEnumType function, set the 'DataScope' pair argument to 'Exported' and, optionally, specify the 'HeaderFile' pair argument.
3. Use the data type in the models.
Before generating code from each model, set the model configuration parameter **Shared code placement** to **Shared location**.

Generate code from the models.

**Note** You can configure the definition of the custom data type to appear in a header file in the `sharedutils` folder. The shared utility functions that the model build generates into the `sharedutils` folder do not use the custom data type name. Only model code located in code folders for each model uses the custom data type name.

Shared Constant Parameters for Code Reuse

You can share the generated code for constant parameters across models if either of the following conditions applies:

• Constant parameters are shared in a model reference hierarchy.
• The model configuration parameter “Shared code placement” (Simulink Coder) is set to Shared location.

If you do not want to generate shared constants, and Shared code placement is set to Shared location, set the parameter GenerateSharedConstants to off. For example, to turn off shared constants for the current model, in the Command Window, type the following.

```matlab
set_param(gcs,'GenerateSharedConstants','off');
```

The code generator produces shared constant parameters individually and places them in the file `const_params.c`. The code generator places that file in the shared utilities folder slprj/target/_sharedutils.

For example, if a constant has multiple uses within a model reference hierarchy where the top model is named topmod, the code for the shared constant is as follows:

• In the shared utility folder, slprj/grt/_sharedutils, the constant parameters are defined in `const_params.c` and named rtCP_pooled_ appended to a unique checksum:

```c
extern const real_T rtCP_pooled_lfcjjmohiecj[7];
const real_T rtCP_pooled_lfcjjmohiecj[7] = { 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0 };
```

```c
extern const real_T rtCP_pooled_ppphohdbfcba[7];
const real_T rtCP_pooled_ppphohdbfcba[7] = { 7.0, 6.0, 5.0, 4.0, 3.0, 2.0, 1.0 };;
```

• In `top_model_private.h` or in a referenced model, `ref_model_private.h`, for better readability, the constants are renamed as follows:

```c
extern const real_T rtCP_pooled_lfcjjmohiecj[7];
extern const real_T rtCP_pooled_ppphohdbfcba[7];
```

```c
#define rtCP_Constant_Value   rtCP_pooled_lfcjjmohiecj  /* Expression: [1 2 3 4 5 6 7] */
#define rtCP_Constant_Value   rtCP_pooled_lfcjjmohiecj  /* Expression: [1 2 3 4 5 6 7] */
```

* Referenced by: '<Root>/Constant'*/

```c
#define rtCP_Gain_Gain        rtCP_pooled_ppphohdbfcba  /* Expression: [7 6 5 4 3 2 1] */
#define rtCP_Gain_Gain        rtCP_pooled_ppphohdbfcba  /* Expression: [7 6 5 4 3 2 1] */
```

* Referenced by: '<Root>/Gain' */

• In `topmod.c` or `refmod.c`, the call site might be:

```c
for (i = 0; i < 7; i++) {
    topmod_Y.Out1[i] = (topmod_U.In1 + rtCP_Constant_Value[i]) * rtCP_Gain_Gain[i];
}
```
The code generator attempts to generate constants as individual constants to the `const_params.c` file in the shared utilities folder. Otherwise, constants are generated as described in “Code Generation of Constant Parameters” on page 3-13.

**Suppress Shared Constants in the Generated Code**

You can choose whether the code generator produces shared constants and shared functions. You might want to be able to keep the code and data separate between subsystems, or you might find that sharing constants results in a memory shortage during code generation.

You can change this setting programmatically by using the parameter `GenerateSharedConstants` with `set_param` and `get_param`.

In the following example, when `GenerateSharedConstants` is set to `on`, the code generator defines the constant values in the `_sharedutils` folder in the `const_params.c` file. When `GenerateSharedConstants` is set to `off`, the code generator defines the constant values in a nonshared area, in the `model_ert_rtw` file in the `model_data.c` file.

Open the model `rtwdemo_throttlecntrl`:

In the Configuration parameters dialog box, on the **Code Generation > Interface** pane, verify that “Shared code placement” (Simulink Coder) is set to `Shared location`. If
**Shared code placement** is set to Auto, the GenerateSharedConstants setting is ignored. If you try to set the parameter value, an error message appears. The default value of GenerateSharedConstants is on.

In the Command Window, set GenerateSharedConstants to on:

```
>> set_param('rtwdemo_throttlecntrl','GenerateSharedConstants','on')
```

You see the shared constant definitions in the folder `slprj/grt/_sharedutils`, in the file `const_params.c`:

```c
extern const real_T rtCP_pooled_H4eTKtECwveN[9];
const real_T rtCP_pooled_H4eTKtECwveN[9] = { 1.0, 0.75, 0.6, 0.0, 0.0, 0.0, 0.6, 0.75, 1.0 };

extern const real_T rtCP_pooled_SghuHxKVKGHD[9];
const real_T rtCP_pooled_SghuHxKVKGHD[9] = { -1.0, -0.5, -0.25, -0.05, 0.0, 0.05, 0.25, 0.5, 1.0 };

extern const real_T rtCP_pooled_WqWb2t17NA2R[7];
const real_T rtCP_pooled_WqWb2t17NA2R[7] = { -1.0, -0.25, -0.01, 0.0, 0.01, 0.25, 1.0 };

extern const real_T rtCP_pooled_Ygnal0wM3c14[7];
const real_T rtCP_pooled_Ygnal0wM3c14[7] = { 1.0, 0.25, 0.0, 0.0, 0.0, 0.25, 1.0 };
```

In the Command Window, set GenerateSharedConstants to off:

```
>> set_param('rtwdemo_throttlecntrl','GenerateSharedConstants','off')
```

You can see the unshared constants in the folder `rtwdemo_throttlecntrl_grt_rtw`, in the file `rtwdemo_throttlecntrl_data.c`:

```c
/* Constant parameters (auto storage) */
const ConstP_rtwdemo_throttlecntrl_T rtwdemo_throttlecntrl_ConstP = {
    /* Pooled Parameter (Expression: P_OutMap)
       * Referenced by:
       *   '<S2>/Proportional Gain Shape'
       *   '<S3>/Proportional Gain Shape'
       */
    { 1.0, 0.25, 0.0, 0.0, 0.0, 0.25, 1.0 },

    /* Pooled Parameter (Expression: P_InErrMap)
       * Referenced by:
       *   '<S2>/Proportional Gain Shape'
       *   '<S3>/Proportional Gain Shape'
       */
    { -1.0, -0.25, -0.01, 0.0, 0.01, 0.25, 1.0 },

    /* Pooled Parameter (Expression: I_OutMap)
       * Referenced by:
       */
```
*  '<S2>/Integral  Gain Shape'
*  '<S3>/Integral  Gain Shape'
  */
  { 1.0, 0.75, 0.6, 0.0, 0.0, 0.0, 0.6, 0.75, 1.0 },

/* Pooled Parameter (Expression: I_InErrMap)
 * Referenced by:
 *  '<S2>/Integral  Gain Shape'
 *  '<S3>/Integral  Gain Shape'
 */
  { -1.0, -0.5, -0.25, -0.05, 0.0, 0.05, 0.25, 0.5, 1.0 }
};

**Shared constant Parameters Limitations**

No shared constants or shared functions are generated for a model when:

- The model has a code replacement library (CRL) that is specified for data alignment.
- The model is specified to replace data type names in the generated code.
- The **Memory Section** for constants is **MemVolatile** or **MemConstVolatile**.
- The parameter **GenerateSharedConstants** is set to **off**.

Individual constants are not shared, if:

- A constant is referenced by a non-inlined S-function.
- A constant has a user-defined type where **Data Scope** is not set to **Exported**.

Configure Model Parameters for Simulink Coder
Configure Run-Time Environment Options

When you use Simulink software to create and execute a model and use the code generator to produce C or C++ code, consider your configuration for up to three run-time environments:

• The MATLAB development computer run-time environment that runs MathWorks software during application development.
• The production hardware run-time environment in which you deploy an application when it is put into production.
• The test hardware run-time environment in which you test an application under development before deployment.

One run-time environment can serve in multiple capacities, but the run-time environments remain conceptually distinct. Often, the MATLAB development computer is the test hardware. Typically, the production hardware is different from, and less powerful than, the MATLAB development or the test hardware. Many types of production hardware can do little more than run a downloaded executable file.

Provide information about the production hardware board and the compiler that you use with it when:

• You use Simulink software to simulate a model for which you later generate code
• You use the code generator to produce code for deployment on production hardware

The software uses the board and compiler information to get bit-true agreement for the results of integer and fixed-point operations performed in simulation and in code generated for the production hardware. The code generator uses the information to create code that executes with maximum efficiency.

When you generate code for testing on test hardware, provide information about the test hardware board and the compiler that you use. The code generator uses this information to create code that provides bit-true agreement between results from:

• Integer and fixed-point operations performed in simulation
• Generated code run on the production hardware
• Generated code run on the test hardware
You can achieve bit-true agreement for results even if the production and test hardware are different. Where the C standard does not completely define behavior, the compilers for the two types of hardware can use different defaults.

**Configure Production and Test Hardware**

You can specify model simulation or code generation for a specific hardware board and its device type. For example, you can set the data size, byte ordering, and compiler behavior, such as integer rounding. You can configure:

- The production hardware and the compiler that you use with it. This information affects simulation and code generation. See “Example Production Hardware Setting That Affects Normal Mode Simulation” on page 7-14.
- The test hardware and the compiler that you use with it. This information affects only code generation.

Configure production hardware by selecting **Configuration Parameters > Hardware Implementation**. By default, the Hardware Implementation pane lists **Hardware board**, **Device vendor**, and **Device type** parameter fields only. Unless you have installed hardware support packages, **Hardware board** lists values None or Determine by Code Generation system target file, and Get Hardware Support Packages. After installing a hardware support package, the list also includes the corresponding hardware board name. If you select a hardware board name, parameters for that board appear. To set device details, such as data size and byte ordering, click **Device details**.

Configure test hardware on the **Configuration Parameters > Hardware Implementation > Advanced parameters** pane. To enable parameters for configuring test hardware details, disable the **Configuration Parameters > Hardware Implementation > Advanced parameters > Test hardware is the same as production hardware** parameter. Code generated for test hardware executes in the environment specified by the test hardware parameters. The code behaves as if it were executing in the environment specified for the production hardware. For more information, see “Test Hardware Considerations” on page 7-14.

Default values and properties appear as initial values in the **Hardware Implementation** pane when:

- You specify a **System target file** in the **Code Generation** pane.
- The system target file specifies a default microprocessor and its hardware properties.
You cannot change parameters that have only one possible value. Parameters that have more than one possible value provide a list of valid values. If you specify hardware properties manually in **Hardware Implementation** pane, verify that these values are consistent with the system target file. Otherwise, the generated code can fail to compile or execute, or can execute but produce incorrect results.

Hardware implementation parameters describe hardware and compiler properties to MATLAB software. The code generator uses the information to produce code for the runtime environment that runs as efficiently as possible. The generated code gives bit-true agreement for the results of integer and fixed-point operations in simulation, production code, and test code.

For details about specific parameters, see “Hardware Implementation Pane” (Simulink). To see an example of **Hardware Implementation** pane capabilities, see the `rtwdemo_targetsettings` example model. For details related to configuring a hardware implementation, see:

**Specify Hardware Board**

Specify the hardware board that runs the code generated from your model. Select a value for **Configuration Parameters > Hardware Implementation > Hardware board**.

The Hardware Implementation pane identifies the system target file selected on **Configuration Parameters > Code Generation**.

To configure test hardware, use the **Configuration Parameters > Hardware Implementation > Advanced parameters** pane.

To enable parameters for configuring test hardware details, set `ProdEqTarget` to `off`. 
Ways to Specify the Hardware Board

<table>
<thead>
<tr>
<th>If</th>
<th>Select</th>
</tr>
</thead>
<tbody>
<tr>
<td>The menu <em>includes</em> the name of the hardware board that you want to use.</td>
<td>The name of that hardware board. If you select a hardware board name, parameters for that board appear.</td>
</tr>
<tr>
<td>The menu <em>does not include</em> the name of the hardware board that you want to use.</td>
<td>Get Hardware Support Packages. That value opens the Support Package Installer. Install the support package that you want. After you install the support package, the menu includes relevant hardware board names.</td>

<td>None. No hardware board is specified for the hardware implementation.</td>
</tr>
<tr>
<td>The model configuration <em>does not use</em> system target file ert.tlc, realtime.tlc, or autosar.tlc.</td>
<td>Determine by Code Generation system target file. The code generator uses the specified system target file to determine the hardware implementation.</td>
</tr>
</tbody>
</table>

Specify Device Vendor

To specify the vendor of the microprocessor of the hardware device, use the **Device vendor** parameter. Your selection determines the available microprocessors in the **Device type** menu. If the vendor name does not appear, select **Custom Processor**. Then, use the **Device type** parameter to specify the microprocessor.

- For complete lists of **Device vendor** and **Device type** values, see “Device vendor” (Simulink) and “Device type” (Simulink).
- To add **Device vendor** and **Device type** values to the default set that is displayed on the **Hardware Implementation** pane, see “Register More Device Vendor and Device Type Values” on page 7-6.

Specify the Device Type

To specify the microprocessor name from the supported devices listed for your **Device vendor** selection, use the **Device type** parameter. If the microprocessor does not appear
in the menu, change **Device vendor** to **Custom Processor**. Then, specify device details for your custom device.

If you select a device type for which the system target file specifies default hardware properties, the properties appear as initial values. You cannot change the value of parameters with only one possible selection. Parameters that have more than one possible value provide a menu. Select values for your hardware.

**Register More Device Vendor and Device Type Values**

To add **Device vendor** and **Device type** values to the default set that is displayed on the **Hardware Implementation** pane, you can use a hardware device registration API provided by the code generator.

To use this API, you create an `sl_customization.m` file, on your MATLAB path, that invokes the `registerTargetInfo` function and fills in a hardware device registry entry with device information. The device information is registered with Simulink software for each subsequent Simulink session. (To register your device information without restarting MATLAB, issue the MATLAB command `sl_refresh_customizations`.)

For example, the following `sl_customization.m` file adds device vendor `MyDevVendor` and device type `MyDevType` to the Simulink device lists.

```matlab
function sl_customization(cm)
    cm.registerTargetInfo(@loc_register_device);
end

function thisDev = loc_register_device
    thisDev = RTW.HWDeviceRegistry;
    thisDev.Vendor = 'MyDevVendor';
    thisDev.Type = 'MyDevType';
    thisDev.Alias = {};
    thisDev.Platform = {'Prod', 'Target'};
    thisDev.setWordSizes([8 16 32 32 32]);
    thisDev.LargestAtomicInteger = 'Char';
    thisDev.LargestAtomicFloat = 'None';
    thisDev.Endianess = 'Unspecified';
    thisDev.IntDivRoundTo = 'Undefined';
    thisDev.ShiftRightIntArith = true;
    thisDev.setEnabled({'IntDivRoundTo'});
end
```

After device registration, you can select the device in the **Hardware Implementation** pane.
To register multiple devices, specify an array of `RTW.HWDeviceRegistry` objects in your `sl_customization.m` file. For example:

```matlab
function sl_customization(cm)
    cm.registerTargetInfo(@loc_register_device);
end

function thisDev = loc_register_device

    thisDev(1) = RTW.HWDeviceRegistry;
    thisDev(1).Vendor = 'MyDevVendor';
    thisDev(1).Type = 'MyDevType1';
    ...

    thisDev(4) = RTW.HWDeviceRegistry;
    thisDev(4).Vendor = 'MyDevVendor';
    thisDev(4).Type = 'MyDevType4';
    ...
end
```

You can specify various `RTW.HWDeviceRegistry` properties in the `registerTargetInfo` function call in your `sl_customization.m` file.
## Properties for `registerTargetInfo` Function Call

<table>
<thead>

<td>Boolean value specifying whether your compiler implements a signed integer right shift as an arithmetic right shift (true) or not (false).</td>
</tr>
</tbody>
</table>

| setEnabled              | Cell array of character vectors specifying which device properties you can modify in the Hardware Implementation pane when you select this device type. This property applies for the 'Endianess', 'IntDivRoundTo', and 'ShiftRightIntArith' properties. You can apply this property to individual Number of bits parameters by using the property names 'BitPerChar', 'BitPerShort', 'BitPerInt', 'BitPerLong', and 'NativeWordSize'. |

### Set Bit Lengths for Device Data Types

The **Number of bits** parameters describe the native word size of the microprocessor and the bit lengths of **char**, **short**, **int**, and **long** data. For code generation to succeed:

- The bit lengths must be such that **char** <= **short** <= **int** <= **long**.
- Bit lengths must be multiples of 8, with a maximum of 32.
- The bit length for **long** data must not be less than 32.

The `rtwtypes.h` file defines integer type names. The values that you provide must be consistent with the word sizes as defined in the compiler `limits.h` header file. The code generator maps its integer type names to the corresponding Simulink integer type names.

If no ANSI® C type with a matching word size is available, but a larger ANSI C type is available, the code generator uses the larger type for `int8_T`, `uint8_T`, `int16_T`, `uint16_T`, `int32_T`, and `uint32_T`. When the code generator uses a larger type, the resulting logged values (for example, MAT-file logging) can have different data types than logged values for simulation.

An application can use an integer data of length from 1 (unsigned) or 2 (signed) bits up to 32 bits. If the integer length matches the length of an available type, the code generator uses that type. If a matching type is not available, the code generator uses the smallest available type that can hold the data, generating code that does not use unnecessary higher-order bits. For example, on hardware that supports 8-bit, 16-bit, and 32-bit...
integers, for a signal specified as 24 bits, the code generator implements the data as an int32_T or uint32_T.

Code that uses emulated integer data is not maximally efficient. This code can be useful during application development for emulating integer lengths that are available only on production hardware. Emulation does not affect the results of execution.

During code generation, the software checks the compatibility of model data types with the data types that you specify for production hardware.

- If none of the lengths that you specify for production hardware integers is 32 bits, the software generates an error.
- If the lengths of data types that the model uses are smaller than the available production hardware integer lengths, the software generates a warning.

### Mapping of Integer Types from Code Generator to Simulink

<td>uint32</td>
</tr>
</tbody>
</table>

### Set Byte Ordering for Device

The Byte ordering parameter specifies whether the hardware uses BigEndian (most significant byte first) or LittleEndian (least significant byte first) byte ordering. If left as Unspecified, the code generator produces code that determines the endianness of the hardware. This setting is the least efficient.

### Set Quotient Rounding Behavior for Signed Integer Division

ANSI C does not completely define the quotient rounding technique for compilers to use when dividing one signed integer by another. So, the behavior is implementation-dependent. If both integers are positive, or both are negative, the quotient must round
down. If either integer is positive and the other is negative, the quotient can round up or down.

The *Signed integer division rounds to* parameter instructs the code generator about how the compiler rounds the result of signed integer division. Providing this information does not change the operation of the compiler. It only describes that behavior to the code generator, which uses the information to optimize code generated for signed integer division. The parameter values are:

- **Zero** — If the quotient is between two integers, the compiler chooses the integer that is closer to zero as the result.
- **Floor** — If the quotient is between two integers, the compiler chooses the integer that is closer to negative infinity.
- **Undefined** — If Zero or Floor do not describe the compiler behavior or if that behavior is unknown, choose this value.

Avoid selecting Undefined. When the code generator does not know the signed integer division rounding behavior of the compiler, the model build generates extra code.

The compiler quotient rounding behavior varies according to these values.

You can obtain the compiler implementation for signed integer division rounding from the compiler documentation. If documentation is not available, you can determine this behavior by experiment.

**Example Quotient Rounding for Zero, Floor, and Undefined**

<table>

<td>8</td>
<td>8 or 9</td>
</tr>
</tbody>
</table>

**Set Arithmetic Right Shift Behavior for Signed Integers**

ANSI C does not define the behavior of right shifts on negative integers for compilers. So, the behavior is implementation-dependent. The *Shift right on a signed integer as arithmetic shift* option instructs the code generator about how the compiler implements right shifts on negative integers. Providing this information does not change the operation
of the compiler. It only describes that behavior to the code generator, which uses the information to optimize the code generated for arithmetic right shifts.

If the C compiler implements a signed integer right shift as an arithmetic right shift, select the option. Otherwise, clear the option. An arithmetic right shift fills bits vacated by the right shift with the value of the most significant bit, which indicates the sign of the number in two's-complement notation. The option is selected by default. If your compiler handles right shifts as arithmetic shifts, this setting is preferred.

- When you select the option, the code generator produces efficient code whenever the Simulink model performs arithmetic shifts on signed integers.
- When the option is cleared, the code generator produces fully portable but less efficient code to implement right arithmetic shifts.

You can obtain the compiler implementation for arithmetic right shifts from the compiler documentation. If documentation is not available, you can determine this behavior by experiment.

**Update Release 14 Hardware Configuration**

If your model was created before Release 14 and you have not updated the model, the Configure current execution hardware device parameter (TargetUnknown) value is 'on' by default.

To update your model, clear the box for Configuration Parameters > Hardware Implementation > Advanced parameters > Test hardware > Configure test hardware. Or in the Command Window, type:

```matlab
cs = getActiveConfigSet('your_model_name');
set_param(cs,'TargetUnknown','off');
```

This update to your model:

- Enables the Test Hardware is the same as production hardware parameter (ProdEqTarget), setting the parameter to 'on'.
- Copies the Production device vendor and type parameter (ProdHWDeviceType) value to the Test device vendor and type parameter (TargetHWDeviceType).

To complete the update:

1. Clear the box for Configuration Parameters > Hardware Implementation > Advanced parameters > Test hardware > Test Hardware is the same as
**Production Hardware Considerations**

When you configure production hardware, consider these points:

- Production hardware can have word sizes and other hardware characteristics that differ from the MATLAB development computer. You can prototype code on hardware that is different from the production hardware or the MATLAB development computer. When producing code, the code generator accounts for these differences.

- The Simulink product uses some of the information in the production hardware configuration. That information enables simulations without code generation to give the same results as executing generated code. For example, the results can detect error conditions that arise on the production hardware, such as hardware overflow.

- The code generator produces code that provides bit-true agreement with Simulink results for integer and fixed-point operations. Generated code that emulates unavailable data lengths runs less efficiently than without emulation. The emulation does not affect bit-true agreement with Simulink for integer and fixed-point results.

- If you change run-time environments during application development, before generating or regenerating code, reconfigure the hardware implementation parameters for the new run-time environment. When code executes on hardware for which it was not generated, bit-true agreement is not always achieved for results of integer and fixed-point operations in simulation, production code, and test code.

- To compile code generated from the model, use the **Integer rounding mode** parameter on model blocks to simulate the rounding behavior of the C compiler that you intend. This setting appears on the **Signal Attributes** pane in the parameter dialog boxes of blocks that can perform signed integer arithmetic, such as the Product and n-D Lookup Table blocks.

- For most blocks, the value of **Integer rounding mode** completely defines rounding behavior. For blocks that support fixed-point data and the simplest rounding mode, the value of **Signed integer division rounds to** also affects rounding. For details, see “Precision” (Fixed-Point Designer).

- When models contain Model blocks, configure models that they reference to use identical hardware settings.
Test Hardware Considerations

By default, the test hardware configuration is the same as the configuration for the production hardware. You can use the generated code for testing in an environment that is identical to the production environment.

If the test and production environments differ, you can generate code that runs on test hardware as if it were running on production hardware:

1 To enable test hardware parameters, clear the box for **Configuration Parameters > Hardware Implementation > Advanced parameters > Test hardware > Test hardware is the same as production hardware**. Or, in the Command Window type:

   ```
   cs = getActiveConfigSet('your_model_name');
   set_param(cs,'ProdEqTarget','off');
   ```

2 Specify device type details through the test hardware (**Target*”) parameters.

If you select a system target file that specifies a default microprocessor and its hardware properties, these default values and properties appear as initial values.

Parameters with only one possible value cannot be changed. If you modify hardware properties, check that their values are consistent with the system target file. Otherwise, the generated code can fail to compile or execute, or can execute but produce incorrect results.

Example Production Hardware Setting That Affects Normal Mode Simulation

Changing some production hardware settings, for example, **ProdLongLongMode** and **ProdIntDivRoundTo**, can affect normal mode simulation results. The following example simulates an adder with four inputs. In the first simulation, **ProdLongLongMode** is disabled. In the second simulation, **ProdLongLongMode** is enabled. In the plot of simulation outputs, you observe small differences between output values in the time step range 125–175.

```
pos = [75 155 105 175];
add_block('built-in/Inport',[model '/In1'],'Position',pos)
set_param([model '/In1'], 'OutDataTypeStr', ... 'int32','PortDimensions','1','SampleTime','1');
add_line(model, 'In1/1','sum_int32/1')

pos = [75 205 105 225];
add_block('built-in/Inport',[model '/In2'],'Position',pos)
set_param([model '/In2'], 'OutDataTypeStr', ... 'int32','PortDimensions','1','SampleTime','1');
add_line(model, 'In2/1','sum_int32/2')

pos = [75 255 105 275];
add_block('built-in/Inport',[model '/In3'],'Position',pos)
set_param([model '/In3'], 'OutDataTypeStr', ... 'int32','PortDimensions','1','SampleTime','1');
add_line(model, 'In3/1','sum_int32/3')

pos = [75 305 105 325];
add_block('built-in/Inport',[model '/In4'],'Position',pos)
set_param([model '/In4'], 'OutDataTypeStr', ... 'int32','PortDimensions','1','SampleTime','1');
add_line(model, 'In4/1','sum_int32/4')

pos = [275 230 305 250];
add_block('built-in/Outport',[model '/Out1'],'Position',pos)
add_line(model, 'sum_int32/1','Out1/1')

% Specify input data
  t = 0:200;
  peakValue = 1.5e9;
  in1 = peakValue * sin(t*2*pi/100);
  in2 = peakValue * cos(t*2*pi/70);
  in3 = -peakValue * sin(t*2*pi/40);
  in4 = -peakValue * cos(t*2*pi/30);
  set = Simulink.SimulationData.Dataset;
  set = set.addElement(1, timeseries(int32(in1),t,'Name','sig1'));
  set = set.addElement(2, timeseries(int32(in2),t,'Name','sig2'));
  set = set.addElement(3, timeseries(int32(in3),t,'Name','sig3'));
  set = set.addElement(4, timeseries(int32(in4),t,'Name','sig4'));
  set_param(model, 'LoadExternalInput', 'on');
  set_param(model, 'ExternalInput', 'set');
  set_param(model, 'StopTime', '50');

  % Disable production hardware setting and run first simulation
  set_param(model, 'ProdLongLongMode', 'off');
  [~, ~, y1] = sim(model, 200);
The difference in behavior is due to the accumulator data type in the Sum block. The **Accumulator data type** block parameter is set to Inherit: Inherit via internal rule. For this example, the resulting accumulator data type is 64 bits wide if the use of the C long long data type is enabled. Otherwise, it is 32 bits wide. Depending on the input values for the sum block, the 32-bit accumulator can saturate when the 64-bit accumulator does not. Therefore, normal mode behavior can depend on the ProdLongLongMode setting. In both cases, the normal mode behavior and production hardware behavior matches bitwise.

Protect Models for Third-Party Use

Protect a model when you want to share a model with a third party without revealing intellectual property. Protecting a model does not use encryption technology unless you use the optional password protection available for read-only view, simulation, and code generation. If you choose password protection for one of these options, the software protects the supporting files by using AES–256 encryption.

When you create a protected model (Simulink):

- By default, Simulink creates and stores a protected version of the model in the current working folder. The protected model has the same name as the source model, with an \*.slxp extension.
- To share a protected model, share only the protected model file.
- The original Model block does not change. If the Model block parameter Model name does not specify an extension, a protected model, \*.slxp, takes precedence over a model file, \*.slx.
- You can optionally create a harness model which includes the protected model. A badge icon appears in the lower-left corner of the protected model block in the harness model. For more information, see “Harness Model” on page 8-4.
- You can optionally include generated code with the protected model so that a third party can generate code for a model that contains the protected model. For more information, see “Code Generation Support in Protected Models” on page 8-6.
- If the Model block uses variants, only the active variant is protected. For more information, see “Set up Model Variants Using a Model Block” (Simulink).
- If the model defines callbacks, the model protection process does not preserve these callbacks. For more information on creating callbacks for use with a protected model, see “Define Callbacks for Protected Models” (Simulink Coder).
- If you rename a protected model, or change its suffix, the model is unusable until you restore its original name and suffix. You cannot change a protected model file internally because such changes make the file unusable.

Create a protected model by using one of these options:

- The Model block context menu. For more information, see “Create a Protected Model” on page 8-11.
- The Simulink.ModelReference.protect function.
• The Simulink Editor menu bar. To create a protected model from the current model, select **File > Export Model To > Protected Model**.

**Requirements for Protecting a Model**

To protect a model, the model must meet all requirements listed in “Model Referencing Limitations” (Simulink) and these requirements:

• You must have a Simulink Coder license to create a protected model.
• The model must be available on the MATLAB path.
• The model cannot have unsaved changes.
• The model cannot use a noninlined S-function directly or indirectly.
• All protected referenced models must support simulation in **Accelerator** mode. The protected referenced model creator must select **Simulate** in the Create Protected Model dialog box or set the 'Mode' to 'Accelerator' or 'CodeGeneration' by using the `Simulink.ModelReference.protect` function.
• All protected referenced models must use the default 'CodeInterface' setting: 'Model reference'.
• Protected referenced models cannot have password protection on simulation.
• Protected referenced models cannot have callbacks.
• The model cannot support operations that a protected referenced model does not support or supports with password protection. For example, a protected model can support code generation only if all protected referenced models support code generation without password protection.
• When protecting a model for code generation, the model must use a **Content type** that is compatible with the **Content type** of each protected referenced model. See “Code Generation Support in Protected Models” (Simulink Coder).

To use a protected model that requires passwords across platforms, before you create the protected model, set the MATLAB character set encoding to 'US-ASCII'. For more information, see `slCharacterEncoding`.
Harness Model

You can create a harness model for the generated protected model. The harness model opens as a new, untitled model that contains only a Model block that references the protected model. This Model block:

- Specifies the Model block parameter, Model name, as the name of the protected model.
- Has a badge icon in the lower-left corner.
- Has the same number of input and output ports as the protected model.
- Defines model reference arguments that the protected model uses, but does not provide values.

To create a harness model, see “Create a Protected Model” on page 8-11. You can use a harness model to test your protected model. For more information, see “Test the Protected Model” on page 8-22. You can also copy the Model block in your harness model to another model, where it is an interface to the protected model.
Protected Model Report

You can generate a protected model report when you create the protected model. The report is included as part of the protected model. The report has:

• A Summary, including the following tables:
  • Environment, providing the Simulink version and platform used to create the protected model.
  • Supported functionality, reporting On, Off, or On with password protection for each possible functionality that the protected model supports.
  • Licenses, listing licenses required to run the protected model.
• An Interface Report, including model interface information such as input and output specifications, exported function information, interface parameters, and data stores.

When you create the protected model from the Simulink Editor, the protected model report is generated. To generate a report when using the Simulink.ModelReference.protect function, set the ‘Report’ option to true.

If you configure your protected model for multiple targets, the Summary includes a list of supported targets in the Supported functionality table. When you build a model that references a protected model with multiple targets, the protected model code generation report represents the currently configured target.

To view the protected model report, right-click the protected-model badge icon and select Display Report. Or, call the Simulink.ProtectedModel.open function with the report option.
Code Generation Support in Protected Models

You can create a protected model that supports code generation. When a protected model includes generated code, a third party can generate code for a model that includes the protected model. If you choose to obfuscate the code, the code is obfuscated before compilation. The protected model file contains only headers and binaries. Source code, such as .c and .cpp, is not present in the protected model file, although the headers are documented in the protected model report. For more information, see “Protected Model File” on page 8-9 and “Protected Model Report” on page 8-5.

In the Create Protected Model dialog box, select the Use generated code check box. The Content type determines the appearance of the generated code. If you select Readable source code or Obfuscated source code, the header files match the appearance of the generated code. If you select Binaries, the header files can appear readable or obfuscated based on the 'ObfuscateCode' argument. By default, the header files appear obfuscated.

When you create a protected model that supports code generation:

* Simulink ignores source code comments in the Code Generation > Comments pane. Obfuscation of the generated code removes comments because comments can reveal intellectual property.
* Simulink obfuscates custom code specified in the Code Generation > Custom Code pane, but does not obfuscate identifiers.

For an example on including code generation support, see “Create a Protected Model” on page 8-11.

Protected Model Requirements to Support Code Generation

Contents and configuration of a model can prevent code generation support of the protected model. Interaction between the parent model and the protected referenced model can also prevent code generation.

To create a protected model that supports code generation, your model must meet all requirements as described in “Requirements for Protecting a Model” (Simulink Coder) and these requirements:

* The protected model must use normal, accelerator, software-in-the-loop (SIL), or processor-in-the-loop (PIL) mode and a single target.
• To avoid an error during code generation of a model that includes a protected model:
  • The protected model name must be unique from other model names in the same model reference hierarchy.
  • The interfaces must match.
  • The parameters must be compatible.
• You must not select the Code Generation > Verification > Measure function execution time check box. If you have this option selected when you protect your model, the software turns off the parameter and displays a warning.
• The protected model Existing shared code (ExistingSharedCode) parameter must not specify a value.
• All protected referenced models must support code generation without password protection.
• The protected model must be compatible with the Content type of each protected referenced model. This table provides compatibility information.

**Code Generation Content Type Compatibility**

<table>
<thead>
<tr>
<th>Protected Parent Model Content Type</th>
<th>Compatible Protected Referenced Model Content Types</th>
</tr>
</thead>
<tbody>
<tr>
<td>Binaries</td>
<td>• Binaries</td>
</tr>
<tr>
<td></td>
<td>• Obfuscated source code</td>
</tr>
<tr>
<td>Binaries with 'ObfuscateCode' set to 'false'</td>
<td>• Binaries</td>
</tr>
<tr>
<td></td>
<td>• Binaries with 'ObfuscateCode' set to 'false'</td>
</tr>
<tr>
<td></td>
<td>• Obfuscated source code</td>
</tr>
<tr>
<td></td>
<td>• Readable source code</td>
</tr>
<tr>
<td>Obfuscated source code</td>
<td>• Obfuscated source code</td>
</tr>
<tr>
<td>Readable source code</td>
<td>• Obfuscated source code</td>
</tr>
<tr>
<td></td>
<td>• Readable source code</td>
</tr>
</tbody>
</table>

When the **Content type** of the protected parent model and protected referenced models do not match, code generation applies the more secure **Content type**. For example, a protected parent model set for **Binaries** generates Binaries for protected referenced models that are set to **Obfuscated source code**. A protected
parent model set for Readable source code generates Obfuscated source code for protected referenced models that are set to Obfuscated source code.
Protected Model File

A protected model file (.slxp) consists of the model itself and supporting files, depending on the options that you selected when you created the protected model.

If you created a protected model for simulation only and the referencing model is in Normal mode, after simulation, the model.mexext file is placed in the build folder.

If you created a protected model for simulation only and the referencing model is in Accelerator or Rapid Accelerator mode, after simulation, the following files are unpacked:

- slprj/sim/model/* .h
- slprj/sim/model/modellib.a (or modellib.lib)
- slprj/sim/model/tmwinternal/*
- slprj/sim/_sharedutils/*

For the protected model report, these additional files are unpacked (but not in the build folder):

- slprj/sim/model/html/*
- slprj/sim/model/buildinfo.mat

If you included code generation support when you created the protected model, after building your model the following files are unpacked (in addition to the preceding files):

- slprj/sim/model/* .h
- slprj/sim/model/modellib.a (or modellib.lib)
- slprj/sim/model/tmwinternal/*
- slprj/sim/_sharedutils/*
- slprj/target/model/* .h
- slprj/target/model/model_rtwlib.a (or model_rtwlib.lib)
- slprj/target/model/buildinfo.mat
- slprj/target/model/codeinfo.mat
- slprj/target/_sharedutils/*
- slprj/target/model/tmwinternal/*
With an Embedded Coder license, you can specify a Top model code interface. In this case, if you opted to include code generation support when you created the protected model, after building your model the following files are unpacked:

- `slprj/sim/model/*\.h`
- `slprj/sim/model/modellib.a` (or `modellib.lib`)
- `slprj/sim/model/tmwinternal/*`
- `slprj/sim/_sharedutils/*`
- `model_target_rtw/*\.h`
- `model_target_rtw/*\.objExt`
- `model_target_rtw/buildinfo.mat`
- `model_target_rtw/codeinfo.mat`
- `slprj/target/_sharedutils/*`
- `slprj/target/model/tmwinternal/*`

For the protected model report, after building your model these files are unpacked (in addition to the preceding files):

- `slprj/target/model/html/*`
- `slprj/target/model/buildinfo.mat`
- `slprj/target/_sharedutils/html/*`

**Note** The `slprj/sim/model/*` files are deleted after they are used.
Create a Protected Model

This example shows how to create a protected model for read-only viewing, simulation, or code generation.

1. Open your model. For this example, sldemo_mdlref_basic is used as a demonstration.

2. In the Simulink Editor, right-click the model block that references the model for which you want to generate protected model code. In this example, right-click CounterA.

3. From the context menu, select Block Parameters (ModelReference).

4. In the Block Parameters dialog box, in the Model name field, specify the extension for the model, .slx. When both the model and the protected model exist in the same folder, .slxp takes precedence over .slx. In the Model name field, if you do not specify an extension, then the original model block in the model becomes protected.

5. Click OK.

6. Right-click the model block. From the context menu, select Subsystem & Model Reference > Create Protected Model for Selected Model Block.
In the Create Protected Model dialog box, select the **Simulate** and **Use generated code** check boxes. If you want to password-protect the functionality of the protected model, enter a password with a minimum of four characters. Each functionality can have a unique password.

If you have an Embedded Coder license and specify an ERT-based system target file (for example, `ert.tlc`) for the model, the **Code interface** field is visible. From the **Code interface** drop-down list, select one of the following options:

- **Model reference** — Specifies code access through the model reference code interface, which allows use of the protected model within a model reference hierarchy. Users of the protected model can generate code from a parent model that contains the protected model. In addition, users can run Model block SIL/PIL simulations with the protected model.

- **Top model** — Specifies code access through the standalone interface. Users of the protected model can run Model block SIL/PIL simulations with the protected model.
Note In this example, sldemo_mdlref_basic does not specify an ERT-based system target file, therefore the Code interface options are not available on the Create Protected Model dialog box.

9 From the Content type list, select Obfuscated source code to conceal the source code purpose and logic of the protected model.

10 In the Create protected model in field, specify the folder path for the protected model. The default value is the current working folder.

11 To create a harness model for the protected model, select the Create harness model for protected model check box.

12 Click Create. An untitled harness model opens. It contains a model block, which refers to the protected model sldemo_mdlref_counter.slxp. The Simulation mode for the Model block is set to Accelerator. You cannot change the mode.

13 To view the protected model report, right-click the protected-model badge icon on the CounterA block and select Display Report.

More About
- “Code Generation Support in Protected Models” on page 8-6
- “Protected Model Creation Settings” on page 8-16
- “Code Interfaces for SIL and PIL” on page 67-6
Protected Model Creation Settings

When you create a protected model, in the Create Protected Model dialog box, you can select which settings you want configured. The settings provide certain functionality permissions when using a protected model. The functionality choices are:

- Read-only viewing
- Simulation
- Code Generation

Password-protection is optional. You must have a minimum of four characters.
Open Read-Only View of Model

If you want to share a view-only version of your model, this option allows someone using the protected model to open a Web view of the model. The contents and block parameters are viewable in the model Web view.

Simulate

The Simulate check box allows someone to simulate a protected model. When you select this check box, the Web view is not inherited. To enable the Web view with simulation functionality, select the Open Read-Only View of Model check box. The Simulate functionality:

- Enables protected model Simulation Report.
- Sets Mode to Accelerator. You can run Normal Mode and Accelerator simulations.
- Displays only binaries and headers.
- Enables code obfuscation.

Use Generated Code

The Use generated code check box allows simulation and code generation for a protected model. To generate code, the Simulate check box must also be selected. This functionality:

- Sets Mode to enable code generation.
- Enables support for simulation.
- Supports the Model block if you have an Embedded Coder license and specify an ERT system target file (ert.tlc) for the model. From the Code interface drop-down list, select one of the following options:

  - Model reference — Specifies the model reference code interface, which allows use of the protected model within a model reference hierarchy. Users of the protected model can generate code from a parent model that contains the protected model. In addition, users can run Model block SIL/PIL simulations with the protected model.
• **Top model** — Specifies code access through the standalone interface. Users of the protected model can run Model block SIL/PIL simulations with the protected model.

• Determines the appearance of the generated code by the **Content type** list. The options are:
  
  • **Binaries**
  • **Obfuscated source code** (default)
  • **Readable source code**, which also includes readable code comments
Create a Protected Model with Multiple Targets

You can create a protected model that supports multiple code generation targets. This example shows how to use command-line functions to create a protected model that supports code generation for GRT and ERT targets.

1. Load a model and save a local copy. This model is configured for a GRT target.
   ```matlab
   sldemo_mdlref_counter
   save_system('sldemo_mdlref_counter','mdlref_counter.slx');
   ```

2. Add a required password for modifying a protected model. If you do not add a password, you are prompted to set a password when you create a modifiable, protected model.
   ```matlab
   Simulink.ModelReference.ProtectedModel.setPasswordForModify(...
   'mdlref_counter','password');
   ```

3. Create a modifiable, protected model with support for code generation.
   ```matlab
   Simulink.ModelReference.protect('mdlref_counter','Mode',...
   'CodeGeneration', 'Modifiable',true, 'Report',true);
   ```

4. Get a list of targets that the protected model supports.
   ```matlab
   st = Simulink.ProtectedModel.getSupportedTargets('mdlref_counter')
   st =
   'grt'    'sim'
   ```

5. Configure the unprotected model to support an ERT target.
   ```matlab
   set_param('mdlref_counter', 'SystemTargetFile', 'ert.tlc');
   save_system('mdlref_counter');
   ```

6. Add support to the protected model for the ERT target. You are prompted for the modification password.
   ```matlab
   Simulink.ProtectedModel.addTarget('mdlref_counter');
   ```

7. Verify that the list of supported targets now includes the ERT target.
   ```matlab
   st = Simulink.ProtectedModel.getSupportedTargets('mdlref_counter')
   ```
st =

'ert'    'grt'    'sim'
Use a Protected Model with Multiple Targets

When using a protected model with multiple targets, prepare your model for code generation.

1. Get a list of the targets that the protected model supports using the `Simulink.ProtectedModel.getSupportedTargets` function.

   You can also get this information from the protected model report. To view the report, on the protected model block, right-click the badge icon. Select **Display Report**. The **Summary** lists the supported targets.

2. Get the configuration set for your chosen target using the `Simulink.ProtectedModel.getConfigSet` function. You can use the configuration set to verify that the protected model interface is compatible with the parent model.

3. Generate code. The build process selects the corresponding target.
Test the Protected Model

To test a protected model that you created, you use the generated harness model and the procedure described in “Simulate a Protected Model” (Simulink).

You can also compare the output of the protected model to the output of the original model. Because you are the supplier, both the original and the protected model might exist on the MATLAB path. In the original model, if the Model block Model name parameter names the model without providing a suffix, the protected model takes precedence over the unprotected model. To override this default when testing the output, in the Model block Model name parameter, specify the file name with the extension of the unprotected model, .slx.

To compare the unprotected and protected versions of a Model block, use the Simulation Data Inspector. This example uses sldemo_mdlref_basic and the protected model, sldemo_mdlref_counter.slxp, which is created in “Create a Protected Model” on page 8-11.

1 If it is not already open, open sldemo_mdlref_basic.

2 Enable logging for the output signal of the Model block, CounterA. In the Configuration Parameters dialog box, in the Data Import/Export pane, select the Signal logging parameter. Click Apply and OK.

3 Right-click the output signal. From the context menu, select Properties. In the Signal Properties dialog box, select Log signal data. Click Apply and OK. For more information, see “Export Signal Data Using Signal Logging” (Simulink).

4 Right-click the CounterA block. From the context menu, select Block Parameters (ModelReference). In the Block Parameters dialog box, specify the Model name parameter with the name of the unprotected model and the extension, sldemo_mdlref_counter.slx. Click Apply and OK. Repeat this step for CounterB block and CounterC block.

5 In the Simulink Editor, click the Simulation Data Inspector button arrow and select Send Logged Workspace Data to Data Inspector from the menu.

6 Simulate the model. When the simulation is complete, click the Simulation Data Inspector button to open the Simulation Data Inspector.

7 In the Simulation Data Inspector, rename the run to indicate that it is for the unprotected model.

8 In the Simulink Editor, right-click the CounterA block. From the context menu, select Block Parameters (ModelReference). In the Block Parameters dialog
box, specify the **Model name** parameter with the name of the protected model, `sldemo_mdlref_counter.slx`. A badge icon appears on the Model block. Repeat this step for **CounterB** block and **CounterC** block.

9. Simulate the model, which now refers to the protected model. When the simulation is complete, a new run appears in the Simulation Data Inspector.

10. In the Simulation Data Inspector, rename the new run to indicate that it is for the protected model.

11. In the Simulation Data Inspector, click the **Compare** tab. From the **Baseline** and **Compare To** lists, select the runs from the unprotected and protected model, respectively. To compare the runs, click **Compare Runs**. For more information about comparing runs, see “Compare Simulation Data” (Simulink).
Save Base Workspace Definitions

Referenced models can use object definitions or tunable parameters that are defined in the MATLAB base workspace. These variables are not saved with the model. When you protect a model, you must obtain the definitions of required base workspace entities and ship them with the model.

The following base workspace variables must be saved to a MAT-file:

- Global tunable parameter
- Global data store
- The following objects used by a signal that connects to a root-level model Inport or Outport:
  - Simulink.Signal
  - Simulink.Bus
  - Simulink.Alias
  - Simulink.NumericType that is an alias

For more information, see “Edit and Manage Workspace Variables by Using Model Explorer” (Simulink).

Before executing the protected model as a part of a third-party model, the receiver of the protected model must load the MAT-file.
Package a Protected Model

In addition to the protected model file (.slxp), you can include additional files in the protected model package:

- Harness model file.
- Any required definitions saved in a MAT-file. For more information, see “Save Base Workspace Definitions” on page 8-24.
- Instructions on how to retrieve the files.

Some ways to deliver the protected model package are:

- Provide the .slxp file and other supporting files as separate files.
- Combine the files into a ZIP or other container file.
- Combine the files using a manifest. For more information, see “Export Files in a Manifest” (Simulink).
- Provide the files in some other standard or proprietary format specified by the receiver.

Whichever approach you use to deliver a protected model, include information on how to retrieve the original files. One approach to consider is to use the Simulink Manifest Tools, as described in “Analyze Model Dependencies” (Simulink).
Specify Custom Obfuscator for Protected Model

When creating a protected model, you can specify your own postprocessing function for files that the protected model creation process generates. Before packaging the protected model files, this function is called by the `Simulink.ModelReference.protect` function. You can use this functionality to run your own custom obfuscator on the generated files by following these steps:

1. Create your postprocessing function. Use this function to call your custom obfuscator. The function must be on the MATLAB path and accept a `Simulink.ModelReference.ProtectedModel.HookInfo` object as an input variable.

2. In your function, get the files and exported symbol information that your custom obfuscator requires to process the protected model files. To get the files and information, access the properties of your function input variable. The variable is a `Simulink.ModelReference.ProtectedModel.HookInfo` object with the following properties:
   - `SourceFiles`
   - `NonSourceFiles`
   - `ExportedSymbols`

3. Pass the protected model file information to your custom obfuscator. The following is an example of a postprocessing function for custom obfuscation:

   ```matlab
   function myHook(protectedModelInfo)
     % Get source file list information.
     srcFileList = protectedModelInfo.SourceFiles;
     disp('### Obfuscating...');
     for i=1:length(srcFileList)
       disp(['### Obfuscator: Processing ' srcFileList{i} '...']);
       % call to custom obfuscator
       customObfuscator(srcFileList{i});
     end
   end
   ```

4. Specify your postprocessing function when creating the protected model:

   ```matlab
   Simulink.ModelReference.protect('myModel, ...
     'Mode', ...
     'CodeGeneration', ...
'CustomPostProcessingHook', ...
@protectedModelInfo myHook(protectedModelInfo)

The protected model creator can also enable obfuscation of simulation target code and generated code through the 'ObfuscateCode' option of the Simulink.ModelReference.protect function. Your custom obfuscator runs only on the generated code and not on the simulation target code. If both obfuscators are in use, the custom obfuscator is the last to run on the generated code before the files are packaged.
Define Callbacks for Protected Models

When you create a protected model, you can customize its behavior by defining callbacks. Callbacks specify code that executes when you view, simulate, or generate code for the protected model. A protected model user cannot view or modify a callback. If a model references a protected model with callbacks, you cannot protect the model.

To create a protected model with callbacks:

1. Define Simulink.ProtectedModel.Callback objects for each callback.
2. To create your protected model, call the Simulink.ModelReference.protect function. Use the 'Callbacks' option to specify a cell array of callbacks to include in the protected model.

Creating Callbacks

To create and define a protected model callback, create a Simulink.ProtectedModel.Callback object. Callback objects specify:

- The code to execute for the callback. The code can be a character vector of MATLAB commands or a script on the MATLAB path.
- The event that triggers the callback. The event can be 'PreAccess' or 'Build'.
- The protected model functionality that the event applies to. The functionality can be 'CODEGEN', 'SIM', 'VIEW', or 'AUTO'. If you select 'AUTO', and the event is 'PreAccess', the callback applies to each functionality. If you select 'AUTO', and the event is 'Build', the callback applies only to 'CODEGEN' functionality. If you do not select any functionality, the default behavior is 'AUTO'.
- The option to override the protected model build process. This option applies only to 'CODEGEN' functionality.

You can create only one callback per event and per functionality.

Defining Callback Code

You can define the code for a callback by using either a character vector of MATLAB commands or a script on the MATLAB path. When you write callback code, follow these guidelines:
Callbacks must use MATLAB code (.m or .p).
The code can include protected model functions or any MATLAB command that does not require loading the model.
Callback code must not call out to external utilities unless those utilities are available in the environment where the protected model is used.
Callback code cannot reference the source protected model unless you are using protected model functions.

You can use the Simulink.ProtectedModel.getCallbackInfo function in callback code to get information on the protected model. The function returns a Simulink.ProtectedModel.CallbackInfo object that provides the protected model name and the names of submodels. If the callback is specified for 'CODEGEN' functionality and 'Build' event, the object provides the target identifier and model code interface type ('Top model' or 'Model reference').

Create a Protected Model with Callbacks

This example creates a protected model with a callback for code generation.

1. On the MATLAB path, create a callback script, pm_callback.m, containing:

   ```matlab
   s1 = 'Code interface is: ';
   cbinfobj = Simulink.ProtectedModel.getCallbackInfo(...
     'sldemo_mdlref_counter','Build','CODEGEN');
   disp([s1 cbinfobj.CodeInterface]);
   ```

2. Create a callback that uses the script. If the callback code replaces the protected model build process, set the override option.

   ```matlab
   pmCallback = Simulink.ProtectedModel.Callback('Build',...
     'CODEGEN', 'pm_callback.m');
   pmCallback.setOverrideBuild(true);
   ```

3. Create the protected model and specify the code generation callback.

   ```matlab
   Simulink.ModelReference.protect('sldemo_mdlref_counter',...
     'Mode', 'CodeGeneration','Callbacks',{pmCallback})
   ```

4. Build the protected model. In place of the build, the callback displays the code interface.

   ```matlab
   rtwbuild('sldemo_mdlref_basic')
   ```

Component Initialization, Reset, and Termination in Simulink Coder
Generate Code That Responds to Initialize, Reset, and Terminate Events

To generate code from a modeling component that responds to initialize, reset, and terminate events during execution, use the blocks Initialize Function and Terminate Function. For information on how to use these blocks, see “Customize Initialize, Reset, and Terminate Functions” (Simulink). You can use the blocks anywhere in a model hierarchy.

Examples of when to generate code that responds to initialize, reset, or terminate events include:

- Starting and stopping a component.
- Calculating initial conditions.
- Saving and restoring state from nonvolatile memory.
- Generating reset entry-point functions that respond to external events.

Each nonvirtual subsystem and referenced model can have its own set of initialize, reset, and terminate functions.

The code generator produces initialization and termination code differently than reset code. For initialization and termination code, the code generator includes your component initialization and termination code in the default entry-point functions, `model_initialize` and `model_terminate`. The code generator produces reset code only if you model reset behavior.

Generate Code for Initialize and Terminate Events

When you generate code for a component that includes Initialize Function and Terminate Function blocks, the code generator:

- Includes initialize event code with default initialize code in entry-point function `model_initialize`.
- Includes terminate event code with default terminate code in entry-point function `model_terminate`.

Consider the model `rtwdemo_irt_base`.
For this model, the code generator produces initialize and terminate entry-point functions that other code can interface with.

```c
void rtwdemo_irt_base_initialize(void)
void rtwdemo_irt_base_terminate(void)
```

This code appears in the generated file `rtwdemo_irt_base.c`. The initialize function, `rtwdemo_irt_base_initialize`:

- Initializes an error status.
- Allocates memory for block I/O and state parameters.
- Sets the output value
- Sets the initial condition for the discrete integrator.

The terminate function, `rtwdemo_irt_base_terminate`, requires no code.

This code assumes that support for nonfinite numbers and MAT-file logging is disabled.

```c
void rtwdemo_irt_base_initialize(void)
{
    rtmSetErrorStatus(rtwdemo_irt_base_M, (NULL));

    (void) memset((void *)&rtwdemo_irt_base_DW, 0,
                   sizeof(DW_rtwdemo_irt_base_T));

    rtwdemo_irt_base_Y.Out1 = 0.0;

    rtwdemo_irt_base_DW.DiscreteIntegrator_DSTATE = 0.0;
}

void rtwdemo_irt_base_terminate(void)
{
    /* (no terminate code required) */
}
```
Add Initialize Function and Terminate Function blocks to the model (see rtwdemo_irt_initterm). The Initialize Function block uses the State Writer block to set the initial condition of a Discrete Integrator block. The Terminate Function block includes a State Reader block, which reads the state of the Discrete Integrator block.

The Event type parameter of the Event Listener block for the initialize and terminate functions is set to Initialize and Terminate, respectively. The initialize function uses the State Writer block to initialize the input value for the Discrete Integrator block to 10. The terminate function uses the State Reader block to read the state of the Discrete Integrator block.
Generate Code That Responds to Initialize, Reset, and Terminate Events

![Diagram showing Event Listener, Constant, Discrete Integrator, and State Writer with Block Parameters dialog box showing event type set to Initialize]
The code generator includes the event code that it produces for the Initialize Function and Terminate Function blocks with standard initialize and terminate code in entry-point functions `rtwdemo_irt_initterm_initialize` and `rtwdemo_irt_initterm_terminate`. This code assumes that support for nonfinite numbers and MAT-file logging is disabled.

```c
void rtwdemo_irt_initterm_initialize(void)
{
    rtmSetErrorStatus(rtwdemo_irt_initterm_M, (NULL));

    (void) memset((void *)&rtwdemo_irt__initterm_DW, 0,
                   sizeof(DW_rtwdemo_irt__initterm_T));

    rtwdemo_irt_initterm_Y.Out1 = 0.0;
}```
rtwdemo_irt_initterm_DW.DiscreteIntegrator_DSTATE = 10.0;
}

void rtwdemo_irt__initterm_terminate(void)
{
    /* (no terminate code required) */
}

**Generate Code for Reset Events**

Generate code that responds to a reset event by including an Initialize Function or Terminate Function block in a modeling component. Configure the block for a reset by setting the **Event type** parameter of its Event Listener block to **Reset**. Also set the **Event name** parameter. The default name is **reset**.

The code generator produces a reset entry-point function *only* if you model reset behavior. If a component contains multiple reset specifications, the code that the code generator produces depends on whether reset functions share an event name. For a given component hierarchy:

- For reset functions with unique event names, the code generator produces a separate entry-point function for each named event. The name of each function is the name of the corresponding event.
- For reset functions that share an event name, the code generator aggregates the reset code into one entry-point function. The code for the reset functions appears in order, starting with the lowest level (innermost) of the component hierarchy and ending with the root (outermost). The name of the function is **model_reset**. For more information, see “Event Names and Code Aggregation” (Simulink Coder).

Consider the model **rtwdemo_irt_reset**, which includes a Reset Function block derived from an Initialize Function block.
The **Event type** and **Event name** parameters of the Event Listener block are set to **Reset** and **reset**, respectively. The function uses the State Writer block to reset the input value for the Discrete Integrator block to 5.
The code generator produces reset function `rtwdemo_irt_reset_reset`.

```c
void rtwdemo_irt_reset_reset(void)
{
    rtwdemo_irt_reset_DW.DiscreteIntegrator_DSTATE = 5.0;
}
```

**Event Names and Code Aggregation**

Use the Initialize Function and Terminate Function blocks to define multiple initialize, reset, and terminate functions for a component hierarchy. Define only one initialize function and one terminate function per hierarchy level. You can define multiple reset functions for a hierarchy level. The event names that you configure for the functions at a given level must be unique.
When producing code, the code generator aggregates code for functions that have a given event name across the entire component hierarchy into one entry-point function. The code for reset functions appears in order, starting with the lowest level (innermost) of the component hierarchy and ending with the root (outermost). The code generator uses the event name to name the function.

For example, the model `rtwdemo_irt_shared` includes a subsystem that replicates the initialize, reset, and terminate functions that are in the parent model.

Although the model includes multiple copies of the initialize, reset, and terminate functions, the code generator produces one entry-point function for reset.
Generate Code That Responds to Initialize, Reset, and Terminate Events

(void) rtwdemo_irt_shared_reset(void)
{
    rtwdemo_irt_shared_DW.SubIntegrator2_DSTATE = 5.0;
    rtwdemo_irt_shared_DW.Integrator2_DSTATE = 5.0;
}

(void) rtwdemo_irt_shared_initialize(void)
{
    rtmSetErrorStatus(rtwdemo_irt_shared_M, (NULL));
    (void) memset((void *)&rtwdemo_irt_shared_DW, 0, sizeof(DW_rtwdemo_irt_shared_T));
    rtwdemo_irt_shared_Y.Out1 = 0.0;
    rtwdemo_irt_shared_DW.Integrator1_DSTATE = 0.0;
    rtwdemo_irt_shared_DW.SubIntegrator2_DSTATE = 2.0;
    rtwdemo_irt_shared_DW.Integrator2_DSTATE = 10.0;
}

(void) rtwdemo_irt_shared_terminate(void)
{
    /* (no terminate code required) */
}
If you rename the event configured for the subsystem reset function to reset_02, the code generator produces two reset entry-point functions, rtwdemo_irt_shared_reset and rtwdemo_irt_shared_reset_02.

```c
void rtwdemo_irt_shared_reset(void)
{
    rtwdemo_irt_shared_DW.SubIntegrator2_DSTATE = 5.0;
}

void rtwdemo_irt_shared_reset_02(void)
{
    rtwdemo_irt_shared_DW.Integrator2_DSTATE = 5.0;
}
```

**Limitation**

You cannot generate code from a harness model—a root model that contains a Model block, which exposes initialize, reset, or terminate function ports.

Code Generation of Stateflow Blocks

The code generator produces code for Stateflow blocks for rapid prototyping. If you have an Embedded Coder license, you can generate production code for Stateflow blocks.

Comparison of Code Generation Methods

The following sections compare two ways of generating code.

Code Generation Without Atomic Subcharts

You generate code for the entire model in one file and look through that entire file to find code for a specific part of the chart.
Code Generation With Atomic Subcharts

You specify code generation parameters so that code for an atomic subchart appears in a separate file. This method of code generation enables unit testing for a specific part of a chart. You can avoid searching through unrelated code and focus only on the part that interests you.
/* Function for Stateflow: '<s1>/A' */
void ex_reuse_states_A_during(real_T rtu_u1, real_T *rty_y1,
    rtMW_u_ex_reuse_states *localDW)
{
    /* During: Chart/A */
    localDW->isStable = TRUE;
    switch(localDW->is_c2_ex_reuse_states)
    case ex_reuse_states_IN_Neg:
        /* During 'Neg': '<s2>17' */
        if (rtu_u1 > 0.0) {
            /* Transition: '<s2>5' */
            localDW->isStable = FALSE;
            localDW->is_c2_ex_reuse_states = ex_reuse_states_IN_Pos;
            /* Entry 'Pos': '<s2>16' */
            (*rty_y1) = 1.0;
            break;
        }
        case ex_reuse_states_IN_Pos:
        /* During 'Pos': '<s2>16' */
        if (rtu_u1 < 0.0) {
            /* Transition: '<s2>4' */
            localDW->isStable = FALSE;
            localDW->is_c2_ex_reuse_states = ex_reuse_states_IN_Neg;
            /* Entry 'Neg': '<s2>17' */
            (*rty_y1) = -1.0;
            break;
        }
        default:
        if (rtu_u1 > 0.0) {
            /* Transition: '<s2>12' */
            localDW->isStable = FALSE;
            localDW->is_c2_ex_reuse_states = ex_reuse_states_IN_Pos;
            /* Entry 'Pos': '<s2>16' */
            (*rty_y1) = 1.0;
        }
        else {
            /* Transition: '<s2>9' */
            localDW->isStable = FALSE;
            localDW->is_c2_ex_reuse_states = ex_reuse_states_IN_Neg;
            /* Entry 'Neg': '<s2>17' */
            (*rty_y1) = -1.0;
        }
    break;
}
Note  Unreachable Stateflow states are optimized out and are not included in the generated code.

Generate Reusable Code for Atomic Subcharts

In this section...

“How to Generate Reusable Code for Linked Atomic Subcharts” on page 10-6
“How to Generate Reusable Code for Unlinked Atomic Subcharts” on page 10-7

How to Generate Reusable Code for Linked Atomic Subcharts

To specify code generation parameters for linked atomic subcharts from the same library:

1. Open the library model that contains your atomic subchart.
2. Unlock the library.
3. Right-click the library chart and select Block Parameters.
4. In the dialog box, specify the following parameters:
   a. On the Main tab, select Treat as atomic unit.
   b. On the Code Generation tab, set Function packaging to Reusable function.
   c. Set File name options to User specified.
   d. For File name, enter the name of the file with no extension.
   e. Click OK to apply the changes.
5. (OPTIONAL) Customize the generated function names for atomic subcharts:
   a. Open the Model Configuration Parameters dialog box.
   c. Navigate to the Code Generation > Symbols pane.
   d. For Subsystem methods, specify the format of the function names using a combination of the following tokens:
      • $R — root model name
      • $F — type of interface function for the atomic subchart
      • $N — block name
      • $H — subsystem index
      • $M — name-mangling text
Click **OK** to apply the changes.

When you generate code for your model, a separate file stores the code for linked atomic subcharts from the same library.

**How to Generate Reusable Code for Unlinked Atomic Subcharts**

To specify code generation parameters for an unlinked atomic subchart:

1. In your chart, right-click the atomic subchart and select **Properties**.
2. In the dialog box, specify the following parameters:
   a. Set **Code generation function packaging** to **Reusable function**.
   b. Set **Code generation file name options** to **User specified**.
   c. For **Code generation file name**, enter the name of the file with no extension.
   d. Click **OK** to apply the changes.
3. **(OPTIONAL)** Customize the generated function names for atomic subcharts:
   a. Open the Model Configuration Parameters dialog box.
   b. On the **Code Generation** pane, set **System target file** to **ert.tlc**.
   c. Navigate to the **Code Generation > Symbols** pane.
   d. For **Subsystem methods**, specify the format of the function names using a combination of the following tokens:
      - $R$ — root model name
      - $F$ — type of interface function for the atomic subchart
      - $N$ — block name
      - $H$ — subsystem index
      - $M$ — name-mangling text
   e. Click **OK** to apply the changes.

When you generate code for your model, a separate file stores the code for the atomic subchart. For more information, see “Generate Reusable Code for Unit Testing” on page 10-8.
Generate Reusable Code for Unit Testing

In this section...

"Goal of the Tutorial" on page 10-8
"Convert a State to an Atomic Subchart" on page 10-9
"Specify Code Generation Parameters" on page 10-10
"Generate Code for Only the Atomic Subchart" on page 10-11

Goal of the Tutorial

Assume that you have the following model, and the chart has two states:
Suppose that you want to generate reusable code so that you can perform unit testing on state A. You can convert that part of the chart to an atomic subchart and then specify a separate file to store the generated code.

**Convert a State to an Atomic Subchart**

To convert state A to an atomic subchart, right-click the state and select **Group & Subchart > Atomic Subchart**. State A changes to an atomic subchart:
Specify Code Generation Parameters

Set Up a Standalone C File for the Atomic Subchart

1. Open the properties dialog box for A.
2. Set Code generation function packaging to Reusable function.
4. For Code generation file name, enter saturator as the name of the file.
5. Click OK.

Set Up the Code Generation Report

1. Open the Model Configuration Parameters dialog box.
2. In the Code Generation pane, set System target file to ert.tlc.

   This step automatically selects Open report automatically and Code-to-model.
4 Select **Model-to-code**.
5 Click **Apply**.

**Customize the Generated Function Names**

1 In the Model Configuration Parameters dialog box, go to the **Code Generation > Symbols** pane.
2 Set **Subsystem methods** to the format scheme $R$N$M$F, where:
   - $R$ is the root model name.
   - $N$ is the block name.
   - $M$ is the mangle token.
   - $F$ is the type of interface function for the atomic subchart.
   
   For more information, see “Subsystem methods” (Simulink Coder).
3 Click **Apply**.

**Generate Code for Only the Atomic Subchart**

To generate code for your model, press **Ctrl+B**. In the code generation report that appears, you see a separate file that contains the generated code for the atomic subchart.

To inspect the code for **saturator.c**, click the hyperlink in the report to see the following code:
void ex_reuse_states_A_during(real_T rtu_u1, real_T *rty_v1, real_T *localDW)
{
    /* During: Chart/A */
    localDW->isStable = TRUE;
    switch (localDW->is_c2_ex_reuse_states) {
        case ex_reuse_states_IN_Neg:
            /* During 'Neg': '<S2>:17' */
            if (rtu_u1 > 0.0) {
                /* Transition: '<S2>:5' */
                localDW->isStable = FALSE;
                localDW->is_c2_ex_reuse_states = ex_reuse_states_IN_Pos;
            } else {
                /* Entry 'Pos': '<S2>:16' */
                (*rty_v1) = 1.0;
            }
            break;
        case ex_reuse_states_IN_Pos:
            /* During 'Pos': '<S2>:16' */
            if (rtu_u1 < 0.0) {
                /* Transition: '<S2>:4' */
                localDW->isStable = FALSE;
                localDW->is_c2_ex_reuse_states = ex_reuse_states_IN_Neg;
            } else {
                /* Entry 'Neg': '<S2>:17' */
                (*rty_v1) = -1.0;
            }
            break;
        default:
            if (rtu_u1 > 0.0) {
                /* Transition: '<S2>:3' */
                localDW->isStable = FALSE;
                localDW->is_c2_ex_reuse_states = ex_reuse_states_IN_Pos;
            } else {
                /* Transition: '<S2>:3' */
                localDW->isStable = FALSE;
                localDW->is_c2_ex_reuse_states = ex_reuse_states_IN_Neg;
            }
            break;
    }
}
Line 28 shows that the during function generated for the atomic subchart has the name `ex_reuse_states_A_during`. This name follows the format scheme $R$N$M$F specified for **Subsystem methods**:

- $R$ is the root model name, `ex_reuse_states`.
- $N$ is the block name, `A`.
- $M$ is the mangle token, which is empty.
- $F$ is the type of interface function for the atomic subchart, `during`.

**Note** The line numbers shown can differ from the numbers that appear in your code generation report.
Inline State Functions in Generated Code

In this section...

“Inlined Generated Code for State Functions” on page 10-14
“How to Set the State Function Inline Option” on page 10-16
“Best Practices for Controlling State Function Inlining” on page 10-16

Inlined Generated Code for State Functions

By default, the code generator uses an internal heuristic to determine whether to inline generated code for state functions. The heuristic takes into consideration an inlining threshold. As code grows and shrinks in size, generated code for state functions can be unpredictable.

If your model includes Stateflow objects and you have rigorous requirements for traceability between generated code and the corresponding state functions, you can override the default behavior. Use the state property Function Inline Option to explicitly force or prevent inlining of state functions.

What Happens When You Force Inlining

If you force inlining for a state, the code generator inlines code for state actions into the parent function. The parent function contains code for executing the state actions, outer transitions, and flow charts. It does not include code for empty state actions.

What Happens When You Prevent Inlining

If you prevent inlining for a state, the code generator produces these static functions for state foo.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>enter_atomic_foo</td>
<td>Marks foo active and performs entry actions.</td>
</tr>
<tr>
<td>enter_internal_foo</td>
<td>Calls default paths.</td>
</tr>
</tbody>
</table>
Function | Description
--- | ---
inner_default_foo | Executes flow charts that originate when an inner transition and default transition reach the same junction inside a state.

The code generator produces this function only when the flow chart is complex enough to exceed the inlining threshold.

In generated code, Stateflow software calls this function from both the enter_internal_foo and foo functions.

foo | Checks for valid outer transitions and if none, performs during actions.

exit_atomic_foo | Performs exit actions and marks foo inactive.

exit_internal_foo | Performs exit actions of the child substates and then exits foo.

Suppose the following chart is in model M.

If you prevent inlining for state A, the code generator produces this code.
static void M_inner_default_A(void);
static void M_exit_atomic_A(void);
static void M_A(void);
static void M_enter_atomic_A(void);
static void M_enter_internal_A(void);

### How to Set the State Function Inline Option

To set the function inlining property for a state:

1. Right-click inside the state and, from the context menu, select **Properties**.

   The State properties dialog box opens.

2. In the **Function Inline Option** field, select one of these options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Behavior</th>
</tr>
</thead>
<tbody>
<tr>
<td>Inline</td>
<td>Forces inlining of state functions into the parent function, as long as the function is not part of a recursion. See “What Happens When You Force Inlining” on page 10-14.</td>
</tr>
<tr>
<td>Function</td>
<td>Prevents inlining of state functions. Generates up to six static functions for the state. See “What Happens When You Prevent Inlining” on page 10-14.</td>
</tr>
<tr>
<td>Auto</td>
<td>Uses internal heuristics to determine whether or not to inline the state functions.</td>
</tr>
</tbody>
</table>

3. Click **Apply**.

### Best Practices for Controlling State Function Inlining

<table>
<thead>
<tr>
<th>To</th>
<th>Set Function Inline Option Property To</th>
</tr>
</thead>
<tbody>
<tr>
<td>Generate a separate function for each action of a state and a separate function for each action of its substates</td>
<td><strong>Function</strong> for the state and each substate</td>
</tr>
<tr>
<td>Generate a separate function for each action of a state, but include code for the associated action of its substates</td>
<td><strong>Function</strong> for the state and <strong>Inline</strong> for each substate</td>
</tr>
</tbody>
</table>
Air-Fuel Ratio Control System with Stateflow Charts

Generate code for an air-fuel ratio control system designed with Simulink® and Stateflow®.

Figures 1, 2, and 3 show relevant portions of the sldemo_fuelsys model, a closed-loop system containing a plant and controller. The plant validates the controller in simulation early in the design cycle. In this example, you generate code for the relevant controller subsystem, "fuel_rate_control". Figure 1 shows the top-level simulation model.

Open sldemo_fuelsys via rtwdemo_fuelsys and compile the diagram to see the signal data types.

rtwdemo_fuelsys
sldemo_fuelsys([],[],[],'compile');
sldemo_fuelsys([],[],[],'term');

Fault-Tolerant Fuel Control System

Open the Dashboard subsystem to simulate any combination of sensor failures.

Figure 1: Top-level model of the plant and controller
The air-fuel ratio control system is comprised of Simulink® and Stateflow®. The control system is the portion of the model for which you generate code.

open_system('sldemo_fuelsys/fuel_rate_control');

**Figure 2: The air-fuel ratio controller subsystem**

The control logic is a Stateflow® chart that specifies the different modes of operation.

Configure and Build the Model with Simulink® Coder™

Simulink® Coder™ generates generic ANSI® C code for Simulink® and Stateflow® models via the Generic Real-Time (GRT) target. You can configure a model for code generation programmatically.

```matlab
rtwconfiguredemo('sldemo_fuelsys','GRT');
```

For this example, build only the air-fuel ratio control system. Once the code generation process is complete, an HTML report detailing the generated code is displayed. The main body of the code is located in `fuel_rate_control.c`.

```matlab
rtwbuild('sldemo_fuelsys/fuel_rate_control');
```  
### Starting build procedure for model: fuel_rate_control
### Successful completion of build procedure for model: fuel_rate_control

Configure and Build the Model with Embedded Coder®

Embedded Coder® generates production ANSI® C/C++ code via the Embedded Real-Time (ERT) target. You can configure a model for code generation programmatically.

```matlab
rtwconfiguredemo('sldemo_fuelsys','ERT');
```

Repeat the build process and inspect the generated code. In the Simulink® Coder™ Report, you can navigate to the relevant code segments interactively by using the Previous and Next buttons. From the chart context menu (right-click the Stateflow® block), select Code Generation > Navigate to Code. Programmatically, use the `rtwtrace` utility.

```matlab
rtwbuild('sldemo_fuelsys/fuel_rate_control');
rtwtrace('sldemo_fuelsys/fuel_rate_control/control_logic')
```  
### Starting build procedure for model: fuel_rate_control
### Successful completion of build procedure for model: fuel_rate_control

View the air-fuel ratio control logic in the generated code.

```matlab
rtwdemodbtype('fuel_rate_control_ert_rtw/fuel_rate_control.c','/* Function for Chart:','case IN_Warmup:',1,0);
/* Function for Chart: '<S1>/control_logic' */
static void Fueling_Mode(const int32_T *sfEvent)
{
    /* This state interprets the other states in the chart to directly control the fueling
```
switch (rtDW.bitsForTID0.is_Fueling_Mode) {
    case IN_Fuel_Disabled:
        rtDW.fuel_mode = DISABLED;

        /* The fuel is completely shut off while in this state. */
        switch (rtDW.bitsForTID0.is_Fuel_Disabled) {
            case IN_Overspeed:
                /* Inport: '<Root>/sensors' */
                /* The speed is dangerously high, so shut off the fuel. */
                if ((rtDW.bitsForTID0.is_Speed == IN_normal) && (rtU.sensors.speed < 603.0F)) {
                    if (!((rtDW.bitsForTID0.is_Fail == IN_Multi))) {
                        rtDW.bitsForTID0.is_Fuel_Disabled = IN_NO_ACTIVE_CHILD;
                        rtDW.bitsForTID0.is_Fueling_Mode = IN_Running;
                        switch (rtDW.bitsForTID0.was_Running) {
                            case IN_Low_Emissions:
                                if (rtDW.bitsForTID0.is_Running != IN_Low_Emissions) {
                                    rtDW.bitsForTID0.is_Running = IN_Low_Emissions;
                                    rtDW.bitsForTID0.was_Running = IN_Low_Emissions;
                                    rtDW.fuel_mode = LOW;
                                }
                        }
                    }
                }
            case IN_Low_Emissions:
                switch (rtDW.bitsForTID0.was_Low_Emissions) {
                    case IN_Normal:
                        rtDW.bitsForTID0.is_Low_Emissions = IN_Normal;
                        rtDW.bitsForTID0.was_Low_Emissions = IN_Normal;
                        break;
                }
        }
}

Close the model and code generation report.

S-Functions and Code Generation

You use S-functions to extend Simulink support for simulation and code generation. For example, you can use them to:

- Represent custom algorithms
- Interface existing external code with Simulink and the code generator
- Represent device drivers for interfacing with hardware
- Generate highly optimized code for embedded systems
- Verify code generated for a subsystem as part of a Simulink simulation

The application program interface (API) for writing S-functions allows you to implement generic algorithms in the Simulink environment with a great deal of flexibility. If you intend to use S-functions in a model for code generation, the level of flexibility can vary. For example, it is not possible to access the MATLAB workspace from an S-function that you use with the code generator. This topic explains conditions to be aware of for using S-functions. However, using the techniques presented in this topic, you can create S-functions for most applications that work with the generated code.

Although S-functions provide a generic and flexible solution for implementing complex algorithms in a model, the underlying API incurs overhead in terms of memory and computation resources. Most often the additional resources are acceptable for real-time rapid prototyping systems. In many cases, though, additional resources are unavailable in real-time embedded applications. You can minimize memory and computational requirements by using the Target Language Compiler technology provided with the code generator to inline your S-functions. If you are producing an S-function for existing external code, consider using the Legacy Code Tool to generate your S-function and relevant TLC file.

This content assumes that you understand the following concepts:

- Level 2 S-functions
• Target Language Compiler (TLC) scripting
• How the code generator produces and builds C/C++ code

Notes This information is for code generator users. Even if you do not currently use the code generator, follow these practices when writing S-functions, especially if you are creating general-purpose S-functions.

Types of S-Functions

Examples for which you might choose to implement an S-function for simulation and code generation include:

1. “I'm not concerned with efficiency. I just want to write one version of my algorithm and have it work in the Simulink and code generator products automatically.”
2. “I want to implement a highly optimized algorithm in the Simulink and code generator products that looks like a built-in block and generates very efficient code.”
3. “I have a lot of hand-written code that I need to interface. I want to call my function from the Simulink and code generator products in an efficient manner.”

Respectively, the preceding situations map to the following MathWorks terminology:

1. Noninlined S-function
2. Inlined S-function
3. Autogenerated S-function for external code

Noninlined S-Functions

A noninlined S-function is a C or C++ MEX S-function that is treated identically by the Simulink engine and generated code. In general, you implement your algorithm once according to the S-function API. The Simulink engine and generated code call the S-function routines (for example, mdlOutputs) during model execution.

Additional memory and computation resources are required for each instance of a noninlined S-Function block. However, this routine of incorporating algorithms into models and code generation applications is typical during the prototyping phase of a project where efficiency is not important. The advantage gained by forgoing efficiency is the ability to change model parameters and structures rapidly.
Writing a noninlined S-function does not involve TLC coding. Noninlined S-functions are the default case for the build process in the sense that once you build a MEX S-function in your model, there is no additional preparation prior to pressing Ctrl+B to build your model.

Some restrictions exist concerning the names and locations of noninlined S-function files when generating makefiles. See “Write Noninlined S-Function and TLC Files” on page 11-67.

**Inlined S-Functions**

For S-functions to work in the Simulink environment, some overhead code is generated. When the code generator produces code from models that contain S-functions (without *sfunction*.tlc files), it embeds some of this overhead code in the generated code. If you want to optimize your real-time code and eliminate some of the overhead code, you must *inline* (or embed) your S-functions. This involves writing a TLC (*sfunction*.tlc) file that eliminates overhead code from the generated code. The Target Language Compiler processes *sfunction*.tlc files to define how to inline your S-function algorithm in the generated code.

**Note** The term *inline* should not be confused with the C++ *inline* keyword. Inline means to specify text in place of the call to the general S-function API routines (for example, *mdlOutputs*). For example, when a TLC file is used to inline an S-function, the generated code contains the C/C++ code that would normally appear within the S-function routines and the S-function itself has been removed from the build process.

A fully inlined S-function builds your algorithm (block) into generated code in a manner that is indistinguishable from a built-in block. Typically, a fully inlined S-function requires you to implement your algorithm twice: once for the Simulink model (C/C++ MEX S-function) and once for code generation (TLC file). The complexity of the TLC file depends on the complexity of your algorithm and the level of efficiency you're trying to achieve in the generated code. TLC files vary from simple to complex in structure. See “Inlining S-Functions” (Simulink Coder)

**Autogenerated S-Functions for Legacy or Custom Code**

If you need to invoke hand-written C/C++ code in your model, consider using the Simulink Legacy Code Tool. The Legacy Code Tool can automate the generation of a fully inlined S-function and a corresponding TLC file based on information that you register in a Legacy Code Tool data structure.
For more information, see “Integrate C Functions Using Legacy Code Tool” (Simulink) and see “Import Calls to External Code into Generated Code with Legacy Code Tool” on page 11-7.

**Files Required for Implementing Noninlined and Inlined S-Functions**

This topic briefly describes what files and functions you need to create noninlined and inlined S-functions.

- Noninlined S-functions require the C or C++ MEX S-function source code (*sfunction.c* or *sfunction.cpp*).
- Fully inlined S-functions require an *sfunction.tlc* file. Fully inlined S-functions produce the optimal code for a parameterized S-function. This is an S-function that operates in a specific mode dependent upon fixed S-function parameters that do not change during model execution. For a given operating mode, the *sfunction.tlc* file specifies the exact code that is generated to implement the algorithm for that mode. For example, the direct-index lookup table S-function in “Write Fully Inlined S-Functions with mdlRTW Routine” on page 11-79 contains two operating modes — one for evenly spaced x-data and one for unevenly spaced x-data.

**Note** Fully-inlined S-functions that are generated to invoke legacy or custom C/C++ code also require an *sfunction.tlc* file, which is generated by Legacy Code Tool.

Fully inlined S-functions might require the placement of the *mdlRTW* routine in your S-function MEX-file *sfunction.c* or *sfunction.cpp*. The *mdlRTW* routine lets you place information in *model.rtw*, the record file that specifies a model, and which the code generator invokes the Target Language Compiler to process prior to executing *sfunction.tlc* when generating code.

Including a *mdlRTW* routine is useful when you want to introduce nontunable parameters into your TLC file. Such parameters are generally used to determine which operating mode is active in a given instance of the S-function. Based on this information, the TLC file for the S-function can generate highly efficient, optimal code for that operating mode.
Guidelines for Writing S-Functions that Support Code Generation

• You can use C/C++ MEX, MATLAB language, and Fortran MEX S-functions with code generation.
• You can inline S-functions for code generation by providing an inlining TLC file. See S-Function Inlining in “Target Language Compiler” (Simulink Coder). MATLAB and Fortran MEX S-functions must be inlined. C/C++ MEX S-functions can be inlined for code efficiency, or noninlined.
• To automatically generate a fully inlined C MEX S-function for invoking legacy or custom code, use the Legacy Code Tool. For more information, see “Integrate C Functions Using Legacy Code Tool” (Simulink) and see “Import Calls to External Code into Generated Code with Legacy Code Tool” (Simulink Coder).
• If code efficiency is not an overriding consideration, for example, if you are rapid prototyping, you can choose not to inline a C/C++ MEX S-function. For more information, see “Write Noninlined S-Function and TLC Files” on page 11-67.

Legacy Code Tool and Code Generation

You can use the Simulink Legacy Code Tool to generate fully inlined C MEX S-functions for legacy or custom code. The S-functions are optimized for embedded components, such as device drivers and lookup tables, and they call existing C or C++ functions.

Note The Legacy Code Tool can interface with C++ functions, but not C++ objects. To work around this issue so that the tool can interface with C++ objects, see “Legacy Code Tool Limitations” (Simulink).

You can use the tool to:

• Compile and build the generated S-function for simulation.
• Generate a masked S-Function block that is configured to call the existing external code.

If you want to include these types of S-functions in models for which you intend to generate code, use the tool to generate a TLC block file. The TLC block file specifies how the generated code for a model calls the existing C or C++ function.

If the S-function depends on files in folders other than the folder containing the S-function dynamically loadable executable file, use the tool to generate an
**sFunction_makecfg.m or rtwmakecfg.m file for the S-function.** Generating the file maintains those dependencies when you build a model that includes the S-function. For example, for some applications, such as custom targets, you might want to locate files in a target-specific location. The build process looks for sFunction_makecfg.m or rtwmakecfg.m in the same folder as the S-function dynamically loadable executable and calls the function in the file.

For more information, see “Integrate C Functions Using Legacy Code Tool” (Simulink).

### Generate Inlined S-Function Files for Code Generation

Depending on the code generation requirements of your application, to generate code for a model that uses the S-function, do either of the following:

- Generate one .cpp file for the inlined S-function. In the Legacy Code Tool data structure, set the value of the Options.singleCPPMexFile field to true before generating the S-function source file from your existing C function. For example:

  ```
  def.Options.singleCPPMexFile = true;
  legacy_code('sfcn_cmex_generate', def);
  ```

- Generate a source file and a TLC block file for the inlined S-function. For example:

  ```
  def.Options.singleCPPMexFile = false;
  legacy_code('sfcn_cmex_generate', def);
  legacy_code('sfcn_tlc_generate', def);
  ```

**singleCPPMexFile Limitations**

You cannot set the singleCPPMexFile field to true if

- **Options.language='C++'**
- You use one of the following Simulink objects with the IsAlias property set to true:
  - Simulink.Bus
  - Simulink.AliasType
  - Simulink.NumericType
- The Legacy Code Tool function specification includes a void* or void** to represent scalar work data for a state argument
- HeaderFiles field of the Legacy Code Tool structure specifies multiple header files
Apply Code Style Settings to Legacy Functions

To apply the model configuration parameters for code style to a legacy function:

1 Initialize the Legacy Code Tool data structure. For example:
   ```matlab
def = legacy_code('initialize');
```

2 In the data structure, set the value of the `Options.singleCPPMexFile` field to `true`. For example:
   ```matlab
def.Options.singleCPPMexFile = true;
```

To check the setting, enter:
   ```matlab
def.Options.singleCPPMexFile
```

**singleCPPMexFile Limitations**

You cannot set the `singleCPPMexFile` field to `true` if
- `Options.language='C++'
- You use one of the following Simulink objects with the `IsAlias` property set to `true`:
  - `Simulink.Bus`
  - `Simulink.AliasType`
  - `Simulink.NumericType`
- The Legacy Code Tool function specification includes a `void*` or `void**` to represent scalar work data for a state argument
- HeaderFiles field of the Legacy Code Tool structure specifies multiple header files

**Address Dependencies on Files in Different Locations**

By default, the Legacy Code Tool assumes that files on which an S-function depends reside in the same folder as the dynamically loadable executable file for the S-function. If your S-function depends on files that reside elsewhere and you are using the template makefile build process, generate an `sFunction_makecfg.m` or `rtwmakecfg.m` file for the S-function. For example, you might generate this file if your Legacy Code Tool data structure defines compilation resources as path names.

To generate the `sFunction_makecfg.m` or `rtwmakecfg.m` file, call the `legacy_code` function with `'sfcn_makecfg_generate' or 'rtwmakecfg_generate' as the first argument.
argument, and the name of the Legacy Code Tool data structure as the second argument. For example:

```
legacy_code('sfcn_makecfg_generate', lct_spec);
```

If you use multiple registration files in the same folder and generate an S-function for each file with a single call to `legacy_code`, the call to `legacy_code` that specifies 'sfcn_makecfg_generate' or 'rtwmakecfg_generate' must be common to all registration files. For more information, see “Handling Multiple Registration Files” (Simulink).

For example, if you define `defs` as an array of Legacy Code Tool structures, you call `legacy_code` with 'sfcn_makecfg_generate' once.

```
defs = [defs1(:);defs2(:);defs3(:)];
legacy_code('sfcn_makecfg_generate', defs);
```

For more information, see “Build Support for S-Functions” (Simulink Coder).

**Deploy S-Functions for Simulation and Code Generation**

You can deploy the S-functions that you generate with the Legacy Code Tool so that other people can use them. To deploy an S-function for simulation and code generation, share the following files:

- Registration file
- Compiled dynamically loadable executable
- TLC block file
- `sFunction_makecfg.m` or `rtwmakecfg.m` file
- Header, source, and include files on which the generated S-function depends

When you use these deployed files:

- Before using the deployed files in a Simulink model, add the folder that contains the S-function files to the MATLAB path.
- If the Legacy Code Tool data structure registers required files as absolute paths and the location of the files changes, regenerate the `sFunction_makecfg.m` or `rtwmakecfg.m` file.
Integrate External C++ Object Methods

Integrate legacy C++ object methods by using the Legacy Code Tool.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C++ MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a block TLC file and optional rtwmakecfg.m file that calls the legacy code during code generation.

Provide the Legacy Function Specification

Functions provided with the Legacy Code Tool take a specific data structure or array of structures as the argument. The data structure is initialized by calling the function legacy_code() using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. For detailed help on the properties, call legacy_code('help'). The definition of the legacy C++ class in this example is:

```cpp
class adder {
    private:
        int int_state;
    public:
        adder();
        int add_one(int increment);
        int get_val();
};
```

The legacy source code is in the files adder_cpp.h and adder_cpp.cpp.

```matlab
% rtwdemo_sfun_adder_cpp
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_adder_cpp';
def.StartFcnSpec = 'createAdder()';
def.OutputFcnSpec = 'int32 y1 = adderOutput(int32 u1)';
def.TerminateFcnSpec = 'deleteAdder()';
def.HeaderFiles = {'adder_cpp.h'};
def.SourceFiles = {'adder_cpp.cpp'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
```
def.Options.language = 'C++';
def.Options.useTlcWithAccel = false;

**Generate an S-Function for Simulation**

To generate a C-MEX S-function according to the description provided by the input argument 'def', call the function legacy_code() again with the first input set to 'sfcn_cmex_generate'. The S-function calls the legacy functions during simulation. The source code for the S-function is in the file rtwdemo_sfun_adder_cpp.cpp.

legacy_code('sfcn_cmex_generate', def);

**Compile the Generated S-Function for Simulation**

After you generate the C-MEX S-function source file, to compile the S-function for simulation with Simulink®, call the function legacy_code() again with the first input set to 'compile'.

legacy_code('compile', def);

### Start Compiling rtwdemo_sfun_adder_cpp
   mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc18a_815039_17936 \IB0BF173\25	pee81d21a\ex06428671', 'C:\TEMP\Bdoc18a_815039_17936\IB0BF173\25\tpba37660e_343f_48b6_8efd_0453b4157c11\adder_cpp.obj')
   Building with 'Microsoft Visual C++ 2015'.
   MEX completed successfully.
### Finish Compiling rtwdemo_sfun_adder_cpp

**Generate a TLC Block File for Code Generation**

After you compile the S-function and use it in simulation, you can call the function legacy_code() again. Set the first input to 'sfcn_tlc_generate' to generate a TLC block file that supports code generation through Simulink® Coder™. If the TLC block file is not created and you try to generate code for a model that includes the S-function, code generation fails. The TLC block file for the S-function is: rtwdemo_sfun_adder_cpp.tlc.

legacy_code('sfcn_tlc_generate', def);

**Generate an rtwmakecfg.m File for Code Generation**

After you create the TLC block file, you can call the function legacy_code() again. Set the first input to 'rtwmakecfg_generate' to generate an rtwmakecfg.m file that supports code
generation through Simulink® Coder™. If the required source and header files for the S-function are not in the same folder as the S-function, and you want to add these dependencies in the makefile produced during code generation, generate the rtwmakecfg.m file.

```
legacy_code('rtwmakecfg_generate', def);
```

### Generate a Masked S-Function Block for Calling the Generated S-Function

After you compile the C-MEX S-function source, you can call the function legacy_code() again. Set the first input to 'slblock_generate' to generate a masked S-function block that is configured to call that S-function. The software places the block in a new model. You can copy the block to an existing model.

```
% legacy_code('slblock_generate', def);
```

### Show the Generated Integration with Legacy Code

The model rtwdemo_lct_cpp shows integration with the legacy code.

```
open_system('rtwdemo_lct_cpp')
sim('rtwdemo_lct_cpp')
```
Integrate External C++ Objects

The Legacy Code Tool can interface with C++ functions, but not C++ objects. Using the previous example as a starting point, here is an example of how you can work around this limitation.

- Modify the class definition for `adder` in a new file `adder_cpp.hpp`. Add three new macros that dynamically allocate a new `adder` object, invoke the method `add_one()`, and free the memory allocated. Each macro takes a pointer to an `adder` object.

Because each function called by the Legacy Code Tool must have a C-like signature,
the pointer is cached and passed as a void*. Then you must explicitly cast to adder* in the macro. The new class definition for adder:

```cpp
#ifndef _ADDER_CPP_
define _ADDER_CPP_

class adder {
private:
    int int_state;
public:
    adder(): int_state(0) {};
    int add_one(int increment);
    int get_val() {return int_state;};
};

// Method wrappers implemented as macros
define createAdder(work1) \ (*work1) = new adder

define deleteAdder(work1) \ delete(static_cast<adder*>(*(work1)))

define adderOutput(work1, u1) \ (static_cast<adder*> ((work1))->add_one(u1)

#endif /* _ADDER_CPP_ */
```

- Update adder_cpp.cpp. With the class modification, instead of one global instance, each generated S-function manages its own adder object.

```cpp
#include "adder_cpp.hpp"

int adder::add_one(int increment) {
    int_state += increment;
    return int_state;
}
```

- Update rtwdemo_sfun_adder_cpp.cpp with the following changes:
  - StartFcnSpec calls the macro that allocates a new adder object and caches the pointer.
    ```cpp
def.StartFcnSpec = 'createAdder(void **work1)';
```
  - OutputFcnSpec calls the macro that invokes the method add_one() and provides the S-function specific adder pointer object.
def.OutputFcnSpec = 'int32 y1 = adderOutput(void *work1, int32 u1)';

- TerminateFcnSpec calls the macro that frees the memory.

def.TerminateFcnSpec = 'deleteAdder(void **work1)';

**Legacy Code Tool Examples**

**Integrate External C Functions That Pass Input Arguments By Value Versus Address**

This example shows how to use the Legacy Code Tool to integrate legacy C functions that pass their input arguments by value versus address.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional rtwmakecfg.m file that specifies how the generated code for a model calls the legacy code.

**Provide the Legacy Function Specification**

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function legacy_code() using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. For detailed help on the properties, call legacy_code('help'). The prototypes of the legacy functions being called in this example are:

- FLT filterV1(const FLT signal, const FLT prevSignal, const FLT gain)
- FLT filterV2(const FLT* signal, const FLT prevSignal, const FLT gain)

FLT is a typedef to float. The legacy source code is in the files your_types.h, myfilter.h, filterV1.c, and filterV2.c.

Note the difference in the OutputFcnSpec defined in the two structures; the first case specifies that the first input argument is passed by value, while the second case specifies pass by pointer.
defs = [];

% rtwdemo_sfun_filterV1
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_filterV1';
def.OutputFcnSpec = 'single y1 = filterV1(single u1, single u2, single p1)';
def.HeaderFiles = {'myfilter.h'};
def.SourceFiles = {'filterV1.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
defs = [defs; def];

% rtwdemo_sfun_filterV2
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_filterV2';
def.OutputFcnSpec = 'single y1 = filterV2(single u1[1], single u2, single p1)';
def.HeaderFiles = {'myfilter.h'};
def.SourceFiles = {'filterV2.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
defs = [defs; def];

### Generate S-Functions for Simulation

To generate C-MEX S-functions according to the description provided by the input argument 'defs', call the function legacy_code() again with the first input set to 'sfcn_cmex_generate'. The S-functions call the legacy functions in simulation. The source code for the S-functions is in the files rtwdemo_sfun_filterV1.c and rtwdemo_sfun_filterV2.c.

legacy_code('sfcn_cmex_generate', defs);

### Compile the Generated S-Functions for Simulation

After you generate the C-MEX S-function source files, to compile the S-functions for simulation with Simulink®, call the function legacy_code() again with the first input set to 'compile'.

legacy_code('compile', defs);

### Start Compiling rtwdemo_sfun_filterV1
mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', ...'-IC:\TEMP\Bdoc18a_815039_1')
Building with 'Microsoft Visual C++ 2015 (C)'.
MEX completed successfully.
Generate TLC Block Files for Code Generation

After you compile the S-functions and use them in simulation, you can call the function `legacy_code()` again with the first input set to 'sfcn_tlc_generate' to generate TLC block files. Block files specify how the generated code for a model calls the legacy code. If you do not generate TLC block files and you try to generate code for a model that includes the S-functions, code generation fails. The TLC block files for the S-functions are `rtwdemo_sfun_filterV1.tlc` and `rtwdemo_sfun_filterV2.tlc`.

```matlab
legacy_code('sfcn_tlc_generate',defs);
```

Generate an rtwmakecfg.m File for Code Generation

After you create the TLC block files, you can call the function `legacy_code()` again with the first input set to 'rtwmakecfg_generate' to generate an rtwmakecfg.m file to support code generation. If the required source and header files for the S-functions are not in the same folder as the S-functions, and you want to add these dependencies in the makefile produced during code generation, generate the rtwmakecfg.m file.

```matlab
legacy_code('rtwmakecfg_generate',defs);
```

Generate Masked S-Function Blocks for Calling the Generated S-Functions

After you compile the C-MEX S-function source, you can call the function `legacy_code()` again with the first input set to 'slblock_generate' to generate masked S-function blocks that call the S-functions. The software places the blocks in a new model. From there you can copy them to an existing model.
Show the Generated Integration with Legacy Code

The model rtwdemo_lct_filter shows integration of the model with the legacy code. The subsystem TestFilter serves as a harness for the calls to the legacy C functions via the generate S-functions, with unit delays serving to store the previous output values.

```
open_system('rtwdemo_lct_filter')
open_system('rtwdemo_lct_filter/TestFilter')
sim('rtwdemo_lct_filter')
```
Integrate External C Functions That Pass the Output Argument As a Return Argument

This example shows how to use the Legacy Code Tool to integrate legacy C functions that pass their output as a return argument.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional rtwmakecfg.m file that specifies how the generated code for a model calls the legacy code.
Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function legacy_code() using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. For detailed help on the properties, call legacy_code('help'). The prototype of the legacy functions being called in this example is:

\[
\text{FLT gainScalar(const FLT in, const FLT gain)}
\]

FLT is a typedef to float. The legacy source code is in the files your_types.h, gain.h, and gainScalar.c.

\%
rtwdemo_sfun_gain_scalar

def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_gain_scalar';
def.OutputFcnSpec = 'single y1 = gainScalar(single u1, single p1)';
def.HeaderFiles = {'gain.h'};
def.SourceFiles = {'gainScalar.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};

Generate an S-Function for Simulation

To generate a C-MEX S-function according to the description provided by the input argument 'def', call the function legacy_code() again with the first input set to 'sfcn_cmex_generate'. The S-function calls the legacy functions during simulation. The source code for the S-function is in the file rtwdemo_sfun_gain_scalar.c.

legacy_code('sfcn_cmex_generate', def);

Compile the Generated S-Function for Simulation

After you generate the C-MEX S-function source file, to compile the S-function for simulation with Simulink®, call the function legacy_code() again with the first input set to 'compile'.

legacy_code('compile', def);

### Start Compiling rtwdemo_sfun_gain_scalar

mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', ...'B:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src\gainScalar.c')

Building with 'Microsoft Visual C++ 2015 (C)'.
MEX completed successfully.
mex('rtwdemo_sfun_gain_scalar.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', ... 'C:\TEMP\Bdoc18a_815039_17936\ib0BF173\25\tp9f71770d_c2e9_4de0_8472_aa6163bbf38b\gainScalar.obj')

The model rtwdemo_lct_gain shows integration of the model with the legacy code. The subsystem TestGain serves as a harness for the call to the legacy C function via the generate S-function.

```plaintext
open_system('rtwdemo_lct_gain')
open_system('rtwdemo_lct_gain/TestGain')
sim('rtwdemo_lct_gain')
```

Integrate External C Functions That Pass Input and Output Arguments as Signals with a Fixed-Point Data Type

This example shows how to use the Legacy Code Tool to integrate legacy C functions that pass their inputs and outputs by using parameters of fixed-point data type.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional rtwmakecfg.m file that specifies how the generated code for a model calls the legacy code.

Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function legacy_code() using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. For detailed help on the properties, call legacy_code('help'). The prototype of the legacy functions being called in this example is:

```plaintext
myFixpt timesS16(const myFixpt in1, const myFixpt in2, const uint8_T fracLength)
```
myFixpt is logically a fixed-point data type, which is physically a typedef to a 16-bit integer:

```matlab
myFixpt = Simulink.NumericType;
myFixpt.DataTypeMode = 'Fixed-point: binary point scaling';
myFixpt.Signed = true;
myFixpt.WordLength = 16;
myFixpt.FractionLength = 10;
myFixpt.IsAlias = true;
myFixpt.HeaderFile = 'timesFixpt.h';
```

The legacy source code is in the files timesFixpt.h, and timesS16.c.

```matlab
% rtwdemo_sfun_times_s16
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_times_s16';
def.OutputFcnSpec = 'myFixpt y1 = timesS16(myFixpt u1, myFixpt u2, uint8 p1)';
def.HeaderFiles = {'timesFixpt.h'};
def.SourceFiles = {'timesS16.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
```

**Generate an S-Function for Simulation**

To generate a C-MEX S-function according to the description provided by the input argument 'def', call the function legacy_code() again with the first input set to 'sfcn_cmex_generate'. The S-function calls the legacy functions during simulation. The source code for the S-function is in the file rtwdemo_sfun_times_s16.c.

```matlab
legacy_code('sfcn_cmex_generate', def);
```

**Compile the Generated S-Function for Simulation**

After you generate the C-MEX S-function source file, to compile the S-function for simulation with Simulink®, call the function legacy_code() again with the first input set to 'compile'.

```matlab
legacy_code('compile', def);
```
Building with 'Microsoft Visual C++ 2015 (C)'.
MEX completed successfully.
### Finish Compiling rtwdemo_sfun_times_s16

    sim('rtwdemo_lct_cplxgain')
end
```
Integrate External C Functions That Pass Arguments That Have Inherited Dimensions

This example shows how to use the Legacy Code Tool to integrate legacy C functions whose arguments have inherited dimensions.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional rtwmakecfg.m file that specifies how the generated code for a model calls the legacy code.

Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function legacy_code() using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. For detailed help on the properties, call legacy_code('help'). The prototypes of the legacy functions being called in this example are:

- void mat_add(real_T *u1, real_T *u2, int32_T nbRows, int32_T nbCols, real_T *y1)
- void mat_mult(real_T *u1, real_T *u2, int32_T nbRows1, int32_T nbCols1, int32_T nbCols2, real_T *y1)

real_T is a typedef to double, and int32_T is a typedef to a 32-bit integer. The legacy source code is in the files mat_ops.h, and mat_ops.c.

defs = [];

% rtwdemo_sfun_mat_add
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_mat_add';
def.OutputFcnSpec = ['void mat_add(double u1[][], double u2[][], ' ...  
                     'int32 u3, int32 u4, double y1[size(u1,1)][size(u1,2)])'];
def.HeaderFiles   = {'mat_ops.h'};
def.SourceFiles   = {'mat_ops.c'};
def.IncPaths      = {'rtwdemo_lct_src'};
def.SrcPaths      = {'rtwdemo_lct_src'};
defs = [defs; def];

% rtwdemo_sfun_mat_mult
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_mat_mult';
def.OutputFcnSpec = ['void mat_mult(double u1[p1][p2], double u2[p2][p3], ' ...  
                     'int32 p1, int32 p2, int32 p3, double y1[p1][p3])'];
def.HeaderFiles   = {'mat_ops.h'};
def.SourceFiles   = {'mat_ops.c'};
def.IncPaths      = {'rtwdemo_lct_src'};
def.SrcPaths      = {'rtwdemo_lct_src'};
defs = [defs; def];

Generate S-Functions for Simulation

To generate C-MEX S-functions according to the description provided by the input 
argument 'defs', call the function legacy_code() again with the first input set to 
'sfcn_cmex_generate'. The S-functions call the legacy functions during simulation. The 
source code for the S-function is in the files rtwdemo_sfun_mat_add.c and 
rtwdemo_sfun_mat_mult.c.

legacy_code('sfcn_cmex_generate', defs);

Compile the Generated S-Functions for Simulation

After you generate the C-MEX S-function source files, to compile the S-functions for 
simulation with Simulink®, call the function legacy_code() again with the first input set to 
'compile'.

legacy_code('compile', defs);

### Start Compiling rtwdemo_sfun_mat_add

**Generate TLC Block Files for Code Generation**

After you compile the S-functions and use them in simulation, you can call the function `legacy_code()` again with the first input set to 'sfcn_tlc_generate' to generate TLC block files. Block files specify how the generated code for a model calls the legacy code. If you do not generate TLC block files and you try to generate code for a model that includes the S-functions, code generation fails. The TLC block files for the S-functions are `rtwdemo_sfun_mat_add.tlc` and `rtwdemo_sfun_mat_mult.tlc`.

`legacy_code('sfcn_tlc_generate', defs);`

**Generate an rtwmakecfg.m File for Code Generation**

After you create the TLC block files, you can call the function `legacy_code()` again with the first input set to 'rtwmakecfg_generate' to generate an rtwmakecfg.m file to support code generation. If the required source and header files for the S-functions are not in the same folder as the S-functions, and you want to add these dependencies in the makefile produced during code generation, generate the rtwmakecfg.m file.

`legacy_code('rtwmakecfg_generate', defs);`

**Generate Masked S-Function Blocks for Calling the Generated S-Functions**

After you compile the C-MEX S-function source, you can call the function `legacy_code()` again with the first input set to 'slblock_generate' to generate masked S-function blocks that call the S-functions. The software places the blocks in a new model. From there you can copy them to an existing model.

`legacy_code('slblock_generate', defs);`
Show the Generated Integration with Legacy Code

The model rtwdemo_lct_inherit_dims shows integration of the model with the legacy code. The subsystem TestMatOps serves as a harness for the calls to the legacy C functions, with unit delays serving to store the previous output values.

```matlab
open_system('rtwdemo_lct_inherit_dims')
open_system('rtwdemo_lct_inherit_dims/TestMatOps')
sim('rtwdemo_lct_inherit_dims')
```
Integrate External C Functions That Implement Start and Terminate Actions

Integrate legacy C functions that have start and terminate actions by using the Legacy Code Tool.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional rtwmakecfg.m file that specifies how the generated code for a model calls the legacy code.

Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function legacy_code() using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. For detailed help on the properties,
call legacy_code('help'). The prototypes of the legacy functions being called in this example are:

- void initFaultCounter(unsigned int *counter)
- void openLogFile(void **fid)
- void incAndLogFaultCounter(void *fid, unsigned int *counter, double time)
- void closeLogFile(void **fid)

The legacy source code is in the files your_types.h, fault.h, and fault.c.

```matlab
% rtwdemo_sfun_fault
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_fault';
def.InitializeConditionsFcnSpec = 'initFaultCounter(uint32 work2[1])';
def.StartFcnSpec = 'openLogFile(void **work1)';
def.OutputFcnSpec = ...
    'incAndLogFaultCounter(void *work1, uint32 work2[1], double u1)';
def.TerminateFcnSpec = 'closeLogFile(void **work1)';
def.HeaderFiles = {'fault.h'};
def.SourceFiles = {'fault.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
def.Options.useTlcWithAccel = false;
```

**Generate an S-Function for Simulation**

To generate a C-MEX S-function according to the description provided by the input argument 'def', call the function legacy_code() again with the first input set to 'sfcn_cmex_generate'. The S-function calls the legacy functions during simulation. The source code for the S-function is in the file rtwdemo_sfun_fault.c.

legacy_code('sfcn_cmex_generate', def);

**Compile the Generated S-Function for Simulation**

After you generate the C-MEX S-function source file, to compile the S-function for simulation with Simulink®, call the function legacy_code() again with the first input set to 'compile'.

legacy_code('compile', def);

```matlab
### Start Compiling rtwdemo_sfun_fault
```
Generate a TLC Block File for Code Generation

After you compile the S-function and use it in simulation, you can call the function `legacy_code()` again with the first input set to 'sfcn_tlc_generate' to generate a TLC block file. The block file specifies how the generated code for a model calls the legacy code. If you do not generate a TLC block file and you try to generate code for a model that includes the S-function, code generation fails. The TLC block file for the S-function is: rtwdemo_sfun_fault.tlc.

```
legacy_code('sfcn_tlc_generate', def);
```

Generate an rtwmakecfg.m File for Code Generation

After you create the TLC block file, you can call the function `legacy_code()` again with the first input set to 'rtwmakecfg_generate' to generate an rtwmakecfg.m file to support code generation. If the required source and header files for the S-function are not in the same folder as the S-function, and you want to add these dependencies in the makefile produced during code generation, generate the rtwmakecfg.m file.

```
legacy_code('rtwmakecfg_generate', def);
```

Generate a Masked S-Function Block for Calling the Generated S-Function

After you compile the C-MEX S-function source, you can call the function `legacy_code()` again with the first input set to 'slblock_generate' to generate a masked S-function block that calls that S-function. The software places the block in a new model. From there you can copy it to an existing model.

```
legacy_code('slblock_generate', def);
```
**Showing the Generated Integration with Legacy Code**

The model `rtwdemo_lct_start_term` shows integration of the model with the legacy code. The subsystem `TestFixpt` serves as a harness for the call to the legacy C function, and the scope compares the output of the function with the output of the built-in Simulink® product block; the results should be identical.

```matlab
open_system('rtwdemo_lct_start_term')
open_system('rtwdemo_lct_start_term/TestFault')
sim('rtwdemo_lct_start_term')
```

**Integrate External C Functions That Pass Arguments as Multi-Dimensional Signals**

This example shows how to use the Legacy Code Tool to integrate legacy C functions with multi-dimensional Signals.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional `rtwmakecfg.m` file that specifies how the generated code for a model calls the legacy code.

**Provide the Legacy Function Specification**

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function `legacy_code()` using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. For detailed help on the properties, call `legacy_code('help')`. The prototype of the legacy functions being called in this example is:
void array3d_add(real_T y1, real_T u1, real_T u2, int32_T nbRows, int32_T nbCols, int32_T nbPages);

real_T is a typedef to double, and int32_T is a typedef to a 32-bit integer. The legacy source code is in the files ndarray_ops.h, and ndarray_ops.c.

% rtwdemo_sfun_ndarray_add
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_ndarray_add';
def.OutputFcnSpec = ...
    ['void array3d_add(double y1['size(u1,1)']['size(u1,2)']['size(u1,3)'], ',...
        'double u1[][], double u2[][], ' ... 
        'int32 size(u1,1), int32 size(u1,2), int32 size(u1,3))'];
def.HeaderFiles   = {'ndarray_ops.h'};
def.SourceFiles   = {'ndarray_ops.c'};
def.IncPaths      = {'rtwdemo_lct_src'};
def.SrcPaths      = {'rtwdemo_lct_src'};

y1 is a 3-D output signal of same dimensions as the 3-D input signal u1. Note that the last 3 arguments passed to the legacy function correspond to the number of element in each dimension of the 3-D input signal u1.

Generate an S-Function for Simulation

To generate a C-MEX S-function according to the description provided by the input argument 'def', call the function legacy_code() again with the first input set to 'sfcn_cmex_generate'. The S-function calls the legacy functions during simulation. The source code for the S-function is in the file rtwdemo_sfun_ndarray_add.c.

legacy_code('sfcn_cmex_generate', def);

Compile the Generated S-Function for Simulation

After you generate the C-MEX S-function source file, to compile the S-function for simulation with Simulink®, call the function legacy_code() again with the first input set to 'compile'.

legacy_code('compile', def);

### Start Compiling rtwdemo_sfun_ndarray_add
mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', ...
    '-IC:\TEMP\Bdoc18a_815039_1

**Generate a TLC Block File for Code Generation**

After you compile the S-function and use it in simulation, you can call the function legacy_code() again with the first input set to 'sfcn_tlc_generate' to generate a TLC block file. The block file specifies how the generated code for a model calls the legacy code. If you do not generate a TLC block file and you try to generate code for a model that includes the S-function, code generation fails. The TLC block file for the S-function is: rtwdemo_sfun_ndarray_add.tlc.

legacy_code('sfcn_tlc_generate', def);

**Generate an rtwmakecfg.m File for Code Generation**

After you create the TLC block file, you can call the function legacy_code() again with the first input set to 'rtwmakecfg_generate' to generate an rtwmakecfg.m file to support code generation. If the required source and header files for the S-function are not in the same folder as the S-function, and you want to add these dependencies in the makefile produced during code generation, generate the rtwmakecfg.m file.

legacy_code('rtwmakecfg_generate', def);

**Generate a Masked S-Function Block for Calling the Generated S-Function**

After you compile the C-MEX S-function source, you can call the function legacy_code() again with the first input set to 'slblock_generate' to generate a masked S-function block that calls that S-function. The software places the block in a new model. From there you can copy it to an existing model.

legacy_code('slblock_generate', def);
Showing the Generated Integration with Legacy Code

The model `rtwdemo_lct_ndarray` shows integration of the model with the legacy code. The subsystem `ndarray_add` serves as a harness for the call to the legacy C function.

```matlab
open_system('rtwdemo_lct_ndarray')
open_system('rtwdemo_lct_ndarray/ndarray_add')
sim('rtwdemo_lct_ndarray')
```

Integrate External C Functions with a Block Sample Time Specified, Inherited, and Parameterized

This example shows how to use the Legacy Code Tool to integrate legacy C functions with the block's sample time specified, inherited and parameterized.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional `rtwmakecfg.m` file that specifies how the generated code for a model calls the legacy code.

Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function `legacy_code()` using 'initialize' as the first input. After initializing the structure, assign its properties to values
corresponding to the legacy code being integrated. For detailed help on the properties, call legacy_code('help'). The prototype of the legacy functions being called in this example is:

```c
FLT gainScalar(const FLT in, const FLT gain)
```

FLT is a typedef to float. The legacy source code is in the files your_types.h, gain.h, and gainScalar.c.

defs = [];

```c
% rtwdemo_sfun_st_inherited
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_st_inherited';
def.OutputFcnSpec = 'single y1 = gainScalar(single u1, single p1)';
def.HeaderFiles = {'gain.h'};
def.SourceFiles = {'gainScalar.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
defs = [defs; def];
```

```c
% rtwdemo_sfun_st_fixed
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_st_fixed';
def.OutputFcnSpec = 'single y1 = gainScalar(single u1, single p1)';
def.HeaderFiles = {'gain.h'};
def.SourceFiles = {'gainScalar.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
def.SampleTime = [2 1];
defs = [defs; def];
```

```c
% rtwdemo_sfun_st_parameterized
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_st_parameterized';
def.OutputFcnSpec = 'single y1 = gainScalar(single u1, single p1)';
def.HeaderFiles = {'gain.h'};
def.SourceFiles = {'gainScalar.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
def.SampleTime = 'parameterized';
defs = [defs; def];
```
Generate S-Functions for Simulation

To generate C-MEX S-functions according to the description provided by the input argument 'defs', call the function legacy_code() again with the first input set to 'sfcn_cmex_generate'. The S-functions call the legacy functions during simulation. The source code for the S-functions is in the files rtwdemo_sfun_st_inherited.c and rtwdemo_sfun_st_fixed.c. rtwdemo_sfun_st_parameterized.c.

legacy_code('sfcn_cmex_generate', defs);

Compile the Generated S-Functions for Simulation

After you generate the C-MEX S-function source files, to compile the S-functions for simulation with Simulink®, call the function legacy_code() again with the first input set to 'compile'.

legacy_code('compile', defs);

External Code Integration Examples

This topic shows various scenarios of external code integration.

Insert External C and C++ Code Into Stateflow Charts for Code Generation

This example shows how to use Stateflow® to integrate external code into a model.

Open Model

```matlab
model='rtwdemo_sfcustom';
open_system(model);
```

---

**Integrating c-code into model**

Custom written c-files can be easily integrated into Stateflow models. This code can be used to augment Stateflow's capabilities or to take advantage of legacy code.

To add custom c-files open the simulation target and enter the following:

- **Include Code** - Header that defines functions, structures, and data to be accessible by Stateflow.
- **Include Path** - Path to this include file.
- **Source Files** - c-files that define the functions and data accessible by Stateflow.

**Open simulation custom code settings**

If generating code via Simulink Coder, these same settings must also be added to the Model's configuration parameters custom code settings.

**Open Code Generation custom code settings**

**Build model using Simulink Coder**

---

**Calling c-code from Stateflow**

**Functions**

Custom c-code functions can be called from Stateflow using the same syntax as graphical function calls. The statement takes the form:

```matlab
result = my_custom_function(input_args);
```

**Structures**

Variables of structure type can be accessed in Stateflow via the "dot" notation. The expression takes the form:

```matlab
result = my_var.my_field;
```

To view the custom source for this example demonstration double-click the links below:

- **Open my_header.h**
- **Open my_function.c**

---

**Calling C++ code from Stateflow**

Custom C++ code can also be integrated into Stateflow and Simulink Coder. Double-click below for an example.

- **Open rtwdemo_stepp**

---

**Additional documentation**

Additional documentation is available for integrating C and C++ code in your model by double-clicking the link below.

Integrate Code

1. The example includes the custom header file `my_header.c` and the custom source file `my_function.c`.

```matlab
%Open files my_header.h and my_function.c
eval('edit my_header.h')
eval('edit my_function.c')
```

2. On the Configuration Parameters dialog box **Simulation Target** pane, enter the custom source file and header file. Also enter additional include directories and source files.

In this example, the custom header file `my_header.c` and source file `my_function.c` are entered on the **Simulation Target** pane.

```matlab
%Open Configuration Parameters dialog box
slCfgPrmDlg(model,'Open');
slCfgPrmDlg(bdroot,'TurnToPage','Simulation Target');
```

3. If you generate code with Simulink Coder®, on the Configuration Parameters dialog box **Code Generation > Custom Code** pane, enter the same custom source file and header file. Also enter the same additional include directories and source files.

In this example, the custom header file `my_header.c` and source file `my_function.c` are entered on the **Code Generation > Custom Code** pane.

```matlab
%Open Configuration Parameters dialog box
slCfgPrmDlg(model,'Open');
slCfgPrmDlg(bdroot,'TurnToPage','Code Generation/Custom Code');
```

Generate Code

```matlab
rtwbuild('rtwdemo_sfcustom')
```

### Starting build procedure for model: rtwdemo_sfcustom
### Successful completion of build procedure for model: rtwdemo_sfcustom

Call C Code from Stateflow

To call custom C code functions from Stateflow, use the same syntax as graphical function calls: `result = my_custom_function(in_args);`

To call variables of structure type, use the dot notation: `result = my_var.my_field;`

Close Model

rtwdemoclean;
close_system('rtwdemo_sfcustom',0);

Integrate External C Code Into Generated Code By Using Custom Code Blocks and Model Configuration Parameters

This example shows how to place external code in generated code by using custom code blocks and model configuration parameters.

1. Open the model rtwdemo_slcustcode.

open_system('rtwdemo_slcustcode')
2. Open the Model Configuration Parameters dialog box and navigate to the Custom Code pane.

3. Examine the settings for parameters Source file and Initialize function.
• **Source file** specifies a comment and sets the variable `GLOBAL_INT2` to -1.
• **Initialize function** initializes the variable `GLOBAL_INT2` to 1.

4. Close the dialog box.

5. Double-click the Model Source block. The **Top of Model Source** field specifies that the code generator declare the variable `GLOBAL_INT1` and set it to 0 at the top of the generated file `rtwdemo_slcustcode.c`.

6. Open the triggered subsystem **Amplifier**. The subsystem includes the System Outputs block. The code generator places code that you specify in that block in the generated code for the nearest parent atomic subsystem. In this case, the code generator places the external code in the generated code for the **Amplifier** subsystem. The external code:
   - Declares the pointer variable `*intPtr` and initializes it with the value of variable `GLOBAL_INT1`.
   - Sets the pointer variable to -1 during execution.
   - Resets the pointer variable to 0 before exiting.

7. Generate code and a code generation report.

8. Examine the code in the generated source file `rtwdemo_slcustcode.c`. At the top of the file, after the `#include` statements, you find the following declaration code. The example specifies the first declaration with the **Source file** configuration parameter and the second declaration with the Model Source block.

   ```c
   int_T GLOBAL_INT2 = -1;
   int_T GLOBAL_INT1 = 0;
   ```

   The Output function for the **Amplifier** subsystem includes the following code, which shows the external code integrated with generated code that applies the gain. The example specifies the three lines of code for the pointer variable with the System Outputs block in the **Amplifier** subsystem.

   ```c
   int_T *intPtr = &GLOBAL_INT1;
   *intPtr = -1;
   rtwdemo_slcustcode_Y.Output = rtwdemo_slcustcode_U.Input << 1;
   ```
*intPtr = 0;

The following assignment appears in the model initialize entry-point function. The example specifies this assignment with the Initialize function configuration parameter.

GLOBAL_INT2 = 1;

Integrate External C Code Into Generated Code By Using Custom Code Blocks and Model Configuration Parameters

This example shows how to place external code in generated code by using custom code blocks and model configuration parameters.

1. Open the model `rtwdemo_slcustcode`.

```matlab
open_system('rtwdemo_slcustcode')
```
2. Open the Model Configuration Parameters dialog box and navigate to the **Custom Code** pane.

3. Examine the settings for parameters **Source file** and **Initialize function**.
- **Source file** specifies a comment and sets the variable `GLOBAL_INT2` to -1.
- **Initialize function** initializes the variable `GLOBAL_INT2` to 1.

4. Close the dialog box.

5. Double-click the Model Source block. The **Top of Model Source** field specifies that the code generator declare the variable `GLOBAL_INT1` and set it to 0 at the top of the generated file `rtwdemo_slcustcode.c`.

6. Open the triggered subsystem **Amplifier**. The subsystem includes the System Outputs block. The code generator places code that you specify in that block in the generated code for the nearest parent atomic subsystem. In this case, the code generator places the external code in the generated code for the **Amplifier** subsystem. The external code:

   - Declares the pointer variable `*intPtr` and initializes it with the value of variable `GLOBAL_INT1`.
   - Sets the pointer variable to -1 during execution.
   - Resets the pointer variable to 0 before exiting.

7. Generate code and a code generation report.

8. Examine the code in the generated source file `rtwdemo_slcustcode.c`. At the top of the file, after the `#include` statements, you find the following declaration code. The example specifies the first declaration with the **Source file** configuration parameter and the second declaration with the Model Source block.

   ```
   int_T GLOBAL_INT2 = -1;
   int_T GLOBAL_INT1 = 0;
   ```

   The Output function for the **Amplifier** subsystem includes the following code, which shows the external code integrated with generated code that applies the gain. The example specifies the three lines of code for the pointer variable with the System Outputs block in the **Amplifier** subsystem.

   ```
   int_T *intPtr = &GLOBAL_INT1;
   *intPtr = -1;
   rtwdemo_slcustcode_Y.Output = rtwdemo_slcustcode_U.Input << 1;
   ```
*intPtr = 0;

The following assignment appears in the model initialize entry-point function. The example specifies this assignment with the Initialize function configuration parameter.

GLOBAL_INT2 = 1;

Insert External C and C++ Code Into Stateflow Charts for Code Generation

This example shows how to use Stateflow® to integrate external code into a model.

Open Model

```matlab
model = 'rtwdemo_sfcustom';
open_system(model);
```

---

**Integrating c-code into model**

Custom written c-files can be easily integrated into Stateflow models. This code can be used to augment Stateflow's capabilities or to take advantage of legacy code.

To add custom c-files open the simulation target and enter the following:

- **Include Code** - Header that defines functions, structures, and data to be accessible by Stateflow.
- **Include Path** - Path to this include file.
- **Source Files** - c-files that define the functions and data accessible by Stateflow.

**Open simulation custom code settings**

If generating code via Simulink Coder, these same settings must also be added to the Model's configuration parameters custom code settings.

**Open Code Generation custom code settings**

**Build model using Simulink Coder**

**Calling c-code from Stateflow**

- **Functions**
  Custom c-code functions can be called from Stateflow using the same syntax as graphical function calls. The statement takes the form:

  ```c
  result = my_custom_function(input_args);
  ```

- **Structures**
  Variables of structure type can be accessed in Stateflow via the "dot" notation. The expression takes the form:

  ```c
  result = my_var.my_field;
  ```

To view the custom source for this example, open the links below.

**Open my_header.h**

**Open my_function.c**

**Calling C++ code from Stateflow**

Custom C++ code can also be integrated into Stateflow and Simulink Coder. Double-click below for an example.

**Open rtwdemo_stopp**

**Additional documentation**

Additional documentation is available for integrating C and C++ code in your model by double-clicking the links below.

**C-Code integration**

**C++-Code integration**

Integrate Code

1. The example includes the custom header file `my_header.c` and the custom source file `my_function.c`.

```matlab
%Open files my_header.h and my_function.c
eval('edit my_header.h')
eval('edit my_function.c')
```

2. On the Configuration Parameters dialog box Simulation Target pane, enter the custom source file and header file. Also enter additional include directories and source files.

   In this example, the custom header file `my_header.c` and source file `my_function.c` are entered on the Simulation Target pane.

```matlab
%Open Configuration Parameters dialog box
slCfgPrmDlg(model,'Open');
slCfgPrmDlg(bdroot,'TurnToPage','Simulation Target');
```

3. If you generate code with Simulink Coder®, on the Configuration Parameters dialog box Code Generation > Custom Code pane, enter the same custom source file and header file. Also enter the same additional include directories and source files.

   In this example, the custom header file `my_header.c` and source file `my_function.c` are entered on the Code Generation > Custom Code pane.

```matlab
%Open Configuration Parameters dialog box
slCfgPrmDlg(model,'Open');
slCfgPrmDlg(bdroot,'TurnToPage','Code Generation/Custom Code');
```

Generate Code

```matlab
rtwbuild('rtwdemo_sfcustom')
### Starting build procedure for model: rtwdemo_sfcustom
### Successful completion of build procedure for model: rtwdemo_sfcustom
```

Call C Code from Stateflow

To call custom C code functions from Stateflow, use the same syntax as graphical function calls: `result = my_custom_function(in_args);`

To call variables of structure type, use the dot notation: `result = my_var.my_field;`

Close Model

rtwdemoclean;
close_system('rtwdemo_sfcustom',0);
Generate S-Function from Subsystem

The Generate S-function feature automates the process of generating an S-function from a subsystem. In addition, the Generate S-function feature presents a display of parameters used within the subsystem, and lets you declare selected parameters tunable.

As an example, consider SourceSubsys, the same subsystem illustrated in the example “Create S-Function Blocks from a Subsystem” on page 49-63. The objective is to automatically extract SourceSubsys from the model and build an S-Function block from it, as in the previous example. In addition, the workspace variable K, which is the gain factor of the Gain block within SourceSubsys (as shown in the Gain block parameter dialog box below), is declared and generated as a tunable variable.

To auto-generate an S-function from SourceSubsys with tunable parameter K,

1. With the SourceSubsys model open, click the subsystem to select it.
2. From the Code menu, select C/C++ Code > Generate S-Function. This menu item is enabled when a subsystem is selected in the current model.

   Alternatively, you can right-click the subsystem and select C/C++ Code > Generate S-Function from the subsystem block's context menu.
3. The Generate S-Function window is displayed (see the next figure). This window shows variables (or data objects) that are referenced as block parameters in the subsystem, and lets you declare them as tunable.
The upper pane of the window displays three columns:

- **Variable Name**: name of the parameter.
- **Class**: If the parameter is a workspace variable, its data type is shown. If the parameter is a data object, its name and class is shown.
- **Tunable**: Lets you select tunable parameters. To declare a parameter tunable, select the check box. In the next figure, the parameter $K$ is declared tunable.

When you select a parameter in the upper pane, the lower pane shows the blocks that reference the parameter, and the parent system of each such block.

**Generate S-Function Window**

4. After selecting tunable parameters, click the **Build** button. This initiates code generation and compilation of the S-function, using the S-function target. The **Create New Model** option is automatically enabled.

5. The build process displays status messages in the MATLAB Command Window. When the build completes, the tunable parameters window closes, and a new untitled model window opens.
6 The model window contains an S-Function block with the same name as the subsystem from which the block was generated (in this example, SourceSubsys). Optionally, you can save the generated model containing the generated block.

7 The generated code for the S-Function block is stored in the current working folder. The following files are written to the top level folder:

- `subsys_sf.c` or `cpp`, where `subsys` is the subsystem name (for example, `SourceSubsys_sf.c`)
- `subsys_sf.h`
- `subsys_sf.mexext`, where `mexext` is a platform-dependent MEX-file extension (for example, `SourceSubsys_sf.mexw64`)

The source code for the S-function is written to the subfolder `subsys_sfcn_rtw`. The top-level `.c` or `.cpp` file is a stub file that simply contains an include directive that you can use to interface other C/C++ code to the generated code.

Note For a list of files required to deploy your S-Function block for simulation or code generation, see “Required Files for S-Function Deployment” on page 49-60.

8 The generated S-Function block has inports and outports whose widths and sample times correspond to those of the original model.

The following code, from the `mdlOutputs` routine of the generated S-function code (in `SourceSubsys_sf.c`), shows how the tunable variable K is referenced by using calls to the MEX API.

```c
static void mdlOutputs(SimStruct *S, int_T tid) {
    ...
```
/* Gain: '<S1>/Gain' incorporates:
 *  Sum: '<S1>/Sum'
 */
rtb_Gain_n[0] = (rtb_Product_p + (*((const
    real_T**)ssGetInputPortSignalPtrs(S, 2)[0]))) * (*(real_T
    *)mxGetData(K(S)));
rtb_Gain_n[1] = (rtb_Product_p + (*((const
    real_T**)ssGetInputPortSignalPtrs(S, 2)[1]))) * (*(real_T
    *)mxGetData(K(S)));

- In automatic S-function generation, the **Use Value for Tunable Parameters** option is cleared or at the command line is set to 'off'.
- Use a MEX S-function wrapper only in the MATLAB version in which the wrapper is created.

If you specify paths and files with absolute

### Macro Parameters

Suppose that you apply a custom storage class such as **Define** to a `Simulink.Parameter` object so that the parameter appears as a macro in the generated code. If you use the parameter object inside a subsystem from which you generate an ERT S-function, you cannot select the parameter object as a tunable parameter. Instead, the S-function code generator applies the custom storage class to the parameter object. This generation of macros in the S-function code allows you to generate S-functions from subsystems that contain variant elements, such as Variant Subsystem blocks, that you configure to produce preprocessor conditionals in the generated code. However, you cannot change the value of the parameter during simulation of the S-function.

To select the parameter object as a tunable parameter, apply a different storage class or custom storage class. Custom storage classes that treat parameters as macros include **Define, ImportedDefine, CompilerFlag**, and custom storage classes that you create by setting **Data initialization** to **Macro** in the Custom Storage Class Designer. If you use a non-macro storage class or custom storage class, you cannot use the parameter object as a variant control variable and generate preprocessor conditionals.

If you apply a custom storage class that treats the parameter object as an imported macro, provide the macro definition before you generate the ERT S-function. For example, suppose you apply the custom storage class **ImportedDefine** to a `Simulink.Parameter` object, and use the parameter object as a variant control variable in the subsystem. If you set the custom attribute **HeaderFile** to 'myHdr.h', when you generate the S-function, place the custom header file `myHdr.h` in the current folder. The
generated S-function uses the macro value from your header file instead of the value from the Value property of the parameter object.

To use a macro that you define through a compiler option, for example by applying the custom storage class CompilerFlag, use the model configuration parameter Configuration Parameters > Code Generation > Custom Code > Additional build information > Defines to specify the compiler option. For more information, see Code Generation Pane: Custom Code: Additional Build Information: Defines (Simulink Coder).

Write S-Function and TLC Files By Hand

You can choose from several approaches for writing S-function and TLC files by hand.

Write Noninlined S-Function and TLC Files

- “About Noninlined S-Functions” on page 11-67
- “Guidelines for Writing Noninlined S-Functions” on page 11-67
- “Noninlined S-Function Parameter Type Limitations” on page 11-68

About Noninlined S-Functions

Noninlined S-functions are identified by the absence of an sfuntion.tlc file for your S-function. The filename varies depending on your platform. For example, on a 64-bit Microsoft Windows system, the file name would be sfuntion.mexw64. Type mexext in the MATLAB Command Window to see which extension your system uses.

Guidelines for Writing Noninlined S-Functions

- The MEX-file cannot call MATLAB functions.
- If the MEX-file uses functions in the MATLAB External Interface libraries, include the header file cg_sfun.h instead of mex.h or simulink.c. To handle this case, include the following lines at the end of your S-function:

```c
#ifdef MATLAB_MEX_FILE /* Is this file being compiled as a MEX-file? */
#include "simulink.c" /* MEX-file interface mechanism */
#else
#include "cg_sfun.h" /* Code generation registration function */
#endif
```

- Use only MATLAB API function that the code generator supports, which include:
  - mxGetEps
  - mxGetInf
  - mxGetM
  - mxGetN
  - mxGetNaN
  - mxGetPr
  - mxGetScalar
  - mxGetString
  - mxIsEmpty
  - mxIsFinite
mXIsInf

- MEX library calls are not supported in generated code. To use such calls in MEX-file and not in the generated code, conditionalize the code as follows:

```c
#ifdef MATLAB_MEX_FILE
#endif
```

- Use only full matrices that contain only real data.
- Do not specify a return value for calls to `mxGetString`. If you do specify a return value, the MEX-file will not compile. Instead, use the function's second input argument, which returns a pointer to a character vector.
- Make sure that the `#define s-function_name` statement is correct. The S-function name that you specify must match the S-function's filename.
- Use the data types `real_T` and `int_T` instead of `double` and `int`, if possible. The data types `real_T` and `int_T` are more generic and can be used in multiple environments.
- Provide the build process with the names of the modules used to build the S-function. You can do this by using a template make file, the `set_param` function, or the `S-function modules` field of the S-Function block parameters dialog box. For example, suppose you build your S-function with the following command:

```c
mex sfun_main.c sfun_module1.c sfun_module2.c
```

    You can then use the following call to `set_param` to include the required modules:

```c
set_param(sfun_block, "SFunctionModules","sfun_module1 sfun_module2")
```

    When you are ready to generate code, force the code generator to rebuild the top model, as explained in “Control Regeneration of Top Model Code” (Simulink Coder).

### Noninlined S-Function Parameter Type Limitations

Parameters to noninlined S-functions can be of the following types only:

- Double precision
- Characters in scalars, vectors, or 2-D matrices

For more flexibility in the type of parameters you can supply to S-functions or the operations in the S-function, inline your S-function and consider using an `mdlRTW` S-function routine.

Use of other functions from the MATLAB `matrix.h` API or other MATLAB APIs, such as `mex.h` and `mat.h`, is not supported. If you call unsupported APIs from an S-function
source file, compiler errors occur. See the files `matlabroot/rtw/c/src/rt_matrix.h` and `matlabroot/rtw/c/src/rt_matrix.c` for details on supported MATLAB API functions.

If you use `mxGetPr` on an empty matrix, the function does not return `NULL`; rather, it returns a random value. Therefore, you should protect calls to `mxGetPr` with `mxIsEmpty`.

**Write Wrapper S-Function and TLC Files**

This topic describes how to create S-functions that work seamlessly with the Simulink and code generator products using the wrapper concept. This topic begins by describing how to interface your algorithms in Simulink models by writing MEX S-function wrappers (`sfunction.mex`). It finishes with a description of how to direct the code generator to insert your algorithm into the generated code by creating a TLC S-function wrapper (`sfunction.tlc`).

- “MEX S-Function Wrapper” on page 11-69
- “TLC S-Function Wrapper” on page 11-74
- “Code Overhead for Noninlined S-Functions” on page 11-74
- “How to Inline” on page 11-75
- “The Inlined Code” on page 11-77

**MEX S-Function Wrapper**

Creating S-functions using an S-function wrapper allows you to insert C/C++ code algorithms in Simulink models and the generated code with little or no change to your original C/C++ function. A **MEX S-function wrapper** is an S-function that calls code that resides in another module. A **TLC S-function wrapper** is a TLC file that specifies how the code generator should call your code (the same code that was called from the C MEX S-function wrapper).

**Note** A MEX S-function wrapper must only be used in the MATLAB version in which the wrapper is created.

Suppose you have an algorithm (that is, a C function) called `my_alg` that resides in the file `my_alg.c`. You can integrate `my_alg` into a Simulink model by creating a MEX S-function wrapper (for example, `wrapsfcn.c`). Once this is done, a Simulink model can call `my_alg` from an S-Function block. However, the Simulink S-function contains a set of
empty functions that the Simulink engine requires for various API-related purposes. For example, although only \texttt{mdlOutputs} calls \texttt{my\_alg}, the engine calls \texttt{mdlTerminate} as well, even though this S-function routine performs no action.

You can integrate \texttt{my\_alg} into generated code (that is, embed the call to \texttt{my\_alg} in the generated code) by creating a TLC S-function wrapper (for example, \texttt{wrapsfcn.tlc}). The advantage of creating a TLC S-function wrapper is that the empty function calls can be eliminated and the overhead of executing the \texttt{mdlOutputs} function and then the \texttt{my\_alg} function can be eliminated.

Wrapper S-functions are useful when you are creating new algorithms that are procedural in nature or when you are integrating legacy code into a Simulink model. However, if you want to create code that is

- Interpretive in nature (that is, highly parameterized by operating modes)
- Heavily optimized (that is, no extra tests to decide what mode the code is operating in)

then you must create a \textit{fully inlined TLC file} for your S-function.

The next figure shows the wrapper S-function concept.
Using an S-function wrapper to import algorithms in your Simulink model means that the S-function serves as an interface that calls your C/C++ algorithms from mdlOutputs. S-function wrappers have the advantage that you can quickly integrate large standalone C/C++ programs into your model without having to make changes to the code.

The following sample model includes an S-function wrapper.
There are two files associated with the \texttt{wrapsfcn} block, the S-function wrapper and the C/C++ code that contains the algorithm. The S-function wrapper code for \texttt{wrapsfcn.c} appears below. The first three statements do the following:

1. Defines the name of the S-function (what you enter in the Simulink S-Function block dialog).
2. Specifies that the S-function is using the level 2 format.
3. Provides access to the SimStruct data structure, which contains pointers to data used during simulation and code generation and defines macros that store data in and retrieve data from the SimStruct.

For more information, see “Templates for C S-Functions” (Simulink).

```c
#define S_FUNCTION_NAME wrapsfcn
#define S_FUNCTION_LEVEL 2
#include "simstruc.h"

extern real_T my_alg(real_T u); /* Declare \texttt{my_alg} as \texttt{extern} */

/* mdlInitializeSizes - initialize the sizes array */
static void mdlInitializeSizes(SimStruct *S)
{
    ssSetNumSFcnParams( S, 0); /*number of input arguments*/
    if (!ssSetNumInputPorts(S, 1)) return;
    ssSetInputPortWidth(S, 0, 1);
    ssSetInputPortDirectFeedThrough(S, 0, 1);
    if (!ssSetNumOutputPorts(S,1)) return;
    ssSetOutputPortWidth(S, 0, 1);
    ssSetNumSampleTimes( S, 1);
}
/*
The S-function routine `mdlOutputs` contains a function call to `my_alg`, which is the C function containing the algorithm that the S-function performs. This is the code for `my_alg.c`:

```c
real_T my_alg(real_T u)
{
    return(u * 2.0);
}
```

For more information, see “Manage Build Process File Dependencies” (Simulink Coder).

The wrapper S-function `wrapsfcn` calls `my_alg`, which computes `u * 2.0`. To build `wrapsfcn.mex`, use the following command:

```bash
mex wrapsfcn.c my_alg.c
```
**TLC S-Function Wrapper**

This topic describes how to inline the call to `my_alg` in the `mdlOutputs` section of the generated code. In the above example, the call to `my_alg` is embedded in the `mdlOutputs` section as

```c
*y = my_alg(*uPtrs[0]);
```

When you are creating a TLC S-function wrapper, the goal is to embed the same type of call in the generated code.

It is instructive to look at how the code generator executes S-functions that are not inlined. A noninlined S-function is identified by the absence of the file `sfunction.tlc` and the existence of `sfunction.mex`. When generating code for a noninlined S-function, the code generator produces a call to `mdlOutputs` through a function pointer that, in this example, then calls `my_alg`.

The wrapper example contains one S-function, `wrapsfcn.mex`. You must compile and link an additional module, `my_alg`, with the generated code. To do this, specify

```c
set_param('wrapper/S-Function','SFunctionModules','my_alg')
```

**Code Overhead for Noninlined S-Functions**

The code generated when using `grt.tlc` as the system target file *without* `wrapsfcn.tlc` is

```c
#include <math.h>
#include <string.h>
#include "wrapper.h"
#include "wrapper.prm"

/* Start the model */
void mdlStart(void)
{
   /* (start code not required) */
}

/* Compute block outputs */
void mdlOutputs(int_T tid)
{
   /* Sin Block: <Root>/Sin */
   rtB.Sin = rtP.Sin.Amplitude *
      sin(rtP.Sin.Frequency * ssGetT(rtS) + rtP.Sin.Phase);

   /* Level2 S-Function Block: <Root>/S-Function (wrapsfcn) */
   
```
In addition to the overhead outlined above, the wrapper.reg generated file contains the initialization of the SimStruct for the wrapper S-Function block. There is one child SimStruct for each S-Function block in your model. You can significantly reduce this overhead by creating a TLC wrapper for the S-function.

**How to Inline**

The generated code makes the call to your S-function, wrapsfcn.c, in mdlOutputs by using this code:

```c
SimStruct *rts = ssGetSFunction(rtS, 0);
sfcnOutputs(rts, tid);
```

This call has computational overhead associated with it. First, the Simulink engine creates a SimStruct data structure for the S-Function block. Second, the code generator constructs a call through a function pointer to execute mdlOutputs, then mdlOutputs calls my_alg. By inlining the call to your C/C++ algorithm, my_alg, you can eliminate
both the SimStruct and the extra function call, thereby improving the efficiency and reducing the size of the generated code.

Inlining a wrapper S-function requires an sfunction.tlc file for the S-function (see the “Target Language Compiler” (Simulink Coder) for details). The TLC file must contain the function call to my_alg. The following figure shows the relationships between the algorithm, the wrapper S-function, and the sfunction.tlc file.

The wrapsfcn.tlc file tells Simulink Coder how to inline the call to my_alg using this statement.

```
%<y> = my_alg(%<u>);
...
```

To inline this call, you have to place your function call in an sfunction.tlc file with the same name as the S-function (in this example, wrapsfcn.tlc). This causes the Target Language Compiler to override the default method of placing calls to your S-function in the generated code.

This is the wrapsfcn.tlc file that inlines wrapsfcn.c.

```
%% File    : wrapsfcn.tlc
%% Abstract:
%%      Example inlined tlc file for S-function wrapsfcn.c
%%
%% %implements "wrapsfcn" "C"

%% Function: BlockTypeSetup ===============================

%function Outputs(block, system) Output
/* %<Type> Block: %<Name> */
%assign u = LibBlockInputSignal(0, "", "", 0)
%assign y = LibBlockOutputSignal(0, "", "", 0)
%% PROVIDE THE CALLING STATEMENT FOR “algorithm”
%<y> = my_alg(%<u>);
%endfunction % Outputs

The first section of this code inlines the wrapsfcn S-Function block and generates the code in C:

%implements "wrapsfcn" "C"

The next task is to tell the code generator that the routine my_alg needs to be declared external in the generated wrapper.h file for any wrapsfcn S-Function blocks in the model. You only need to do this once for all wrapsfcn S-Function blocks, so use the BlockTypeSetup function. In this function, you tell the Target Language Compiler to create a buffer and cache the my_alg as extern in the wrapper.h generated header file.

The final step is the inlining of the call to the function my_alg. This is done by the Outputs function. In this function, you access the block’s input and output and place a direct call to my_alg. The call is embedded in wrapper.c.

**The Inlined Code**

The code generated when you inline your wrapper S-function is similar to the default generated code. The mdlTerminate function does not contain a call to an empty function and the mdlOutputs function now directly calls my_alg.

```c
void mdlOutputs(int_T tid)
{
    /* Sin Block: <Root>/Sin */
    rtB.Sin = rtP.Sin.Amplitude * sin(rtP.Sin.Frequency * ssGetT(rtS) + rtP.Sin.Phase);

    /* S-Function Block: <Root>/S-Function */
    rtB.S_Function = my_alg(rtB.Sin); /* Inlined call to my_alg */

    /* Outport Block: <Root>/Out */
    rtY.Out = rtB.S_Function;
}
```

11-77
In addition, `wrapper.reg` does not create a child `SimStruct` for the S-function because the generated code is calling `my_alg` directly. This eliminates over 1 KB of memory usage.

**Write Fully Inlined S-Functions**

Using the example from “Write Wrapper S-Function and TLC Files” (Simulink Coder), you could eliminate the call to `my_alg` entirely by specifying the explicit code (that is, `2.0 * u`) in `wrapsfcn.tlc`. This is referred to as a **fully inlined S-function**. While this can improve performance, if you are working with a large amount of C/C++ code, this can be a lengthy task. In addition, you now have to maintain your algorithm in two places, the C/C++ S-function itself and the corresponding TLC file. However, the performance gains might outweigh the disadvantages. To inline the algorithm used in this example, in the Outputs section of your `wrapsfcn.tlc` file, instead of writing

```%
y = my_alg(%u);
```

use

```%
y = 2.0 * %u;
```

This is the code produced in `mdlOutputs`:

```c
void mdlOutputs(int_T tid)
{
    /* Sin Block: <Root>/Sin */
    rtB.Sin = rtP.Sin.Amplitude *
        sin(rtP.Sin.Frequency * ssGetT(rtS) + rtP.Sin.Phase);

    /* S-Function Block: <Root>/S-Function */
    rtB.S_Function = 2.0 * rtB.Sin; /* Explicit embedding of algorithm */

    /* Outport Block: <Root>/Out */
    rtY.Out = rtB.S_Function;
}
```

The Target Language Compiler has replaced the call to `my_alg` with the algorithm itself.

**Multiport S-Function**

A more advanced multiport inlined S-function example is `sfun_multiport.c` and `sfun_multiport.tlc`. This S-function illustrates how to create a fully inlined TLC file for an S-function that contains multiple ports. You might find that looking at this example helps you to understand fully inlined TLC files.
Write Fully Inlined S-Functions with mdlRTW Routine

You can inline more complex S-functions that use the S-function `mdlRTW` routine. The purpose of the `mdlRTW` routine is to provide the code generation process with more information about how the S-function is to be inlined, by creating a parameter record of a nontunable parameter for use with a TLC file. The `mdlRTW` routine does this by placing information in the `model.rtw` file. The `mdlRTW` function is described in the text file `matlabroot/simulink/src/sfuntmpl_doc.c`.

As an example of how to use the `mdlRTW` function, this topic discusses the steps you must take to create a direct-index lookup S-function. Lookup tables are collections of ordered data points of a function. Typically, these tables use some interpolation scheme to approximate values of the associated function between known data points. To incorporate the example lookup table algorithm into a Simulink model, the first step is to write an S-function that executes the algorithm in `mdlOutputs`. To produce the most efficient code, the next step is to create a corresponding TLC file to eliminate computational overhead and improve the speed of the lookup computations.

For your convenience, the Simulink product provides support for two general-purpose lookup 1-D and 2-D algorithms. You can use these algorithms as they are or create a custom lookup table S-function to fit your requirements. This topic illustrates how to create a 1-D lookup S-function, `sfun_directlook.c`, and its corresponding inlined `sfun_directlook.tlc` file (see “Target Language Compiler” (Simulink Coder) for more details). This 1-D direct-index lookup table example illustrates the following concepts that you need to know to create your own custom lookup tables:

- Error checking of S-function parameters
- Caching of information for the S-function that doesn't change during model execution
- How to use the `mdlRTW` function to customize the code generator to produce the optimal code for a given set of block parameters
- How to generate an inlined TLC file for an S-function in a combination of the fully inlined form and/or the wrapper form

- “S-Function RTWdata” on page 11-80
- “Direct-Index Lookup Table Algorithm” on page 11-80
- “Direct-Index Lookup Table Example” on page 11-82
- “Error Handling” on page 11-83
- “User Data Caching” on page 11-83
S-Function RTWdata

There is a property of blocks called RTWdata, which can be used by the Target Language Compiler when inlining an S-function. RTWdata is a structure of character vectors that you can attach to a block. It is saved with the model and placed in the model.rtw file when generating code. For example, this set of MATLAB commands,

```matlab
mydata.field1 = 'information for field1';
mydata.field2 = 'information for field2';
set_param(gcb,'RTWdata',mydata)
get_param(gcb,'RTWdata')
```

produces this result:

```matlab
ans =
    field1: 'information for field1'
    field2: 'information for field2'
```

Inside the model.rtw file for the associated S-Function block is this information.

```plaintext
Block {
    Type                    "S-Function"
    RTWdata {
        field1                  "information for field1"
        field2                  "information for field2"
    }
```

**Note** RTWdata is saved in the model file for S-functions that are not linked to a library. However, RTWdata is **not persistent** for S-Function blocks that are linked to a library.

Direct-Index Lookup Table Algorithm

The 1-D lookup table block provided in the Simulink library uses interpolation or extrapolation when computing outputs. This extra accuracy might not be required. In this example, you create a lookup table that directly indexes the output vector (y-data vector) based on the current input (x-data) point.

This direct 1-D lookup example computes an approximate solution \( p(x) \) to a partially known function \( f(x) \) at \( x=x0 \), given data point pairs \( (x,y) \) in the form of an x-data vector and a y-data vector. For a given data pair (for example, the \( i^{th} \) pair), \( y_i = f(x_i) \). It is assumed that the x-data values are monotonically increasing. If \( x0 \) is outside the range of the x-data vector, the first or last point is returned.
The parameters to the S-function are

XData, YData, XEvenlySpaced

XData and YData are double vectors of equal length representing the values of the unknown function. XDataEvenlySpaced is a scalar, 0.0 for false and 1.0 for true. If the XData vector is evenly spaced, XDataEvenlySpaced is 1.0 and more efficient code is generated.

The following graph shows how the parameters XData=[1:6] and YData=[1,2,7,4,5,9] are handled. For example, if the input (x-value) to the S-Function block is 3, the output (y-value) is 7.
Direct-Index Lookup Table Example

This topic shows how to improve the lookup table by inlining a direct-index S-function with a TLC file. This direct-index lookup table S-function does not require a TLC file. Here the example uses a TLC file for the direct-index lookup table S-function to reduce the code size and increase efficiency of the generated code.

Implementation of the direct-index algorithm with inlined TLC file requires the S-function main module, sfun_directlook.c, and a corresponding lookup_index.c module. The lookup_index.c module contains the GetDirectLookupIndex function that is used to locate the index in the XData for the current x input value when the XData is unevenly
spaced. The `GetDirectLookupIndex` routine is called from both the S-function and the generated code. Here the example uses the wrapper concept for sharing C/C++ code between Simulink MEX-files and the generated code.

If the `XData` is evenly spaced, then both the S-function main module and the generated code contain the lookup algorithm (not a call to the algorithm) to compute the y-value of a given x-value, because the algorithm is short. This illustrates the use of a fully inlined S-function for generating optimal code.

The inlined TLC file is `sfun_directlook.tlc`, which is used to either perform a wrapper call or embed the optimal C/C++ code for the S-function. (See the example in “mdlRTW Usage” (Simulink Coder)).

**Error Handling**

In `sfun_directlook.tlc`, the `mdlCheckParameters` routine verifies that:

- The new parameter settings are valid.
- `XData` and `YData` are vectors of the same length containing real finite numbers.
- `XDataEvenlySpaced` is a scalar.
- The `XData` vector is a monotonically increasing vector and evenly spaced.

The `mdlInitializeSizes` function explicitly calls `mdlCheckParameters` after it verifies the number of parameters passed to the S-function. After the Simulink engine calls `mdlInitializeSizes`, it then calls `mdlCheckParameters` whenever you change the parameters or there is a need to reevaluate them.

**User Data Caching**

In `sfun_directlook.tlc`, the `mdlStart` routine shows how to cache information that does not change during the simulation (or while the generated code is executing). The example caches the value of the `XDataEvenlySpaced` parameter in `UserData`, a field of the `SimStruct`. The following line in `mdlInitializeSizes` tells the Simulink engine to disallow changes to `XDataEvenlySpaced`.

```c
ssSetSFcnParamTunable(S, iParam, SS_PRM_NOT_TUNABLE);
```

During execution, `mdlOutputs` accesses the value of `XDataEvenlySpaced` from `UserData` rather than calling the `mxGetPr` MATLAB API function.
**mdlRTW Usage**

The code generator calls the mdlRTW routine while generating the `model.rtw` file. To produce optimal code for your Simulink model, you can add information to the `model.rtw` file about the mode in which your S-Function block is operating.

The following example adds parameter settings to the `model.rtw` file. The parameter settings do not change during execution. In this case, the XDataEvenlySpaced S-function parameter cannot change during execution (`ssSetSFcnParamTunable` was specified as false (0) for it in `mdlInitializeSizes`). The example writes it out as a parameter setting (XSpacing) using the function `ssWriteRTWParamSettings`.

Because xData and yData are registered as run-time parameters in `mdlSetWorkWidths`, the code generator handles writing to the `model.rtw` file automatically.

Before examining the S-function and the inlined TLC file, consider the generated code for the following model.

![S-function model diagram](image)

The model uses evenly spaced XData in the top S-Function block and unevenly spaced XData in the bottom S-Function block. When creating this model, you need to specify the following for each S-Function block.

```matlab
set_param('sfun_directlook_ex/S-Function','SFunctionModules','lookup_index')
set_param('sfun_directlook_ex/S-Function1','SFunctionModules','lookup_index')
```
This informs the build process to use the module lookup_index.c when creating the executable.

When generating code for this model, the code generator uses the S-function mdlRTW method to generate a model.rtw file with the value EvenlySpaced for the XSpacing parameter for the top S-Function block, and the value UnevenlySpaced for the XSpacing parameter for the bottom S-Function block. The TLC-file uses the value of XSpacing to determine what algorithm to include in the generated code. The generated code contains the lookup algorithm when the XData is evenly spaced, but calls the GetDirectLookupIndex routine when the XData is unevenly spaced. The generated model.c or model.cpp code for the lookup table example model is similar to the following:

```c
/*
 * sfun_directlook_ex.c
 *
 * Code generation for Simulink model
 * "sfun_directlook_ex.slx".
 *
 */

#include "sfun_directlook_ex.h"
#include "sfun_directlook_ex_private.h"

/* External outputs (root outports fed by signals with auto storage) */
ExtY_sfun_directlook_ex_T sfun_directlook_ex_Y;

/* Real-time model */
RT_MODEL_sfun_directlook_ex_T sfun_directlook_ex_M;
RT_MODEL_sfun_directlook_ex_T *const sfun_directlook_ex_M =
    &sfun_directlook_ex_M;

/* Model output function */
void sfun_directlook_ex_output(void)
{
    /* local block i/o variables */
    real_T rtb_SFunction;
    real_T rtb_SFunction1;

    /* Sin: '<Root>/Sine Wave' */
    rtb_SFunction1 = sin(sfun_directlook_ex_M->Timing.t[0]);

    /* Code that is inlined for the top S-function block in the
     * sfun_directlook_ex model
     */
    /* S-Function (sfun_directlook): '<Root>/S-Function' */
    {
        const real_T *xData = sfun_directlook_ex_ConstP.SFunction_XData;
        const real_T *yData = sfun_directlook_ex_ConstP.SFunction_YData;
        real_T spacing = xData[1] - xData[0];
    }
```

11-85
if (rtb_SFunction1 <= xData[0]) {
    rtb_SFunction = yData[0];
} else if (rtb_SFunction1 >= yData[20]) {
    rtb_SFunction = yData[20];
} else {
    int_T idx = (int_T)((rtb_SFunction1 - xData[0]) / spacing);
    rtb_SFunction = yData[idx];
}

/* Outport: '<Root>/Out1' */
sfun_directlook_ex_Y.Out1 = rtb_SFunction;

/* Code that is inlined for the bottom S-function block in the
* sfun_directlook_ex model */
/* S-Function (sfun_directlook): '<Root>/S-Function1' */
{
    const real_T *xData = sfun_directlook_ex_ConstP.SFunction1_XData;
    const real_T *yData = sfun_directlook_ex_ConstP.SFunction1_YData;
    int_T idx;
    idx = GetDirectLookupIndex(xData, 5, rtb_SFunction1);
    rtb_SFunction1 = yData[idx];
}

/* Outport: '<Root>/Out2' */
sfun_directlook_ex_Y.Out2 = rtb_SFunction1;

/* Model update function */
void sfun_directlook_ex_update(void)
{
    /* signal main to stop simulation */
    {                                    /* Sample time: [0.0s, 0.0s] */
        if ((rtmGetTFinal(sfun_directlook_ex_M) != -1) &&
            !(rtmGetTFinal(sfun_directlook_ex_M) - sfun_directlook_ex_M->Timing.t[0]) >
            sfun_directlook_ex_M->Timing.t[0] * (DBL_EPSILON)) {
            rtmSetErrorStatus(sfun_directlook_ex_M, "Simulation finished");
        }
    }

    /* Update absolute time for base rate */
    /* The "clockTick0" counts the number of times the code of this task has
    * been executed. The absolute time is the multiplication of "clockTick0"
    * and "Timing.stepSize0". Size of "clockTick0" ensures timer will not
    * overflow during the application lifespan selected.
    * Timer of this task consists of two 32 bit unsigned integers.
    * The two integers represent the low bits Timing.clockTick0 and the high bits
    * Timing.clockTickH0. When the low bit overflows to 0, the high bits increment.
    * */
    if (!(++sfun_directlook_ex_M->Timing.clockTick0)) {
        ++sfun_directlook_ex_M->Timing.clockTickH0;
    }
    sfun_directlook_ex_M->Timing.t[0] = sfun_directlook_ex_M->Timing.clockTick0 *
Guidelines for Writing Inlined S-Functions

- Consider using the block property `RTWdata` (see “S-Function RTWdata” (Simulink Coder)). This property is a structure of character vectors that you can associate with a block. The code generator saves the structure with the model in the `model.rtw` file and makes the `.rtw` file more readable. For example, suppose you enter the following commands in the MATLAB Command Window:
  ```matlab
  mydata.field1 = 'information for field1';
  mydata.field2 = 'information for field2';
  set_param(sfun_block, 'RTWdata', mydata);
  
  The `.rtw` file that the code generator produces for the block includes the comments specified in the structure `mydata`.
- Consider using the `mdlRTW` function to inline your C MEX S-function in the generated code. This is useful when you want to
  - Rename tunable parameters in the generated code
  - Introduce nontunable parameters into a TLC file

S-Functions That Support Expression Folding

- “About S-Functions that Support Expression Folding” on page 11-87
- “Categories of Output Expressions” on page 11-88
- “Acceptance or Denial of Requests for Input Expressions” on page 11-93
- “Expression Folding in a TLC Block Implementation” on page 11-95

About S-Functions that Support Expression Folding

This topic describes how you can take advantage of expression folding to increase the efficiency of code generated by your own inlined S-Function blocks, by calling macros provided in the S-Function API. This topic assumes that you are familiar with:

- Writing inlined S-functions (see “S-Function Basics” (Simulink)).
- “Target Language Compiler” (Simulink Coder)
The S-Function API lets you specify whether a given S-Function block should nominally accept expressions at a given input port. A block should not always accept expressions. For example, if the address of the signal at the input is used, expressions should not be accepted at that input, because it is not possible to take the address of an expression.

The S-Function API also lets you specify whether an expression can represent the computations associated with a given output port. When you request an expression at a block's input or output port, the Simulink engine determines whether or not it can honor that request, given the block's context. For example, the engine might deny a block's request to output an expression if the destination block does not accept expressions at its input, if the destination block has an update function, or if multiple output destinations exist.

The decision to honor or deny a request to output an expression can also depend on the category of output expression the block uses (see “Categories of Output Expressions” on page 11-88).

The topics that follow explain

- When and how you can request that a block accept expressions at an input port
- When and how you can request that a block generate expressions at an output port
- The conditions under which the Simulink engine will honor or deny such requests

To take advantage of expression folding in your S-functions, you should understand when to request acceptance and generation of expressions for specific blocks. You do not have to understand the algorithm by which the Simulink engine chooses to accept or deny these requests. However, if you want to trace between the model and the generated code, it is helpful to understand some of the more common situations that lead to denial of a request.

**Categories of Output Expressions**

When you implement a C MEX S-function, you can specify whether the code corresponding to a block's output is to be generated as an expression. If the block generates an expression, you must specify that the expression is *constant*, *trivial*, or *generic*.

A *constant* output expression is a direct access to one of the block's parameters. For example, the output of a Constant block is defined as a constant expression because the output expression is simply a direct access to the block's *Value* parameter.
A trivial output expression is an expression that can be repeated, without a performance penalty, when the output port has multiple output destinations. For example, the output of a Unit Delay block is defined as a trivial expression because the output expression is simply a direct access to the block’s state. Because the output expression does not have computations, it can be repeated more than once without degrading the performance of the generated code.

A generic output expression is an expression that should be assumed to have a performance penalty if repeated. As such, a generic output expression is not suitable for repeating when the output port has multiple output destinations. For instance, the output of a Sum block is a generic rather than a trivial expression because it is costly to recompute a Sum block output expression as an input to multiple blocks.

**Examples of Trivial and Generic Output Expressions**

Consider the following block diagram. The Delay block has multiple destinations, yet its output is designated as a trivial output expression, so that it can be used more than once without degrading the efficiency of the code.

The following code excerpt shows code generated from the Unit Delay block in this block diagram. The three root outputs are directly assigned from the state of the Unit Delay block, which is stored in a field of the global data structure `rtDWork`. Since the assignment is direct, without expressions, there is no performance penalty associated with using the trivial expression for multiple destinations.

```c
void MdlOutputs(int_T tid)
{
    ... /* Outport: <Root>/Out1 incorporates:
        * UnitDelay: <Root>/Unit Delay */
    rtY.Out1 = rtDWork.Unit_Delay_DSTATE;
}  
```

11-89
On the other hand, consider the Sum blocks in the following model:

The upper Sum block in the preceding model generates the signal labeled `non_triv`. Computation of this output signal involves two multiplications and an addition. If the Sum block’s output were permitted to generate an expression even when the block had multiple destinations, the block’s operations would be duplicated in the generated code. In the case illustrated, the generated expressions would proliferate to four multiplications and two additions. This would degrade the efficiency of the program. Accordingly the output of the Sum block is not allowed to be an expression because it has multiple destinations.

The code generated for the previous block diagram shows how code is generated for Sum blocks with single and multiple destinations.

The Simulink engine does not permit the output of the upper Sum block to be an expression because the signal `non_triv` is routed to two output destinations. Instead, the result of the multiplication and addition operations is stored in a temporary variable (`rtb_non_triv`) that is referenced twice in the statements that follow, as seen in the code excerpt below.
In contrast, the lower Sum block, which has only a single output destination (Out2), does generate an expression.

```c
void MdlOutputs(int_T tid)
{
    /* local block i/o variables */
    real_T rtb_non_triv;
    real_T rtb_Sine_Wave;

    /* Sum: <Root>/Sum incorporates:
     *   Gain: <Root>/Gain
     *   Inport: <Root>/u1
     *   Gain: <Root>/Gain1
     *   Inport: <Root>/u2
     *
     * Regarding <Root>/Gain:
     *   Gain value: rtP.Gain_Gain
     *   Gain value: rtP.Gain1_Gain
     */
    rtb_non_triv = (rtP.Gain_Gain * rtU.u1) + (rtP.Gain1_Gain * rtU.u2);

    /* Outport: <Root>/Out1 */
    rtY.Out1 = rtb_non_triv;

    /* Sin Block: <Root>/Sine Wave */
    rtb_Sine_Wave = rtP.Sine_Wave_Amp *
        sin(rtP.Sine_Wave_Freq * rtmGetT(rtM_model) +
        rtP.Sine_Wave_Phase) + rtP.Sine_Wave_Bias;

    /* Outport: <Root>/Out2 incorporates:
     *   Sum: <Root>/Sum1
     */
    rtY.Out2 = (rtb_non_triv + rtb_Sine_Wave);
}
```

**Specify the Category of an Output Expression**

The S-Function API provides macros that let you declare whether an output of a block should be an expression, and if so, to specify the category of the expression. The following table specifies when to declare a block output to be a constant, trivial, or generic output expression.
Types of Output Expressions

<table>
<thead>
<tr>
<th>Category of Expression</th>
<th>When to Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>Constant</td>
<td>Use only if block output is a direct memory access to a block parameter.</td>
</tr>
<tr>
<td>Trivial</td>
<td>Use only if block output is an expression that can appear multiple times in the code without reducing efficiency (for example, a direct memory access to a field of the DWork vector, or a literal).</td>
</tr>
<tr>
<td>Generic</td>
<td>Use if output is an expression, but not constant or trivial.</td>
</tr>
</tbody>
</table>

You must declare outputs as expressions in the `mdlSetWorkWidths` function using macros defined in the S-Function API. The macros have the following arguments:

- `SimStruct *S`: pointer to the block's `SimStruct`.
- `int idx`: zero-based index of the output port.
- `bool value`: pass in `TRUE` if the port generates output expressions.

The following macros are available for setting an output to be a constant, trivial, or generic expression:

- `void ssSetOutputPortConstOutputExprInRTW(SimStruct *S, int idx, bool value)`
- `void ssSetOutputPortTrivialOutputExprInRTW(SimStruct *S, int idx, bool value)`
- `void ssSetOutputPortOutputExprInRTW(SimStruct *S, int idx, bool value)`

The following macros are available for querying the status set by prior calls to the macros above:

- `bool ssGetOutputPortConstOutputExprInRTW(SimStruct *S, int idx)`
- `bool ssGetOutputPortTrivialOutputExprInRTW(SimStruct *S, int idx)`
- `bool ssGetOutputPortOutputExprInRTW(SimStruct *S, int idx)`

The set of generic expressions is a superset of the set of trivial expressions, and the set of trivial expressions is a superset of the set of constant expressions.

Therefore, when you query an output that has been set to be a constant expression with `ssGetOutputPortTrivialOutputExprInRTW`, it returns `True`. A constant expression
is considered a trivial expression, because it is a direct memory access that can be repeated without degrading the efficiency of the generated code.

Similarly, an output that has been configured to be a constant or trivial expression returns True when queried for its status as a generic expression.

**Acceptance or Denial of Requests for Input Expressions**

A block can request that its output be represented in code as an expression. Such a request can be denied if the destination block cannot accept expressions at its input port. Furthermore, conditions independent of the requesting block and its destination blocks can prevent acceptance of expressions.

This topic discusses block-specific conditions under which requests for input expressions are denied. For information on other conditions that prevent acceptance of expressions, see “Denial of Block Requests to Output Expressions” on page 11-94.

A block should not be configured to accept expressions at its input port under the following conditions:

- The block must take the address of its input data. It is not possible to take the address of most types of input expressions.
- The code generated for the block references the input more than once (for example, the Abs or Max blocks). This would lead to duplication of a potentially complex expression and a subsequent degradation of code efficiency.

If a block refuses to accept expressions at an input port, then a block that is connected to that input port is not permitted to output a generic or trivial expression.

A request to output a constant expression is not denied, because there is no performance penalty for a constant expression, and the software can take the parameter’s address.

**S-Function API to Specify Input Expression Acceptance**

The S-Function API provides macros that let you:

- Specify whether a block input should accept nonconstant expressions (that is, trivial or generic expressions)
- Query whether a block input accepts nonconstant expressions

By default, block inputs do not accept nonconstant expressions.
You should call the macros in your `mdlSetWorkWidths` function. The macros have the following arguments:

- `SimStruct *S`: pointer to the block's SimStruct.
- `int idx`: zero-based index of the input port.
- `bool value`: pass in TRUE if the port accepts input expressions; otherwise pass in FALSE.

The macro available for specifying whether or not a block input should accept a nonconstant expression is as follows:

```c
void ssSetInputPortAcceptExprInRTW(SimStruct *S, int portIdx, bool value)
```

The corresponding macro available for querying the status set by any prior calls to `ssSetInputPortAcceptExprInRTW` is as follows:

```c
bool ssGetInputPortAcceptExprInRTW(SimStruct *S, int portIdx)
```

**Denial of Block Requests to Output Expressions**

Even after a specific block requests that it be allowed to generate an output expression, that request can be denied for generic reasons. These reasons include, but are not limited to

- The output expression is nontrivial, and the output has multiple destinations.
- The output expression is nonconstant, and the output is connected to at least one destination that does not accept expressions at its input port.
- The output is a test point.
- The output has been assigned an external storage class.
- The output must be stored using global data (for example is an input to a merge block or a block with states).
- The output signal is complex.

You do not need to consider these generic factors when deciding whether or not to utilize expression folding for a particular block. However, these rules can be helpful when you are examining generated code and analyzing cases where the expression folding optimization is suppressed.
Expression Folding in a TLC Block Implementation

To take advantage of expression folding, you must modify the TLC block implementation of an inlined S-Function such that it informs the Simulink engine whether it generates or accepts expressions at its

- Input ports, as explained in “S-Function API to Specify Input Expression Acceptance” on page 11-93.
- Output ports, as explained in “Categories of Output Expressions” on page 11-88.

This topic discusses required modifications to the TLC implementation.

Expression Folding Compliance

In the `BlockInstanceSetup` function of your S-function, register your block to be compliant with expression folding. Otherwise, expression folding requested or allowed at the block's outputs or inputs will be disabled, and temporary variables will be used.

To register expression folding compliance, call the TLC library function `LibBlockSetIsExpressionCompliant(block)`, which is defined in `matlabroot/rtw/c/tlc/lib/utillib.tlc`. For example:

```matlab
%% Function: BlockInstanceSetup ===========================================
%%
%function BlockInstanceSetup(block, system) void
%%
 ;%<LibBlockSetIsExpressionCompliant(block)>
%
%endfunction
```

You can conditionally disable expression folding at the inputs and outputs of a block by making the call to this function conditionally.

If you override one of the TLC block implementations provided by the code generator with your own implementation, you should not make the preceding call until you have updated your implementation, as described by the guidelines for expression folding in the following topics.

Output Expressions

The `BlockOutputSignal` function is used to generate code for a scalar output expression or one element of a nonscalar output expression. If your block outputs an expression, you should add a `BlockOutputSignal` function. The prototype of the `BlockOutputSignal` is

```matlab
%function BlockOutputSignal(block, system, portIdx, ucv, lcv, idx, retType) void
```
The arguments to BlockOutputSignal are as follows:

- **block**: the record for the block for which an output expression is being generated
- **system**: the record for the system containing the block
- **portIdx**: zero-based index of the output port for which an expression is being generated
- **ucv**: user control variable defining the output element for which code is being generated
- **lcv**: loop control variable defining the output element for which code is being generated
- **idx**: signal index defining the output element for which code is being generated
- **retType**: character vector defining the type of signal access desired:
  - "Signal" specifies the contents or address of the output signal.
  - "SignalAddr" specifies the address of the output signal

The BlockOutputSignal function returns a character vector for the output signal or address. The character vector should enforce the precedence of the expression by using opening and terminating parentheses, unless the expression consists of a function call. The address of an expression can only be returned for a constant expression; it is the address of the parameter whose memory is being accessed. The code implementing the BlockOutputSignal function for the Constant block is shown below.

```matlab
%% Function: BlockOutputSignal
function BlockOutputSignal(block,system,portIdx,ucv,lcv,idx,retType) void
switch retType
    case "Signal"
        return LibBlockParameter(Value,ucv,lcv,idx)
    case "SignalAddr"
        return LibBlockParameterAddr(Value,ucv,lcv,idx)
    default
        assign errTxt = "Unsupported return type: %<retType>"
        <LibBlockReportError(block,errTxt)>
endswitch
endfunction
```

The code implementing the BlockOutputSignal function for the Relational Operator block is shown below.

```matlab
%% Function: BlockOutputSignal
function BlockOutputSignal = BlockOutputSignal(block,system,portIdx,ucv,lcv,idx,retType) void
switch retType
    case "Signal"
        return LibBlockParameter(Value,ucv,lcv,idx)
    case "SignalAddr"
        return LibBlockParameterAddr(Value,ucv,lcv,idx)
    default
        assign errTxt = "Unsupported return type: %<retType>"
        <LibBlockReportError(block,errTxt)>
endswitch
endfunction
```

The code implementing the BlockOutputSignal function for the Relational Operator block is shown below.

```matlab
%% Function: BlockOutputSignal
function BlockOutputSignal = BlockOutputSignal(block,system,portIdx,ucv,lcv,idx,retType) void
switch retType
    case "Signal"
        return LibBlockParameter(Value,ucv,lcv,idx)
    case "SignalAddr"
        return LibBlockParameterAddr(Value,ucv,lcv,idx)
    default
        assign errTxt = "Unsupported return type: %<retType>"
        <LibBlockReportError(block,errTxt)>
endswitch
endfunction
```
%% Return an output expression. This function *may*
%% be used by Simulink when optimizing the Block IO data structure.
%function BlockOutputSignal(block,system,portIdx,ucv,lcv,idx,retType) void
%switch retType
%case "Signal"
%assign logicOperator = ParamSettings.Operator
%if ISEQUAL(logicOperator, "--")
%assign op = "=="
elseif ISEQUAL(logicOperator, "==") %assign op = "=="
%else
%assign op = logicOperator
%endif
%assign u0 = LibBlockInputSignal(0, ucv, lcv, idx)
%assign u1 = LibBlockInputSignal(1, ucv, lcv, idx)
%return "(%<u0> %<op> %<u1>)"
%default
%assign errTxt = "Unsupported return type: %<retType>"
%<LibBlockReportError(block,errTxt)>
%endswitch
%endfunction

**Expression Folding for Blocks with Multiple Outputs**

When a block has a single output, the `Outputs` function in the block's TLC file is called only if the output port is not an expression. Otherwise, the `BlockOutputSignal` function is called.

If a block has multiple outputs, the `Outputs` function is called if any output port is not an expression. The `Outputs` function should guard against generating code for output ports that are expressions. This is achieved by guarding sections of code corresponding to individual output ports with calls to `LibBlockOutputSignalIsExpr()`.

For example, consider an S-Function with two inputs and two outputs, where

- The first output, y0, is equal to two times the first input.
- The second output, y1, is equal to four times the second input.

The `Outputs` and `BlockOutputSignal` functions for the S-function are shown in the following code excerpt.

```matlab
%% Function: BlockOutputSignal
%function BlockOutputSignal(block,system,portIdx,ucv,lcv,idx,retType) void
%switch retType
%case "Signal"
%assign u = LibBlockInputSignal(portIdx, ucv, lcv, idx)
```

11-97
%case "Signal"
%if portIdx == 0
%return "(2 * %<u>)"
%elseif portIdx == 1
%return "(4 * %<u>)"
%endif
%default
%assign errTxt = "Unsupported return type: %<retType>"
%<LibBlockReportError(block,errTxt)>
%endswitch
%endfunction

%% Function: Outputs ==============================================================
%% Abstract:
%%      Compute output signals of block
%%
%%function Outputs(block,system) Output
%assign rollVars = ["U", "Y"]
%roll sigIdx = RollRegions, lcv = RollThreshold, block, "Roller", rollVars
%assign u0 = LibBlockInputSignal(0, "", lcv, sigIdx)
%assign u1 = LibBlockInputSignal(1, "", lcv, sigIdx)
%assign y0 = LibBlockOutputSignal(0, "", lcv, sigIdx)
%assign y1 = LibBlockOutputSignal(1, "", lcv, sigIdx)
%if !LibBlockOutputSignalIsExpr(0)
<y0> = 2 * %<u0>;
%endif
%if !LibBlockOutputSignalIsExpr(1)
<y1> = 4 * %<u1>;
%endif
%endroll
%endfunction

Comments for Blocks That Are Expression-Folding-Compliant

In the past, blocks preceded their outputs code with comments of the form

/* %<Type> Block: %<Name> */

When a block is expression-folding-compliant, the initial line shown above is generated automatically. You should not include the comment as part of the block's TLC implementation. Additional information should be registered using the LibCacheBlockComment function.

The LibCacheBlockComment function takes a character vector as an input, defining the body of the comment, except for the opening header, the final newline of a single or multiline comment, and the closing trailer.

The following TLC code illustrates registering a block comment. Note the use of the function LibBlockParameterForComment, which returns a character vector, suitable for a block comment, specifying the value of the block parameter.
S-Functions That Specify Port Scope and Reusability

You can use the following SimStruct macros in the mdlInitializeSizes method to specify the scope and reusability of the memory used for your S-function's input and output ports:

- `ssSetInputPortOptimOpts`: Specify the scope and reusability of the memory allocated to an S-function input port
- `ssSetOutputPortOptimOpts`: Specify the scope and reusability of the memory allocated to an S-function output port
- `ssSetInputPortOverWritable`: Specify whether one of your S-function's input ports can be overwritten by one of its output ports
- `ssSetOutputPortOverwritesInputPort`: Specify whether an output port can share its memory buffer with an input port

You declare an input or output as local or global, and indicate its reusability, by passing one of the following four options to the `ssSetInputPortOptimOpts` and `ssSetOutputPortOptimOpts` macros:

- `SS_NOT_REUSABLE_AND_GLOBAL`: Indicates that the input and output ports are stored in separate memory locations in the global block input and output structure
- `SS_NOT_REUSABLE_AND_LOCAL`: Indicates that the code generator can declare individual local variables for the input and output ports
- `SS_REUSABLE_AND_LOCAL`: Indicates that the code generator can reuse a single local variable for these input and output ports
- `SS_REUSABLE_AND_GLOBAL`: Indicates that these input and output ports are stored in a single element in the global block input and output structure

**Note** Marking an input or output port as a local variable does not imply that the code generator uses a local variable in the generated code. If your S-function accesses the inputs and outputs only in its mdlOutputs routine, the code generator declares the inputs and outputs as local variables. However, if the inputs and outputs are used elsewhere in the S-function, the code generator includes them in the global block input and output structure.
The reusability setting indicates if the memory associated with an input or output port can be overwritten. To reuse input and output port memory:

1. Indicate the ports are reusable using either the SS_REUSABLE_AND_LOCAL or SS_REUSABLE_AND_GLOBAL option in the ssSetInputPortOptimOpts and ssSetOutputPortOptimOpts macros.
2. Indicate the input port memory is overwritable using ssSetInputPortOverWritable.
3. If your S-function has multiple input and output ports, use ssSetOutputPortOverwritesInputPort to indicate which output and input ports share memory.

The following example shows how different scope and reusability settings affect the generated code. The following model contains an S-function block pointing to the C MEX S-function `matlabroot/toolbox/simulink/sidemos/simfeatures/src/sfun_directlook.c`, which models a direct 1-D lookup table.

![Model diagram](image)

The S-function's `mdlInitializeSizes` method declares the input port as reusable, local, and overwritable and the output port as reusable and local, as follows:

```c
static void mdlInitializeSizes(SimStruct *S)
{
    /* snip */
    ssSetInputPortOptimOpts(S, 0, SS_REUSABLE_AND_LOCAL);
    ssSetInputPortOverWritable(S, 0, TRUE);

    /* snip */
    ssSetOutputPortOptimOpts(S, 0, SS_REUSABLE_AND_LOCAL);

    /* snip */
}
```

The generated code for this model stores the input and output signals in a single local variable `rtb_SFunction`, as shown in the following output function:

```c
static void sl_directlook_output(int_T tid)
{
    /* local block i/o variables */
    real_T rtb_SFunction[2];
    /* snip */
}
```
/* Sin: '<Root>/Sine Wave' */
rtb_SFunction[0] = sin(((real_T)sl_directlook_DWork.counter[0] + 
    sl_directlook_P.SineWave_Offset) * 2.0 * 3.1415926535897931E+000 / 
    sl_directlook_P.SineWave_NumSamp) * sl_directlook_P.SineWave_Amp[0] + 
    sl_directlook_P.SineWave_Bias;
rtb_SFunction[1] = sin(((real_T)sl_directlook_DWork.counter[1] + 
    sl_directlook_P.SineWave_Offset) * 2.0 * 3.1415926535897931E+000 / 
    sl_directlook_P.SineWave_NumSamp) * sl_directlook_P.SineWave_Amp[1] + 
    sl_directlook_P.SineWave_Bias;

/* S-Function Block: <Root>/S-Function */
{ 
    const real_T *xData = &sl_directlook_P.SFunction_XData[0]; 
    const real_T *yData = &sl_directlook_P.SFunction_YData[0]; 
    real_T spacing = xData[1] - xData[0]; 
    if (rtb_SFunction[0] <= xData[0]) { 
        rtb_SFunction[0] = yData[0]; 
    } else if (rtb_SFunction[0] >= yData[20]) { 
        rtb_SFunction[0] = yData[20]; 
    } else { 
        int_T idx = (int_T)( (rtb_SFunction[0] - xData[0]) / spacing ); 
        rtb_SFunction[0] = yData[idx]; 
    }

    if (rtb_SFunction[1] <= xData[0]) { 
        rtb_SFunction[1] = yData[0]; 
    } else if (rtb_SFunction[1] >= yData[20]) { 
        rtb_SFunction[1] = yData[20]; 
    } else { 
        int_T idx = (int_T)( (rtb_SFunction[1] - xData[0]) / spacing ); 
        rtb_SFunction[1] = yData[idx]; 
    }
}

/* Outport: '<Root>/Out1' */
sl_directlook_Y.Out1[0] = rtb_SFunction[0];
sl_directlook_Y.Out1[1] = rtb_SFunction[1];
UNUSED_PARAMETER(tid);
}

The following table shows variations of the code generated for this model when using the generic real-time target (GRT). Each row explains a different setting for the scope and reusability of the S-function's input and output ports.
<table>

### S-Functions That Specify Sample Time Inheritance Rules

For the Simulink engine to determine whether a model can inherit a sample time, the S-functions in the model need to specify how they use sample times. You can specify this information by calling the macro `ssSetModelReferenceSampleTimeInheritanceRule` from `mdlInitializeSizes` or `mdlSetWorkWidths`. To use this macro:

1. Check whether the S-function calls any of the following macros:

   - `ssGetSampleTime`
   - `ssGetInputPortSampleTime`
   - `ssGetOutputPortSampleTime`
   - `ssGetInputPortOffsetTime`
   - `ssGetOutputPortOffsetTime`
   - `ssGetSampleTimePtr`

<table>
<thead>
<tr>
<th>Scope and reusability</th>
<th>S-function <code>mdlInitializeSizes</code> code</th>
<th>Generated code</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Inputs:</strong> Global, not reusable</td>
<td></td>
<td>The model.h file defines a block signal structure with individual elements to store the S-function's input and output.</td>
</tr>
<tr>
<td><strong>Outputs:</strong> Global, not reusable</td>
<td><code>ssSetInputPortOptimOpts(S, 0, SS_NOT_REUSABLE_AND_GLOBAL);</code>&lt;br&gt;<code>ssSetInputPortOverWritable(S, 0, FALSE);</code>&lt;br&gt;<code>ssSetOutputPortOptimOpts(S, 0, SS_NOT_REUSABLE_AND_GLOBAL);</code></td>
<td>The model.c file uses the different elements in this structure when calculating the S-function's input and output.</td>
</tr>
</tbody>
</table>

```c
/* Block signals (auto storage) */
typedef struct {
    real_T SineWave[2];
    real_T SFunction[2];
} BlockIO_sl_directlook;

/* Sin: '<Root>/Sine Wave' */
sl_directlook_B.SineWave[0] = sin ...
/* snip */
/*S-Function Block:<Root>/S-Function*/
{
    const real_T *xData =
        &sl_directlook_P.SFunction_XData[0]
```
Check for the following in your S-function TLC code:

- `ssGetInputPortSampleTimeIndex`
- `ssGetOutputPortSampleTimeIndex`
- `ssGetSampleTimeTaskID`
- `ssGetSampleTimeTaskIDPtr`

Depending on your search results, use `ssSetModelReferenceSampleTimeInheritanceRule` as indicated in the following table.

<table>
<thead>
<tr>
<th>If...</th>
<th>Use...</th>
</tr>
</thead>
<tbody>
<tr>
<td>None of the macros or functions are present, the S-function does not preclude the model from inheriting a sample time.</td>
<td><code>ssSetModelReferenceSampleTimeInheritanceRule (S, USE_DEFAULT_FOR_DISCRETE_INHERITANCE)</code></td>
</tr>
<tr>
<td>Any of the macros or functions are used for</td>
<td><code>ssSetModelReferenceSampleTimeInheritanceRule (S, USE_DEFAULT_FOR_DISCRETE_INHERITANCE)</code></td>
</tr>
<tr>
<td>• Throwing errors if sample time is inherited, continuous, or constant</td>
<td></td>
</tr>
<tr>
<td>• Checking <code>ssIsSampleHit</code></td>
<td></td>
</tr>
<tr>
<td>• Checking whether sample time is inherited in either mdlSetInputPortSampleTime or mdlSetOutputPortSampleTime before setting</td>
<td></td>
</tr>
</tbody>
</table>
If... | Use...
---|---
The S-function uses its sample time for computing parameters, outputs, and so on | `ssSetModelReferenceSampleTimeInheritanceRule(S, DISALLOW_SAMPLE_TIME_INHERITANCE)`

**Note** If an S-function does not set the `ssSetModelReferenceSampleTimeInheritanceRule` macro, by default the Simulink engine assumes that the S-function does not preclude the model containing that S-function from inheriting a sample time. However, the engine issues a warning indicating that the model includes S-functions for which this macro is not set.

You can use settings on **Configuration Parameters > Diagnostics > Advanced parameters** to control how the Simulink engine responds when it encounters S-functions that have unspecified sample time inheritance rules. Toggle the **Configuration Parameters > Diagnostics > Sample Time > Unspecified inheritability of sample time** diagnostic to none, warning, or error. The default is warning.

### S-Functions That Support Code Reuse

You can reuse the generated code for identical subsystems that occur in multiple instances within a model and across referenced models. For more information about code generation of subsystems for code reuse, see “Control Generation of Subsystem Functions” (Simulink Coder). If you want your S-function to support code reuse for a subsystem, the S-function must meet the following requirements:

- The S-function must be inlined.
- Code generated from the S-function must not use static variables.
- The S-function must initialize its pointer work vector in `mdlStart` and not before.
- The S-function must not be a sink that logs data to the workspace.
- The S-function must register its parameters as run-time parameters in `mdlSetWorkWidths`. (It must not use `ssWriteRTWParameters` in its `mdlRTW` function for this purpose.)
- The S-function must not be a device driver.

In addition to meeting the preceding requirements, your S-function must set the `SS_OPTION_WORKS_WITH_CODE_REUSE` flag (see the description of `ssSetOptions` in... 11-105
the Simulink Writing S-Function documentation). This flag indicates that your S-function meets the requirements for subsystem code reuse.

S-Functions for Multirate Multitasking Environments

• “About S-Functions for Multirate Multitasking Environments” on page 11-106
• “Rate Grouping Support in S-Functions” on page 11-106
• “Create Multitasking, Multirate, Port-Based Sample Time S-Functions” on page 11-107

About S-Functions for Multirate Multitasking Environments

S-functions can be used in models with multiple sample rates and deployed in multitasking target environments. Likewise, S-functions themselves can have multiple rates at which they operate. The code generator produces code for multirate multitasking models using an approach called rate grouping. In code generated for ERT-based targets, rate grouping generates separate model_step functions for the base rate task and each subrate task in the model. Although rate grouping is a code generation feature found in ERT targets only, your S-functions can use it in other contexts when you code them as explained below.

Rate Grouping Support in S-Functions

To take advantage of rate grouping, you must inline your multirate S-functions if you have not done so. You need to follow certain Target Language Compiler protocols to exploit rate grouping. Coding TLC to exploit rate grouping does not prevent your inlined S-functions from functioning properly in GRT. Likewise, your inlined S-functions will still generate valid ERT code even if you do not make them rate-grouping-compliant. If you do so, however, they will generate more efficient code for multirate models.

For instructions and examples of Target Language Compiler code illustrating how to create and upgrade S-functions to generate rate-grouping-compliant code, see “Rate Grouping Compliance and Compatibility Issues” on page 52-17.

For each multirate S-function that is not rate grouping-compliant, the code generator issues the following warning when you build:

Warning: Simulink Coder: Code of output function for multirate block '<Root>/S-Function' is guarded by sample hit checks rather than being rate grouped. This will generate the same code for all rates used by the block, possibly generating dead code. To avoid dead code, you must update the TLC file for the block.
You will also find a comment such as the following in code generated for each noncompliant S-function:

```c
/* Because the output function of multirate block
<Root>/S-Function is not rate grouped,
the following code might contain unreachable blocks of code.
To avoid this, you must update your block TLC file. */
```

The words “update function” are substituted for “output function” in these warnings.

**Create Multitasking, Multirate, Port-Based Sample Time S-Functions**

The following instructions show how to support both data determinism and data integrity in multirate S-functions. They do not cover cases where there is no determinism nor integrity. Support for frame-based processing does not affect the requirements.

**Note** The slow rates must be multiples of the fastest rate. The instructions do not apply when two rates being interfaced are not multiples or when the rates are not periodic.

**Rules for Properly Handling Fast-to-Slow Transitions**

The rules that multirate S-functions should observe for inputs are

- The input should only be read at the rate that is associated with the input port sample time.
- Generally, the input data is written to `DWork`, and the `DWork` can then be accessed at the slower (downstream) rate.

The input can be read at every sample hit of the input rate and written into `DWork` memory, but this `DWork` memory cannot then be directly accessed by the slower rate. `DWork` memory that will be read by the slow rate must only be written by the fast rate when there is a *special sample hit*. A special sample hit occurs when both this input port rate and rate to which it is interfacing have a hit. Depending on their requirements and design, algorithms can process the data in several locations.

The rules that multirate S-functions should observe for outputs are

- The output should not be written by a rate other than the rate assigned to the output port, except in the optimized case described below.
- The output should always be written when the sample rate of the output port has a hit.
If these conditions are met, the S-Function block can specify that the input port and output port can both be made local and reusable.

You can include an optimization when little or no processing needs to be done on the data. In such cases, the input rate code can directly write to the output (instead of by using DWork) when there is a special sample hit. If you do this, however, you must declare the outport port to be *global* and *not reusable*. This optimization results in one less memcpy but does introduce nonuniform processing requirements on the faster rate.

Whether you use this optimization or not, the most recent input data, as seen by the slower rate, is the value when both the faster and slower rate had their hits (and possible earlier input data as well, depending on the algorithm). Subsequent steps by the faster rate and the associated input data updates are not seen by the slower rate until the next hit for the slow rate occurs.

**Pseudocode Examples of Fast-to-Slow Rate Transition**

The pseudocode below abstracts how you should write your C MEX code to handle fast-to-slow transitions, illustrating with an input rate of 0.1 second driving an output rate of one second. A similar approach can be taken when inlining the code. The block has following characteristics:

- File: `sfun_multirate_zoh.c`, Equation: \( y = u(t_{slow}) \)
- Input: local and reusable
- Output: local and reusable
- DirectFeedthrough: yes

```c
OutputFcn  
if (ssIsSampleHit(".1")) {  
   if (ssIsSepcialSampleHit("1")) {  
      DWork = u;  
   }  
}  
if (ssIsSampleHit("1")) {  
   y = DWork;  
}
```

An alternative, slightly optimized approach for simple algorithms:

- Input: local and reusable
- Output: global and not reusable because it needs to persist between special sample hits
- DirectFeedthrough: yes
Example adding a simple algorithm:

- File: `sfun_multirate_avg.c`; Equation: $y = \text{average}(u)$
- Input: local and reusable
- Output: local and reusable
- DirectFeedthrough: yes

(Assume `DWork[0:10]` and `DWork[mycounter]` are initialized to zero)

```
OutputFcn
if (ssIsSampleHit(".1")) {
    /* In general, processing on 'u' could be done here, 
       it runs on every hit of the fast rate. */
    DWork[DWork[mycounter]++] = u;
    if (ssIsSpecialSampleHit("1")) {
        /* In general, processing on DWork[0:10] can be done 
           here, but it does cause the faster rate to have 
           nonuniform processing requirements (every 10th hit, 
           more code needs to be run). */
        DWork[10] = sum(DWork[0:9])/10;
        DWork[mycounter] = 0;
    }
}
if (ssIsSampleHit("1")) {
    /* Processing on DWork[10] can be done here before 
        outputing. This code runs on every hit of the 
        slower task. */
    y = DWork[10];
}
```

**Rules for Properly Handling Slow-to-Fast Transitions**

When output rates are faster than input rates, input should only be read at the rate that is associated with the input port sample time, observing the following rules:

- Always read input from the update function.
- Use no special sample hit checks when reading input.
- Write the input to a DWork.
- When there is a special sample hit between the rates, copy the DWork into a second DWork in the output function.
• Write the second DWork to the output at every hit of the output sample rate.

The block can request that the input port be made local but it cannot be set to reusable. The output port can be set to local and reusable.

As in the fast-to-slow transition case, the input should not be read by a rate other than the one assigned to the input port. Similarly, the output should not be written to at a rate other than the rate assigned to the output port.

An optimization can be made when the algorithm being implemented is only required to run at the slow rate. In such cases, you use only one DWork. The input still writes to the DWork in the update function. When there is a special sample hit between the rates, the output function copies the same DWork directly to the output. You must set the output port to be global and not reusable in this case. This optimization results in one less memcpy operation per special sample hit.

In either case, the data that the fast rate computations operate on is always delayed, that is, the data is from the previous step of the slow rate code.

**Pseudocode Examples of Slow-to-Fast Rate Transition**

The pseudocode below abstracts what your S-function needs to do to handle slow-to-fast transitions, illustrating with an input rate of one second driving an output rate of 0.1 second. The block has following characteristics:

• File: `sfun_multirate_delay.c`, Equation: \( y = u(t_{slow} - 1) \)
• Input: Set to local, will be local if output/update are combined (ERT) otherwise will be global. Set to not reusable because input needs to be preserved until the update function runs.
• Output: local and reusable
• DirectFeedthrough: no

```c
OutputFcn
if (ssIsSampleHit(".1") {
   if (ssIsSpecialSampleHit("1") {
      DWork[1] = DWork[0];
   }
   y = DWork[1];
}
UpdateFcn
if (ssIsSampleHit("1")) {
   DWork[0] = u;
}
```

An alternative, optimized approach can be used by some algorithms:
• Input: Set to local, will be local if output/update are combined (ERT) otherwise will be global. Set to not reusable because input needs to be preserved until the update function runs.

• Output: global and not reusable because it needs to persist between special sample hits.

• DirectFeedthrough: no

```matlab
OutputFcn
if (ssIsSampleHit(".1") { 
  if (ssIsSpecialSampleHit("1") { 
    y = DWork;
  }
}
UpdateFcn
if (ssIsSampleHit("1")) { 
  DWork = u;
}
```

Example adding a simple algorithm:

• File: sfun_multirate_modulate.c, Equation: \( y = \sin(t_{fast}) + u(t_{slow}-1) \)

• Input: Set to local, will be local if output/update are combined (an ERT feature) otherwise will be global. Set to not reusable because input needs to be preserved until the update function runs.

• Output: local and reusable

• DirectFeedthrough: no

```matlab
OutputFcn
if (ssIsSampleHit(".1") { 
  if (ssIsSpecialSampleHit("1") { 
    /* Processing not likely to be done here. It causes 
    * the faster rate to have nonuniform processing 
    * requirements (every 10th hit, more code needs to 
    * be run).*
    DWork[1] = DWork[0];
  }
  /* Processing done at fast rate */
  y = sin(ssGetTaskTime(".1")) + DWork[1];
}
UpdateFcn
if (ssIsSampleHit("1")) { 
  /* Processing on 'u' can be done here. There is a delay of 
  one slow rate period before the fast rate sees it.*/
  DWork[0] = u;
}
```

MAAB Guidelines

The MathWorks Automotive Advisory Board (MAAB) involves major automotive OEMs and suppliers in the process of evolving MathWorks controls, simulation, and code generation products, including Simulink, Stateflow, and Simulink Coder. An important result of the MAAB has been the “MAAB Control Algorithm Modeling” (Simulink) guidelines.

If you have a Simulink Check product license, you can check that your Simulink model or subsystem, and the code that you generate from it, complies with MAAB guidelines. To check your model or subsystem, open the Simulink Model Advisor (Simulink). Navigate to By Product > Simulink Check > Modeling Standards > MathWorks Automotive Advisory Board Checks and run the MathWorks Automotive Advisory Board checks (Simulink Check).

For more information on using the Model Advisor, see “Run Model Checks” (Simulink).
MISRA C Guidelines

The Motor Industry Software Reliability Association (MISRA\(^2\)) has established “Guidelines for the Use of the C Language in Critical Systems” (MISRA C).

For information about MISRA C, see www.misra.org.uk.

In 1998, MIRA Ltd. published MISRA C (MISRA C:1998) to provide a restricted subset of a standardized, structured language that met Safety Integrity Level (SIL) 2 and higher. A major update based on feedback was published in 2004 (MISRA C:2004), followed by a minor update in 2007 known as Technical Corrigendum (TC1).

In 2013, MIRA Ltd. published the MISRA C:2012 standard, “Guidelines for the use of the C language in critical systems.” MISRA C:2012 provides improvements based on user feedback and includes guidance on automatic code generation.

Embedded Coder and Simulink offer capabilities to minimize the potential for MISRA C rule violations.

To configure a model or subsystem so that the code generator is most likely to produce MISRA C:2012 compliant code, use the Code Generation Advisor. For more information, see “Configure Model for Code Generation Objectives by Using Code Generation Advisor” on page 32-2.

The Model Advisor (Simulink) also checks that you developed your model or subsystem to increase the likelihood of generating MISRA C:2012 compliant code. To check your model or subsystem:

1. Open the Model Advisor.
2. Navigate to **By Task > Modeling Guidelines for MISRA C:2012**.
3. Run the checks in the folder.

For more information about using the Model Advisor, see “Run Model Checks” (Simulink).

---

1. MISRA and MISRA C are registered trademarks of MIRA Ltd., held on behalf of the MISRA Consortium.
For information about using Embedded Coder software within MISRA C guidelines, see Technical Solution 1-1IFP0W on the MathWorks website.
Secure Coding Standards

These coding standards are for software developers to use in the development of code in the C language:

- CERT® C — Published by the CERT Division of the Software Engineering Institute (SEI), these guidelines help eliminate constructs with undefined behavior that can lead to unexpected results at runtime and expose security weaknesses.
- Common Weakness Enumeration (CWE™) — Published by The MITRE Corporation, this list identifies common software weakness types that can occur in software architecture, design, code, or implementation. These weaknesses can lead to security vulnerabilities.
- ISO/IEC TS 19761:2013 — Published by International Organization for Standardization and International Electrotechnical Commission, these rules are designed so that they can be enforced by static analysis tools without excessive false positives.

If you have an Embedded Coder or Simulink Check product license, you can check that your Simulink model or subsystem, and the code that you generate from it, conforms to these secure coding standards. To check your model or subsystem:

1. Open the Model Advisor.
3. Run the checks in the folder.

For more information about using the Model Advisor, see “Run Model Checks” (Simulink).

If you have a Polyspace Bug Finder product license, you can evaluate your code against these secure coding standards. For more information, see “Check C/C++ Code for Security Standards” (Polyspace Bug Finder)
IEC 61508 Standard

Apply Simulink and Embedded Coder to the IEC 61508 Standard

Applying Model-Based Design to a safety-critical system requires extra consideration and rigor so that the system adheres to defined safety standards. IEC 61508, Functional safety of electrical/electronic/programmable electronic safety related systems, is such a standard. Because the standard was published when most software was coded by hand, the standard needs to be mapped to Model-Based Design technologies. For further information about MathWorks support for IEC 61508, see IEC 61508 Support in MATLAB and Simulink.

MathWorks provides an IEC Certification Kit product that you can use to certify MathWorks code generation and verification tools for projects based on the IEC 61508 standard. For more information, see https://www.mathworks.com/products/iec-61508/.

Check for IEC 61508 Standard Compliance Using the Model Advisor

If you have a Simulink Check product license, you can check that your Simulink model or subsystem and the code that you generate from it complies with selected aspects of the IEC 61508 standard by running the Simulink Model Advisor (Simulink). Navigate to By Task > Modeling Standards for IEC 61508 and run the “IEC 61508, IEC 62304, ISO 26262, and EN 50128 Checks” (Simulink Check).

For more information on using the Model Advisor, see “Run Model Checks” (Simulink).

Validate Traceability

Typically, applications that require certification require some level of traceability between requirements, models, and corresponding code.

Develop a Model that Complies with the IEC 61508 Standard

This example shows how to use Model Advisor checks for the IEC 61508 standard to develop a model and code that comply with the standard.

The IEC 61508 checks identify issues with a model that impede deployment in safety-related applications or limit traceability.

**Understanding the Model**

According to the functional requirements, a model shall be created that checks whether the 1-norm distance between points \((x_1, x_2)\) and \((y_1, y_2)\) is less than or equal to a given threshold \(\text{thr}\). For two points \((x_1, x_2)\) and \((y_1, y_2)\), the 1-norm distance is given as:

\[
\sum_{i=1}^{2} |x_i - y_i|
\]

The `rtwdemo_iec61508` model implements the preceding requirement. Open and get familiar with the model.

```matlab
model='rtwdemo_iec61508';
open_system(model)
```
Apply the IEC 61508 Modeling Standard Checks

To deploy the model in a safety-related software component that must comply with the IEC 61508 safety standard, check the model for issues that might impede deployment in such an environment or limit traceability between the model and generated source code.

To identify possible compliance issues with the model:
1 Start the Model Advisor by selecting **Analysis > Model Advisor** or by entering `modeladvisor('rtwdemo_IEC61508')` at the MATLAB command line.

2 In the **Task Hierarchy**, expand **By Task > Modeling Standards for IEC 61508**.

3 Select the checks within the group.

4 Select **Show report after run** to generate an HTML report that shows the check results.

5 Click **Run Selected Checks**. Model Advisor processes the IEC 61508 checks and displays the results.

To review the check results and make changes:

1 Review the **Summary** in the **Report** section of the right pane.

2 In the **Task Hierarchy**, select a check that did not pass. Review the results that appear in the right pane for that check. For more information on the check and on how to resolve reported issues, with the check selected, click **Help**.

3 Click the **Generate Code Using Embedded Coder** button in the model to inspect the generated code and the traceability report.

4 Resolve the reported issues and rerun the checks.

5 Review the generated HTML report of the check results by clicking the link in the **Report** box.

6 Print the generated HTML report. You can use the report as evidence in the IEC 61508 compliance example process.

**See Also**

IEC 62304 Standard

Apply Simulink and Embedded Coder to the IEC 62304 Standard

Applying Model-Based Design to a safety-critical system requires extra consideration and rigor so that the system adheres to defined safety standards. Standard: IEC 62304, Medical device software - Software life cycle processes, is such a standard.

MathWorks provides an IEC Certification Kit product that you can use to certify MathWorks code generation and verification tools for projects based on the IEC 62304 standard. For more information, see https://www.mathworks.com/products/iec-61508/.

Check for IEC 62304 Standard Compliance Using the Model Advisor

If you have a Simulink Check product license, you can check that your Simulink model or subsystem and the code that you generate from it complies with selected aspects of the IEC 62304 standard by running the Simulink Model Advisor (Simulink). Navigate to By Task > Modeling Standards for IEC 62304 and run the “IEC 61508, IEC 62304, ISO 26262, and EN 50128 Checks” (Simulink Check).

For more information on using the Model Advisor, see “Run Model Checks” (Simulink).
ISO 26262 Standard

Apply Simulink and Embedded Coder to the DO-178C Standard

Applying Model-Based Design to a high-integrity system requires extra consideration and rigor so that the system adheres to defined safety standards. DO-178C Software Considerations in Airborne Systems and Equipment Certification is such a standard. A supplement to DO-178C, DO-331, provides guidance on the use of Model-Based Design technologies. MathWorks provides a DO Qualification Kit product that you can use to qualify MathWorks verification tools for projects based on the DO-178C, DO-331, and related standards. For more information, see https://www.mathworks.com/products/do-178/.

For information about Model-Based Design and MathWorks support of aerospace and defense industry standards, see https://www.mathworks.com/aerospace-defense/.

Check for Standard Compliance Using the Model Advisor

If you have a Simulink Check product license, you can check that your Simulink model or subsystem and the code that you generate from it complies with selected aspects of the DO-178C standard by running the Simulink Model Advisor (Simulink). Navigate to By Product > Simulink Check > Modeling Standards > DO-178C/DO-331 Checks or By Task > Modeling Standards for DO-178C/DO-331 and run the DO-178C/DO-331 checks (Simulink Check).

For more information on using the Model Advisor, see “Run Model Checks” (Simulink).

MISRA C:2012 Compliance and Deviations for Code Generated by Using Embedded Coder

- “Using This Documentation When Developing a MISRA C:2012 Compliance Statement” on page 13-2
- “Evaluate Your Generated Code for MISRA C:2012 Compliance” on page 13-4
- “Compliance Information Summary Tables” on page 13-7
- “Modeling Guidelines for MISRA C:2012 Compliance” on page 13-21
- “Deviations Rationale” on page 13-30
Using This Documentation When Developing a MISRA C: 2012 Compliance Statement

As part of the model development process, it is important that C code generated by Embedded Coder from Simulink and Stateflow complies with industry coding standards.

When using MISRA C:2012 coding guidelines to evaluate the quality of your generated C code, you are required per section 5.3 of the MISRA C:2012 Guidelines for the Use of C Language in Critical Systems document to prepare a compliance statement for the project being evaluated. To assist you in the development of this compliance statement, MathWorks evaluates the MISRA C:2012 guidelines against C code generated by using Embedded Coder and provides the following information:

- Compliance Summary Tables on page 13-7, which identify the method used to obtain compliance for each rule and directive.
- Deviations on page 13-30, which identify rules or directives that are not compliant.

For additional information about the MISRA organization, their coding guidelines, and the MISRA publication timeline, see www.misra.org.uk.

Disclaimer While adhering to the recommendations in the MISRA C:2012 Compliance and Deviations for Code Generated using Embedded Coder documentation will reduce the risk that an error is introduced during development and not be detected, it is not a guarantee that the system being developed will be safe. Conversely, if some of the recommendations are not followed, it does not mean that the system being developed will be unsafe.

MathWorks Process for Identifying Violations of MISRA C:2012 Guidelines in Generated C Code

To determine any potential violations in the generated code, MathWorks maintains an extensive set of test models that cover the standard usage of compliant blocks. For each release, MathWorks uses these test models with the following products to evaluate the modeling, code generation, and analysis of generated code.
<table>
<thead>
<tr>
<th><strong>Product</strong></th>
<th><strong>Purpose</strong></th>

<td>Identify bug/coding defects.</td>
</tr>
<tr>
<td></td>
<td>Use the Polyspace Bug Finder MISRA C:2012 Checker (Polyspace Bug Finder) to analyze the generated code against the MISRA C:2012 Directives and Rules (Polyspace Bug Finder) and provide information about violations.</td>
</tr>
<tr>
<td></td>
<td>Use the Polyspace Code Prover MISRA C:2012 checker (Polyspace Code Prover) to analyze the generated code against the MISRA C:2012 Directives and Rules (Polyspace Code Prover) and provide information about violations.</td>
</tr>
</tbody>
</table>

**Note** The compliance analysis performed by the Polyspace MISRA C:2012 Checker assesses C code generated by Embedded Coder. No assessment is made of the Embedded Coder tool chain. Handwritten C code and third-party libraries that are used with code generated by Embedded Coder are not considered. Other MISRA C code analysis tools can yield different results.

---

*a. MISRA C:2012 checks are available only when you have an Simulink Check or Embedded Coder license.*
Evaluate Your Generated Code for MISRA C:2012 Compliance

It is important to check that C code generated by Embedded Coder from Simulink and Stateflow complies with MISRA C:2012 coding standards. This workflow illustrates the process of evaluating your generated code for compliance to MISRA C:2012 guidelines.

1. Design the model in Simulink (Simulink) or Stateflow (Stateflow).
2. Open the Model Advisor (Simulink) and run the MISRA C:2012 checks (Simulink Check), which are available in By Task > Modeling Standards for MISRA C:2012.

   ![Modeling Standards for MISRA C:2012]

3. If necessary, modify the model to adhere to the “Modeling Guidelines for MISRA C: 2012 Compliance” on page 13-21.
4. After all MISRA C:2012 checks pass successfully, generate code by using Embedded Coder.

To avoid possible name clashes, multiple functions definitions, and multiple data definitions, use one of these code generation approaches:

- Single model: Generate code from a single model, including submodels, by using Model blocks.
- Multiple models: Generate code from multiple models, including:
- A shared utility folder to synchronize functions
- Data ownership to control data definitions
- Hand integration to manage code generated from various models

5 Execute the Polyspace Bug Finder MISRA C:2012 Checker (Polyspace Bug Finder).

For more information about running a Polyspace analysis on your generated code, including analysis options and results, see:

- Analysis of Generated Code using Polyspace Bug Finder (Polyspace Bug Finder)

6 Justify violations to the MISRA C:2012 coding standards using Polyspace annotations (Polyspace Bug Finder).
Compliance Information Summary Tables

In this section...

“Compliance Summary Tables” on page 13-7
“Explanatory Notes” on page 13-17

Compliance Summary Tables

MathWorks evaluates C code generated by Embedded Coder from Simulink and Stateflow against the MISRA C:2012 coding standards. The results from this effort are available in these compliance summary tables. These tables identify:

- Methods used to obtain compliance:
  - Compliant: Compliance to the rule/directive is achieved through adherence to the code generation process, modeling guidelines, or Model Advisor checks. When applicable, there are explanatory notes that provide information relevant to compliance methods or actions that you can perform to satisfy the directive or rule.
  - Deviation: The rule or directive is not compliant.
- Whether the Polyspace MISRA C:2012 Checker supports the rule or directive.

You can use these tables when preparing the MISRA C:2012 compliance statement for your project as required per section 5.3 of the MISRA C:2012 Guidelines for the Use of C Language in Critical Systems document. These tables align with the published MISRA C: 2012 rule and directives tables.

"Implementation" MISRA C:2012 Directives

<table>
<thead>
<tr>
<th>Directive</th>
<th>Category</th>
<th>Compliance</th>
<th>Polyspace Support?</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.1</td>
<td>Required</td>
<td>Compliant:</td>
<td></td>

<td>Yes(^a)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Check for missing error ports for AUTOSAR receiver interfaces</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Deviation:</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Deviation for AUTOSAR target-based code generator - sender ports. See “MISRA C:2012 Directive 4.7 Deviation Rationale” on page 13-30</td>
<td></td>
</tr>
<tr>
<td>4.10</td>
<td>Required</td>
<td>Compliant</td>
<td>Yes</td>
</tr>
<tr>
<td>4.11</td>
<td>Required</td>
<td>Compliant:</td>
<td>Yes</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• “Explanatory Note for Directive 4.11” on page 13-19</td>
<td></td>
</tr>
</tbody>
</table>
The Polyspace MISRA C:2012 Checker might flag Directive 4.7 as a Rule 17.7 violation for user-defined functions if there is no knowledge about whether the return value contains error information.

Explanatory Notes

These explanatory notes are referenced from the “Compliance Information Summary Tables” on page 13-7.

Explanatory Note for Directive 1.1

Information about the implementation-defined behavior for Embedded Coder is available in “Configure Run-Time Environment Options” on page 7-2. Compiler documentation is out of scope.

Character set encoding is managed by using the SavedCharacterEncoding model parameter. For additional information, including a list of supported character encodings, see slCharacterEncoding.

Configure the integer division method in the Model Configuration Parameters dialog box, on the Hardware Implementation pane. For additional information, see “Configure Run-Time Environment Options” on page 7-2.

Embedded Coder generates #pragma when the user:

- Selects the use of memory sections (Simulink Coder)
- Creates a custom storage class with memory sections on page 26-26

In both instances, you are responsible for documenting the intended use of the #pragma. For more information, see “Control Data and Function Placement in Memory by Inserting Pragmas” on page 30-2.
To enable the generation of bitfields:

1. Select at least one of these model configuration parameters:
   - Pack Boolean data into bitfields. This parameter is available only for ERT-based system target files on page 33-2.
   - Use bitsets for storing state configuration.
   - Use bitsets for storing Boolean data.

2. Create a custom storage class with defined bitfields. See “Create Custom Storage Classes by Using the Custom Storage Class Designer” on page 26-26 for more information.

**Explanatory Note for MISRA Directive 3.1**

You can link requirements model elements. These links are included in the generated C code to provide traceability from a requirements document, to the model elements, and to the generated code. For additional information, see “View Linked Requirements in Models and Blocks” (Simulink) and “Link Blocks and Requirements” (Simulink Requirements).

**Explanatory Note for Directive 4.1**

You can use Polyspace Bug Finder to identify run-time errors and Polyspace Code Prover to prove the absence of run-time errors.

For information about running an analysis, see:

- “Configure and Run Analysis” (Polyspace Code Prover)
- “Configure and Run Analysis” (Polyspace Bug Finder)

**Explanatory Note for Directive 4.3**

Embedded Coder does not directly call assembly language code. You can add calls to assembly language functions through S-functions, code replacement libraries, Stateflow, and in MATLAB blocks. These calls are documented as calls to “External C Functions” on page 14-65. In these cases, you are responsible for encapsulation.

For additional information, see:

- “External C Functions” on page 14-65
- “Code Replacement Customization”
“Control Data and Function Placement in Memory by Inserting Pragmas” on page 30-2

**Explanatory Note for Directive 4.6**

Embedded Coder replaces basic data types with typedefs types, which are compatible with Directive 4.6. A guideline is not required because this behavior is default behavior in Embedded Coder. For additional information, see “Replace and Rename Data Types to Conform to Coding Standards” on page 24-27 and Typedefs on page 14-75.

**Explanatory Note for Directive 4.11**

The requirements of this directive are satisfied by:

“Demonstrate statically that the input parameters can never take invalid values”.

You can use Polyspace Code Prover to analyze parameter ranges and prove the absence of run-time errors caused by out-of-range values. For additional information, see “Run Polyspace Analysis on Code Generated with Embedded Coder” (Polyspace Code Prover).

**Explanatory Note for Rules 5.1, 5.2, 5.4, 5.5, 5.6, 5.7, and 5.8**

Embedded Coder is configurable to limit the number of characters imposed by the implementation. For additional information, see Maximum identifier length.

To ensure unique names for different types of variables (local scope variables, global scope variables, macros, and so on), implement a naming convention. For additional information, see Model Configuration Parameters: Code Generation Symbols.

**Explanatory Note for Rule 8.12**

Embedded Coder supports the use of enumerated data. The file used to define the enumeration can be either manually or automatically generated. Files defining enumerations generated by Embedded Coder are compliant with MISRA C:2012 Rule 8.12 by design. If you manually create the definition file, you are responsible for ensuring compliance. For additional information, see “Use Enumerated Data in Simulink Models” (Simulink).

**Explanatory Note for Rules 10.1 and 10.2**

Embedded Coder does not directly create data of type char. Data of char type can be introduced by user-defined S-functions, code replacement libraries, and custom storage classes. In this case, limit the usage of plain char to:
• Plain char type for character values
• Signed and unsigned char type for numeric values
Modeling Guidelines for MISRA C:2012 Compliance

The “Compliance Information Summary Tables” on page 13-7 identifies modeling guidelines that are relevant to the compliance of generated C code with MISRA C:2012 coding standards. For a list of these guidelines and their corresponding Model Advisor check, see “High-Integrity System Modeling Guidelines for MISRA C:2012 Compliance” on page 13-21. For information about the MISRA rationale for Model Advisor checks, see “MISRA C:2012 Rationale for Model Advisor Checks” on page 13-23.

High-Integrity System Modeling Guidelines for MISRA C:2012 Compliance

To augment the modeling guidelines developed by the MathWorks Automotive Advisory Board (MAAB), MathWorks has published a set of modeling guidelines that focus on high-integrity applications.

Many high-integrity modeling guidelines have Model Advisor checks that you can use to verify adherence of your model to the guideline. This table identifies the high-integrity modeling guidelines for Simulink and provides the corresponding Model Advisor check. Not all modeling guidelines have a corresponding Model Advisor check.

Deviations Rationale

Instances in which the generated code does not comply with the MISRA C:2012 guidelines are marked as deviations in the “Compliance Information Summary Tables” on page 13-7. In accordance with Section 5.4 of the MISRA C:2012 guidelines, information about the deviations includes:

- The guideline being deviated
- The circumstances in which the deviation is permitted
- Justification for the deviation, including a risk assessment
- Demonstration of how safety is assured
- Potential consequences of non-conformance

Deviations to the MISRA C:2012 directives and rules include:

- “MISRA C:2012 Directive 4.7 Deviation Rationale” on page 13-30
- “MISRA C:2012 Rule 13.5 Deviation Rationale” on page 13-34
- “MISRA C:2012 Rule 21.1 Deviation Rationale” on page 13-36

MISRA C:2012 Directive 4.7 Deviation Rationale

Directive Definition

If a function returns error information, then that error information shall be tested.

Rationale

Note This directive is violated only when an AUTOSAR-based code generation target is used.

When a function call provides information that indicates an unsuccessful operation, the calling program has to check for the indication of an error when the function is returned. The function calls are not limited to calls in the standard library.

Description

AUTOSAR sender interface function calls, such as Rte_Write..., have return type Std_ReturnType that indicates if writing the value was successful. The matching
Simulink pattern is a top-level output port that is configured as an AUTOSAR Sender Interface.

**Model Example**

![Model Diagram]

**AUTOSAR Configuration**
Generated Code Sample

In the sample code, note the use of AUTOSAR function call `Rte_Write ... in
Rte_Write_OUT_DE1_OUT_DE1(rtb_TmpSignalConversionAtIN_DE1);.`
void Runnable_Step(void)
{
    /* local block i/o variables */
    real_T rtb_TmpSignalConversionAtIN_DE1;
    ...
    rtb_TmpSignalConversionAtIN_D_l = Rte_Read_IN_DE1_IN_DE1
        (&rtb_TmpSignalConversionAtIN_DE1);
    ...
    if (rtb_TmpSignalConversionAtIN_D_l > 0) {
        ...
        Rte_Write_OUT_DE1_OUT_DE1(rtb_TmpSignalConversionAtIN_DE1);
    }
    ...
}

Justification

Failures of Rte_Write_... function calls are typically handled on the receiver side because function call returns do not always include all potential errors.

Conditions Under Which the Deviation is Requested

The deviation is requested for all instances of AUTOSAR sender ports.

Consequences of Noncompliance

The calling program cannot react when the sender operation is unsuccessful.

Actions to Control Reporting

When a Polyspace analysis of your code finds known or acceptable coding rule violations, you can suppress the violations in subsequent analyses by adding code annotations (Polyspace Bug Finder) to the Outport block. In future analyses, Polyspace hides results justified through annotations in the Results List pane. To review the coding rule violations, see “Filter and Group Results” (Polyspace Bug Finder).

If you have already provided annotations for MISRA C:2004 violations, Polyspace imports these justifications when you check your code for MISRA C:2012 violations. For additional information, see “Import Existing MISRA C: 2004 Justifications to MISRA C: 2012 Results” (Polyspace Bug Finder).

For additional information, see:
MISRA C:2012 Rule 13.5 Deviation Rationale

Rule Definition

The right hand operand of a logical && or || operator shall not contain persistent side effects.

Rationale

Persistent side effects of the right hand side operand of the && and || operators can occur depending on the left hand side operand, which is contrary to the expectations of the programmer.

Description

Using math operations as second input to Logical Operator blocks configured as AND or OR operation.

Model Example
Generated Code Sample

In the sample code, note the use of operand && in $Y1 = (U1 \&\& (\text{sqrt}(U2) \leq 3.0))$;

/* Exported block signals */
boolean_T U1;                /* '<Root>/U1' */
real_T U2;                   /* '<Root>/U2' */
boolean_T Y1;                /* '<Root>/Logical Operator' */

/* Model step function */
void DEV_R1305_01main_step(void)
{
   /* Logic: '<Root>/Logical Operator' incorporates:
      * Constant: '<S1>/Constant'
      * Inport: '<Root>/U1'
      * Inport: '<Root>/U2'
      * RelationalOperator: '<S1>/Compare'
      * Sqrt: '<Root>/Sqrt'
   */
   Y1 = (U1 && (sqrt(U2) <= 3.0));
}

Justification

Some standard math functions have at least one persistent side effect of modifying the
global errno variable, as defined in the C90 or C99 standard. Since the errno variable is
not used by Embedded Coder, the second operand can be treated as not having persistent
side effects.

Note  Polyspace Bug Finder treats every function with no available source code as
potentially having side effects.

Conditions Under Which the Deviation is Requested

This deviation is requested for all calls to standard math functions used as right hand side
argument of && and || operators.

Consequences of Noncompliance
There are no consequences associated with noncompliance with MISRA C:2012 Rule 13.5 in the circumstances described in this deviation record. There are no additional verification and validation requirements resulting from this deviation.

**Actions to Control Reporting**

When a Polyspace analysis of your code finds known or acceptable coding rule violations, you can suppress the violations in subsequent analyses by adding code annotations (Polyspace Bug Finder) to the Logical Operator block. In future analyses, Polyspace hides results justified through annotations in the Results List pane. To review the coding rule violations, see “Filter and Group Results” (Polyspace Bug Finder).

If you have already provided annotations for MISRA C:2004 violations, Polyspace imports these justifications when you check your code for MISRA C:2012 violations. For additional information, see “Import Existing MISRA C: 2004 Justifications to MISRA C: 2012 Results” (Polyspace Bug Finder).

For additional information, see “Compliance Information Summary Tables” on page 13-7.

**MISRA C:2012 Rule 21.1 Deviation Rationale**

**Rule Definition**

`#define` and `#undef` shall not be used on a reserved identifier or reserved macro name.

**Rationale**

Identifiers that begin with an underscore (_) are treated as reserved identifiers and apply to MISRA C:2012 Rule 21.1. Reserved identifiers are intended to be used for implementation only.

**Description**

Depending on modeling patterns and used features, identifiers with leading underscores might be present in generated and static code files. For example, the generated `rtwtypes.h` file might redefine the following macros with leading underscores:

- `__RTWTYPES_H__`
- `__TMWTYPES_H__`
- `__ZERO_CROSSING_TYPES__`
**Justification**

A symbol with a leading underscore is not defined by the compiler implementation: Code behaves as expected because the compiler-provided headers are included before headers provided by Embedded Coder.

A symbol is a variable or function name and is already defined: Flagged by compiler warnings/errors for symbol redefinition.

A symbol is a macro name and is already defined: Flagged by compiler warnings/errors for macro redefinition.

**Conditions Under Which the Deviation is Requested**

The deviation is requested for all instances of identifiers starting with an underscore in the generated code.

**Consequences of Noncompliance**

A reserved identifier that is redefined in the generated code can result in undefined or unexpected behavior.

**Actions to Control Reporting**

Review violations caused by leading underscores to check whether there is a conflict with compiler implementation.

Prepare a Model for Code Generation

In this section...

“Configure Input Ports, Output Ports, and Arbitrary Signals” on page 14-3
“Initialize and Configure States” on page 14-4
“Set Up Configuration Parameters for Code Generation” on page 14-4
“Set Up an Example Model With a Stateflow Chart” on page 14-5
“Set Up an Example Model With a MATLAB Function Block” on page 14-6

Several standard methods are available for setting up a model to generate specific C constructs in your code. For preparing your model for code generation, some of these methods include: configuring signals and ports, initializing states, and setting up configuration parameters for code generation. Depending on the components of your model, some of these methods are optional. Methods for configuring a model to generate specific C constructs are organized by category, for example, the Control Flow category includes constructs if-else, switch, for, and while. Refer to the name of a construct to see how you should configure blocks and parameters in your model. Different modeling methodologies are available, such as Simulink blocks, Stateflow charts, and MATLAB Function blocks, to implement a C construct.

Model examples in “Modeling Patterns for C Code” have the following naming conventions:

<table>
<thead>
<tr>
<th>Model Components</th>
<th>Naming Convention</th>
</tr>
</thead>
<tbody>
<tr>
<td>Inputs</td>
<td>u1, u2, u3, and so on</td>
</tr>
<tr>
<td>Outputs</td>
<td>y1, y2, y3, and so on</td>
</tr>
<tr>
<td>Parameters</td>
<td>p1, p2, p3, and so on</td>
</tr>
<tr>
<td>States</td>
<td>x1, x2, x3, and so on</td>
</tr>
</tbody>
</table>

Input ports are named to reflect the signal names that they propagate.

Configure Input Ports, Output Ports, and Arbitrary Signals

1. Create a model in Simulink. For more information, see “Model Editing Fundamentals” (Simulink).
2 In the model, select View > Model Data Editor.
3 In the Model Data Editor, on the Inports/Outports tab or the Signals tab, use the Signal Name column or the Name column to give the target signal a name.
4 Set the Change view drop-down list to Code.
5 Use the Storage Class column to apply a storage class to the signal.

For example, apply the storage class ExportedGlobal, which makes the signal appear in the generated code as a separate global variable. The variable has the same name as the signal in the model.

Initialize and Configure States

1 In the Model Data Editor, on the States tab, use the Initial Value column to specify initial values for a block state (such as the state of a Unit Delay block).
2 Set the Change view drop-down list to Code.
3 Use the Name column to give the state a name.
4 Use the Storage Class column to apply a storage class to the state.

Set Up Configuration Parameters for Code Generation

1 Open the Configuration Parameter dialog box by selecting Simulation > Model Configuration parameters. You can also use the keyboard shortcut Ctrl+E.
2 Open the Solver pane and select
   - **Solver type**: Fixed-Step
   - **Solver**: discrete (no continuous states)
3 Open the Optimization pane, and set Default parameter behavior to Inlined.
4 Open the Code Generation pane, and specify ert.tlc as the System Target File.
5 Clear Generate makefile.
6 Select Generate code only.
7 Enable the HTML report generation by opening the Code Generation > Report pane and selecting Create code generation report and Open report automatically. Click the horizontal ellipsis and, under Advanced parameters, select Code-to-model. Enabling the HTML report generation is optional.
8 Click Apply and then OK to exit.
Set Up an Example Model With a Stateflow Chart

Follow this general procedure to create a simple model containing a Stateflow chart.

1. From the **Stateflow > Chart** library, add a Stateflow chart to your model.
2. Add Inport blocks and Outport blocks according to the example model.
3. Open the **Stateflow Editor** by performing one of the following:
   - Double-click the Stateflow chart.
   - Press **Ctrl+R**.
4. Select **Chart > Add Inputs & Outputs > Data Input from Simulink** to add the inputs to the chart. A Data dialog box opens for each input.
5. Specify the **Name** \((u_1, u_2, \ldots)\) and the **Type** (Inherit: Same as Simulink) for each input, unless specified differently in the example. Click **OK**.
   - Click **Apply** and close each dialog box.
6. Select **Chart > Add Inputs & Outputs > Data Output from Simulink** to add the outputs to the chart. A Data dialog opens for each output.
7. Specify the **Name** \((y_1, y_2, \ldots)\) and **Type** (Inherit: Same as Simulink) for each output, unless specified differently in the example. Click **OK**.
   - Click **Apply** and close each dialog box.
8. In the **Stateflow Editor**, create the Stateflow diagram specific to the example.
9. The inputs and outputs appear on the chart in your model.
10. Connect the Inport and Outport blocks to the Stateflow Chart.
11. Configure the input and output signals; see “Configure Input Ports, Output Ports, and Arbitrary Signals” on page 14-3.
1 Add the number of Inport and Outport blocks according to a C construct example included in this chapter.
2 From the Simulink User-defined Functions library drag a MATLAB Function block into the model.
3 Double-click the block. The MATLAB Function Block Editor opens. Edit the function to implement your application.
4 Click **File > Save** and close the MATLAB Function Block Editor.
5 Connect the Inport and Outport blocks to the MATLAB Function block. See “Configure Input Ports, Output Ports, and Arbitrary Signals” on page 14-3.
6 Save your model.
Definition, Initialization, and Declaration of Parameter Data

This example shows how to export the definition, initialization, and declaration of a global variable that the generated code uses as a parameter.

**C Construct**

```c
int32 myParam = 3;
extern int32 myParam;
```

**Procedure**

1. Create the `ex_defn_decl` model by using a Gain block.

2. In the model, select **View > Property Inspector**.

3. In the model, select the Gain block.

4. In the Property Inspector, set the value of the **Gain** parameter to `myParam`.

5. Next to the parameter value, click the action button ″ and select **Create**.

6. In the Create New Data dialog box, set **Value** to `Simulink.Parameter(3)`. Click **Create**.

A `Simulink.Parameter` object, `myParam`, appears in the base workspace. The Gain block uses the object to set the value of the **Gain** parameter, in this case, 3.

7. In the Simulink.Parameter property dialog box, set **Data type** to `int32`.

8. Set **Storage class** to `ExportToFile`.

9. Set **HeaderFile** to `myDecls.h`.

10. Set **DefinitionFile** to `myDefns.c`. Click **OK**.

11. Generate code from the model.
Results

The generated header file `myDecls.h` declares the global variable `myParam` by using the `extern` keyword.

/* Declaration for custom storage class: ExportToFile */
extern int32_T myParam;

The generated source file `myDefns.c` defines and initializes `myParam`.

/* Definition for custom storage class: ExportToFile */
int32_T myParam = 3;

Definition and Declaration of Signal Data

This example shows how to export the definition and declaration of a global variable that
the generated code uses as a signal.

**C Construct**

```c
float mySig;
extern float mySig;
```

**Procedure**

1. Create the `ex_defn_decl` model by using a Gain block.

2. In the model, select View > Model Data Editor.
3. In the Model Data Editor, view the Inports/Outports tab.
4. From the Change view drop-down list, select Design.
5. In the model, select the Inport block.
6. In the Model Data Editor, for the Inport block, set Signal Name to `mySig`.
7. Set Data Type to single.
8. From the Change View drop-down list, select Code.
9. For the Inport block, set Storage Class to ExportToFile.
10. Set Header File to `myDecls.h`.
11. Set Definition File to `myDefns.c`.
12. Generate code from the model.

**Results**

The generated header file `myDecls.h` declares the global variable `mySig` by using the
`extern` keyword.
The generated source file `myDefns.c` defines the variable `mySig`.

Modeling Pattern for Data Type Conversion — Simulink Block

One method to create a data type conversion is to use a Data Type Conversion block from the Simulink > Commonly Used Blocks library.

![Data Type Conversion Diagram](image)

ex_data_type_SL

1. From the Commonly Used Blocks library, drag a Data Type Conversion block into your model and connect to the Inport and Outport blocks.
2. Double-click on the Data Type Conversion block to open the Block Parameters dialog box.
3. Select the Output data type parameter as double.
4. Press Ctrl+B to build the model and generate code.

The generated code appears in ex_data_type_SL.c, as follows:

```c
int32_T u1;
real_T y1;
```
void ex_data_type_SL_step(void)
{
    y1 = (real_T)u1;
}

The code generator type definition for double is real_T.

Modeling Pattern for Data Type Conversion — Stateflow Chart

Stateflow Chart Type Conversion

Procedure

1. Follow the steps for “Set Up an Example Model With a Stateflow Chart” on page 14-5. This example contains one Inport block and one Outport block.
2. Name the example model ex_data_type_SF.
3. Double-click the Inport block and select the Signal Attributes tab. Specify the Data Type as int32 from the drop down menu.
4. Double-click the Outport block and select the Signal Attributes tab. Specify the Data Type as Inherit: auto from the drop down menu.
5. Press Ctrl+B to build the model and generate code.

Results

The generated code appears in ex_data_type_SF.c, as follows:

int32_T u1;
real_T y1;
RT_MODEL_ex_data_type_SF ex_data_type_SF M_;
RT_MODEL_ex_data_type_SF *const ex_data_type_SF M = &ex_data_type_SF M_;
void ex_data_type_SF_step(void)
{
    y1 = u1;
}
**Modeling Pattern for Data Type Conversion — MATLAB Function Block**

**Procedure**

1. Follow the steps for “Set Up an Example Model With a MATLAB Function Block” on page 14-6. This example model contains one Inport block and one Outport block.

2. Name the model `ex_data_type_ML_Func`.

3. In the MATLAB Function Block Editor enter the function, as follows:

   ```matlab
   function y1 = typeconv(u1)
   y1 = double(u1);
   end
   ```

4. Press **Ctrl+B** to build the model and generate code.

**Results**

The generated code appears in `ex_data_type_ML_func.c`, where `real32_T` is a float and `real_T` is a double. Type conversion occurs across assignments.

```c
real32_T u1;
real_T y1;

void ex_data_type_ML_func_step(void)
{
    y1 = u1;
}
```

**Other Type Conversions in Modeling**

Type conversions can also occur on the output of blocks where the output variable is specified as a different data type. For example, in the Gain block, you can select the **Inherit via internal rule** parameter to control the output signal data type. Another example of type conversion can occur at the boundary of a Stateflow chart. You can specify the output variable as a different data type.

**See Also**

Data Type Conversion
Type Qualifiers

This example shows how to apply the const and volatile keywords to a global variable that represents parameter data.

C Construct

const volatile double myParam = 9.8;

Procedure

1 Create the ex_const_volatile model by using a Gain block.

2 In the model, select View > Model Data Editor.

3 In the Model Data Editor, on the Parameters tab, set the value of the Gain parameter to myParam.

4 Next to myParam, click the action button ➕ and select Create.

5 In the Create New Data dialog box, set Value to Simulink.Parameter(9.8) and click Create.

A Simulink.Parameter object, myParam, appears in the base workspace. The Gain block uses the object to set the value of the Gain parameter, in this case, 9.8.

6 In the Simulink.Parameter property dialog box, set Storage class to ConstVolatile.

Alternatively, to apply only one of the keywords, you can use the storage classes Const or Volatile.

7 Generate code from the model.
Results

The generated source file ex_const_volatile.c defines myParam by using the const and volatile keywords.

/* Definition for custom storage class: ConstVolatile */
const volatile real_T myParam = 9.8;

Relational and Logical Operators

Modeling Patterns for Relational and Logical Operators

- “Modeling Pattern for Relational or Logical Operators — Simulink Blocks” on page 14-16
- “Modeling Pattern for Relational and Logical Operators – Stateflow Chart” on page 14-17
- “Modeling Pattern for Relational and Logical Operators — MATLAB Function Block” on page 14-18

Modeling Pattern for Relational or Logical Operators — Simulink Blocks

![Logical Operator Diagram]

ex_logical_SL

Procedure

1. From the Logic and Bit Operations library, drag a Logical Operator block into your model.
2. Double-click the block to configure the logical operation. Set the Operator field to OR.
3. Name the blocks, as shown in the model exLogical_SL.
4. Connect the blocks and name the signals, as shown in the model exLogical_SL.
5. Press Ctrl+B to build the model and generate code.

Note You can use the above procedure to implement relational operators by replacing the Logical Operator block with a Relational Operator block.
Results

Code implementing the logical operator OR is in the `ex_logical_SL_step` function in `ex_logical_SL.c`:

```c
/* Exported block signals */
boolean_T u1;  /* '<Root>/u1' */
boolean_T u2;  /* '<Root>/u2' */
boolean_T y1;  /* '<Root>/Logical Operator' */

/* Logic: '<Root>/Logical Operator' incorporates:
 * Inport: '<Root>/u1'
 * Inport: '<Root>/u2'
 */
y1 = (u1 || u2);
```

Modeling Pattern for Relational and Logical Operators - Stateflow Chart

![Stateflow Chart Diagram]

**ex_logical_SF/Logical Operator Stateflow Chart**

**Procedure**

1. Follow the steps for “Set Up an Example Model With a Stateflow Chart” on page 14-5. This example model contains two Inport blocks and one Outport block.
2. Name the example model `ex_logical_SF`.
3. In the Stateflow Editor, specify the Data Type for `y1` as Boolean.
4. In the Stateflow Editor, create the Stateflow diagram as shown. The relational or logical operation actions are on the transition from one junction to another. Relational statements specify conditions to conditionally allow a transition. In that case, the statement would be within square brackets.
5 Press Ctrl+B to build the model and generate code.

Results

Code implementing the logical operator OR is in the ex_logical_SF_step function in ex_logical_SF.c:

```c
boolean_T u1;       /* '<Root>/u1' */
boolean_T u2;       /* '<Root>/u2' */
boolean_T y1;       /* '<Root>/Chart' */

void ex_logical_SF_step(void)
{
    y1 = (u1 || u2);
}
```

Modeling Pattern for Relational and Logical Operators — MATLAB Function Block

This example demonstrates the MATLAB Function block method for incorporating operators into the generated code using a relational operator.

Procedure

1 Follow the steps for “Set Up an Example Model With a MATLAB Function Block” on page 14-6. This example model contains two Inport blocks and one Outport block.

2 Name the example model ex_rel_operator_ML.

3 In the MATLAB Function Block Editor enter the function, as follows:

```matlab
function y1 = fcn(u1, u2)
    y1 = u1 > u2;
end
```

4 Press Ctrl+B to build the model and generate code.

Results

Code implementing the relational operator '>' is in the ex_rel_operator_ML_step function in ex_rel_operator_ML.c:

```c
real_T u1;     /* '<Root>/u1' */
real_T u2;     /* '<Root>/u2' */
boolean_T y;   /* '<Root>/MATLAB Function' */
```
void ex_rel_operator_ML_step(void)
{
    y = (u1 > u2);
}

Bitwise Operations

Simulink Bitwise-Operator Block

ex_bit_logic_SL

Procedure

1. Drag a Bitwise Operator block from the Logic and Bit Operations library into your model.
2. Double-click the block to open the Block Parameters dialog.
3. Select the type of Operator. In this example, select AND.
4. In order to perform Bitwise operations with a bit-mask, select Use bit mask.

Note If another input uses Bitwise operations, clear the Use bit mask parameter and enter the number of input ports.

5. In the Bit Mask field, enter a decimal number. Use bin2dec or hex2dec to convert from binary or hexadecimal. In this example, enter hex2dec('D9').
6. Name the blocks, as shown in, model ex_bit_logic_SL.
7. Connect the blocks and name the signals, as shown in, model ex_bit_logic_SL.
8. Press Ctrl+B to build the model and generate code.

Results

Code implementing the logical operator OR is in the ex_bit_logic_SL_step function in ex_bit_logic_SL.c:
uint8_T u1;
uint8_T y1;

void ex_bit_logic_SL_step(void)
{
    y1 = (uint8_T)(u1 & 217);
}

**Stateflow Chart**

![Stateflow Chart](image)

**ex_bit_logic_SF/BitLogic Stateflow Chart**

**Procedure**

1. Follow the steps for “Set Up an Example Model With a Stateflow Chart” on page 14-5. This example contains one Inport block and one Outport block.
2. Name the example model `ex_bit_logic_SF`.
3. From the **Stateflow Editor**, select **Tools > Explore** to open the Model Explorer.
4. In the Model Explorer, on the right pane, select **Enable C-bit operations**.
5. In the **Stateflow Editor**, create the Stateflow diagram, `ex_bit_logic_SF/BitLogic`.
6. Press **Ctrl+B** to build the model and generate code.

**Results**

Code implementing the logical operator OR is in the `ex_bit_logic_SF_step` function in `ex_bit_logic_SF.c`:

```c
uint8_T u1;
uint8_T y1;

void bit_logic_SF_step(void)
```
MATLAB Function Block

In this example, to demonstrate the MATLAB Function block method for implementing bitwise logic into the generated code, use the bitwise OR, '|'.

Procedure

1. Follow the steps for “Set Up an Example Model With a MATLAB Function Block” on page 14-6. This example model contains two Inport blocks and one Outport block.
2. Name your model ex_bit_logic_ML.
3. In the MATLAB Function Block Editor enter the function, as follows:

   ```matlab
   function y1 = fcn(u1, u2)
     y1 = bitor(u1, u2);
   end
   ```

4. Press Ctrl+B to build the model and generate code.

Results

Code implementing the bitwise operator OR is in the ex_bit_logic_ML_step function in ex_bit_logic_ML.c:

```c
#define int8_T int8_t
#define uint8_T uint8_t

uint8_T u1;
uint8_T u2;
uint8_T y1;

void ex_bit_logic_ML_step(void)
{
    y1 = (uint8_T)(u1 | u2);
}
```
**Enumeration**

To generate an enumerated data type, define an enumeration class in a MATLAB file. Then, use the enumeration class as the data type of signals, block parameters, and states in a model.

**C Construct**

```c
typedef enum {  
    Choice1 = 0,  
    Choice2
} myEnumType;
```

**Procedure**

In your current folder, create the MATLAB file `ex_myEnumType.m`. The file defines an enumeration class `ex_myEnumType`.

```matlab
classdef ex_myEnumType < Simulink.IntEnumType
    enumeration
        Choice1(0)
        Choice2(1)
    end %enumeration

    methods (Static)
        function retVal = getHeaderFile()
            retVal = 'myEnumHdr.h';
        end %function

        function retVal = getDataScope()
            retVal = 'Exported';
        end %function
    end %methods
end %classdef
```

Create the model `ex_pattern_enum` by using an Enumerated Constant block and a Multiport Switch block.

```matlab
open_system('ex_pattern_enum')
```
In the model, select **View > Model Data Editor**.

In the Model Data Editor, select the **Parameters** tab.

In the model, click the Enumerated Constant block.

In the Model Data Editor, use the **Value** column to set the constant value to `myChoice`.

Next to `myChoice`, click the action button (with three vertical dots) and select **Create**.

In the Create New Data dialog box, set **Value** to `Simulink.Parameter(ex_myEnumType.Choice1)` and click **Create**. A Simulink.Parameter object named `myChoice` appears in the base workspace. The object stores the enumerated value `Choice1` of the type `ex_myEnumType`.

In the property dialog box for `myChoice`, set **Storage Class** to `ExportedGlobal`. With this setting, the object appears in the generated code as a global variable.

Alternatively, at the command prompt, use these commands to create the object:

```matlab
myChoice = Simulink.Parameter(ex_myEnumType.Choice1);
myChoice.CoderInfo.StorageClass = 'ExportedGlobal';
```

In the Model Data Editor, select the **Signals** tab.

In the model, select the output signal of the Enumerated Constant block.

In the Model Data Editor, use the **Data Type** column to set the signal data type to `Enum: ex_myEnumType`.

In the model, select **View > Property Inspector**.
In the model, select the Multiport Switch block.

In the Property Inspector, set:

- **Data port order** to Specify indices.
- **Data port indices** to enumeration('ex_myEnumType'). This expression returns all of the enumeration members of ex_myEnumType.

Set **Configuration Parameters > File packaging format** to Modular. With this setting, in the generated code, the definition of ex_myEnumType can appear in the specified header file, myEnumHdr.h.

Generate code from the model.

```matlab
trwbuild('ex_pattern_enum');

### Starting build procedure for model: ex_pattern_enum
### Successful completion of build procedure for model: ex_pattern_enum
```

**Results**

View the generated header file myEnumHdr.h. The file defines the enumerated data type.

```matlab
file = fullfile('ex_pattern_enum_ert_rtw','myEnumHdr.h');
rtwdemodbtype(file,'typedef enum {','} ex_myEnumType;',1,1)

typedef enum {
   Choice1 = 0,                         /* Default value */
    Choice2
} ex_myEnumType;
```

View the source file ex_pattern_enum.c. The file defines the variable myChoice. The algorithm in the step function uses myChoice to route one of the input signals to the output signal.

```matlab
file = fullfile('ex_pattern_enum_ert_rtw','ex_pattern_enum.c');
rtwdemodbtype(file,'ex_myEnumType myChoice = Choice1;','/* Variable: myChoice',1,1)
rtwdemodbtype(file,'/* Model step function */','/* Model initialize function */',1,0)

ex_myEnumType myChoice = Choice1;    /* Variable: myChoice */
/* Model step function */
void ex_pattern_enum_step(void)
{
    /* MultiPortSwitch: '<Root>/Multiport Switch' incorporates:
       * Constant: '<S1>/Constant'
    */
    if (myChoice == Choice1) {
        /* Outport: '<Root>/Data Out' incorporates:
           * Inport: '<Root>/Data In 1'
        */
        rtY.DataOut = rtU.DataIn1;
    } else {
        /* Outport: '<Root>/Data Out' incorporates:
           * Inport: '<Root>/Data In 2'
        */
        rtY.DataOut = rtU.DataIn2;
    }

    /* End of MultiPortSwitch: '<Root>/Multiport Switch' */
}

- “Modeling Pattern for If-Else: Stateflow Chart” on page 14-29
- “Modeling Pattern for If-Else: MATLAB Function Block” on page 14-30

Modeling Pattern for If-Else: Switch block

One method to create an if-else statement is to use a Switch block from the Simulink > Signal Routing library.
Model **ex_if_else_SL**

**Procedure**

1. Drag the Switch block from the Simulink>Signal Routing library into your model.
2. Connect the data inputs and outputs to the block.
3. Drag a Relational Operator block from the Logic & Bit Operations library into your model.
4. Connect the signals that are used in the if-expression to the Relational Operator block. The order of connection determines the placement of each signal in the if-expression.
5. Configure the Relational Operator block to be a greater than operator.
6. Connect the controlling input to the middle input port of the Switch block.
7. Double-click the Switch block and set **Criteria for passing first input** to \( u_2 \approx 0 \). The software selects \( u_1 \) if \( u_2 \) is TRUE; otherwise \( u_2 \) passes.
8. Enter Ctrl+B to build the model and generate code.

**Results**

The generated code includes the following **ex_if_else_SL_step** function in the file **ex_if_else_SL.c**:

```c
/* External inputs (root inport signals with auto storage) */
ExternalInputs U;
```
/* External outputs (root outports fed by signals with auto storage) */
ExternalOutputs Y;

/* Model step function */
void ex_if_else_SL_step(void)
{
  /* Switch: '<Root>/Switch' incorporates:
   * Inport: '<Root>/u1'
   * Inport: '<Root>/u2'
   * Outport: '<Root>/y1'
   * RelationalOperator: '<Root>/Relational Operator'
   */
  if (U.u1 > U.u2) {
    Y.y1 = U.u1;
  } else {
    Y.y1 = U.u2;
  }
}

Modeling Pattern for If-Else: Stateflow Chart

ex_if_else_SF/Chart

Procedure

1  Follow the steps for “Set Up an Example Model With a Stateflow Chart” on page 14-5. This example model contains two Inport blocks and one Outport block.

2  Name your model ex_if_else_SF.

3  When configuring your Stateflow chart, select Chart > Add Patterns > Decision > If-Else. The Stateflow Pattern dialog opens. Fill in the fields as follows:

<table>
<thead>
<tr>
<th>Description</th>
<th>If-Else (optional)</th>
</tr>
</thead>
</table>
If condition          u1 > u2
If action             y1 = u1
Else action           y1 = u2

4 Press Ctrl+B to build the model and generate code.

Results

The generated code includes the following ex_if_else_SF_step function in the file If_Else_SF.c:

/* External inputs (root inport signals with auto storage) */
ExternalInputs U;

/* External outputs (root outports fed by signals with auto storage) */
ExternalOutputs Y;

/* Model step function */
void ex_if_else_SF_step(void)
{
    /* Chart: '<Root>/Chart' incorporates:
    * Inport: '<Root>/u1'
    * Inport: '<Root>/u2'
    */
    /* Gateway: Chart */
    /* During: Chart */
    /* Entry Internal: Chart */
    /* Transition: '<S1>:15' */
    /* If-Else */
    if (U.u1 > U.u2) {
        /* Outport: '<Root>/y1' */
        /* Transition: '<S1>:16' */
        /* Transition: '<S1>:18' */
        Y.y1 = U.u1;
        /* Transition: '<S1>:19' */
    } else {
        /* Outport: '<Root>/y1' */
        /* Transition: '<S1>:17' */
        Y.y1 = U.u2;
    }

    /* End of Chart: '<Root>/Chart' */
    /* Transition: '<S1>:20' */
}

Modeling Pattern for If-Else: MATLAB Function Block

Procedure

1 Follow the steps for “Set Up an Example Model With a MATLAB Function Block” on page 14-6. This example model contains two Inport blocks and one Outport block.
2 Name your model `ex_if_else_ML`.

3 In the MATLAB Function Block Editor enter the function, as follows:

```matlab
function y1 = fcn(u1, u2)
    if u1 > u2;
        y1 = u1;
    else
        y1 = u2;
    end
```

4 Press `Ctrl+B` to build the model and generate code.

**Results**

The generated code includes the following `ex_if_else_ML_step` function in the file `ex_if_else_ML.c`:

```c
/* External inputs (root inport signals with auto storage) */
ExternalInputs U;

/* External outputs (root outports fed by signals with auto storage) */
ExternalOutputs Y;

/* Model step function */
void ex_if_else_ML_step(void)
{
    /* MATLAB Function Block: '<Root>/MATLAB Function' incorporates:
     * Inport: '<Root>/u1'
     * Inport: '<Root>/u2'
     * Outport: '<Root>/y1'
     */
    /* MATLAB Function 'MATLAB Function': '<S1>:1' */
    if (U.u1 > U.u2) {
        /* '<S1>:1:4' */
        /* '<S1>:1:5' */
        Y.y1 = U.u1;
    } else {
        /* '<S1>:1:6' */
        Y.y1 = U.u2;
    }
}
```
Switch

C Construct

```c
switch (u1)
{
    case 2:
        y1 = u2;
        break;
    case 3:
        u3;
        break;
    default:
        y1 = u4;
        break;
}
```

Modeling Patterns

- “Modeling Pattern for Switch: Switch Case block” on page 14-32
- “Modeling Pattern for Switch: MATLAB Function block” on page 14-35
- “Convert If-Elseif-Else to Switch statement” on page 14-36

Modeling Pattern for Switch: Switch Case block

One method for creating a switch statement is to use a Switch Case block from the Simulink > Ports and Subsystems library.
Model ex_switch_SL

Procedure

1. Drag a Switch Case block from the Simulink > Ports and Subsystems library into your model.
2. Double-click the block. In the Block Parameters dialog box, fill in the Case Conditions parameter. In this example, the two cases are: \{2, 3\}.
3. Select the Show default case parameter. The default case is optional in a switch statement.
4. Connect the condition input u1 to the input port of the Switch block.
5. Drag Switch Case Action Subsystem blocks from the Simulink>Ports and Subsystems library to correspond with the number of cases.
6. Configure the Switch Case Action Subsystem subsystems.
7. Drag a Merge block from the Simulink > Signal Routing library to merge the outputs.
8. The Switch Case block takes an integer input, therefore, the input signal u1 is type cast to an int32.
Enter Ctrl+B to build the model and generate code.

Results

The generated code includes the following `ex_switch_SL_step` function in the file `ex_switch_SL.c`:

```c
/* Exported block signals */
int32_T u1;                            /* '<Root>/u1' */

/* External inputs (root import signals with auto storage) */
ExternalInputs U;

/* External outputs (root outputs fed by signals with auto storage) */
ExternalOutputs Y;

/* Model step function */
void ex_switch_SL_step(void)
{
    switch (u1) {
    case 2:
        /* Inport: '<S1>/u2' incorporates:
           * Inport: '<Root>/u2'
           * Outport: '<Root>/y1'
        */
        Y.y1 = U.u2;
        break;

    case 3:
        /* Inport: '<S2>/u3' incorporates:
           * Inport: '<Root>/u3'
           * Outport: '<Root>/y1'
        */
        Y.y1 = U.u3;
        break;

    default:
        /* Inport: '<S3>/u4' incorporates:
           * Inport: '<Root>/u4'
           * Outport: '<Root>/y1'
        */
        Y.y1 = U.u4;
        break;
    }
}
```
Modeling Pattern for Switch: MATLAB Function block

Procedure

1. Follow the steps for “Set Up an Example Model With a MATLAB Function Block” on page 14-6. This example model contains four Inport blocks and one Outport block.

2. Name your model `ex_switch_ML`.

3. In the MATLAB Function Block Editor enter the function, as follows:

   ```matlab
   function y1 = fcn(u1, u2, u3, u4)
   switch u1
   case 2
       y1 = u2;
   case 3
       y1 = u3;
   otherwise
       y1 = u4;
   end
   ```

4. Press `Ctrl+B` to build the model and generate code.

Results

The generated code includes the following `ex_switch_ML_step` function in the file `ex_switch_ML.c`:

```c
/* External inputs (root inport signals with auto storage) */
ExternalInputs U;

/* External outputs (root outports fed by signals with auto storage) */
ExternalOutputs Y;

/* Model step function */
void ex_switch_ML_step(void)
{
    /* MATLAB Function Block: '<Root>/MATLAB Function' incorporates:
    * Inport: '<Root>/u1'
    * Inport: '<Root>/u2'
    * Inport: '<Root>/u3'
    * Inport: '<Root>/u4'
    * Outport: '<Root>/y1'
    */
    /* MATLAB Function 'MATLAB Function': '<S1>:1' */
    /* '<S1>:1:4' */
    switch (U.u1) {
    case 2:
    /* '<S1>:1:6' */
        Y.y1 = U.u2;
        break;
```
case 3:
    /* '<S1>:1:8' */
    Y.y1 = U.u3;
    break;

default:
    /* '<S1>:1:10' */
    Y.y1 = U.u4;
    break;
}

Convert If-Elseif-Else to Switch statement

If a MATLAB Function block or a Stateflow chart uses if-elseif-else decision logic, you can convert it to a switch statement by using a configuration parameter. In the Configuration Parameters dialog box, on the Code Generation > Code Style pane, select the “Convert if-elseif-else patterns to switch-case statements” parameter. For more information, see “Converting If-Elseif-Else Code to Switch-Case Statements” (Simulink). For more information on this conversion using a Stateflow chart, see “Enhance Readability of Code for Flow Charts” on page 39-108.

Modeling Pattern for For Loop: For-Iterator Subsystem block

One method for creating a for loop is to use a For Iterator Subsystem block from the Simulink > Ports and Subsystems library.

Model ex_for_loop_SL
For Iterator Subsystem

Procedure

1. Drag a For Iterator Subsystem block from the Simulink > Ports and Subsystems library into your model.
2. Connect the data inputs and outputs to the For Iterator Subsystem block.
3. Open the Inport block.
4. In the Block Parameters dialog box, select the Signal Attributes pane and set the Port dimensions parameter to 10.
5. Double-click the For Iterator Subsystem block to open the subsystem.
6. Drag an Index Vector block from the Signal-Routing library into the subsystem.
7. Open the For Iterator block. In the Block Parameters dialog box set the Index-mode parameter to Zero-based and the Iteration limit parameter to 10.
8. Connect the controlling input to the topmost input port of the Index Vector block, and the other input to the second port.
9. Drag an Add block from the Math Operations library into the subsystem.
10. Drag a Unit Delay block from Commonly Used Blocks library into the subsystem.
11. Double-click the Unit Delay block and set the Initial Conditions parameter to 0. This parameter initializes the state to zero.
12. Connect the blocks as shown in the model diagram.
13 Save the subsystem and the model.
14 Enter Ctrl+B to build the model and generate code.

**Results**

The generated code includes the following `ex_for_loop_SL_step` function in the file `ex_for_loop_SL.c`:

```c
/* External inputs (root import signals with auto storage) */
ExternalInputs U;

/* External outputs (root outlets fed by signals with auto storage) */
ExternalOutputs Y;

/* Model step function */
void ex_for_loop_SL_step(void)
{
    int32_T s1_iter;
    int32_T rtb_y1;

    /* Outputs for iterator SubSystem: '<Root>/For Iterator Subsystem' incorporates:
     * ForIterator: '<S1>/For Iterator'
     */
    for (s1_iter = 0; s1_iter < 10; s1_iter++) {
        /* Sum: '<S1>/Add' incorporates:
         * Inport: '<Root>/u1'
         * MultiPortSwitch: '<S1>/Index Vector'
         * UnitDelay: '<S1>/Unit Delay'
         */
        rtb_y1 = U.u1[s1_iter] + DWork.UnitDelay_DSTATE;
        /* Update for UnitDelay: '<S1>/Unit Delay' */
        DWork.UnitDelay_DSTATE = rtb_y1;
    }

    /* end of Outputs for SubSystem: '<Root>/For Iterator Subsystem' */

    /* Outport: '<Root>/y1' */
    Y.y1 = rtb_y1;
}
```
Modeling Pattern for For Loop: Stateflow Chart

Model ex_for_loop_SF

Procedure

1 Follow the steps for “Set Up an Example Model With a Stateflow Chart” on page 14-5. This example model contains one Inport block and one Outport block.

2 Name the model ex_for_loop_SF.

3 Enter Ctrl+R to open the Model Explorer.

4 In the Model Explorer, select the output variable, u1, and in the right pane, select the General tab and set the Initial Value to 0.

5 In the Stateflow Editor, select Chart > Add Patterns > Loop > For. The Stateflow Pattern dialog opens.

6 Fill in the fields in the Stateflow Pattern dialog box as follows:

- **Description** For Loop (optional)
- **Initializer expression** inx = 0
- **Loop test expression** inx < 10
- **Counting expression** inx++
- **For loop body** y1 = u1[inx] + y1

The Stateflow diagram is shown.
7 Press **Ctrl+B** to build the model and generate code.

**Results**

The generated code includes the following `ex_for_loop_SF_step` function in the file `ex_for_loop_SF.c`:

```c
/* External inputs (root import signals with auto storage) */
ExternalInputs U;

/* External outputs (root outports fed by signals with auto storage) */
ExternalOutputs Y;

/* Model step function */
void ex_for_loop_SF_step(void)
{
    int32_T inx;
    /* Chart: '<Root>/Chart' */
    /* Gateway: Chart */
    /* During: Chart */
    /* Entry Internal: Chart */
    /* Transition: '<S1>:13' */
    /* Transition: '<S1>:14' */
    for (inx = 0; inx < 10; inx++) {
        /* Outport: '<Root>/y1' incorporates:
        *  Inport: '<Root>/u1'
        */
        /* Transition: '<S1>:11' */
        /* Transition: '<S1>:12' */
        Y.y1 += U.u1[inx];
    }
    /* Transition: '<S1>:10' */
}
/* End of Chart: '<Root>/Chart' */
/* Transition: '<S1>:9' */
```

**Modeling Pattern for For Loop: MATLAB Function block**

**Procedure**

1. Follow the directions for “Set Up an Example Model With a MATLAB Function Block” on page 14-6. This example model contains one Inport block and one Outport block.
2. Name your model `ex_for_loop_ML`.
3. In the MATLAB Function Block Editor enter the function, as follows:

```matlab
function y1 = fcn(u1)
    y1 = 0;
```
4 Press Ctrl+B to build the model and generate code.

**Results**

The generated code includes the following `ex_for_loop_ML_step` function in the file `ex_for_loop_ML.c`:

```c
/* Exported block signals */
real_T u1[10];                         /* '<Root>/u1' */
real_T y1;                             /* '<Root>/MATLAB Function' */

/* Model step function */
void ex_for_loop_ML_step(void)
{
    int32_T inx;

    /* MATLAB Function Block: '<Root>/MATLAB Function' incorporates:
     * Inport: '<Root>/u1'
     */
    /* MATLAB Function 'MATLAB Function': '<S1>:1' */
    /* '<S1>:1:3' */
    y1 = 0.0;
    for (inx = 0; inx < 10; inx++) {
        /* '<S1>:1:5' */
        /* '<S1>:1:6' */
        y1 = u1[inx] + y1;
    }
}
```

Modeling Pattern for While Loop: While Iterator Subsystem block

One method for creating a while loop is to use a While Iterator Subsystem block from the Simulink > Ports and Subsystems library.

![Diagram of While Iterator Subsystem block]

Model ex_while_loop_SL
**Procedure**

1. Drag a While Iterator Subsystem block from the Simulink > Ports and Subsystems library into the model.

2. Drag a Constant block from the Simulink > Commonly Used Blocks library into the model. In this case, set the **Initial Condition** to 1 and the **Data Type** to Boolean. You do not have to set the initial condition to FALSE. The initial condition can be dependent on the input to the block.

3. Connect the Constant block to the While Iterator Subsystem block.

4. Double-click the While Iterator Subsystem block to open the subsystem.

5. Place a Subsystem block next to the While Iterator block.

6. Right-click the subsystem and select **Block Parameters (Subsystem)**. The Block Parameters dialog box opens.

7. Select the **Treat as atomic unit** parameter to configure the subsystem to generate a function. This enables parameters on the **Code Generation** tab.

8. Select the **Code Generation** tab. From the **Function packaging** list, select the option, **Nonreusable function**.

9. From the **Function name options** list, select the option, **User specified**. The **Function name** parameter is displayed.

10. Specify the name as **func**.

11. Click **Apply**.
12 Double-click the func subsystem block. In this example, function func() has an output flag set to 0 or 1 depending on the result of the algorithm in func(). Create the func() algorithm as shown in the following diagram:

![Diagram](image)

**func**

13 Double-click the While Iterator block to set the **Maximum number of iterations** to 100.

14 Connect blocks as shown in the model and subsystem diagrams.

**Results**

The generated code includes the following ex_while_loop_SL_step function in the file ex_while_loop_SL.c:

```c
/* Model step function */
void ex_while_loop_SL_step(void)
{
    int32_T s1_iter;
    boolean_T loopCond;

    /* Constant: '<Root>/Initial Condition SET to TRUE' */
    IC = P.InitialConditionSETtoTRUE_Value;

    /* Outputs for Iterator SubSystem: 
     *   '<Root>/While Iterator Subsystem' incorporates:
     *     WhileIterator: '<S1>/While Iterator'
     */
    s1_iter = 1;

    /* InitializeConditions for Atomic SubSystem: '<S1>/func' */
    func_Init();
}
```
/* End of InitializeConditions for SubSystem: '<S1>/func' */
loopCond = IC;
while (loopCond && (s1_iter <= 100)) {
    /* Outputs for Atomic SubSystem: '<S1>/func' */
    func();

    /* End of Outputs for SubSystem: '<S1>/func' */
    loopCond = flag;
    s1_iter++;
}

/* End of Outputs for SubSystem: '<Root>/While Iterator Subsystem' */

Modeling Pattern for While Loop: Stateflow Chart

Model ex_while_loop_SF
**ex_while_loop_SF/Chart** Executes the desired while-loop

**Procedure**

1. Add a Stateflow Chart to your model from the **Stateflow > Chart** library.
2. Double-click the chart.
3. Add the input, `flag`, and output, `func`, to the chart and specify their data type.
4. Connect the data input and output to the Stateflow chart as shown in the model diagram.
5. In the Model Explorer, select the output variable, then, in the right pane, select the **General** tab and set the **Initial Value** to 0.
6. Select **Chart > Add Patterns > Loop > While**. The Stateflow Pattern dialog box opens.
7. Fill in the fields for the Stateflow Pattern dialog box as follows:
   - **Description**: While Loop (optional)
   - **While condition**: `(flag) && (num_iter<=100)`
   - **Do action**: `func; num_iter++;`
8. Place a Subsystem block in your model.
9. Right-click the subsystem and select **Block Parameters (Subsystem)**. The Block Parameters dialog box opens.
10. Select the **Treat as atomic unit** parameter to configure the subsystem to generate a function. This enables parameters on the **Code Generation** tab.
11. Select the **Code Generation** tab. From the **Function packaging** list, select the option, Nonreusable function.
From the **Function name options** list, select the option, **User specified**. The **Function name** parameter is displayed.

Specify the name as **func**.

Click **Apply** to apply the changes.

Double-click the **func** subsystem block. In this example, function **func** has an output **flag** set to 0 or 1 depending on the result of the algorithm in func( ). The Trigger block parameter **Trigger type** is function-call. Create the func() algorithm, as shown in the following diagram:

![Diagram showing a subsystem with blocks labeled Random Number, Relational Operator, and Trigger.]

**ex_while_loop_SF/func** A function that updates the flag

Save and close the subsystem.

Connect blocks to the Stateflow chart as shown in the model diagram for **ex_while_loop_SF**.

Save your model.

**Results**

The generated code includes the following **ex_while_loop_SF_step** function in the file **ex_while_loop_SF.c**:

```c
/* Exported block signals */
int32_T num_iter; /* '<Root>/Chart' */
boolean_T flag; /* '<S2>/Relational Operator' */

/* Block states (auto storage) */
D_Work DWork;

/* Model step function */
void ex_while_loop_SF_step(void) {
```
/* Chart: '<Root>/Chart' */
/* Gateway: Chart */
/* During: Chart */
/* Entry Internal: Chart */
/* Transition: '<S1>:2' */
num_iter = 1;
while (flag && (num_iter <= 100)) {
    /* Outputs for Function Call SubSystem: '<Root>/func' */

    /* Transition: '<S1>:3' */
    /* Transition: '<S1>:4' */
    /* Event: '<S1>:12' */
    func();

    /* End of Outputs for SubSystem: '<Root>/func' */
    num_iter++;

    /* Transition: '<S1>:5' */
}

/* End of Chart: '<Root>/Chart' */
/* Transition: '<S1>:1' */
}

Modeling Pattern for While Loop: MATLAB Function Block

Model ex_while_loop_ML
Procedure

1. In the Simulink Library Browser, click **Simulink > User Defined Functions**, and drag a MATLAB Function block into your model.

2. Double-click the MATLAB Function block. The MATLAB Function Block Editor opens.

3. In the MATLAB Function Block Editor enter the function, as follows:

   ```matlab
   function fcn(func_flag)
   flag = true;
   num_iter = 1;
   while(flag && (num_iter<=100))
       func;
       flag = func_flag;
       num_iter = num_iter + 1;
   end
   ```

4. Select **Edit Data** on the Editor tab. The Ports and Data Manager opens.

5. Select **Add > Function Call Output**. Change the name of the function call output to `func`.

6. Click **Save** and close the MATLAB Function Block Editor.

7. Place a Subsystem block in your model, right-click the subsystem and select **Block Parameters (Subsystem)**. The Block Parameters dialog box opens.

8. Select the **Treat as atomic unit** parameter to configure the subsystem to generate a function. This enables parameters on the **Code Generation** tab.

9. Select the **Code Generation** tab. From the **Function packaging** list, select the option, **Nonreusable function**.

10. From the **Function name options** list, select the option, **User specified**. The **Function name** parameter is displayed.

11. Specify the name as `func`.

12. Click **Apply**.

13. Double-click the `func()` subsystem block. In this example, function `func()` has an output `flag` set to 0 or 1 depending on the result of the algorithm in `func()`. The Trigger block parameter **Trigger type** is function-call. Create the `func()` algorithm, as shown in the following diagram:
Model ex_while_loop_ML_func

14  Save and close the subsystem.
15  Connect the MATLAB Function block to the func() subsystem.
16  Save your model.

Results

The generated code includes the following while_loop_ML_step function in the file while_loop_ML.c. In some cases an equivalent for loop might be generated instead of a while loop.

```c
/* Model step function */
void ex_while_loop_ML_step(void)
{
    boolean_T func_flag_0;
    boolean_T flag;
    int32_T num_iter;

    /* MATLAB Function: '<Root>/MATLAB Function' */
    func_flag_0 = func_flag;

    /* MATLAB Function 'MATLAB Function': '<S1>:1' */
    /* '<S1>:1:3' */
    flag = true;

    /* '<S1>:1:4' */
    num_iter = 1;
    while (flag && (num_iter <= 100)) {
        /* Outputs for Function Call SubSystem: '<Root>/func' */

        /* '<S1>:1:6' */
        /* '<S1>:1:7' */
```
func();

/* End of Outputs for SubSystem: '<Root>/func' */

/* '<S1>:1:8' */
flag = func_flag_0;

/* '<S1>:1:9' */
um_iter++;
}

/* End of MATLAB Function: '<Root>/MATLAB Function' */

**Modeling Pattern for Do While Loop: While Iterator Subsystem block**

One method for creating a `while` loop is to use a While Iterator Subsystem block from the Simulink > Ports and Subsystems library.

![Do While Loop Diagram](ex_do_while_loop_SL)
**ex_do_while_loop_SL/While Iterator Subsystem**

**Procedure**

1. Drag a While Iterator Subsystem block from the Simulink > Ports and Subsystems library into the model.
2. Double-click the While Iterator Subsystem block to open the subsystem.
3. Place a Subsystem block next to the While Iterator block.
4. Right-click the subsystem and select **Block Parameters (Subsystem)**. The Block Parameters dialog box opens.
5. Select the **Treat as atomic unit** parameter to configure the subsystem to generate a function. This enables parameters on the **Code Generation** tab.
6. Select the **Code Generation** tab. From the **Function packaging** list, select the option, **Nonreusable function**.
7. From the **Function name options** list, select the option, **User specified**. The **Function name** parameter is displayed.
8. Specify the name as **func**.
9. Click **Apply**.
10. Double-click the **func** subsystem block. In this example, function **func** has an output **flag** set to 0 or 1 depending on the result of the algorithm in **func**. Create the **func** algorithm as shown in the following diagram:
Double-click the While Iterator block. This opens the Block Parameters dialog.

Set the **Maximum number of iterations** to 100.

Specify the **While loop type** as do-while.

Connect blocks as shown in the model and subsystem diagrams.

Enter **Ctrl+B** to generate code.

**Results**

```c
void func(void)
{
    flag = (DWork.NextOutput > (real_T)P.Constant1_Value);
    DWork.NextOutput =
        rt_NormalRand(&DWork.RandSeed) * P.RandomNumber_StdDev +
        P.RandomNumber_Mean;
}

void ex_do_while_loop_SL_step(void)
{
    int32_T s1_iter;
    s1_iter = 1;
    do {
        func();
        s1_iter++;
    } while (flag && (s1_iter <= 100));
}
```
Modeling Pattern for Do While Loop: Stateflow Chart

1. Add a Stateflow Chart to your model from the Stateflow > Chart library.
2. Double-click the chart to open it.
3. Add the inputs and outputs to the chart and specify their data type.
4. Connect the data input and output to the Stateflow chart.
5. In the Model Explorer, select the output variable, then, in the right pane, select the General tab and set the Initial Value to 0.
6 Select Chart > Add Patterns > Loop > While. The Stateflow Pattern dialog opens.

7 Fill in the fields for the Stateflow Pattern dialog box as follows:

- **Description**: While Loop (optional)
- **While condition**: (flag) && (num_iter<=100)
- **Do action**: func; num_iter++;

8 Place a Subsystem block in your model.

9 Right-click the subsystem and select Block Parameters (Subsystem). The Block Parameters dialog box opens.

10 Select the Treat as atomic unit parameter to configure the subsystem to generate a function. This enables parameters on the Code Generation tab.

11 Select the Code Generation tab. From the Function packaging list, select the option, Nonreusable function.

12 From the Function name options list, select the option, User specified. The Function name parameter is displayed.

13 Specify the name as func.

14 Click Apply to apply the changes.

15 Double-click the func subsystem block. In this example, function func has an output flag set to 0 or 1 depending on the result of the algorithm in func. The Trigger block parameter Trigger type is function-call. Create the func algorithm, as shown in the following diagram:

```
\[\text{ex_do_while_loop_SF/func}\] Updates the flag
```

16 Save and close the subsystem.

17 Connect blocks to the Stateflow chart as shown in the model diagram for ex_do_while_loop_SF.
18  Save your model.

Results

```c
void ex_do_while_loop_SF_step(void)
{
    int32_T sf_num_iter;
    num_iter = 1;
    do {
        func();
        num_iter++;
    } while (flag && (sf_num_iter <= 100));
}
```

### Function Call

To generate a function call, add a subsystem, which implements the operations that you want.

#### C Construct

```c
void add_function(void)
{
    y1 = u1 + u2;
}
```

#### Procedure

1. Create a model containing a subsystem. In this example, the subsystem has two inputs and returns one output.
2. Double-click the subsystem. Create `Add_Subsystem`, as shown.

#### ex_function_call

3. Right-click the subsystem and select **Block Parameters (Subsystem)** to open the Subsystem Parameters dialog box.
4. Select the **Treat as atomic unit** parameter. This enables parameters on the **Code Generation** tab.
Select the **Code Generation** tab. For the **Function packaging** parameter, from the drop-down list, select **Nonreusable function**.

5. For the **Function name options** parameter, from the drop-down list, select **User specified**.

6. In the **Function name** field, enter the subsystem name, `add_function`.

7. In the **File name options** field, select **Use function name**.

8. Click **Apply** and **OK**.

9. Press **Ctrl+B** to build and generate code.

**Results**

In `ex_function_call.c`, the function is called from `ex_function_call_step`:

```c
void ex_function_call_step(void)
{
    add_function();
}
```

The function prototype is externed through the subsystem file, `add_function.h`:

```c
extern void add_function(void);
```

The function definition is in the subsystem file `add_function.c`:

```c
void add_function(void)
{
    function_call_Y.y1 = u1 + u2;
}
```

### Function Prototyping

**C Construct**

```c
double add_function(double u1, double u2)
{
    return u1 + u2;
}
```

**Modeling Patterns**

- “Function Call Using Graphical Functions” on page 14-61
- “Control Function Prototype of the model_step Function” on page 14-63

### Function Call Using Graphical Functions

**Procedure**

1. Follow the steps in “Set Up an Example Model With a Stateflow Chart” on page 14-5. This example model contains two Inport blocks and one Outport block.
2. Name the example model `ex_func_SF`.
3. In the **Stateflow Editor**, create a graphical function by clicking the `fx` button and placing a graphical function into the Stateflow chart.
4. Edit the graphical function signature to: `output = add_function(u1, u2)`.
5. Add the transition action.
In the Stateflow chart, there is an example of a simple transition that calls `add_function`.

6 Open the Model Explorer. From the Model Hierarchy tree, select `ex_func_SF > Chart > f()add_function`. On the right pane, specify the **Function Inline Option** as Function.

7 From the Model Hierarchy tree, click **Chart** and on the right pane select the **Export Chart Level Functions (Make Global)** parameter. The function is now available globally to the entire model.

8 Press **Ctrl+B** to build the model and generate code.

**Results**

`ex_func_SF.c` contains the generated code:

```c
real_T add_function(real_T in1, real_T in2)
{
    return in1 + in2;
}

void ex_func_SF_step(void)
{
    y1 = add_function(u1, u2);
}
```
Control Function Prototype of the model_step Function

ex_control_step_function

Procedure

2. Open the Configuration Parameters dialog box by pressing Ctrl+E.

3. Open the Configure C/C++ Function Interface dialog box. In the Code Generation > Interface pane, click Configure Model Functions. The dialog box opens showing a preview of an execution function prototype with no arguments (void-void). If arguments have been configured for the model previously, the dialog box displays the current settings.

4. Configure step function arguments. If an application requires a void-void interface, clear Configure arguments for function prototype. For this example, select Configure arguments for function prototype.

5. Display current default settings for the entry-point function arguments by clicking Get default. An updated diagram appears and a table that lists external I/O ports with property settings.

6. Configure the step function return argument by setting C return argument to void or Outport. For this example, select void.

7. Configure the function input and output arguments:

   • Switch the order of the two inports. Move the row for Inport below the row for Inport1.
   • For Inport1, set C Type Qualifier to Auto (pass by value) and C Identifier Name to argIn1.
   • For Inport, set C Type Qualifier to Pointer to const and C Identifier Name to argIn2.
For the outport, set **C Identifier Name** to `argOut`.

The function prototype preview is updated as you make these changes.

8 Validate your changes by clicking **Validate**.

9 Close the Configure C/C++ Function Interface dialog box. Click **Apply**. Then, click **OK**.

10 Generate code and a report. Use the report to verify that the generated step function in `ex_control_step_function.c` reflects the argument changes that you made.

For more information about controlling function prototypes, see “Customize Generated C Function Interfaces” on page 29-2.

**Results**

`ex_control_step_function.c` contains the generated code:

```c
void ex_control_step_function_step(real_T argIn1, const real_T *argIn2,...
    real_T *argOut)
{
    y1 = *argIn2 + argIn1;
}
```

**See Also**

**Related Examples**

External C Functions

C Construct

```c
extern double add(double, double);

#include "add.h"
double add(double u1, double u2)
{
    double y1;
    y1 = u1 + u2;
    return (y1);
}
```

Modeling Patterns

There are several methods for integrating legacy C functions into the generated code. These methods either create an S-function or make a call to an external C function. For more information on S-functions, see “S-Functions and Code Generation” (Simulink Coder).

- “Use the Legacy Code Tool to Create S-functions” on page 14-65
- “Use a Stateflow Chart to Make Calls to C Functions” on page 14-67
- “Using a MATLAB Function Block to Make Calls to C Functions” on page 14-69

Use the Legacy Code Tool to Create S-functions

This method uses the Legacy Code Tool to create an S-function and generate a TLC file. The code generation software uses the TLC file to generate code from this S-function. The advantage of using the Legacy Code Tool is that the generated code is fully inlined and does not need wrapper functions to access the custom code.

Procedure

1. Create a C header file named `add.h` that contains the function signature:

   ```c
   extern double add(double, double);
   ```
Create a C source file named `add.c` that contains the function body:

```c
double add(double u1, double u2)
{
    double y1;
    y1 = u1 + u2;
    return (y1);
}
```

To build an S-function for use in both simulation and code generation, run the following script or execute each of these commands at the MATLAB command line:

```matlab
%% Initialize legacy code tool data structure
def = legacy_code('initialize');

%% Specify Source File
def.SourceFiles = {'add.c'};

%% Specify Header File
def.HeaderFiles = {'add.h'};

%% Specify the Name of the generated S-function
def.SFunctionName = 'add_function';

%% Create a c-mex file for S-function
legacy_code('sfcn_cmex_generate', def);

%% Define function signature and target the Output method
def.OutputFcnSpec = ['double y1 = add(double u1, double u2)'];

%% Compile/Mex and generate a block that can be used in simulation
legacy_code('generate_for_sim', def);

%% Create a TLC file for Code Generation
legacy_code('sfcn_tlc_generate', def);

%% Create a Masked S-function Block
legacy_code('slblock_generate', def);

The output of this script produces:

- A new model containing the S-function block
- A TLC file named `add_function.tlc`
- A C source file named `add_function.c`
A mexw32 dll file named `add_function.mexw32`

4 Add inport blocks and an outport block and make the connections, as shown in the model.

```
real_T u1;
real_T u2;
real_T y1;
void ex_function_call_lct_step(void)
{
    y1 = add(u1, u2);
}
```

The user-specified header file, `add.h`, is included in `ex_function_call_lct.h`:

```
#include "add.h"
```

**Use a Stateflow Chart to Make Calls to C Functions**

**Procedure**

1. Create a C header file named `add.h` that contains the example function signature.
2. Create a C source file named `add.c` that contains the function body.
3. Follow the steps for “Set Up an Example Model With a Stateflow Chart” on page 14-5. This example model contains two Inport blocks and one Outport block.
4. Name the example model `ex_exfunction_call_SF`. 
5 Double-click the Stateflow chart and edit the chart as shown. Place the call to the `add` function within a transition action.

6 On the Stateflow Editor, select Simulation > Model Configuration Parameters.

7 On the Configuration Parameters dialog box, select Simulation Target > Custom Code. In the Include custom C code in generated section, on the left pane, select Header file and in the Header file field, enter the `#include` statement:

```
#include "add.h"
```

8 In the Include list of additional section, select Source files and in the Source files field, enter `add.c`.

9 On the Configuration Parameters dialog box, select Code Generation > Custom Code.

10 Select Use the same custom code settings as Simulation Target.

11 Press Ctrl+B to build the model and generate code.

**Results**

`ex_exfunction_call_SF.c` contains the following code in the step function:

```c
real_T u1;
real_T u2;
real_T y1;

void exfunction_call_SF_step(void)
{
  y1 = (real_T)add(u1, u2);
}
```

`ex_exfunction_call_SF.h` contains the include statement for `add.h`:

```
#include "add.h"
```
Using a MATLAB Function Block to Make Calls to C Functions

Procedure

1. Create a C header file named add.h that contains the example function signature.
2. Create a C source file named add.c that contains the function body.
3. In the Simulink Library Browser, click Simulink > User Defined Functions, and drag a MATLAB Function block into your model.
4. Double-click the MATLAB Function block. The MATLAB Function Block Editor opens.
5. Edit the function to include the statement:

```matlab
function y1 = add_function(u1, u2)
% Set the class and size of output
y1 = u1;
% Call external C function
y1 = coder.ceval('add',u1,u2);
end
```
6. Open the Configuration Parameters dialog box, and select Simulation Target > Custom Code.
7. In the Include custom C code in generated section, on the left pane, select Header file and in the Header file field, enter the statement:

```c
#include "add.h"
```
8. In the Include list of additional section, select Source files and in the Source files field, enter add.c.
9. Add two Inport blocks and one Outport block to the model and connect to the MATLAB Function block.
10. Configure the signals: u1, u2, and y1, as described in “Configure Input Ports, Output Ports, and Arbitrary Signals” on page 14-3.
11. Save the model as ex_exfunction_call_ML.
12. Press Ctrl+B to build the model and generate code.

Results

ex_exfunction_call_ML.c contains the following code:
real_T u1;
real_T u2;
real_T y1;

void ex_exfunction_call_ML_step(void)
{
    y1 = add(u1, u2);
}

ex_exfunction_call_ML.h contains the #include statement for add.h:
#include "add.h"

Macro Definitions (#define)

C Construct

#define myParam 9.8;

Export Generated Macro Definition

Procedure

1. Create the ex_param_macro model by using a Gain block.

   ![Gain Block Diagram]

2. Create the ex_defn_decl model by using a Gain block.

   ![Gain Block Diagram]

3. In the model, select View > Model Data Editor.

4. In the Model Data Editor, on the Parameters tab, set the value of the Gain parameter to myParam.

5. Next to myParam, click the action button and select Create.

6. In the Create New Data dialog box, set Value to Simulink.Parameter(9.8) and click Create.

   A Simulink.Parameter object, myParam, appears in the base workspace. The Gain block uses the object to set the value of the Gain parameter, in this case, 9.8.

7. In the Simulink.Parameter property dialog box, set Storage class to Define. Click OK.

8. Generate code from the model.
Results

The generated header file `ex_param_macro.h` defines `myParam` as a macro.

```c
/* Definition for custom storage class: Define */
#define myParam                             9.8
```

Reuse Macro from Handwritten Code

Procedure

1. Follow the steps in “Export Generated Macro Definition” on page 14-71.
2. In the Model Data Editor, on the Parameters tab, click the Show/refresh additional information button.
3. Set the Change view drop-down list to Code.
4. Use the Storage Class column to change the storage class of `myParam` from Define to ImportedDefine.
5. For `myParam`, set Header File to `external_params.h`. With this setting, the generated code imports the macro definition from a custom header file named `external_params.h`.
6. In your current folder, create the C header file `external_params.h`, which contains the `#define` statement.

```c
#ifndef _EXTERNAL_PARAMS
#define _EXTERNAL_PARAMS

#define myParam 9.8

#endif

/* EOF */
```
7. Generate code from the model.

Results

The generated header file `ex_param_macro.h` does not define the macro. Instead, the file includes (#include) the custom header file `external_params.h`.

```c
/* Includes for objects with custom storage classes. */
#include "external_params.h"
```
The source file `ex_param_macro.c` contains a guard to check that a definition for `myParam` exists.

```c
/*
 * Check that imported macros with storage
 * class "ImportedDefine" are defined
 */
#ifndef myParam
#error The variable for the parameter "myParam" is not defined
#endif
```

- “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 26-19
Conditional Inclusions (#if / #endif)

You can generate preprocessor conditional directives in your code by implementing variant blocks (Model Variants block or Variant Subsystem block) in your model. In the generated code, preprocessor conditional directives select a section of code to execute at compile time. To implement variants in your model, see “Create a Simple Variant Model” (Simulink). To generate code for variants, see “Generate Preprocessor Conditionals for Variant Systems” on page 15-35.
Typedef

**C Construct**

typedef float float_32;

**Procedure**

To create a data type alias in Simulink, use a Simulink.AliasType. The code generator creates a typedef statement.

The built-in Simulink data type single corresponds to the C data type float.

1. At the command prompt, create a Simulink.AliasType object named float_32 that represents an alias of single.

   ```
   float_32 = Simulink.AliasType('single')
   ```

2. Create the ex_typedef model by using a Gain block.

   ![Simulink model diagram](image)

3. In the model, select **View > Model Data Editor**.
4. In the Model Data Editor, view the **Inports/Outports** tab.
5. From the **Change View** drop-down list, select **Design**.
6. In the model, select the Inport block.
7. In the Model Data Editor, for the Inport block, set **Data Type** to float_32.
8. From the **Change view** drop-down list, select **Code**.
9. For the Inport block, set **Signal Name** to mySig.
10. Set **Storage Class** to ExportedGlobal.

   With this setting, the Inport block appears in the generated code as a separate global variable.

11. Generate code from the model.
**Results**

The generated header file `ex_typedef.h` defines the data type alias `float_32`.

```c
#ifndef DEFINED_TYPEDEF_FOR_float_32_
#define DEFINED_TYPEDEF_FOR_float_32_

typedef real32_T float_32;
#endif
```

By default, the code generator also creates the alias `real32_T`, which corresponds to the C data type `float`. You can see the `typedef` statement in the generated header file `rtwtypes.h`.

```c
typedef float real32_T;
```

The generated source file `ex_typedef.c` uses `float_32` to define the global variable `mySig`.

```c
/* Exported block signals */
float_32 mySig;                        /* '<Root>/In1' */
```

Simulink.AliasType

**Related Examples**

- “Control Data Type Names in Generated Code” on page 24-2
- “Structures of Signals” on page 14-81
Structures of Parameters

Create a structure in the generated code. The structure stores parameter data.

**C Construct**

typedef struct {
    double G1;
    double G2;
} myStructType;

myStructType myStruct = {
    2.0,
    -2.0
} ;

**Procedure**

Open the example model rtwdemo_paraminline.

rtwdemo_paraminline
Select **View > Model Data Editor**.

In the Model Data Editor, select the **Parameters** tab.

In the model, click the Gain block labeled G1.

In the Model Data Editor, use the **Value** column to set the value of the **Gain** parameter to **myStruct.G1**.

Use the Model Data Editor to set the value of the **Gain** parameter in the G2 block to **myStruct.G2**.

Next to **myStruct.G2**, click the action button (with three vertical dots) and select **Create**.

In the Create New Data dialog box, set **Value** to **Simulink.Parameter(struct)** and click **Create**. A **Simulink.Parameter** object named **myStruct** appears in the base workspace.

In the **Simulink.Parameter** property dialog box, next to the **Value** property, click the action button and select **Open Variable Editor**.

In the Variable Editor, right-click the white space under the **Field** column and select **New**. Name the new structure field **G1**. Use the **Value** column to set the value of the field to 2.

Use the Variable Editor to add a field **G2** whose value is -2 and then close the Variable Editor.

In the **Simulink.Parameter** property dialog box, set **Storage class** to **ExportedGlobal**. With this setting, the structure **myStruct** appears in the generated code as a global variable.

Alternatively, use these commands to configure the blocks and create **myStruct**.

```matlab
rtwdemo_paraminline
set_param('rtwdemo_paraminline/G1','Gain','myStruct.G1')
set_param('rtwdemo_paraminline/G2','Gain','myStruct.G2')

myStruct.G1 = 2;
myStruct.G2 = -2;
myStruct = Simulink.Parameter(myStruct); myStruct.CoderInfo.StorageClass = 'ExportedGlobal';
```
Results

Generate code from the model.

`rtwbuild('rtwdemo_paraminline')`

### Starting build procedure for model: rtwdemo_paraminline
### Successful completion of build procedure for model: rtwdemo_paraminline

The generated header file `rtwdemo_paraminline_types.h` defines a structure type with a random name.

```matlab
file = fullfile('rtwdemo_paraminline_grt_rtw','rtwdemo_paraminline_types.h');
rtwdemodbtype(file,'typedef struct {','} struct_6h72eH5WFuEIyQr5YrdGuB;',1,1)

typedef struct {
    real_T G1;
    real_T G2;
} struct_6h72eH5WFuEIyQr5YrdGuB;
```

The source file `rtwdemo_paraminline.c` defines and initializes the structure variable `myStruct`.

```matlab
file = fullfile('rtwdemo_paraminline_grt_rtw','rtwdemo_paraminline.c');
rtwdemodbtype(file,'struct_6h72eH5WFuEIyQr5YrdGuB myStruct;',1,1)

struct_6h72eH5WFuEIyQr5YrdGuB myStruct = {
    2.0,
    -2.0
} ;                                    /* Variable: myStruct */
```

**Specify Name of Structure Type**

Optionally, specify a name to use for the structure type definition (struct).

At the command prompt, use the function `Simulink.Bus.createObject` to create a `Simulink.Bus` object that represents the structure type.

`Simulink.Bus.createObject(myStruct.Value);`
The default name of the object is `slBus1`. Change the name by copying the object into a new MATLAB variable.

```matlab
myStructType = copy(slBus1);
```

In the Model Data Editor, click the **Show/refresh additional information** button.

In the data table, find the row that corresponds to `myStruct`. Use the **Data Type** column to set the data type of `myStruct` to `Bus: myStructType`.

Alternatively, at the command prompt, use this command to set the data type of `myStruct`.

```matlab
myStruct.DataType = 'Bus: myStructType';
```

Generate code from the model.

```bash
rtwbuild('rtwdemo_paraminline')
```

### Starting build procedure for model: rtwdemo_paraminline
### Successful completion of build procedure for model: rtwdemo_paraminline

The code generates the definition of the structure type `myStructType` and uses this type to define the global variable `myStruct`.

```c
rtwdemodbtype(file,'myStructType myStruct = {','/* Variable: myStruct','...1,1)

myStructType myStruct = {
    2.0,
    -2.0
} ; /* Variable: myStruct
```

Structures of Signals

This example shows how to create a structure of signal data in the generated code.

C Construct

typedef struct {
    double signal1;
    double signal2;
    double signal3;
} my_signals_type;

Procedure

To represent a structure type in a model, create a Simulink.Bus object. Use the object as the data type of bus signals in your model.

Create the ex_signal_struct model with Gain blocks, a Bus Creator block, and a Unit Delay block. The Gain and Unit Delay blocks make the structure more identifiable in the generated code.

To configure the Bus Creator block to accept three inputs, in the block dialog box, set Number of inputs to 3.

In the model, select Edit > Bus Editor.
Use the Bus Editor to create a Simulink.Bus object named `my_signals_type` that contains three signal elements: `signal1`, `signal2`, and `signal3`. To create bus objects with the Bus Editor, see “Create Bus Objects with the Bus Editor” (Simulink).

This bus object represents the structure type that you want the generated code to use.

In the Bus Creator block dialog box, set **Output data type** to `Bus: my_signals_type`.

Select **Output as nonvirtual bus**. Click **OK**. A nonvirtual bus appears in the generated code as a structure.

In the model, select **View > Model Data Editor**.

In the Model Data Editor, on the **Signals** tab, from the **Change view** drop-down list, select **Code**.

In the model, click the output signal of the Bus Creator block.

In the Model Data Editor, for the output of the Bus Creator block, set **Name** to `sig_struct_var`.

Set **Storage Class** to `ExportedGlobal`. With this setting, the output of the Bus Creator block appears in the generated code as a separate global structure variable named `sig_struct_var`.

Generate code from the model.

**Results**

The generated header file `ex_signal_struct_types.h` defines the structure type `my_signals_type`.

```c
typedef struct {
    real_T signal1;
    real_T signal2;
    ...  // other signal elements
} my_signals_type;
```
The source file `ex_signal_struct.c` allocates memory for the global variable `sig_struct_var`, which represents the output of the Bus Creator block.

In the same file, in the model step function, the algorithm accesses `sig_struct_var` and the fields of `sig_struct_var`.

**See Also**
`Simulink.Bus`

**Related Examples**
- “Organize Data into Structures in Generated Code” on page 22-177
- “Combine Buses into an Array of Buses” (Simulink)
Nested Structures of Signals

You can create nested structures of signal data in the generated code.

**C Construct**

```c
typedef struct {
  double signal1;
  double signal2;
  double signal3;
} B_struct_type;

typedef struct {
  double signal1;
  double signal2;
} C_struct_type;

typedef struct {
  B_struct_type subStruct_B;
  C_struct_type subStruct_C;
} A_struct_type;
```

**Procedure**

To represent a structure type in a model, create a `Simulink.Bus` object. Use the object as the data type of bus signals in your model.

To nest a structure inside another structure, use a bus object as the data type of a signal element in another bus object.

Create the `ex_signal_nested_struct` model with Gain blocks, Bus Creator blocks, and a Unit Delay block. The Gain and Unit Delay blocks make the structure more identifiable in the generated code.
To configure a Bus Creator block to accept three inputs, in the block dialog box, set **Number of inputs** to 3.

In the model, select **Edit > Bus Editor**.

Use the Bus Editor to create a Simulink.Bus object named `A_struct_type` that contains two signal elements: `subStruct_B` and `subStruct_C`. To create bus objects with the Bus Editor, see “Create Bus Objects with the Bus Editor” (Simulink). This bus object represents the top-level structure type that you want the generated code to use.

For the `subStruct_B` element, set **DataType** to `Bus: B_struct_type`. Use a similar type name for `subStruct_C`. 

Nested Structures of Signals

14-85
Each signal element in A_struct_type uses another bus object as a data type. Now, these elements represent substructures.

Use the Bus Editor to create the Simulink.Bus objects B_struct_type (with three signal elements) and C_struct_type (with two signal elements).

In the dialog box of the Bus Creator block that collects the three Gain signals, set Output data type to Bus: B_struct_type. Click Apply.

Select Output as nonvirtual bus and click OK.

In the dialog box of the other subordinate Bus Creator block, set Output data type to Bus: C_struct_type and select Output as nonvirtual bus. Click OK.

In the last Bus Creator block dialog box, set Output data type to Bus: A_struct_type and select Output as nonvirtual bus. Click OK.

In the model, select View > Model Data Editor.

In the Model Data Editor, on the Signals tab, from the Change view drop-down list, select Code.
In the model, click the output signal of the A\_struct\_type Bus Creator block, which feeds the Unit Delay block.

In the Model Data Editor, for the output of the Bus Creator block, set Name to sig\_struct\_var.

Set Storage Class to ExportedGlobal. With this setting, the output of the Bus Creator block appears in the generated code as a separate global structure variable named sig\_struct\_var.

Generate code from the model.

**Results**

The generated header file ex\_signal\_nested\_struct\_types.h defines the structure types. Each structure type corresponds to a Simulink.Bus object.

```c
typedef struct {
    real_T signal1;
    real_T signal2;
    real_T signal3;
} B_struct_type;

typedef struct {
    real_T signal1;
    real_T signal2;
} C_struct_type;

typedef struct {
    B_struct_type subStruct_B;
    C_struct_type subStruct_C;
} A_struct_type;
```

The generated source file ex\_signal\_nested\_struct\_c allocates memory for the global structure variable sig\_struct\_var. By default, the name of the A\_struct\_type Bus Creator block is Bus Creator2.

```c
/* Exported block signals */
A_struct_type sig_struct_var;    /* '<Root>/Bus Creator2' */
```
In the same file, in the model step function, the algorithm accesses `sig_struct_var` and the fields of `sig_struct_var`.

Bitfields

C Construct

typedef struct {
    unsigned int p1 : 1;
    unsigned int p2 : 1;
    unsigned int p3 : 1;
} my_struct_type

Procedure

1. Create the `ex_struct_bitfield_CSC` model with three Constant blocks and three Outport blocks.

   ![Diagram of three Constant blocks and one Outport block]

2. In the model, select View > Model Data Editor.
3. In the Model Data Editor, on the Parameters tab, use the Value column to set value of the first Constant block to `p1`.
4. Next to `p1`, click the action button and select Create.
5. In the Create New Data dialog box, set Value to `Simulink.Parameter(false)` and click Create.

   A Simulink.Parameter object named `p1` appears in the base workspace. The object stores a Boolean value, false, and uses the data type boolean.
6. In the Simulink.Parameter property dialog box, click OK.
7. Use the Model Data Editor to configure the other Constant blocks to refer to new parameter objects named `p2` and `p3`. 
In the Model Data Editor, click the **Show/refresh additional information** button.

Set the **Change view** drop-down list to **Code**.

Use the **Storage Class** column to apply the custom storage class **BitField** to the parameter objects.

Use the **Struct Name** column to configure each object to use the same structure type, **my_struct**.

Generate code from the model.

**Results**

The generated header file `ex_struct_bitfield_CSC.h` defines the structure type **my_struct_type**.

```c
/* Type definition for custom storage class: BitField */
typedef struct my_struct_tag {
    uint_T p1 : 1;
    uint_T p2 : 1;
    uint_T p3 : 1;
} my_struct_type;
```

The generated source file `ex_struct_bitfield_CSC.c` defines and initializes the structure variable **my_struct**.

```c
/* Definition for custom storage class: BitField */
my_struct_type my_struct = {
    /* p1 */
    0,

    /* p2 */
    1,

    /* p3 */
    0
};
```

Arrays for Parameters

C Construct

```c
float myParams[5] = {1.0F, 2.0F, 3.0F, 4.0F, 5.0F};
```

Procedure

1. Create the `ex_param_array` model by using a Gain block.

2. In the model, select View > Property Inspector. The Property Inspector opens.
3. In the model, select the Gain block.
4. In the Property Inspector, set the value of the Gain parameter to `myParams`.
5. Next to the parameter value, click the action button `:` and select Create.
6. In the Create New Data dialog box, set Value to `Simulink.Parameter([1 2 3 4 5])`. Click Create.

A Simulink.Parameter object, `myParams`, appears in the base workspace. The Gain block uses the object to set the value of the Gain parameter.

7. In the Simulink.Parameter property dialog box, set Storage class to ExportedGlobal.

   With this setting, `myParams` appears in the generated code as a separate global variable.
8. Set Data type to single. Click OK.
9. Generate code from the model.

Results

The generated source file `ex_param_array.c` defines and initializes the global variable `myParams`.

Related Examples

- “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 22-50
- “Code Generation of Matrices and Arrays” on page 36-77
Arrays for Signals

C Construct

double myIn[5];
double myOut[5];

Procedure

1  Create the ex_signal_array model by using a Gain block.

2  In the model, select View > Model Data Editor.
3  In the Model Data Editor, view the Inports/Outports tab.
4  From the Change View drop-down list, select Design.
5  In the model, select the Inport block.
6  In the Model Data Editor, for the Inport block, set Signal Name to myIn.
7  Set Dimensions to [5 1].
8  For the Outport block, set Signal Name to myOut.
9  From the Change View drop-down list, select Code.
10 For the Inport block and the Outport block, set Storage Class to ExportedGlobal.
   With this setting, the blocks appear in the generated code as separate global variables.
11  Generate code from the model.

Results

The generated source file ex_signal_array.c defines the global variables myIn and myOut as arrays with 5 elements each.
/* Exported block signals */
real_T myIn[5];  /* '<Root>/In1' */
real_T myOut[5]; /* '<Root>/Out1' */

Pointers

When your handwritten code allocates memory for signal, state, or parameter data, you can generate code that accesses that data through a pointer. Apply a storage class such as ImportedExternPointer to a data item in the model. Your handwritten code provides the pointer definition.

C Construct

extern double *myIn;

Procedure

1. Create the ex_pointer model by using a Gain block.

2. In the model, select View > Model Data Editor.
3. In the Model Data Editor, view the Imports/Outports tab.
4. From the Change view drop-down list, select Code.
5. In the model, select the Inport block.
6. In the Model Data Editor, for the Inport block, set Signal Name to myIn.
7. Set Storage Class to ImportedExternPointer.
8. Generate code from the model.

Results

The generated header file ex_pointer.h declares the pointer.

```c
/* Imported (extern) pointer block signals */
extern real_T *myIn;                     /* '<Root>/In1' */
```

In the generated source file ex_pointer.c, in the model step function, the algorithm dereferences the pointer, myIn.
/* Model step function */
void ex_pointer_step(void)
{
    /* Outport: '<Root>/Out1' incorporates:
       * Inport: '<Root>/In1'
    */
    rtY.Out1 = *myIn;
}

Implement Dimension Variants for Array Sizes in Generated Code

**Dimension Variants**

Use symbolic dimensions to simulate various sets of dimension choices without regenerating code for every set. Set up your model with dimensions that you specify as symbols in blocks and data objects. These symbols propagate throughout the model during simulation, and then go into the generated code. Modeling constraints for symbols during simulation (for example, \( C = A + B \)) are output as preprocessor conditionals in either the `model.h` or the `model__types.h` file.

You can directly specify dimension information as a symbol or a numeric constant for these blocks and data objects:

- Inport
- Outport
- Signal Specification
- Data Store Memory
- Interpreted MATLAB Function
- `Simulink.Signal`
- `Simulink.Parameter`
- `Simulink.BusElement`
- `AUTOSAR.Parameter`

The Data Store Memory and Interpreted MATLAB Function blocks also support variable dimension signals. For these blocks, the symbolic dimensions control the maximum allowed size.

You must provide the code for `Simulink.Parameter` objects that contain symbolic dimensions. You can provide this code by using the `ImportedExtern` or `ImportedExternPointer` built-in storage classes.

You use `Simulink.Parameter` objects to specify dimension information as symbols. For more information on signal dimensions, see “Signal Dimensions” (Simulink).
You must fix symbolic dimension values at compile-time. You can not resolve a symbolic dimension to another variable and then vary it during run-time because you define the behavior during simulation.

**Note:** The dimension variants feature is on by default. You can turn off this feature by clearing the “Allow symbolic dimension specification” (Simulink) parameter in the Configuration Parameters dialog box.

**Define Symbolic Dimensions**

This example uses the model `rtwdemo_dimension_variants` to show how to implement symbolic dimensions. This model has four modeling patterns involving vectors and matrices.

1. To show block names, on the **Display** menu, deselect **Hide Automatic Names**.
2. Open the Model Explorer. Select the base workspace pane.
In the base workspace, there are four Simulink.Parameter objects for specifying symbolic dimensions. These Simulink.Parameter objects have the names A, B, C, and D.

Select the Simulink.Parameter object A. Review the information in the Simulink.Parameter dialog box. A has a storage class of CompilerFlag.

Repeat Step 4 for each of the Simulink.Parameter objects B, C, and D.

For Simulink.Parameter objects with an ImportedDefine custom storage class, provide a header file on the MATLAB path. Insert the name of the header file in the HeaderFile field in the Simulink.Parameter dialog box.

To use a Simulink.Parameter object for dimension specification, it must be defined in the base workspace and have one of these storage classes:

- Define or ImportedDefine with header file specified
- CompilerFlag
- User-defined custom storage class that defines data as a macro in a specified header file

You can use MATLAB expressions to specify symbolic dimensions. For a list of supported MATLAB expressions, see the section Operators and Operands in Variant Condition Expressions in “Introduction to Variant Controls” (Simulink).

Specify Symbolic Dimensions for Blocks and Data Objects

1 Open the Source Block Parameters dialog box of Inport Block In2. In the Signal Attributes tab, the Port Dimensions field contains the Simulink.Parameter object A. For Inport blocks, you specify symbolic dimensions in the Port Dimensions field.

2 Open the Source Block Parameters dialog box of Inport block In3. In the Signal Attributes tab, the Port Dimensions field contains the Simulink.Parameter object B.

3 In the base workspace, select the Simulink.Parameter object Data. In the Simulink.Parameter dialog box for Data, the Dimension field has the character vector '{1,C}', which is equivalent to '{1,5}' because C has a value of 5. The Value field contains an array with 5 values, so the dimensions of C are consistent with the dimension of the Data object. The dimensions of the Data object must always be consistent with the value of the Simulink.Parameter object that is in the Data object Dimensions field. Data has a Storage class of ImportedExtern. A Simulink.Parameter object that uses a Simulink.Parameter for symbolic
dimension specification must have a storage class of either ImportedExtern or ImportedExternPointer.

4 Open the Block Parameters dialog box of the 1-D Lookup Table block. The Table data field contains the Simulink.Parameter, PT. The Breakpoints 1 field contains the Simulink.Parameter, PB.

5 In the base workspace, view the information in the Simulink.Parameter dialog boxes for PB and PT. These parameters contain the character vector '[1,D]' in their Dimensions field and are arrays consisting of 15 values. The dimension of D are consistent with the dimension of the PB and PT parameters because D has a value of 15.

6 Simulate the model. Simulink propagates the dimensions symbolically in the diagram. During propagation, Simulink establishes modeling constraints among symbols. Simulink then checks for consistency with these constraints based on current numerical assignments. One modeling constraint for rtwdemo_dimension_variants is that C=A+B. The Diagnostic Viewer produces a warning for any violations of constraints.

7 Change the dimension specification to a different configuration and simulate the model again.
Though not shown in this example, you can specify an n-D dimension expression with one or more of the dimensions being a symbol (for example, '[A,B,C]' or '[1,A,3]').

**Generate Code for a Model with Dimension Variants**

Once you have verified dimension specifications through model simulation, generate code for `rtwdemo_dimension_variants`.

Create a temporary folder for the build and inspection process.

```matlab
currentDir = pwd;
[~, cgDir] = rtwdemodir();
```

Build the model.

```matlab
model='rtwdemo_dimension_variants'; rtwbuild(model)
```
### Starting build procedure for model: rtwdemo_dimension_variants
### Successful completion of build procedure for model: rtwdemo_dimension_variants

View the generated code. In the `rtwdemo_dimension_variants.h` file, symbolic dimensions are in data declarations.

```c
hfile = fullfile(cgDir,'rtwdemo_dimension_variants_ert_rtw','rtwdemo_dimension_variants.h');
rtwdemodbtype(hfile,'/* External inputs', '/* Real-time', 1, 0);

/* External inputs (root inport signals with default storage) */
typedef struct {
    real_T In2[A];                      /* '<Root>/In2' */
    real_T In3[B];                      /* '<Root>/In3' */
} ExtU;

/* External outputs (root outports fed by signals with default storage) */
typedef struct {
    real_T Out1[A + B];                /* '<Root>/Out1' */
    real_T Out2[A + B];                /* '<Root>/Out2' */
} ExtY;
```

The `rtwdemo_dimension_variants.h` file contains data definitions and preprocessor conditionals that define constraints established among the symbols during simulation. One of these constraints is that the value of a symbolic dimension must be greater than 1. This file also includes the user-provided header file for any Simulink.Parameter objects with an ImportedDefine custom storage class.

```c
hfile = fullfile(cgDir,'rtwdemo_dimension_variants_ert_rtw','rtwdemo_dimension_variants.h');
rtwdemodbtype(hfile,'#ifndef A', '/* Macros for accessing', 1, 0);

#ifndef A
#error The variable for the parameter "A" is not defined
#endif

#ifndef B
#error The variable for the parameter "B" is not defined
#endif

#ifndef C
#error The variable for the parameter "C" is not defined
#endif

#ifndef D
```

15-7
#error The variable for the parameter "D" is not defined
#endif

/* Constraints for division operations in dimension variants */
#if (1 == 0) || (((A+B) % 1) != 0)
#error "The preprocessor definition '1' must not be equal to zero and the division of '(A+B)' by '1' must not have a remainder." 
#endif

/* Registered constraints for dimension variants */
/* Constraint 'C == (A+B)' registered by:
 * '<Root>/1-D Lookup Table1'
 */
#if C != (A+B)
#error "The preprocessor definition 'C' must be equal to '(A+B)'"
#endif

#if A <= 1
#error "The preprocessor definition 'A' must be greater than '1'"
#endif

#if B <= 1
#error "The preprocessor definition 'B' must be greater than '1'"
#endif

/* Constraint 'D > 1' registered by:
 * '<Root>/1-D Lookup Table1'
 */
#if D <= 1
#error "The preprocessor definition 'D' must be greater than '1'"
#endif

/* Constraint 'C > 1' registered by:
 * '<S2>/Assignment'
 */
#if C <= 1
#error "The preprocessor definition 'C' must be greater than '1'"
#endif
In the rtwdemo_dimension_variants.c file, symbolic dimensions participate in loop bound calculations, array size and index offset calculations, and a parameterized utility function (for example, Lookup Table block) calculation.

cfile = fullfile(cgDir,'rtwdemo_dimension_variants_ert_rtw',...
       'rtwdemo_dimension_variants.c');
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);

/* Model step function */

      rtY.Out2[ForEach_itr] = rtb_VectorConcatenate[ForEach_itr];
    }
  }
  rtY.Out2[s2_iter] = rtb_VectorConcatenate[s2_iter] * 2.0;
  /* End of Assignment: '<S2>/Assignment' */
}
/* End of Constant: '<Root>/Constant1' */
/* End of Outputs for SubSystem: '<Root>/For Iterator Subsystem' */

Close the model and code generation report.
Set Parameter Value Based on Variant Choice

When you specify the dimensions of a parameter in a model by using a symbol, you must make sure that the parameter value is consistent with the dimension value. To simulate different choices for the dimension value, you must manually correct the parameter value.

For example, in the `rtwdemo_dimension_variants` model, the `Simulink.Parameter` object `Data` stores a vector value, `[1 2 3 4 5]`, and uses a symbolic dimension `C` with initial value 5. If you change the value of `C`, to simulate the model, you must make sure the number of elements in the vector value matches the new value of `C`.

To reduce the effort of maintenance when you change the value of `C`, you can set the value of `Data` to an expression involving `C`.

1. Open the model.

   ```matlab
   rtwdemo_dimension_variants
   ```

2. At the command prompt, inspect the initial values of `Data` and `C`. The value of `Data` is a vector of integers from 1 to `C`.

   ```matlab
   Data.Value
   ans =
   1     2     3     4     5
   C.Value
   ans =
   5
   ```

3. In MATLAB code syntax, the value of `Data` is `1:C`. To preserve this relationship between the parameter objects, set the value of `Data` by using the `slexpr` function.

   ```matlab
   Data.Value = slexpr('1:C');
   ```

4. To prevent data type propagation errors, set the data type of `Data` explicitly to double, which is the data type that the parameter acquired before you set the parameter value to an expression.
Data.DataType = 'double';

5 Set the value of C to a different number, such as 6. Due to dimension constraints in the model, you must set the value of another dimension symbol, A, to 3.

C.Value = 6;
A.Value = 3;

6 Simulate the model. The block diagram shows that the value of Data now has six elements.

For more complicated applications, you can write your own MATLAB function that returns parameter values based on dimension symbols. Set the value of the parameter data to an expression that calls your function.

For general information about using an expression to set the value of a Simulink.Parameter object, see “Set Variable Value by Using a Mathematical Expression” (Simulink).

**Code Generation Optimization Considerations**

When you create a model with symbolic dimensions, be aware of the following optimization considerations:

- The code generator reuses buffers only if dimension propagation establishes equivalence among buffers.
- Two loops with symbolic loop bound calculations are fused together only if they share equivalent symbolic expression.
• Optimizations do not eliminate a symbolic expression or condition check based on the current value of a symbolic dimension.

**Backward Compatibility**

If an existing model uses Simulink.Parameter objects to specify dimensions, it can be incompatible with dimension variants. Here are two common scenarios:

• Only a subset of blocks accepts symbolic dimension specifications. If a block is not compatible with symbolic dimensions, it causes an update diagram error.
• Simulink.Parameter objects that you use to define symbolic dimensions or have symbolic dimensions must have one of the storage classes described in this example. If these specifications are not met, the build procedure for the model fails during code generation.

You can address these backward compatibility issues by doing the following:

• Turn off dimension variants feature by clearing the **Allow symbolic dimension specification** parameter in the Configuration Parameters dialog box.
• Update Simulink.Parameter objects that define symbolic dimensions or have symbolic dimension specifications.
• Update the model so that only supported blocks have symbolic dimensions or propagate symbolic dimensions.

**Supported Blocks**

For a list of supported blocks, see the Block Support Table. To access the information in this table, enter `showblockdatatypetable` at the MATLAB command prompt. Unsupported blocks (for example, MATLAB Function) can still work in a model containing symbolic dimensions as long as these blocks do not directly interact with symbolic dimensions.

In the following cases, supported blocks do not propagate symbolic dimensions.

• For Unit Delay blocks, you specify a Simulink.Signal object that has symbolic dimensions for the **Block Parameters > State Attributes > State name** parameter.
• For Assignment and Selector blocks, you set the **Block Parameters > Index Option** parameter to Index vector (dialog). For Selector and Assignment blocks, if you specify a symbolic dimension for the Index parameter, the code generator does not honor the symbolic dimension in the generated code.
• For the Sum block, you specify \(|+\) for the **Block Parameters > List of signs** parameter, and you set the **Block Parameters > Sum over** parameter to **Specified dimension**.

• For the Product block, you specify a value of 1 for the **Block Parameters > Number of inputs** parameter, and you set the **Multiply over** parameter to **Specified dimensions**.

• For the ForEach block, you specify a symbolic dimension for the **Partition Width** parameter.

Note that the following modeling patterns are among those modeling patterns that can cause Simulink to error out:

• For Switch blocks, an input signal or the **Threshold** parameter has symbolic dimensions, and you select **Allow different data input sizes (Results in variable-size output signal)**.

• A Data Store Read block selects elements of a `Simulink.Bus` signal that has symbolic dimensions.

• For Lookup Table blocks, on the **Block Parameters > Algorithm** tab, you select the parameter **Use one input port for all input data**.

**Limitations**

The following products and software capabilities support dimension variants in that they act on the numeric value of a symbolic dimension. These features do not support the propagation of symbolic dimensions during model simulation and the preservation of symbolic dimensions in the generated code.

• Code Replacement for Lookup Tables
• Software-in-the-Loop (SIL) and Processor-in-the-Loop (PIL) simulations
• Accelerator and rapid accelerator simulation modes
• Scope and simulation observation (for example, logging, SDI, and so on)
• Model coverage
• Simulink Design Verifier
• Fixed-Point Designer
• Data Dictionary
• Simulink PLC Coder
• HDL Coder

The following do not support dimension variants:

• System Object
• Stateflow
• Physical modeling
• Discrete-event simulation
• Frame data
• MATLAB functions

The following limitations also apply to models that utilize symbolic dimensions.

• For simulation, the size of a symbolic dimension can equal 1. For code generation, the size of a symbolic dimension must be greater than 1.
• If a symbolic dimension is a MATLAB expression that contains an arithmetic expression and either a relational or logical expression, you must add +0 after the relational or logical part of the MATLAB expression. If you do not add +0, the model errors out during simulation because you cannot mix a boolean data type with integer or double data types. Adding +0 converts the data type of the relational or logical part of the expression from a boolean to a double.

For example, suppose in the Inport block parameters dialog box, the Port dimensions parameter has the expression \([(C==8)\*D+E, 3]\). The Data type parameter is set to double. Since C==8 is a relational expression, you must change the expression to \([(C==8)+0\)*D+E, 3]\) to prevent the model from producing an error during simulation.

• Simulink propagates symbolic dimensions for an entire structure or matrix, but not for a part of a structure or matrix. For example, the Simulink.Parameter P is a 2x3 matrix with symbolic dimensions [Dim, Dim1].

```matlab
p=Simulink.Parameter(struct('A',[1 2 3;4 5 6]))
p.DataTypes='Bus:bo'
bo=Simulink.Bus
bo.Elements(1).Name='A'
bo.Elements(1).Dimensions='[Dim, Dim1]'
Dim=Simulink.Parameter(2)
Dim1=Simulink.Parameter(3)
p.CoderInfo.StorageClass='Custom'
p.CoderInfo.CustomStorageClass='Define'
```
If you specify `p.A` for a dimensions parameter, Simulink propagates the symbolic dimensions `[Dim, Dim1]`. If you specify `p.A(1,:)`, Simulink propagates the numeric dimension 3 but not the symbolic dimension, `Dim1`.

- The MATLAB expression `A(:)` does not maintain symbolic dimension information. Use `A` instead.
- The MATLAB expression `P(2:A)` does not maintain symbolic dimension information. Use the Selector block instead.
- The MATLAB expression `P(2,:)` is not a tunable expression, so it does not maintain symbolic dimension information.

Suppose that you set the value of a mask parameter, `myMaskParam`, by using a field of a structure or by using a subset of the structures in an array of structures. You store the structure or array of structures in a `Simulink.Parameter` object so that you can use a `Simulink.Bus` object to apply symbolic dimensions to the structure fields. Under the mask, you configure a block parameter to use one of the fields that have symbolic dimensions. The table shows some example cases.

<table>
<thead>
<tr>
<th>Description</th>
<th>Value of mask parameter (<code>myMaskParam</code>)</th>
<th>Value of block parameter</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>myStruct</code> is a structure with field <code>gains</code>, which uses symbolic dimensions.</td>
<td><code>myStruct.gains</code></td>
<td><code>myMaskParam</code></td>
</tr>
<tr>
<td><code>myStruct</code> is a structure with field hierarchy <code>myStruct.subStruct.gains</code>. The field <code>gains</code> uses symbolic dimensions.</td>
<td><code>myStruct.subStruct</code></td>
<td><code>myMaskParam.gains</code></td>
</tr>
<tr>
<td><code>myStructs</code> is an array of structures. Each structure has a field <code>gains</code>, which uses symbolic dimensions.</td>
<td><code>myStructs(2)</code></td>
<td><code>myMaskParam.gains</code></td>
</tr>
</tbody>
</table>

In these cases, you cannot generate code from the model. As a workaround, choose one of these techniques:
• Use the entire structure (myStruct) or array of structures (myStructs) as the value of the mask parameter. Under the mask, configure the block parameter to dereference the target field from the mask parameter by using an expression such as myMaskParam.subStruct.gains.

• Use literal dimensions instead of symbolic dimensions for the target field (gains).

This limitation also applies when you use a field of a structure or a subset of the structures in an array of structures as the value of a model argument in a Model block.

Code Generation for Variant Blocks

The code generator produces code from a Simulink model containing one or more Variant Subsystem, Variant Source, and Variant Sink blocks. To learn how to create a model containing variant blocks, see “Create a Simple Variant Model” (Simulink).

Code is generated for different variant choices, the active variant, and the default variant. To generate code for variants, set the following conditions in the Variant Subsystem, Variant Source, or Variant Sink block:

- Clear the option **Override variant conditions and use the following variant**.
- Select the option **Analyze all choices during update diagram and generate preprocessor conditionals**.

Code generated for Variant Subsystem blocks is surrounded by C preprocessor conditionals `#if`, `#else`, `#elif`, and `#endif`. Code generated for Variant Source and Variant Sink blocks is surrounded by C preprocessor conditionals `#if` and `#endif`. Therefore, the active variant is selected at compile time and the preprocessor conditionals determine which sections of the code to execute.

To construct model reference variants and generate preprocessor directives in the generated code, see the example “Use Model Variants to Generate Code That Uses C Preprocessor Conditionals”.

To construct variant subsystems and generate preprocessor directives in the generated code, see the example “Use Subsystem Variants To Generate Code That Uses C Preprocessor Conditionals”.

To construct models with variant sources and sinks and generate preprocessor directives in the generated code, see the example “Represent Variant Source and Sink Blocks in Generated Code” on page 15-42.

Restrictions on Variant Subsystem Code Generation

To generate preprocessor conditionals, the types of blocks that you can place within the child subsystems of a Variant Subsystem block are limited. Connections are not allowed in the Variant Subsystem block diagram. However, during the code generation process, one VariantMerge block is placed at the input of each Outport block within the Variant Subsystem block diagram. All of the child subsystems connect to each of the VariantMerge blocks.
In the figure below, the code generation process makes the following connections and adds VariantMerge blocks to the sldemo_variant_subsystems model.

When compared to a generic Merge block the VariantMerge block can have only one parameter which is the number of Inputs. The VariantMerge block is used for code generation in variant subsystems internally, and is not available externally to be used in models. The number of inputs for VariantMerge is determined and wired as shown in the figure below.

![Diagram of VariantMerge blocks with connections](image)

The child subsystems of the Variant Subsystem block must be atomic subsystems. Select **Treat as atomic unit** parameter in the Subsystem block parameters dialog, to make the subsystems atomic. The VariantMerge blocks are inserted at the outport of the subsystems if more than one child subsystems are present. If the source block of a VariantMerge block input is nonvirtual, an error message will be displayed during code generation. You must make the source block contiguous, by inserting Signal Conversion blocks inside the variant choices. The signals that enter a Variant Subsystem block must have the same signal properties (for example, signal dimensions, port width, and storage class). The VariantMerge block does not support different signal properties because the
input ports and output ports share the same memory. You can use symbolic dimensions to generate code for a variant subsystem with child subsystems of different output signal dimensions.

**Generated Code Components Not Compiled Conditionally**

The following components are not conditionally compiled even if only code for variant subsystems or models that are conditionally compiled reference them.

- `rtModel` data structure fields
- `#include`'s of utility files
- Global non-constant parameter structure fields; when the configuration parameter `Optimization > Parameter structure` is set to `NonHierarchical`
- Global constant parameter structure fields that are referenced by multiple subsystems activated by different variants
- Parameters that are configured to use an imported, exported, or custom code generation storage class, and are referenced by multiple subsystems that are activated by different variants
- Parameters that are configured to use an imported, exported, or custom code generation storage class, and are used by variant model blocks

**Code Generation for Variant Blocks with One Variant Choice**

For modeling patterns in which a Root Inport block connects to a Variant block with one variant choice, Simulink inserts a hidden block combination of a Ground block, Signal Conversion block, and a Variant Merge block. If the variant choice evaluates to false, this block combination produces an output of 0.0.

For example, the model `Varianttoground` contains a Variant Source block with one variant choice. When the Variant Control `SYSCONST_A==6` evaluates to true, the input to Subsystem is a sine wave. When `SYSCONST_A==6` evaluates to false, the input to Subsystem is 0.0.
The `varianttoground.c` file contains this code:

```c
/* Sin: '<Root>/Sine Wave' */
#if SYSCONST_A == 6
    varianttoground_B.VM_Conditional_Signal_Subsystem_0_r64 = sin
    (varianttoground_M->Timing.t[0]);
#endif /* SYSCONST_A == 6 */
/* End of Sin: '<Root>/Sine Wave' */

/* SignalConversion: '<Root>/VM_SignalConversion_Subsystem_0' */
#if SYSCONST_A != 6
    varianttoground_B.VM_Conditional_Signal_Subsystem_0_r64 = 0.0;
#endif /* SYSCONST_A != 6 */
/* End of SignalConversion: '<Root>/VM_SignalConversion_Subsystem_0' */
```

The comments in the generated code indicate the presence of the hidden signal conversion block. The code does not contain a comment for the Variant Merge block.
because this block does not have associated generated code. The Variant Merge block is used internally and is not in the Simulink library.

Required products: Simulink, Embedded Coder, Simulink Coder

Using Simulink, you can create models that are based on a modular design platform that comprises a fixed common structure with a finite set of variable components. The variability helps you develop a single, fixed master design with variable components. For more information, see “What Are Variants and When to Use Them” (Simulink) (Simulink). When you implement variants in the generated code, you can:

- Reuse generated code from a set of application models that share functionality with minor variations.
- Share generated code with a third party that activates one of the variants in the code.
- Validate the supported variants for a model and then choose to activate one variant for a particular application, without regenerating and re-validating the code.
- Generate code for the default variant that is selected when an active variant does not exist.

Using Embedded Coder, you can generate code from Simulink models containing one or more variant choices. The generated code contains preprocessor conditionals that control the activation of each variant choice.

This example shows how to represent variant choices in a Simulink model and then prepare the model so that those variant choices are represented in generated code.

**Step 1: Represent Variant Choices in Simulink**

Variant choices are two or more configurations of a component in your model. This example uses the model rtwdemo_preprocessor_subsys to illustrate how to represent
variant choices inside Variant Subsystem blocks. For other ways to represent variant choices, see “Options for Representing Variants in Simulink” (Simulink) (Simulink).

1. Open the model `rtwdemo_preprocessor_subsys`.

```
open_system('rtwdemo_preprocessor_subsys')
```

The model contains two Variant Subsystem blocks: **LeftController** and **RightController**.
**Note** You can only add Inport, Outport, Subsystem, and Model blocks inside a Variant Subsystem block.

2 Open the **LeftController** block.

The **LeftController** block serves as the container for the variant choices. It contains two variant choices represented using Subsystem blocks **Nonlinear** and **Linear**. The nonlinear controller subsystems implement hysteresis, whereas the linear controller subsystems act as simple low-pass filters.
The Subsystem blocks have the same number of inports and outports as the containing Variant Subsystem block.

Variant choices can have different numbers of inports and outports. See “Mapping Inports and Outports of Variant Choices” (Simulink) (Simulink).

3 Open the **Nonlinear** block.

The **Nonlinear** block represents one variant choice that Simulink activates when a condition is satisfied. The **Linear** block represents another variant choice.
Tip When you are prototyping variant choices, you can create empty Subsystem blocks with no inputs or outputs inside a Variant Subsystem block. The empty subsystem recreates the situation in which that subsystem is inactive without the need for completely modeling the variant choice.

Step 2: Specify Conditions That Control Variant Choice Selection

You can switch between variant choices by constructing conditional expressions called variant controls for each variant choice represented in a Variant Subsystem block. Variant controls determine which variant choice is active, and changing the value of a variant control causes the active variant choice to switch.

A variant control is a Boolean expression that activates a specific variant choice when it evaluates to true.

For more information, see “Introduction to Variant Controls” (Simulink) (Simulink).

1 Right-click the LeftController block and select Block Parameters (Subsystem).
The **Condition** column displays the Boolean expression that when true activates each variant choice. In this example, these conditions are specified using `Simulink.Variant` objects `LINEAR` and `NONLINEAR`.

2. Use these commands to specify a variant control using a `Simulink.Variant` object.

```matlab
LINEAR = Simulink.Variant;
LINEAR.Condition = 'VSSMODE==0';
NONLINEAR = Simulink.Variant;
NONLINEAR.Condition = 'VSSMODE==1';
```

Here, `VSSMODE` is called a variant control variable that can be specified in one of the ways listed in “Approaches for Specifying Variant Controls” (Simulink).

3. Define the variant control variable `VSSMODE`.

You can define `VSSMODE` as a scalar variable or as a `Simulink.Parameter` object. In addition to enabling the specification of parameter value, `Simulink.Parameter`
objects allow you to specify other attributes such as data type that are required for generating code.

```plaintext
VSSMODE = Simulink.Parameter;
VSSMODE.Value = 1;
VSSMODE.DataType = 'int32';
VSSMODE.CoderInfo.StorageClass = 'Custom';
VSSMODE.CoderInfo.CustomStorageClass = 'ImportedDefine';
VSSMODE.CoderInfo.CustomAttributes.HeaderFile = 'rtwdemo_importedmacros.h';
```

Variant control variables defined as `Simulink.Parameter` objects can have one of these storage classes.

- Define or `ImportedDefine` with header file specified
- `CompilerFlag`
- `SystemConstant` (AUTOSAR)
- Your own custom storage class that defines data as a macro

You can also convert a scalar variant control variable into a `Simulink.Parameter` object. See “Convert Variant Control Variables into Simulink.Parameter Objects” (Simulink) (Simulink).

**Step 3: Configure Model for Generating Preprocessor Conditionals**

Code generated for each variant choice is enclosed within C preprocessor conditionals `#if`, `#else`, `#elif`, and `#endif`. Therefore, the active variant is selected at compile time and the preprocessor conditionals determine which sections of the code to execute.

1. In the Simulink editor, select **Simulation > Model Configuration Parameters**.
2. Select the **Code Generation** pane, and set **System target file** to `ert.tlc`.
3. In the **Report** pane, select **Create code generation report**.
4. In the Configuration Parameters dialog box, clear **Ignore custom storage classes** and click **Apply**.
5. In your model, right-click the **LeftController** block and select **Block Parameters (Subsystem)**.
6. Select the option **Analyze all choices during update diagram and generate preprocessor conditionals**.
When you select this option, Simulink analyzes all variant choices during an update diagram or simulation. This analysis provides early validation of the code generation readiness of all variant choices.

7 Clear the option **Override variant conditions and use following variant**.

8 Build the model.

**Step 4: Review Generated Code**

The code generation report contains a section dedicated to the subsystems that have variants controlled by preprocessor conditionals.

1 To open the Code Generation Report click **Code > C/C++ Code > Code Generation Report > Open Model Report**.
2 Select the **Code Variant Report** from the left.
In this example, the generated code includes references to the Simulink.Variant objects LINEAR and NONLINEAR. The code also includes the definitions of macros corresponding to those variants. The definitions depend on the value of VSSMODE, which is supplied in an external header file rtwdemo_importedmacros.h. The
active variant is determined by using preprocessor conditionals (#if) on the macros (#define) LINEAR and NONLINEAR.

3 Select the `rtwdemo_preprocessor_subsys_types.h` file from the left.

This file contains the definitions of macros LINEAR and NONLINEAR.

```c
#ifndef LINEAR
    #define LINEAR      (VSSMODE == 0)
#endif

#ifndef NONLINEAR
    #define NONLINEAR   (VSSMODE == 1)
#endif
```

4 Select the `rtwdemo_preprocessor_subsys.c` file from the left.

In this file, calls to the step and initialization functions of each variant are conditionally compiled.

```c
/* Outputs for Atomic SubSystem: '<Root>/LeftController' */
#if LINEAR
    /* Output and update for atomic system: '<S1>/Linear' */
    ...
#elif NONLINEAR
    /* Output and update for atomic system: '<S1>/Nonlinear' */
    ...
#endif
```

**Limitations**

- When you are generating code for Model Variants blocks and Variant Subsystem blocks, the blocks cannot have:
  - Mass matrices
  - Function call ports
  - Outports with constant sample time
  - Simscape blocks
- The Model Variants block and its referenced models must have the same number of inports and outports.
- The port numbers and names for each active child subsystem must belong to a subset of the port numbers and names of the parent Variant Subsystem block.

Define Variant Controls

For variant systems, conditional expressions called variant controls determine which variant choice is active. You can specify a variant control as a condition expression, a Simulink.Variant object specifying a condition expression, a MATLAB variable, or a Simulink.Parameter object. This example shows how to define variant controls as Simulink.Parameter objects.

1. Open the Model Explorer. Select the base workspace.
2. In the Model Explorer, select Add > Simulink Parameter. Specify a name for the new parameter.
3. Use the function Simulink.VariantManager.findVariantControlVars to find and convert MATLAB variables used in variant control expressions into Simulink.Parameter objects. For an example, see “Convert Variant Control Variables into Simulink.Parameter Objects” (Simulink).
4. On the Simulink.Parameter property dialog box, specify the Value and Data type.
5. Select one of these Storage class values.
   - Define
   - ImportedDefine(Custom)
   - CompilerFlag(Custom)
   - A storage class created using the Custom Storage Class Designer. Your storage class must have the Data initialization parameter set to Macro and the Data scope parameter set to Imported. See “Control Data Representation by Configuring Custom Storage Class Properties” on page 26-31 for more information.
6. Specify the value of the variant control. If the storage class is ImportedDefine(Custom), do the following:
a Specify the **Header File** parameter as an external header file in the Custom Attributes section of the `Simulink.Parameter` property dialog box.

b Enter the values of the variant controls in the external header file.

---

**Note** The generated code refers to a variant control as a user-defined macro. The generated code does not contain the value of the macro. The value of the variant control determines the active variant in the compiled code.

If the variant control is a `CompilerFlag` custom storage class, the value of the variant control is set at compile time. Use the **Configuration Parameters > Code Generation > Custom Code > Additional build information > Defines** parameter to add a list of variant controls (macro definitions) to the compiler command line. For example, for variant control `VSSMODE`, in the text field for the **Defines** parameter, enter:

```
-DVSSMODE=1
```

If you want to modify the value of the variant control after generating a makefile, use a makefile option when compiling your code. For example, at a command line outside of MATLAB, enter:

```
makecommand -f model.mk DEFINES_CUSTOM="-DVSSMODE=1"
```

---

**Note** You can define the variant controls using `Simulink.Parameter` object of enumerated type. This approach provides meaningful names and improves the readability of the conditions. The generated code includes preprocessor conditionals to check that the variant condition contains valid values of the enumerated type.

---

**Configure Model for Generating Preprocessor Conditional Directives**

1 Open the Configuration Parameters dialog box.

2 Select the **Code Generation** pane, and set **System target file** as `ert.tlc`.

3 In the **Report** pane, select **Create code generation report**.

4 In the Configuration Parameters dialog box, clear the “Ignore custom storage classes” (Simulink Coder) parameter. In order to generate preprocessor conditionals, you must use custom storage classes.
In the Model Variants block parameter dialog box, select the **Generate preprocessor conditionals** parameter option. In the Variant Subsystem, Variant Source, or Variant Sink block parameter dialog boxes, select the **Analyze all choices during update diagram and generate preprocessor conditionals** option.

In both cases, clear the option to **Override variant conditions and use following variant**.

Generate code.

### Special Considerations for Generating Preprocessor Conditionals

- The code generation process checks that the inports and outports of a Model Variants block are identical (same port numbers and names) to the corresponding inports and outports of its variants. The build process for simulation does not make this check. Therefore, if your variant block contains mismatched inports or outports, the code generation process issues an error.

- The port numbers and names for each child variant subsystem must belong to a subset of the port numbers and names of the parent Variant Subsystem block.

- The code generation process checks that there is at least one active variant by using the variant control values stored in the base workspace. The variant control that evaluates to `true` becomes the active variant. If none of the variant controls evaluates to `true`, the default variant, if specified, becomes the active variant. The code generation process issues an error if an active variant does not exist.

- Implement the condition expressions of the variant objects such that only one evaluates to `true`. The generated code includes a test of the variant objects to determine that there is only one active variant. If this test fails, your code will not compile.

- If you comment out child subsystems listed in the **Variant Choices** table in the Variant Subsystem block parameter dialog box, the code generator does not generate code for the commented out subsystems.

- If the sample time for a default variant differs from that of the other variant choices, the `#else` preprocessor conditional is not generated for the default variant. Instead, an `#if !(<variant conditions>)` is generated.

- For Variant Subsystems, the `model_private.h` file contains conditional parameter definitions. For example, if the value of a Constant block is a `Simulink.Parameter` with an `ImportedDefine` custom storage class, and the Constant block is in a Variant...
Subsystem, the conditional definition of the Simulink.Parameter is in the model_private.h file.

**Generate Variant Control Macros in Same Header File**

This example shows how to aggregate multiple variant control macros (#define) into the same generated header file. This aggregation makes it easier for you to manage the complexities inherent in a system with multiple interacting variant conditions.

**Explore Example Model**

Run the script prepare_rtwdemo_preproc_subsys, which opens the model rtwdemo_preprocessor_subsys and prepares it for this example.

run(fullfile(matlabroot,'examples','ecoder','main','prepare_rtwdemo_preproc_subsys'));

The model contains two Variant Subsystem blocks.

Navigate inside the variant subsystems. The subsystems each have a linear and a nonlinear algorithm variant.
At the root level of the model, open the block dialog box of the variant subsystem labeled LeftController. The algorithm variants in the subsystem activate based on the states of two Simulink.Variant objects, LINEAR and NONLINEAR, in the base workspace.

The state of each object depends on the values of two variant control variables, MODE_A and MODE_B, which are Simulink.Parameter objects in the base workspace. The parameter objects use the custom storage class Define and are configured to appear in the generated code as C-code macros in macros.h.

**Change Name of Generated Header File Through Model Data Editor**

In this example, change the name of the generated header file from macros.h to variant_controls.h. You must change the file name in each parameter object.

In the model, select **View > Model Data Editor**.

In the Model Data Editor, select the **Parameters** tab.

Click the **Show/refresh additional information** button.

Set the **Change view** drop-down list to Code.

In the **Filter contents** box, enter MODE. The Model Data Editor shows two rows that correspond to the parameter objects.

Select both rows. Then, for one of the rows, use the **Header File** column to change the header file name from macros.h to variant_controls.h. The Model Data Editor applies the change to both rows.

**Reduce Maintenance Effort by Creating Custom Storage Class**

To change the name of the header file, you must change the configuration of each parameter object. You can use the Model Data Editor to perform batch editing, but when you add a new variant control variable (parameter object), you must remember to specify the name of the header file for that object. Also, the Model Data Editor can show the parameter objects used by only one model at a time.

Instead, you can create a custom storage class and specify the name of the header file only once: In the definition of the custom storage class.

Set your current folder to a writable location.
At the command prompt, copy the built-in SimulinkDemos package into your current folder as myPackage.

```matlab
copyfile(fullfile(matlabroot,...
    'toolbox','simulink','simdemos','dataclasses','+SimulinkDemos'),...
    '+myPackage','f')
```

Navigate inside the +myPackage folder to the file Parameter.m and open the file.

Uncomment the methods section that defines the method setupCoderInfo. In the call to the function useLocalCustomStorageClasses, replace 'packageName' with 'myPackage'. When you finish, the section appears as follows:

```matlab
methods
    function setupCoderInfo(h)
        % Use custom storage classes from this package
        useLocalCustomStorageClasses(h, 'myPackage');
    end
end % methods
```

Save and close the file.

Set your current folder to the folder that contains the package myPackage.

Open the Custom Storage Class Designer.

cscdesigner('myPackage')

Select the custom storage class Define.

Click Copy. A new custom storage class, Define_1, appears. Select this new custom storage class.

Set Name to VariantControlVar.

Set Header file to Specify. In the text box, enter variant_controls.h.

Click Apply, Save, and OK.

At the command prompt, replace the Simulink.Parameter objects MODE_A and MODE_B with myPackage.Parameter objects. Apply the new custom storage class VariantControlVar.
MODE_A = myPackage.Parameter;
MODE_A.Value = 1;
MODE_A.DataType = 'int32';
MODE_A.CoderInfo.StorageClass = 'Custom';
MODE_A.CoderInfo.CustomStorageClass = 'VariantControlVar';

MODE_B = myPackage.Parameter;
MODE_B.Value = 1;
MODE_B.DataType = 'int32';
MODE_B.CoderInfo.StorageClass = 'Custom';
MODE_B.CoderInfo.CustomStorageClass = 'VariantControlVar';

Now, to indicate that a parameter object represents a variant control variable, you can apply the custom storage class VariantControlVar. To change the name of the header file, use the Custom Storage Class Designer.

- “Working with Variant Choices” (Simulink)
Represent Variant Source and Sink Blocks in Generated Code

You can use Variant Source and Variant Sink blocks to perceive multiple implementations of a model in a single, unified block diagram. Each implementation depends on conditions that you set for Variant Source and Variant Sink blocks. Simulink propagates these conditions to upstream and downstream blocks including root input and root output ports.

You can generate:

- Code from a Simulink model containing Variant Sink and Variant Source blocks.
- Code that contains preprocessor conditionals that control the activation of each variant choice.
- Preprocessor conditionals that allow for no active variant choice.

Represent Variant Source and Variant Sink blocks in Simulink

This example shows how Variant Source blocks make model elements conditional.

1. From the Simulink Block Library, add 1 Sine Wave Function block, two Add blocks, three Gain blocks, two Outports, and two Variant Source blocks into a new model.

2. Open the Sine Wave Function block. For the **Sine type** parameter, select **Sample based**. For the **Time (t)** parameter, select **Use simulation time**. For the **Sample time** parameter, insert a value of 0.2.

3. Make four copies of the Sine Wave Function block.

4. Connect and name the blocks as shown.
5 Insert values of 2, 3, and 4 in the Gain2, Gain3, and Gain4 blocks, respectively.
6 Give the model the name inline_variants_example.
7 Open the Block Parameters dialog box for Variant Source.
In the **Variant control** column, for Port 1, replace **Variant_1** with \( V==1 \). For Port 2, replace **Variant_2** with \( V==2 \).

Open the Block Parameters dialog box for **Variant Source1**.

In the **Variant control** column, replace **Variant_1** with \( W==1 \). For Port 2, replace **Variant_2** with \( W==2 \).
In the MATLAB Command Window, use these commands to define \( V \) and \( W \) as Simulink.Parameter objects.

```matlab
V = Simulink.Parameter;
V.Value = 1;
V.DataType='int32';
V.CoderInfo.StorageClass = 'custom';
V.CoderInfo.CustomStorageClass = 'Define';
V.CoderInfo.CustomAttributes.HeaderFile='inline_importedmacro.h'

W = Simulink.Parameter;
W.Value = 2;
W.DataType='int32';
W.CoderInfo.StorageClass = 'custom';
W.CoderInfo.CustomStorageClass = 'Define';
W.CoderInfo.CustomAttributes.HeaderFile='inline_importedmacro.h'
```

In this example, the variant control variables are Simulink.Parameter objects. For code generation, if you use Simulink.Variant objects to specify variant controls, use Simulink.Parameter objects or MATLAB variables to specify their conditions.

Variant control variables defined as Simulink.Parameter objects can have one of these storage classes:

- Define with header file specified
- ImportedDefine with header file specified
- CompilerFlag
- SystemConstant (AUTOSAR)
- User-defined custom storage class that defines data as a macro in a specified header file

If you use scalar variant control variables to simulate the model, you can convert those variables into Simulink.Parameter objects. See “Convert Variant Control Variables into Simulink.Parameter Objects” (Simulink).

Simulate the model.
Input port 1 is the active choice for **Variant Source** because the value of variant control variable V is 1. Input port 2 is the active choice for **Variant Source1** because the value of variant control variable W is 2. The inactive choices are removed from execution, and their paths are grayed-out in the diagram.
Specify Conditions That Control Variant Choice Selection

You can generate code in which each variant choice is enclosed within C preprocessor conditionals \#if and \#endif. The compiler chooses the active variant at compile time and the preprocessor conditionals determine which sections of the code to execute.

1. In the Simulink editor, select **Simulation > Model Configuration Parameters**.
2. Select the **Code Generation** pane, and set **System target file** to ertz.tlc.
3. In the **Report** pane, select **Create code generation report**.
4. In your model, open the block parameters dialog box for **Variant Source**.
5. Select the **Analyze all choices during update diagram and generate preprocessor conditionals** parameter. During an update diagram or simulation, when you select this parameter, Simulink analyzes all variant choices. This analysis provides early validation of the code generation readiness of variant choices. During code generation, when you select this parameter, the code generator generates preprocessor conditionals that control the activation of each variant choice.
6. Clear the **Override variant conditions and use the following variant** parameter.
7. Clear the **Allow zero active variant controls** parameter.
8. Open the Block Parameters dialog box for **Variant Source 1**. Repeat steps 5 through 7.
9. Build the model. When code generation is complete, the Code Generation Report is displayed.

Review the Generated Code

1. In the code generation report, select the **inline_variants_example.c** file.
2. In the **inline_variants_example.c** file, calls to the **inline_variants_example_step** function and the **inline_variants_example_initialize** functions are conditionally compiled as shown:

```c
/* Model step function */
void inline_variants_example_step(void)
{
    real_T rtb_Sine4;
    real_T rtb_VariantMerge_For_Variant_So;

    /* Sin: '<Root>/Sine1' */
```
#if V == 1
    rtb_Sine4 = sin((real_T)inline_variants_example_DW.counter * 2.0 * 3.1415926535897931 / 10.0);
#endif /* V == 1 */

/* End of Sin: '<Root>/Sine1' */

/* Sin: '<Root>/Sine2' incorporates:
*  Sin: '<Root>/Sine3'
*  Sum: '<Root>/Add'
*/
#if V == 2
    rtb_Sine4 = sin((real_T)inline_variants_example_DW.counter_i * 2.0 * 3.1415926535897931 / 10.0) + sin((real_T)
        inline_variants_example_DW.counter_f * 2.0 * 3.1415926535897931 / 10.0);
#endif /* V == 2 */

/* End of Sin: '<Root>/Sine2' */

/* Outport: '<Root>/Out1' incorporates:
*  Gain: '<Root>/Gain3'
*/
inline_variants_example_Y.Out1 = 3.0 * rtb_Sine4;

/* Gain: '<Root>/Gain2' */
#if W == 1
    rtb_VariantMerge_For_Variant_So = 2.0 * rtb_Sine4;
#endif /* W == 1 */

/* End of Gain: '<Root>/Gain2' */

/* Sin: '<Root>/Sine4' incorporates:
*  Sin: '<Root>/Sine5'
*  Sum: '<Root>/Add1'
*/
#if W == 2
    rtb_VariantMerge_For_Variant_So = sin((real_T)
inline_variants_example_DW.counter_fe * 2.0 * 3.1415926535897931 / 10.0) *
2.0 + sin((real_T)inline_variants_example_DW.counter_e * 2.0 *
3.1415926535897931 / 10.0);

#endif /* W == 2 */

/* End of Sin: '<Root>/Sine4' */

/* Outport: '<Root>/Out2' incorporates:
*  Gain: '<Root>/Gain4'
*/
inline_variants_example_Y.Out2 = inline_variants_example_P.Gain4_Gain *
rtb_VariantMerge_For_Variant_So;
...

The variables rtb_Sine4 and rtb_VariantMerge_For_Variant_So hold the input values to the Variant Source blocks. Notice that the code for these variables is conditional. The variables inline_variants_example_Y.Out1 and inline_variants_example_Y.Out2 hold the output values of the Variant Source blocks. Notice that the code for these variables is not conditional.

**Generate Code with Zero Active Variant Controls**

You can generate code in which blocks connected to the input and the output of a Variant Source block are conditional.

1. For Variant Source, open the Block Parameters dialog box. Select the parameter **Allow zero active variant controls**.
2. For Variant Source 1, open the Block Parameters dialog box. Select the parameter **Allow zero active variant controls**.

When you select **Allow zero active variant controls** parameter, you can generate code for a model containing Variant Source and Variant Sink blocks even when you specify a value for a variant control variable that does not allow for an active variant. Choosing a value for a variant control variable that does not allow for an active variant and not selecting the **Allow zero active variant controls** parameter, produces an error.

Generate code for **inline_variants_example**. Notice in the **inline_variants_example.c** file, that the code for the variables inline_variants_example_Y.Out1 and inline_variants_example_Y.Out2 is conditional.
/* Model step function */
void inline_variants_example_step(void)
{
    ...  
    #if V == 1 || V == 2
        inline_variants_example_Y.Out1 = 3.0 * rtb_Sine4;
    #endif /* V == 1 || V == 2 */
    ...  
    #if (V == 1 && W == 1) || (V == 2 && W == 1) || W == 2
        inline_variants_example_Y.Out2 = 4.0 * rtb_VariantMerge_For_Variant_So;
    #endif /* (V == 1 && W == 1) || (V == 2 && W == 1) || W == 2 */
    ...  

Global Data Guarding Limitation

For external ports and most DWork vectors, signals, and states, preprocessor conditionals (#if and #endif) surround global data variable declarations. For models in which you enable C API code for global block output signals, global block parameters, and discrete and continuous states, preprocessor conditionals do not surround global data variable declarations. For information on the C API, see “Exchange Data Between Generated and External Code Using C API” (Simulink Coder).

State Logging Limitation

There are some rare cases in which preprocessor conditionals do not surround global data structures that contain state variable declarations. For models that contain Variant Source blocks or Variant Sink blocks and also contain blocks that maintain state information, such as Unit Delay blocks, the exclusion of preprocessor conditionals surrounding state variable declarations can lead to a mismatch between simulation and code generation results.

For example, suppose that a model has a Variant Source block with four variant choices. One of these choices contains blocks with state information. If you simulate the model with the active variant that is other than the variant choice that contains state information, there is no logged state data. In the model. h file, the generated code still
initializes these global state variables to 0 because #if and #endif guards do not surround the state variable declarations. If you create a \textit{model.mat} file from a \textit{model.exe} file, and compare it to the simulation output, the results do not match. For this example, the simulation output is empty because there is no logged state data. The \textit{model.mat} file contains multiple values of 0.

If the active variant is the variant choice containing state information, the results do match.

Configure Dimension Variants for S-Function Blocks

To configure symbolic dimensions for S-function blocks, you can use the following C/C++ functions. You can configure S-functions to support forward propagation, backward propagation, or forward and backward propagation of symbolic dimensions during simulation.

Many of these functions return the variable SymbDimsId. A SymbDimsId is a unique integer value. This value corresponds to each symbolic dimension specification that you create or is the result of a mathematical operation that you perform with symbolic dimensions.

**Note** If you are writing an S-function with symbolic dimensions, you cannot use the %roll directive. You must write an explicit loop.

<table>

Configure Dimension Variants for S-Function Blocks

15-53
S-Function That Supports Forward Propagation of Symbolic Dimensions

This S-function subtracts the symbolic dimension B from a symbolic input dimension. It does not support backward propagation of symbolic dimensions because the compiled symbolic dimensions of the input port are not set. Symbolic dimensions are set for the output port, so forward propagation occurs.

```c
static void mdlInitializeSizes(SimStruct *S)
{
    // Enable symbolic dimensions for the s-function.
    ssSetSymbolicDimsSupport(S, true);
}

#if defined(MATLAB_MEX_FILE)
#define MDL_SET_INPUT_PORT_SYMBOLIC_DIMENSIONS
static void mdlSetInputPortSymbolicDimensions(SimStruct* S,
                                            int_T portIndex, SymbDimsId symbDimsId)
{
    assert(0 == portIndex);
    // Set the compiled input symbolic dimension.
    ssSetCompInputPortSymbolicDimsId(S, portIndex, symbDimsId);
    // Register "B" and get its symbolic dimensions id.
    const SymbDimsId symbolIdForB = ssRegisterSymbolicDimsString(S, "B");
    // Subtract "B" from the input symbolic dimension.
    const SymbDimsId outputDimsId = ssRegisterSymbolicDimsMinus(S, symbDimsId, symbolIdForB);
    // Set the resulting symbolic dimensions id as the output.
    ssSetCompOutputPortSymbolicDimsId(S, portIndex, outputDimsId);
}
#endif

#if defined(MATLAB_MEX_FILE)
#define MDL_SET_OUTPUT_PORT_SYMBOLIC_DIMENSIONS
static void mdlSetOutputPortSymbolicDimensions(SimStruct *S,
                                                int_T portIndex, SymbDimsId symbDimsId)
{
    assert(0 == portIndex);
    // The input dimensions are not set, so this S-function only
    // supports forward propagation.
    ssSetCompOutputPortSymbolicDimsId(S, portIndex, symbDimsId);
}
#endif
```
S-Function That Supports Forward and Backward Propagation of Symbolic Dimensions

This S-function transposes two symbolic dimensions. It supports forward and backward propagation of symbolic dimensions because the compiled symbolic dimension of both the input and output ports are set.

```c
static void mdlInitializeSizes(SimStruct *S)
{
    // Enable symbolic dimensions for the s-function.
    ssSetSymbolicDimsSupport(S, true);
}

#if defined(MATLAB_MEX_FILE)
#define MDL_SET_INPUT_PORT_SYMBOLIC_DIMENSIONS
static void mdlSetInputPortSymbolicDimensions(SimStruct* S,
    int_T portIndex, SymbDimsId symbDimsId)
{
    assert(0 == portIndex);
    ssSetCompInputPortSymbolicDimsId(S, portIndex, symbDimsId);
    assert(2U == ssGetNumSymbolicDims(S, symbDimsId));
    if (SL_INHERIT ==
        ssGetCompOutputPortSymbolicDimsId(S, portIndex)) {
        const SymbDimsId idVec[] = {
            ssGetSymbolicDim(S, symbDimsId, 1),
            ssGetSymbolicDim(S, symbDimsId, 0)};
        // Register the transposed dimensions.
        // Set the output symbolic dimension to the resulting id.
        const SymbDimsId outputDimsId =
            ssRegisterSymbolicDims(S, idVec, 2U);
        ssSetCompOutputPortSymbolicDimsId(S, portIndex,
            outputDimsId);
    }
}
#endif

#if defined(MATLAB_MEX_FILE)
#define MDL_SET_OUTPUT_PORT_SYMBOLIC_DIMENSIONS
static void mdlSetOutputPortSymbolicDimensions(SimStruct *S,
    Configure Dimension Variants for S-Function Blocks

15-55
int_T portIndex, SymbDimsId symbDimsId)
{
    assert(0 == portIndex);
    ssSetCompOutputPortSymbolicDimsId(S, portIndex, symbDimsId);

    assert(2U == ssGetNumSymbolicDims(S, symbDimsId));

    if (SL_INHERIT ==
        ssGetCompInputPortSymbolicDimsId(S, portIndex)) {

        const SymbDimsId idVec[] = {
            ssGetSymbolicDim(S, symbDimsId, 1),
            ssGetSymbolicDim(S, symbDimsId, 0)};
        const SymbDimsId inputDimsId =
            ssRegisterSymbolicDims(S, idVec, 2U);
        // Register the transposed dimensions.
        // Set the input symbolic dimension to the resulting id.
        ssSetCompInputPortSymbolicDimsId(S, portIndex, inputDimsId);
    }
} #endif

Generate Code for Variant Subsystem with Child Subsystems of Different Output Signal Dimensions

In this section...

“Example Model” on page 15-57
“Simulate Model” on page 15-58
“Generate Code” on page 15-59

This example shows how to use symbolic dimensions to generate code with preprocessor conditionals for a variant subsystem consisting of child subsystems of different output signal dimensions. The value of the variant control variable determines the active variant choice and the output signal dimensions. By changing the value of the variant control variable, you change the active variant and the output signal dimensions in the generated code.

Example Model

The model slexVariantSymbolicDims contains a Variant Subsystem consisting of the child subsystems Subsystem and Subsystem1. When the variant control variable Var has a value of 1, Subsystem is the active variant. When Var has a value of 2, Subsystem1 is the active variant.
Simulate Model

To generate code with preprocessor conditionals, the output signal dimensions of the child subsystems must be the same during simulation. In this example, double-clicking the subsystem Activate Variant Choice changes the active variant and the output signal dimension. When \( \text{Var} \) equals 1, the output signal dimension of each child subsystem is 5. When \( \text{Var} \) equals 2, the output signal dimension of each child subsystem is 6.

1. Open the example model `slexVariantSymbolicDims`.
2. From the Display > Signals & Ports menu, select Signal Dimensions.
3. Open the Variant Subsystem Block Parameters dialog box. The Analyze all choices during update diagram and generate preprocessor conditionals parameter is selected.
4. Open Subsystem. In the Constant Block Parameters dialog box, the Constant value parameter is \( P1 \).
5. Open Subsystem1. In the Constant Block Parameters dialog box, the Constant value parameter is \( P2 \).
Open the base workspace. The Simulink.Parameters P1 and P2 are arrays with dimensions '[1,A]'. The Simulink.Parameter A has a value of 5. Var has a value of 1.

Simulate the model. Subsystem is the active variant with an output signal dimension of 5.

Double-click the masked subsystem ActivateVariant.

In the base workspace, Var has a value of 2. P1 and P2 have a dimension of 6. A has a value of 6.

Simulate the model. Subsystem1 is the active variant with an output signal dimension of 6.

In the base workspace, A has a Storage class of ImportedDefine(Custom). To use a Simulink.Parameter object for dimension specification, it must have one of these storage classes:

- Define or ImportedDefine with header file specified
- CompilerFlag
- User-defined custom storage class that defines data as a macro in a specified header file

In the base workspace, P1 and P2 have a storage class of ImportedExtern. A Simulink.Parameter object that uses a Simulink.Parameter for symbolic dimension specification must have a storage class of either ImportedExtern or ImportedExternPointer.

Generate Code

Open the header file slexVariantSymbolicDims_variant_defines.h. The definition of A is conditional upon the value of Var.

```c
/* Copyright 2016 The MathWorks, Inc. */
// To select variant choice during compile, define Var at compile time,

#ifndef Var
#define Var 1
#endif

#if Var == 1
#define A 5
#elif Var == 2
#endif
```
```c
#define A 6
#else
#error "Variant control variable, Var, must be defined as 1 or 2"
#endif

Generate code.

Open the slexVariantSymbolicDims.h file. The output dimension size is A.

```c
/* External outputs (root outports fed by signals with auto storage) */
typedef struct {
    int32_T Out1[A];                     /* '<Root>/Out1' */
} ExternalOutputs_slexVariantSymb;
```

Open the slexVariantSymbolicDims.c file. If Var equals 1, P1 has five values. If Var equals 2, P2 has six values. In the Configuration Parameters dialog box, on the Code Generation > Custom Code pane, the Source file parameter contains this code.

```c
/* User code (top of source file) */
#if Var == 1
    int32_T P1[] = { 5, 5, 5, 5, 5 };
#else if Var == 2
    int32_T P2[] = { 6, 6, 6, 6, 6, 6 };
#endif
```

Preprocessor conditionals control the size of A and which array, P1 or P2, is active in the generated code. By changing the value of Var, you can change the size of A and the active array.

About Timers

Certain blocks require the value of either *absolute* time (that is, the time from the start of program execution to the present time) or *elapsed* time (for example, the time elapsed between two trigger events). Targets that support the real-time model (*rtModel*) data structure provide efficient time computation services to blocks that request absolute or elapsed time. Absolute and elapsed timer features include

- Timers are implemented as unsigned integers in generated code.
- In multirate models, at most one timer is allocated per rate. If no blocks executing at a given rate require a timer, a timer is not allocated to that rate. This minimizes memory allocated for timers and significantly reduces overhead involved in maintaining timers.
- Allocation of elapsed time counters for use of blocks within triggered subsystems is minimized, further reducing memory usage and overhead.
- S-function and TLC APIs let your S-functions access timers, in simulation and code generation.
- The word size of the timers is determined by a user-specified maximum counter value, **Application lifespan (days)** (Simulink). If you specify this value, timers will not overflow. For more information, see “Control Memory Allocation for Time Counters” (Simulink Coder).

See “Absolute Time Limitations” (Simulink Coder) for more information about absolute time and the restrictions that it imposes.
Timers for Periodic and Asynchronous Tasks

Timing services provided for blocks execute within *periodic* tasks (that is, tasks running at the model base rate or subrates).

The code generator also provides timer support for blocks whose execution is *asynchronous* with respect to the periodic timing source of the model. See the following topics:

- “Timers in Asynchronous Tasks” on page 18-46
- “Create a Customized Asynchronous Library” on page 18-49

Allocation of Timers

If you create or maintain an S-Function block that requires absolute or elapsed time data, it must register the requirement (see “Access Timers Programmatically” on page 16-5). In multirate models, timers are allocated on a per-rate basis. For example, consider a model structured as follows:

- There are three rates, A, B, and C, in the model.
- No blocks running at rate B require absolute or elapsed time.
- Two blocks running at rate C register a requirement for absolute time.
- One block running at rate A registers a requirement for absolute time.

In this case, two timers are generated, running at rates A and C respectively. The timing engine updates the timers as the tasks associated with rates A and C execute. Blocks executing at rates A and C obtain time data from the timers associated with rates A and C.

Integer Timers in Generated Code

In the generated code, timers for absolute and elapsed time are implemented as unsigned integers. The default size is 64 bits. This is the amount of memory allocated for a timer if you specify a value of `inf` for the *Application lifespan* *(days)* (Simulink) parameter. For an application with a sample rate of 1000 MHz, a 64-bit counter will not overflow for more than 500 years. See “Timers in Asynchronous Tasks” on page 18-46 and “Control Memory Allocation for Time Counters” on page 56-11 for more information.
**Elapsed Time Counters in Triggered Subsystems**

Some blocks, such as the Discrete-Time Integrator block, perform computations requiring the elapsed time (delta T) since the previous block execution. Blocks requiring elapsed time data must register the requirement (see “Access Timers Programmatically” on page 16-5). A triggered subsystem then allocates and maintains a single elapsed time counter if required. This timer functions at the subsystem level, not at the individual block level. The timer is generated if the triggered subsystem (or a unconditionally executed subsystem within the triggered subsystem) contains one or more blocks requiring elapsed time data.

**Note** If you are using simplified initialization mode, elapsed time is reset on first execution after becoming enabled, whether or not the subsystem is configured to reset on enable. For more information, see “Underspecified initialization detection” (Simulink).

“About Timer APIs” on page 16-5
“C API for S-Functions” on page 16-5
“TLC API for Code Generation” on page 16-7

About Timer APIs

This topic describes APIs that let your S-functions take advantage of the efficiencies offered by absolute and elapsed timers. SimStruct macros are provided for use in simulation, and TLC functions are provided for inlined code generation. Note that

• To generate and use the new timers as described above, your S-functions must register the need to use an absolute or elapsed timer by calling ssSetNeedAbsoluteTime or ssSetNeedElapsedTime in mdlInitializeSampleTime.
• Existing S-functions that read absolute time but do not register by using these macros continue to operate as expected, but generate less efficient code.

C API for S-Functions

The SimStruct macros described in this topic provide access to absolute and elapsed timers for S-functions during simulation.

In the functions below, the SimStruct *S argument is a pointer to the simstruct of the calling S-function.

• void ssSetNeedAbsoluteTime(SimStruct *S, boolean b): If b is TRUE, registers that the calling S-function requires absolute time data, and allocates an absolute time counter for the rate at which the S-function executes (if such a counter has not already been allocated).
• int ssGetNeedAbsoluteTime(SimStruct *S): returns 1 if the S-function has registered that it requires absolute time.
• double ssGetTaskTime(SimStruct *S, tid): read absolute time for a given task with task identifier tid. ssGetTaskTime operates transparently, regardless of whether or not you use the new timer features. ssGetTaskTime is documented in the SimStruct Functions chapter of the Simulink documentation.
• void ssSetNeedElapseTime(SimStruct *S, boolean b): if b is TRUE, registers that the calling S-function requires elapsed time data, and allocates an elapsed time counter for the triggered subsystem in which the S-function executes (if such a counter has not already been allocated). See also “Elapsed Time Counters in Triggered Subsystems” on page 16-4.

• int ssGetNeedElapseTime(SimStruct *S): returns 1 if the S-function has registered that it requires elapsed time.

• void ssGetElapseTime(SimStruct *S, (double *)elapseTime): returns, to the location pointed to by elapseTime, the value (as a double) of the elapsed time counter associated with the S-function.

• void ssGetElapseTimeCounterDtype(SimStruct *S, (int *)dtype): returns the data type of the elapsed time counter associated with the S-function to the location pointed to by dtype. This function is intended for use with the ssGetElapseTimeCounter function (see below).

• void ssGetElapseResolution(SimStruct *S, (double *)resolution): returns the resolution (that is, the sample time) of the elapsed time counter associated with the S-function to the location pointed to by resolution. This function is intended for use with the ssGetElapseTimeCounter function (see below).

• void ssGetElapseTimeCounter(SimStruct *S, (void *)elapseTime): This function is provided for the use of blocks that require the elapsed time values for fixed-point computations. ssGetElapseTimeCounter returns, to the location pointed to by elapseTime, the integer value of the elapsed time counter associated with the S-function. If the counter size is 64 bits, the value is returned as an array of two 32-bit words, with the low-order word stored at the lower address.

To determine how to access the returned counter value, obtain the data type of the counter by calling ssGetElapseTimeCounterDtype, as in the following code:

```c
int *y_dtype;
ssGetElapseTimeCounterDtype(S, y_dtype);

switch(*y_dtype) {
  case SS_DOUBLE_UINT32:
    {
      uint32_T dataPtr[2];
      ssGetElapseTimeCounter(S, dataPtr);
    }
    break;
  case SS_UINT32:
    {
```
uint32_T dataPtr[1];
ssGetElapseTimeCounter(S, dataPtr);
}
break;
case SS_UINT16:
{
    uint16_T dataPtr[1];
    ssGetElapseTimeCounter(S, dataPtr);
}
break;
case SS_UINT8:
{
    uint8_T dataPtr[1];
    ssGetElapseTimeCounter(S, dataPtr);
}
break;
case SS_DOUBLE:
{
    real_T dataPtr[1];
    ssGetElapseTimeCounter(S, dataPtr);
}
break;
default:
    ssSetErrorStatus(S, "Invalid data type for elaspe time counter");
    break;
}

If you want to use the actual elapsed time, issue a call to the ssGetElapseTime function to access the elapsed time directly. You do not need to get the counter value and then calculate the elapsed time.

double *y_elapseTime;
.
.
.
ssGetElapseTime(S, elapseTime)

**TLC API for Code Generation**

The following TLC functions support elapsed time counters in generated code when you inline S-functions by writing TLC scripts for them.
• **LibGetTaskTimeFromTID**(*block*): Generates code to read the absolute time for the task in which *block* executes.

*LibGetTaskTimeFromTID* is documented with other sample time functions in the TLC Function Library Reference pages of the Target Language Compiler documentation.

**Note** Do not use *LibGetT* for this purpose. *LibGetT* always reads the base rate (*tid 0*) timer. If *LibGetT* is called for a block executing at a subrate, the wrong timer is read, causing serious errors.

• **LibGetElapseTime**(*system*): Generates code to read the elapsed time counter for *system*. (*system* is the parent system of the calling block.) See “Generate Code for an Elapsed Time Counter” on page 16-9 for an example of code generated by this function.

• **LibGetElapseTimeCounter**(*system*): Generates code to read the integer value of the elapsed time counter for *system*. (*system* is the parent system of the calling block.) This function should be used in conjunction with *LibGetElapseTimeCounterDtypeId* and *LibGetElapseTimeResolution*. (See the discussion of *ssGetElapseTimeCounter* above.)

• **LibGetElapseTimeCounterDtypeId**(*system*): Generates code that returns the data type of the elapsed time counter for *system*. (*system* is the parent system of the calling block.)

• **LibGetElapseTimeResolution**(*system*): Generates code that returns the resolution of the elapsed time counter for *system*. (*system* is the parent system of the calling block.)

Generate Code for an Elapsed Time Counter

This example shows a model that includes a triggered subsystem, Amplifier, consisting of a Discrete-Time Integrator block that uses an elapsed time counter. The model ex_elapseTime is in the folder matlab/help/toolbox/rtw/examples.

```
/*
 * Timing:
 * The following substructure contains information regarding
 * the timing information for the model.
 */
struct {
    time_T taskTime0;
    uint32_T clockTick0;
```
The code generator allocates storage for the previous-time value and elapsed-time value of the Amplifier subsystem (Amplifier_PREV_T) in the D_Work(states) structure in ex_elapsedTime.h.

compute time using

The elapsed time computation is performed as follows within the ex_elapsedTime_step function:

```
/* --- 
Outputs for Triggered SubSystem: 
'\texttt{<Root>/Amplifier}' incorporates: 
TriggerPort: '\texttt{<S1>/Trigger}' 
--- */
zcEvent = rt_ZCFcn(RISING ZERO CROSSING, 
                   &ex_elapsedTime_M->Timing.clockTickH0 - 
                   ex_elapsedTime_DW.Amplifier_ELAPS_T[0]; 
if (zcEvent != NO_ZCEVENT) { 
elapseT_H = ex_elapsedTime_M->Timing.clockTickH0 - 
ex_elapsedTime_DW.Amplifier_ELAPS_T[1]; 
if (ex_elapsedTime_DW.Amplifier_ELAPS_T[0] > 
   ex_elapsedTime_M->Timing.clockTick0) { 
   elapseT_H--; 
}

ex_elapsedTime_DW.Amplifier_ELAPS_T[0] = 
   ex_elapsedTime_M->Timing.clockTick0 
   - ex_elapsedTime_DW.Amplifier_ELAPS_T[0]; 
ex_elapsedTime_DW.Amplifier_ELAPS_T[0] = 
```

Timers in Simulink Coder
As shown above, the elapsed time is maintained as a state of the triggered subsystem. The Discrete-Time Integrator block finally performs its output and update computations using the elapsed time.

```c
/* ---
DiscreteIntegrator: '<S1>/Discrete-Time Integrator'
--- */
OUTPUT = ex_elapseTime_DW.DiscreteTimeIntegrator_DSTATE;

/* ---
Update for DiscreteIntegrator:
'&lt;S1&gt;/Discrete-Time Integrator' incorporates:
  Constant: '&lt;Root&gt;/Constant'
--- */
ex_elapseTime_DW.DiscreteTimeIntegrator_DSTATE += 0.3 * (real_T)
ex_elapseTime_DW.Amplifier_ELAPS_T[0] * 1.5;
```

**More About**

- “Absolute and Elapsed Time Computation” (Simulink Coder)
- “Absolute Time Limitations” (Simulink Coder)
Absolute Time Limitations

Absolute time is the time that has elapsed from the beginning of program execution to the present time, as distinct from elapsed time, the interval between two events. See “Absolute and Elapsed Time Computation” on page 16-2 for more information.

When you design an application that is intended to run indefinitely, you must take care when logging time values, or using charts or blocks that depend on absolute time. If the value of time reaches the largest value that can be represented by the data type used by the timer to store time, the timer overflows and the logged time or block output is incorrect.

If your target uses rtModel, you can avoid timer overflow by specifying a value for the Application life span parameter. See “Integer Timers in Generated Code” on page 16-3 for more information.

The following limitations apply to absolute time:

- If you log time values by opening the Configuration Parameters dialog box and enabling Data Import/Export > Time parameter, your model uses absolute time.
- Every Stateflow chart that uses time is dependent on absolute time. The only way to eliminate the dependency is to change the Stateflow chart to not use time.
- The following Simulink blocks depend on absolute time:
  - Backlash
  - Chirp Signal
  - Clock
  - Derivative
  - Digital Clock
  - Discrete-Time Integrator (only when used in triggered subsystems)
  - From File
  - From Workspace
  - Pulse Generator
  - Ramp
  - Rate Limiter
  - Repeating Sequence
• Signal Generator
• Sine Wave (only when the Sine type parameter is set to Time-based)
• Step
• To File
• To Workspace (only when logging to StructureWithTime format)
• Transport Delay
• Variable Time Delay
• Variable Transport Delay

In addition to the Simulink blocks above, blocks in other blocksets may depend on absolute time. See the documentation for the blocksets that you use.

**Sample Time Considerations**

Simulink models run at one or more sample times. The Simulink product provides considerable flexibility in building multirate systems, that is, systems with more than one sample time. However, this same flexibility also allows you to construct models for which the code generator cannot generate real-time code for execution in a multitasking environment. To make multirate models operate as expected in real time (that is, to give the right answers), you sometimes must modify your model or instruct the Simulink engine to modify the model for you. In general, the modifications involve placing Rate Transition blocks between blocks that have unequal sample times. The following sections discuss issues you must address to use a multirate model in a multitasking environment. For a comprehensive discussion of sample times, including rate transitions, see “What Is Sample Time?” (Simulink), “Sample Times in Subsystems” (Simulink), “Sample Times in Systems” (Simulink), “Resolve Rate Transitions” (Simulink), and associated topics.

**Tasking Modes**

There are two execution modes for a fixed-step Simulink model: single-tasking and multitasking. These modes are available only for fixed-step solvers. To select an execution mode, use the **Treat each discrete rate as a separate task** checkbox on the **Solver** pane of the Configuration Parameters dialog box. When this parameter is selected, multitasking execution is applied for a multirate model. When this option is cleared, single-tasking execution is applied.

**Note** A model that is multirate and uses multitasking cannot reference a multirate model that uses single-tasking.
Execution of models in a real-time system can be done with the aid of a real-time operating system, or it can be done on *bare-metal* target hardware, where the model runs in the context of an interrupt service routine (ISR).

The fact that a system (such as The Open Group UNIX or Microsoft Windows systems) is multitasking does not imply that your program can execute in real time. This is because the program might not preempt other processes when required.

In operating systems (such as PC-DOS) where only one process can exist at a given time, an interrupt service routine (ISR) must perform the steps of saving the processor context, executing the model code, collecting data, and restoring the processor context.

Other operating systems, such as POSIX-compliant ones, provide automatic context switching and task scheduling. This simplifies the operations performed by the ISR. In this case, the ISR simply enables the model execution task, which is normally blocked. The next figure illustrates this difference.
Program execution using a real-time operating system primitive. See the Tornado target for an example.

Model Execution and Rate Transitions

To generate code that executes as expected in real time, you (or the Simulink engine) might need to identify and handle sample rate transitions within the model. In multitasking mode, by default the Simulink engine flags errors during simulation if the model contains invalid rate transitions, although you can use the Multitask rate transition diagnostic to alter this behavior. A similar diagnostic, called Single task rate transition, exists for single-tasking mode.
To avoid raising rate transition errors, insert Rate Transition blocks between tasks. You can request that the Simulink engine handle rate transitions automatically by inserting hidden Rate Transition blocks. See “Automatic Rate Transition” on page 17-26 for an explanation of this option.

To understand such problems, first consider how Simulink simulations differ from real-time programs.

**Execution During Simulink Model Simulation**

Before the Simulink engine simulates a model, it orders the blocks based upon their topological dependencies. This includes expanding virtual subsystems into the individual blocks they contain and flattening the entire model into a single list. Once this step is complete, each block is executed in order.

The key to this process is the ordering of blocks. A block whose output is directly dependent on its input (that is, a block with direct feedthrough) cannot execute until the block driving its input executes.

Some blocks set their outputs based on values acquired in a previous time step or from initial conditions specified as a block parameter. The output of such a block is determined by a value stored in memory, which can be updated independently of its input. During simulation, computations are performed prior to advancing the variable corresponding to time. This results in computations occurring instantaneously (that is, no computational delay).

**Model Execution in Real Time**

A real-time program differs from a Simulink simulation in that the program must execute the model code synchronously with real time. Every calculation results in some computational delay. This means the sample intervals cannot be shortened or lengthened (as they can be in a Simulink simulation), which leads to less efficient execution.

Consider the following timing figure.
Note the processing inefficiency in the sample interval $t_1$. That interval cannot be compressed to increase execution speed because, by definition, sample times are clocked in real time.

You can circumvent this potential inefficiency by using the multitasking mode. The multitasking mode defines tasks with different priorities to execute parts of the model code that have different sample rates.

See “Multitasking and Pseudomultitasking Modes” on page 17-12 for a description of how this works. It is important to understand that section before proceeding here.

**Single-Tasking Versus Multitasking Operation**

Single-tasking programs require longer sample intervals, because all computations must be executed within each clock period. This can result in inefficient use of available CPU time, as shown in the previous figure.

Multitasking mode can improve the efficiency of your program if the model is large and has many blocks executing at each rate.

However, if your model is dominated by a single rate, and only a few blocks execute at a slower rate, multitasking can actually degrade performance. In such a model, the overhead incurred in task switching can be greater than the time required to execute the slower blocks. In this case, it is more efficient to execute all blocks at the dominant rate.

If you have a model that can benefit from multitasking execution, you might need to modify your model by adding Rate Transition blocks (or instruct the Simulink engine to do so) to generate expected results.

For more information about the two modes of execution and examples, see “Modeling for Single-Tasking Execution” on page 17-8 and “Modeling for Multitasking Execution” on page 17-12.

Modeling for Single-Tasking Execution

**Single-Tasking Mode**

You can execute model code in a strictly single-tasking manner. While this mode is less efficient with regard to execution speed, in certain situations, it can simplify your model.

In single-tasking mode, the base sample rate must define a time interval that is long enough to allow the execution of all blocks within that interval.

The next figure illustrates the inefficiency inherent in single-tasking execution.

![Diagram of single-tasking execution]

Single-tasking system execution requires a base sample rate that is long enough to execute one step through the entire model.

**Build a Program for Single-Tasking Execution**

To use single-tasking execution, clear the **Treat each discrete rate as a separate task** checkbox on the **Solver** pane of the Configuration Parameters dialog box. If you select the checkbox, single-tasking mode is used in the following cases:

- If your model contains one sample time
- If your model contains a continuous and a discrete sample time and the fixed step size is equal to the discrete sample time

**Single-Tasking Execution**

This example examines how a simple multirate model executes in both real time and simulation, using a fixed-step solver. It considers operation in both single-tasking and multitasking modes, as determined by setting of the **Treat each discrete rate as a separate task** parameter on the **Solver** pane.

The example model is shown in the next figure. The discussion refers to the six blocks of the model as A through F, as labeled in the block diagram.
The execution order of the blocks (indicated in the upper right of each block) has been forced into the order shown by assigning higher priorities to blocks F, E, and D. The ordering shown is one possible valid execution ordering for this model. For more information, see “Simulation Phases in Dynamic Systems” (Simulink).

The execution order is determined by data dependencies between blocks. In a real-time system, the execution order determines the order in which blocks execute within a given time interval or task. This discussion treats the model's execution order as a given, because it is concerned with the allocation of block computations to tasks, and the scheduling of task execution.

Note The discussion and timing diagrams in this section are based on the assumption that the Rate Transition blocks are used in the default (protected/deterministic) mode, with the Ensure data integrity during data transfer and Ensure deterministic data transfer (maximum delay) options on.

This example considers the execution of the above model when the Treat each discrete rate as a separate task checkbox is cleared, which indicates the single-tasking mode.

In a single-tasking system, if the Configuration Parameters > Optimization > Advanced parameters > Block reduction option is selected, fast-to-slow Rate Transition blocks are optimized out of the model. The default case is shown (Block reduction selected), so block B does not appear in the timing diagrams in this section. For more information, see “Block reduction” (Simulink).

The following table shows, for each block in the model, the execution order, sample time, and whether the block has an output or update computation. Block A does not have discrete states, and accordingly does not have an update computation.

Real-Time Single-Tasking Execution

The next figure shows the scheduling of computations when the generated code is deployed in a real-time system. The generated program is shown running in real time, under control of interrupts from a 10 Hz timer.

At time 0.0, 1.0, and every second thereafter, both the slow and fast blocks execute their output computations; this is followed by update computations for blocks that have states. Within a given time interval, output and update computations are sequenced in block execution order.

The fast blocks execute on every tick, at intervals of 0.1 second. Output computations are followed by update computations.

The system spends some portion of each time interval (labeled “wait”) idling. During the intervals when only the fast blocks execute, a larger portion of the interval is spent idling. This illustrates an inherent inefficiency of single-tasking mode.
Simulated Single-Tasking Execution

The next figure shows the execution of the model during the Simulink simulation loop.

Because time is simulated, the placement of ticks represents the iterations of the simulation loop. Blocks execute in exactly the same order as in the previous figure, but without the constraint of a real-time clock. Therefore there is no idle time between simulated sample periods.

Modeling for Multitasking Execution

Multitasking and Pseudomultitasking Modes

When periodic tasks execute in a multitasking mode, by default the blocks with the fastest sample rates are executed by the task with the highest priority, the next fastest blocks are executed by a task with the next higher priority, and so on. Time available in between the processing of high-priority tasks is used for processing lower priority tasks. This results in efficient program execution.

Where tasks are asynchronous rather than periodic, there may not necessarily be a relationship between sample rates and task priorities; the task with the highest priority need not have the fastest sample rate. You specify asynchronous task priorities using Async Interrupt and Task Sync blocks. You can switch the sense of what priority numbers mean by selecting or deselecting the Solver option Higher priority value indicates higher task priority.

In multitasking environments (that is, under a real-time operating system), you can define separate tasks and assign them priorities. For bare-metal target hardware (that is, no real-time operating system present), you cannot create separate tasks. However, generated application modules implement what is effectively a multitasking execution scheme using overlapped interrupts, accompanied by programmatic context switching.

This means an interrupt can occur while another interrupt is currently in progress. When this happens, the current interrupt is preempted, the floating-point unit (FPU) context is saved, and the higher priority interrupt executes its higher priority (that is, faster sample rate) code. Once complete, control is returned to the preempted ISR.

The next figures illustrate how timing of tasks in multirate systems are handled by the code generator in multitasking, pseudomultitasking, and single-tasking environments.
The next figure shows how overlapped interrupts are used to implement pseudomultitasking. In this case, Interrupt 0 does not return until after Interrupts 1, 2, and 3.
Build a Program for Multitasking Execution

To use multitasking execution, select the Treat each discrete rate as a separate task check box on the Solver pane of the Configuration Parameters dialog box. This menu is active only if you select Fixed-step as the solver type. Auto mode results in a multitasking environment if your model has two or more different sample times. A model with a continuous and a discrete sample time runs in single-tasking mode if the fixed-step size is equal to the discrete sample time.

Execute Multitasking Models

In cases where the continuous part of a model executes at a rate that is different from the discrete part, or a model has blocks with different sample rates, the Simulink engine assigns each block a task identifier (tid) to associate the block with the task that executes at the block's sample rate.
You set sample rates and their constraints on the **Solver** pane of the Configuration Parameters dialog box. To generate code, select **Fixed-step** for the solver type. Certain restrictions apply to the sample rates that you can use:

- The sample rate of a block must be an integer multiple of the base (that is, the fastest) sample period.
- When **Periodic sample time constraint** is unconstrained, the base sample period is determined by the **Fixed step size** specified on the **Solvers** pane of the Configuration parameters dialog box.
- When **Periodic sample time constraint** is Specified, the base rate fixed-step size is the first element of the sample time matrix that you specify in the companion option **Sample time properties**. The **Solver** pane from the example model `rtwdemo_mrmtbb` shows an example.

![Simulation time settings](image)

- **Start time**: 0.0
- **Stop time**: 10.0

**Solver options**

- **Type**: Fixed-step
- **Solver**: discrete (no continuous states)

**Additional options**

- **Fixed-step size (fundamental sample time)**: auto

**Tasking and sample time options**

- **Periodic sample time constraint**: Specified
- **Sample time properties**: `[[1,0,0];[2,0,1]]`
- **Treat each discrete rate as a separate task**: selected
- **Automatically handle rate transition for data transfer**: not selected
- **Higher priority value indicates higher task priority**: not selected
Continuous blocks execute by using an integration algorithm that runs at the base sample rate. The base sample period is the greatest common denominator of all rates in the model only when Periodic sample time constraint is set to Unconstrained and Fixed step size is Auto.

The continuous and discrete parts of the model can execute at different rates only if the discrete part is executed at the same or a slower rate than the continuous part and is an integer multiple of the base sample rate.

Multitasking Execution

This example examines how a simple multirate model executes in both real time and simulation, using a fixed-step solver. It considers operation in both single-tasking and multitasking modes, as determined by setting of the Treat each discrete rate as a separate task parameter on the Solver pane.

The example model is shown in the next figure. The discussion refers to the six blocks of the model as A through F, as labeled in the block diagram.

The execution order of the blocks (indicated in the upper right of each block) has been forced into the order shown by assigning higher priorities to blocks F, E, and D. The ordering shown is one possible valid execution ordering for this model. For more information, see “Simulation Phases in Dynamic Systems” (Simulink).

The execution order is determined by data dependencies between blocks. In a real-time system, the execution order determines the order in which blocks execute within a given time interval or task. This discussion treats the model's execution order as a given, because it is concerned with the allocation of block computations to tasks, and the scheduling of task execution.

Note The discussion and timing diagrams in this section are based on the assumption that the Rate Transition blocks are used in the default (protected/deterministic) mode,
with the **Ensure data integrity during data transfer** and **Ensure deterministic data transfer (maximum delay)** options on.

This example considers the execution of the above model when the solver **Tasking mode** is **MultiTasking**. Block computations are executed under two tasks, prioritized by rate:

- The slower task, which gets the lower priority, is scheduled to run every second. This is called the **1 second task**.
- The faster task, which gets higher priority, is scheduled to run 10 times per second. This is called the **0.1 second task**. The 0.1 second task can preempt the 1 second task.

The following table shows, for each block in the model, the execution order, the task under which the block runs, and whether the block has an output or update computation. Blocks A and B do not have discrete states, and accordingly do not have an update computation.

Real-Time Multitasking Execution

The next figure shows the scheduling of computations in MultiTasking solver mode when the generated code is deployed in a real-time system. The generated program is shown running in real time, as two tasks under control of interrupts from a 10 Hz timer.
Simulated Multitasking Execution

The next figure shows the Simulink execution of the same model, in MultiTasking solver mode. In this case, the Simulink engine runs the blocks in one thread of execution, simulating multitasking. No preemption occurs.

Handle Rate Transitions

Rate Transitions

Two periodic sample rate transitions can exist within a model:

- A faster block driving a slower block
- A slower block driving a faster block

The following sections concern models with periodic sample times with zero offset only. Other considerations apply to multirate models that involve asynchronous tasks. For details on how to generate code for asynchronous multitasking, see “Asynchronous Support” (Simulink Coder).

In multitasking and pseudomultitasking systems, differing sample rates can cause blocks to be executed in the wrong order. To prevent possible errors in calculated data, you must control model execution at these transitions. When connecting faster and slower blocks, you or the Simulink engine must add Rate Transition blocks between them. Fast-to-slow transitions are illustrated in the next figure.

Slow-to-fast transitions are illustrated in the next figure.
Note Although the Rate Transition block offers a superset of the capabilities of the Unit Delay block (for slow-to-fast transitions) and the Zero-Order Hold block (for fast-to-slow transitions), you should use the Rate Transition block instead of these blocks.

Data Transfer Problems

Rate Transition blocks deal with issues of data integrity and determinism associated with data transfer between blocks running at different rates.

- **Data integrity**: A problem of data integrity exists when the input to a block changes during the execution of that block. Data integrity problems can be caused by preemption.

Consider the following scenario:

- A faster block supplies the input to a slower block.
- The slower block reads an input value \( V_1 \) from the faster block and begins computations using that value.
- The computations are preempted by another execution of the faster block, which computes a new output value \( V_2 \).
- A data integrity problem now arises: when the slower block resumes execution, it continues its computations, now using the “new” input value \( V_2 \).
Such a data transfer is called unprotected. “Faster to Slower Transitions in Real Time” on page 17-30 shows an unprotected data transfer.

In a protected data transfer, the output \( V_1 \) of the faster block is held until the slower block finishes executing.

- **Deterministic versus nondeterministic** data transfer: In a deterministic data transfer, the timing of the data transfer is completely predictable, as determined by the sample rates of the blocks.

The timing of a nondeterministic data transfer depends on the availability of data, the sample rates of the blocks, and the time at which the receiving block begins to execute relative to the driving block.

You can use the Rate Transition block to protect data transfers in your application and make them deterministic. These characteristics are considered desirable in most applications. However, the Rate Transition block supports flexible options that allow you to compromise data integrity and determinism in favor of lower latency. The next section summarizes these options.

### Data Transfer Assumptions

When processing data transfers between tasks, the code generator makes these assumptions:

- Data transitions occur between a single reading task and a single writing task.
- A read or write of a byte-sized variable is atomic.
- When two tasks interact through a data transition, only one of them can preempt the other.
- For periodic tasks, the faster rate task has higher priority than the slower rate task; the faster rate task preempts the slower rate task.
- All tasks run on a single processor. Time slicing is not allowed.
- Processes do not crash or restart (especially while data is transferred between tasks).

### Rate Transition Block Options

Several parameters of the Rate Transition block are relevant to its use in code generation for real-time execution, as discussed below. For a complete block description, see Rate Transition.
The Rate Transition block handles periodic (fast to slow and slow to fast) and asynchronous transitions. When inserted between two blocks of differing sample rates, the Rate Transition block automatically configures its input and output sample rates for the type of transition; you do not need to specify whether a transition is slow-to-fast or fast-to-slow (low-to-high or high-to-low priorities for asynchronous tasks).

The critical decision you must make in configuring a Rate Transition block is the choice of data transfer mechanism to be used between the two rates. Your choice is dictated by considerations of safety, memory usage, and performance. As the Rate Transition block parameter dialog box in the next figure shows, the data transfer mechanism is controlled by two options.

- **Ensure data integrity during data transfer**: When this option is on, data transferred between rates maintains its integrity (the data transfer is protected).
When this option is off, the data might not maintain its integrity (the data transfer is unprotected). By default, **Ensure data integrity during data transfer** is on.

- **Ensure deterministic data transfer (maximum delay):** This option is supported for periodic tasks with an offset of zero and fast and slow rates that are multiples of each other. Enable this option for protected data transfers (when **Ensure data integrity during data transfer** is on). When this option is on, the Rate Transition block behaves like a Zero-Order Hold block (for fast to slow transitions) or a Unit Delay block (for slow to fast transitions). The Rate Transition block controls the timing of data transfer in a completely predictable way. When this option is off, the data transfer is nondeterministic. By default, **Ensure deterministic data transfer (maximum delay)** is on for transitions between periodic rates with an offset of zero; for asynchronous transitions, it cannot be selected.

Thus the Rate Transition block offers three modes of operation with respect to data transfer. In order of level of safety:

- **Protected/Deterministic (default):** This is the safest mode. The drawback of this mode is that it introduces deterministic latency into the system for the case of slow-to-fast periodic rate transitions. For that case, the latency introduced by the Rate Transition block is one sample period of the slower task. For the case of fast-to-slow periodic rate transitions, the Rate Transition block introduces no additional latency.

- **Protected/NonDeterministic:** In this mode, for slow-to-fast periodic rate transitions, data integrity is protected by double-buffering data transferred between rates. For fast-to-slow periodic rate transitions, a semaphore flag is used. The blocks downstream from the Rate Transition block use the latest available data from the block that drives the Rate Transition block. Maximum latency is less than or equal to one sample period of the faster task.

The drawbacks of this mode are its nondeterministic timing. The advantage of this mode is its low latency.

- **Unprotected/NonDeterministic:** This mode is not recommended for mission-critical applications. The latency of this mode is the same as for Protected/NonDeterministic mode, but memory requirements are reduced since neither double-buffering nor semaphores are required. That is, the Rate Transition block does nothing in this mode other than to pass signals through; it simply exists to notify you that a rate transition exists (and can cause generated code to compute incorrect answers). Selecting this mode, however, generates the least amount of code.
**Note** In unprotected mode (Ensure data integrity during data transfer option off), the Rate Transition block does nothing other than allow the rate transition to exist in the model.

**Rate Transition Blocks and Continuous Time**

The sample time at the output port of a Rate Transition block can only be discrete or fixed in minor time step. This means that when a Rate Transition block inherits continuous sample time from its destination block, it treats the inherited sample time as Fixed in Minor Time Step. Therefore, the output function of the Rate Transition block runs only at major time steps. If the destination block sample time is continuous, Rate Transition block output sample time is the base rate sample time (if solver is fixed-step), or zero-order-hold-continuous sample time (if solver is variable-step).

**Automatic Rate Transition**

The Simulink engine can detect mismatched rate transitions in a multitasking model during an update diagram and automatically insert Rate Transition blocks to handle them. To enable this, in the Solver pane of model configuration parameters, select **Automatically handle rate transition for data transfer**. The default setting for this option is off. When you select this option:

- Simulink handles transitions between periodic sample times and asynchronous tasks.
- Simulink inserts hidden Rate Transition blocks in the block diagram.
- The code generator produces code for the Rate Transition blocks that were automatically inserted. This code is identical to the code generated for Rate Transition blocks that were inserted manually.
- Automatically inserted Rate Transition blocks operate in protected mode for periodic tasks and asynchronous tasks. You cannot alter this behavior. For periodic tasks, automatically inserted Rate Transition blocks operate with the level of determinism specified by the **Deterministic data transfer** parameter in the Solver pane. The default setting is **Whenever possible**, which enables determinism for data transfers between periodic sample-times that are related by an integer multiple. For more information, see “Deterministic data transfer” (Simulink). To use other modes, you must insert Rate Transition blocks and set their modes manually.

For example, in this model, SineWave2 has a sample time of 2, and SineWave3 has a sample time of 3.
When you select **Automatically handle rate transition for data transfer**, Simulink inserts a Rate Transition block between each Sine Wave block and the Product block. The inserted blocks have the parameter values to reconcile the Sine Wave block sample times.

If the input port and output port data sample rates in a model are not multiples of each other, Simulink inserts a Rate Transition block whose sample rate is the greatest common divisor (GCD) of the two rates. If no other block in the model contains this new rate, an error occurs during simulation. In this case, you must insert a Rate Transition block manually.

### Visualize Inserted Rate Transition Blocks

When you select the **Automatically handle rate transition for data transfer** option, Simulink inserts Rate Transition blocks in the paths that have mismatched transition rates. These blocks are hidden by default. To visualize the inserted blocks, update the diagram. Badge labels appear in the model and indicate where Simulink inserted Rate Transition blocks during the compilation phase. For example, in this model, three Rate Transition blocks were inserted between the two Sine Wave blocks and the Multiplexer and Integrator when the model compiled. The ZOH and DbBuf badge labels indicate these blocks.
You can show or hide badge labels using the **Display > Signals and Ports > Hidden Rate Transition Block Indicators** setting.

To configure the hidden Rate Transition blocks, right click on a badge label and click on **Insert rate transition block** to make the block visible.

When you make hidden Rate Transition blocks visible:

- You can see the type of Rate Transition block inserted as well as the location in the model.
• You can set the **Initial Conditions** of these blocks.
• You can change block parameters for rate transfer.

Validate the changes to your model by updating your diagram.

Displaying inserted Rate Transition blocks is not compatible with:

• Concurrent execution environment
• Export-function models

To learn more about the types of Rate Transition blocks, see Rate Transition.

**Periodic Sample Rate Transitions**

These sections describe cases in which Rate Transition blocks are required for periodic sample rate transitions. The discussion and timing diagrams in these sections are based on the assumption that the Rate Transition block is used in its default (protected/deterministic) mode; that is, the **Ensure data integrity during data transfer** and **Ensure deterministic data transfer (maximum delay)** options are both on. These are the settings used for automatically inserted Rate Transition blocks.

**Faster to Slower Transitions in a Simulink Model**

In a model where a faster block drives a slower block having direct feedthrough, the outputs of the faster block are computed first. In simulation intervals where the slower
block does not execute, the simulation progresses more rapidly because there are fewer blocks to execute. The next figure illustrates this situation.

A Simulink simulation does not execute in real time, which means that it is not bound by real-time constraints. The simulation waits for, or moves ahead to, whatever tasks are required to complete simulation flow. The actual time interval between sample time steps can vary.

**Faster to Slower Transitions in Real Time**

In models where a faster block drives a slower block, you must compensate for the fact that execution of the slower block might span more than one execution period of the faster block. This means that the outputs of the faster block can change before the slower block has finished computing its outputs. The next figure shows a situation in which this problem arises (T = sample time). Note that lower priority tasks are preempted by higher priority tasks before completion.

1. The faster task (T=1s) completes.
2. Higher priority preemption occurs.
3. The slower task (T=2s) resumes and its inputs have changed. This leads to unpredictable results.
In the above figure, the faster block executes a second time before the slower block has completed execution. This can cause unpredictable results because the input data to the slow task is changing. Data might not maintain its integrity in this situation.

To avoid this situation, the Simulink engine must hold the outputs of the 1 second (faster) block until the 2 second (slower) block finishes executing. The way to accomplish this is by inserting a Rate Transition block between the 1 second and 2 second blocks. The input to the slower block does not change during its execution, maintaining data integrity.

It is assumed that the Rate Transition block is used in its default (protected/deterministic) mode.

The Rate Transition block executes at the sample rate of the slower block, but with the priority of the faster block.

When you add a Rate Transition block, the block executes before the 2 second block (its priority is higher) and its output value is held constant while the 2 second block executes (it executes at the slower sample rate).
**Slower to Faster Transitions in a Simulink Model**

In a model where a slower block drives a faster block, the Simulink engine again computes the output of the driving block first. During sample intervals where only the faster block executes, the simulation progresses more rapidly.

The next figure shows the execution sequence.

As you can see from the preceding figures, the Simulink engine can simulate models with multiple sample rates in an efficient manner. However, a Simulink simulation does not operate in real time.

**Slower to Faster Transitions in Real Time**

In models where a slower block drives a faster block, the generated code assigns the faster block a higher priority than the slower block. This means the faster block is executed before the slower block, which requires special care to avoid incorrect results.

1. The faster block executes a second time prior to the completion of the slower block.
2. The faster block executes before the slower block.
This timing diagram illustrates two problems:

- Execution of the slower block is split over more than one faster block interval. In this case the faster task executes a second time before the slower task has completed execution. This means the inputs to the faster task can have incorrect values some of the time.
- The faster block executes before the slower block (which is backward from the way a Simulink simulation operates). In this case, the 1 second block executes first; but the inputs to the faster task have not been computed. This can cause unpredictable results.

To eliminate these problems, you must insert a Rate Transition block between the slower and faster blocks.

It is assumed that the Rate Transition block is used in its default (protected/deterministic) mode.

The next figure shows the timing sequence that results with the added Rate Transition block.
Three key points about transitions in this diagram (refer to circled numbers):

1. The Rate Transition block output runs in the 1 second task, but at a slower rate (2 seconds). The output of the Rate Transition block feeds the 1 second task blocks.
2. The Rate Transition update uses the output of the 2 second task to update its internal state.
3. The Rate Transition output in the 1 second task uses the state of the Rate Transition that was updated in the 2 second task.

The first problem is alleviated because the Rate Transition block is updating at a slower rate and at the priority of the slower block. The input to the Rate Transition block (which is the output of the slower block) is read after the slower block completes executing.

The second problem is alleviated because the Rate Transition block executes at a slower rate and its output does not change during the computation of the faster block it is driving. The output portion of a Rate Transition block is executed at the sample rate of the slower block, but with the priority of the faster block. Since the Rate Transition block drives the faster block and has effectively the same priority, it is executed before the faster block.
Note This use of the Rate Transition block changes the model. The output of the slower block is now delayed by one time step compared to the output without a Rate Transition block.

Protect Data Integrity with volatile Keyword

When you select **Ensure data integrity during data transfer**, the code generated for a Rate Transition block defines global buffers and semaphores and uses them to protect the integrity of the transferred data.

Particularly for a multitasking application, the tasks (rates) involved in a data transfer can write to the transferred data, buffers, and semaphores at times that your compiler cannot anticipate. To prevent your compiler from optimizing the assembly code in a manner that compromises the integrity of the transferred data, the code generator applies the keyword `volatile` to the buffers and semaphores. The code generator does not apply `volatile` to the global variable that represents the transferred data because the `volatile` buffers and semaphores typically offer enough protection.

If necessary, with Embedded Coder, you can explicitly apply `volatile` to the transferred data by applying the built-in custom storage class `Volatile` to the input of the Rate Transition block. For example, you can use this technique to help protect the integrity of data that your external code shares with the generated code.

Alternatively, to protect data that your external code shares with the generated code, you can write your own C functions that read and write the data in a protected manner. Then, you can apply the custom storage class `GetSet` to the data in the model, which causes the generated code to call your functions instead of directly accessing the data.

For more information about applying `volatile`, see “Protect Global Data with const and volatile Keywords” on page 30-17. For more information about `GetSet`, see “Access Data Through Functions with Custom Storage Class GetSet” on page 26-42.

Separate Rate Transition Block Code and Data from Algorithm Code and Data

By default, Rate Transition block code is set inline with algorithm code and data. If you have Embedded Coder, you can separate the code and data, so that the generated code contains separate `get` and `set` functions that the `model_step` functions call and a dedicated structure for state data. The generated code also contains separate `start` and
initialize functions that the \texttt{model\_initialize} function calls. To separate Rate Transition block code and data from algorithm code and data, in the Configuration Parameters dialog box, set the Rate Transition block code parameter to \texttt{Function}.

Separating Rate Transition block code and data from algorithm code and data enables you to analyze, optimize, and test Rate Transition block and algorithm code independently from each other.

Configure Time-Based Scheduling

For details about solver options, see “Solver Pane” (Simulink).

Configure Start and Stop Times

The Stop time (Simulink) must be greater than or equal to the Start time (Simulink). If the stop time is zero, or if the total simulation time (Stop minus Start) is less than zero, the generated program runs for one step. If the stop time is set to inf, the generated program runs indefinitely.

When using the GRT or ERT targets, you can override the stop time when running a generated program from the Microsoft Windows command prompt or UNIX³ command line. To override the stop time that was set during code generation, use the -tf switch.

```model -tf n```

The program runs for n seconds. If n = inf, the program runs indefinitely.

Certain blocks have a dependency on absolute time. If you are designing a program that is intended to run indefinitely (Stop time = inf), and your generated code does not use the rtModel data structure (that is, it uses simstructs instead), you must not use these blocks. See “Absolute Time Limitations” on page 16-12 for a list of blocks that can potentially overflow timers.

If you know how long an application that depends on absolute time needs to run, you can prevent the timers from overflowing and force the use of optimal word sizes by specifying the Application lifespan (days) (Simulink) parameter on the Math and Data Types pane. See “Control Memory Allocation for Time Counters” on page 56-11 for details.

Configure the Solver Type

For code generation, you must configure a model to use a fixed-step solver for all targets except the S-function and RSIm targets. You can configure the S-function and RSIm targets with a fixed-step or variable-step solver.

³ UNIX is a registered trademark of The Open Group in the United States and other countries.
Configure the Tasking Mode

The code generator supports both single-tasking and multitasking modes for periodic sample times. See “Time-Based Scheduling and Code Generation” on page 17-2 for details.

Time-Based Scheduling Example Models

Optimize Memory Usage for Time Counters

This example shows how to optimize the amount of memory that the code generator allocates for time counters. The example optimizes the memory that stores elapsed time, the interval of time between two events.

The code generator represents time counters as unsigned integers. The word size of time counters is based on the setting of the model configuration parameter Application lifespan (days), which specifies the expected maximum duration of time the application runs. You can use this parameter to prevent time counter overflows. The default size is 64 bits.

The number of bits that a time counter uses depends on the setting of the Application lifespan (days) parameter. For example, if a time counter increments at a rate of 1 kHz, to avoid an overflow, the counter has the following number of bits:

- Lifespan < 0.25 sec: 8 bits
- Lifespan < 1 min: 16 bits
- Lifespan < 49 days: 32 bits
- Lifespan > 50 days: 64 bits

A 64-bit time counter does not overflow for 590 million years.

Open Example Model

Open the example model rtwdemo_abstime.
The model consists of three subsystems SS1, SS2, and SS3. On the Math and Data Types pane, the Application lifespan (days) parameter is set to the default, which is inf.
The three subsystems contain a discrete-time integrator that requires elapsed time as input to compute its output value. The subsystems vary as follows:

- SS1 - Clocked at 1 kHz. Does not require a time counter. **Sample time type** parameter for trigger port is set to periodic. Elapsed time is inlined as 0.001.
- SS2 - Clocked at 100 Hz. Requires a time counter. Based on a lifespan of 1 day, a 32-bit counter stores the elapsed time.
- SS3 - Clocked at 0.5 Hz. Requires a time counter. Based on a lifespan of 1 day, a 16-bit counter stores the elapsed time.

**Simulate the Model**

Simulate the model. By default, the model is configured to show sample times in different colors. Discrete sample times for the three subsystems appear red, green, and blue. Triggered subsystems are blue-green.

**Generate Code and Report**

1. Create a temporary folder for the build and inspection process.

2. Configure the model for the code generator to use the GRT system target file and a lifespan of inf days.

3. Build the model.

```bash
### Starting build procedure for model: rtwdemo_abstime
### Successful completion of build procedure for model: rtwdemo_abstime
```

**Review Generated Code**

Open the generated source file `rtwdemo_abstime.c`.

```c
struct tag_RTM_rtwdemo_abstime_T {
    const char_T *errorStatus;

    /*
    * Timing:
    * The following substructure contains information regarding
    * the timing information for the model.
    */
    struct {
        uint32_T clockTick1;
    }
```
uint32_T clockTickH1;
uint32_T clockTick2;
uint32_T clockTickH2;
struct {
    uint16_T TID[3];
    uint16_T cLimit[3];
} TaskCounters;
} Timing;
};

/* Block states (default storage) */
extern DW_rtwdemo_abstime_T rtwdemo_abstime_DW;

/* External inputs (root inport signals with default storage) */
extern ExtU_rtwdemo_abstime_T rtwdemo_abstime_U;

/* External outputs (root outports fed by signals with default storage) */
extern ExtY_rtwdemo_abstime_T rtwdemo_abstime_Y;

/* Model entry point functions */
extern void rtwdemo_abstime_initialize(void);
extern void rtwdemo_abstime_step(int_T tid);
extern void rtwdemo_abstime_terminate(void);

/* Real-time Model object */
extern RT_MODEL_rtwdemo_abstime_T *const rtwdemo_abstime_M;

/*-
* The generated code includes comments that allow you to trace directly
* back to the appropriate location in the model. The basic format
* is <system>/block_name, where system is the system number (uniquely
* assigned by Simulink) and block_name is the name of the block.
*
* Use the MATLAB hilite_system command to trace the generated code back
* to the model. For example,
*
* hilite_system('<S3>')    - opens system 3
* hilite_system('<S3>/Kp') - opens and selects block Kp which resides in S3
*
* Here is the system hierarchy for this model
*
* '<Root>' : 'rtwdemo_abstime'
* '<S1>' : 'rtwdemo_abstime/SS1'
* '<S2>' : 'rtwdemo_abstime/SS2'
*/
Four 32-bit unsigned integers, `clockTick1`, `clockTickH1`, `clockTick2`, and `clockTickH2` are counters for storing the elapsed time of subsystems SS2 and SS3.

**Enable Optimization and Regenerate Code**

1. Reconfigure the model to set the lifespan to 1 day.

2. Build the model.

```bash
### Starting build procedure for model: rtwdemo_abstime
### Successful completion of build procedure for model: rtwdemo_abstime
```

**Review the Regenerated Code**

```c
struct tag_RTM_rtwdemo_abstime_T {
    const char_T *errorStatus;

    /*
     * Timing:
     * The following substructure contains information regarding
     * the timing information for the model.
     */
    struct {
        uint32_T clockTick1;
        uint16_T clockTick2;
        struct {
            uint16_T TID[3];
            uint16_T cLimit[3];
        } TaskCounters;
    } Timing;

    /* Block states (default storage) */
    extern DW_rtwdemo_abstime_T rtwdemo_abstime_DW;

    /* External inputs (root inport signals with default storage) */
    extern ExtU_rtwdemo_abstime_T rtwdemo_abstime_U;

    /* External outputs (root outports fed by signals with default storage) */
    extern ExtY_rtwdemo_abstime_T rtwdemo_abstime_Y;
```
/* Model entry point functions */
extern void rtwdemo_abstime_initialize(void);
extern void rtwdemo_abstime_step(int_T tid);
extern void rtwdemo_abstime_terminate(void);

/* Real-time Model object */
extern RT_MODEL_rtwdemo_abstime_T *const rtwdemo_abstime_M;

/*-
* The generated code includes comments that allow you to trace directly
* back to the appropriate location in the model. The basic format
* is <system>/block_name, where system is the system number (uniquely
* assigned by Simulink) and block_name is the name of the block.
*
* Use the MATLAB hilite_system command to trace the generated code back
* to the model. For example,
* * hilite_system('<S3>')    - opens system 3
* hilite_system('<S3>/Kp') - opens and selects block Kp which resides in S3
* *
* Here is the system hierarchy for this model
*
* ' <Root> ' : ' rtwdemo_abstime'
* ' <S1> ' : ' rtwdemo_abstime/SS1'
* ' <S2> ' : ' rtwdemo_abstime/SS2'
* ' <S3> ' : ' rtwdemo_abstime/SS3'
* /
#endif                                 /* RTW_HEADER_rtwdemo_abstime_h_ */

The new setting for the **Application lifespan (days)** parameter instructs the code generator to set aside less memory for the time counters. The regenerated code includes:

- 32-bit unsigned integer, `clockTick1`, for storing the elapsed time of the task for SS2
- 16-bit unsigned integer, `clockTick2`, for storing the elapsed time of the task for SS3

**Single-Rate Modeling (Bare Board, No OS)**

This model shows the code generated for a single-rate discrete-time model configured for a bare-board target (one with no operating system).

**Open Example Model**

Open the example model `rtwdemo_srbb`.

```matlab
open_system('rtwdemo_srbb')
```
The model uses one sample time. Inport block 1 and Inport block 2 both specify a 1-second sample time, which is enforced by the **Periodic sample time constraint** option.
on the **Solver** configuration page. To view the solver page, double-click the corresponding yellow button in the model. To display the sample times in the model, double-click the corresponding yellow button in the model.

This model is configured to display sample-time colors upon diagram update. Red represents the fastest discrete sample time in the model, green represents the second fastest, and yellow represents mixed sample times. Click the yellow button in the model to update the diagram and show sample-time colors.

**Multirate Modeling in Single-Tasking Mode (Bare Board, no OS)***

This model shows the code generated for a multirate discrete-time model configured for single-tasking on a bare-board target (one with no operating system).

**Open Example Model**

Open the example model `rtwdemo_mrstdbb`.

```matlab
open_system('rtwdemo_mrstdbb')
```
The model is configured to display sample-time colors upon diagram update. Red represents the fastest discrete sample time in the model, green represents the second fastest, and yellow represents mixed sample times. Click the yellow button to the right to update the diagram and show sample-time colors.

This model shows the code generated for a multirate discrete-time model configured for single-tasking on a bare-board target (one with no operating system). The model contains two sample times. Inport block 1 and Inport block 2 specify 1-second and 2-second sample times, respectively, which are enforced by the "Periodic sample time constraint" option on the Solver configuration page. The solver is set for single-tasking operation. Rate transition blocks are, therefore, not necessary between blocks executing at different sample times because preemption will not occur.

Generate Code Using Simulink Coder (double-click)

Click the yellow button to the right to update the diagram and show sample-time colors.

This model shows the code generated for a multirate discrete-time model configured for a multitasking bare-board target (one with no operating system). The model contains two sample times. Import block 1 and Import block 2 specify 1-second and 2-second sample times, respectively, which are enforced by the "Periodic sample time constraint" option on the Solver configuration page. The solver is set for multitasking operation, which means a rate transition block is required to ensure that data integrity is enforced when the 1-second task preempts the 2-second task. Proper rate transitions are always enforced by Simulink and Simulink Coder. This model specifies an explicit rate transition block. Alternatively, this block could be automatically inserted by Simulink using the "Automatically handle data transfers between tasks" option on the Solver configuration page.
Explore Example Model

The model contains two sample times. Inport block 1 and Inport block 2 specify 1-second and 2-second sample times, respectively, which are enforced by the Periodic sample time constraint option on the Solver configuration page. The solver is set for multitasking operation, which means a rate transition block is required to ensure that data integrity is enforced when the 1-second task preempts the 2-second task. Proper rate transitions are always enforced by Simulink and Simulink Coder. This model specifies an explicit rate transition block. Alternatively, this block could be automatically inserted by Simulink using the model configuration parameter Automatically handle rate transition for data transfer.

The model is configured to display sample-time colors upon diagram update. Red represents the fastest discrete sample time in the model, green represents the second fastest, and yellow represents mixed sample times. Click the yellow button to the right to update the diagram and show sample-time colors.

Data Transfer Assumptions

Basis of operation for data transfers between tasks:

1. Data transitions occur between a single reading task and a single writing task.
2. A read or write of a byte sized variable is atomic.
3. When two tasks interact through a data transition, only one of them can preempt the other.
4. For periodic tasks, the faster rate task has higher priority than the slower rate task; the faster rate task always preempts the slower rate task.
5. All tasks run on a single processor. Time slicing is not allowed.
6. Processes do not crash/restart (especially while data is being transferred between tasks)

Trade Determinism and Data Integrity to Improve System Performance

This model shows the differences in the operation modes of the Rate Transition block when used in a multirate, multitasking model. The flexible options for the Rate Transition block allow you to select the mode that is best suited for your application. You can trade levels of determinism and data integrity to improve system performance.
Rate Transition Block Modes of Operation

**Ensure data integrity and determinism (DetAndInteg)**: Data is transferred such that all data bytes for the signal (including all elements of a wide signal) are from the same time step. Additionally, it is ensured that the relative sample time (delay) from which the data is transferred from one rate to another is always the same. Only ANSI-C code is used, no target specific 'critical section' protection is needed.

**Ensure integrity (IntegOnly)**: Data is transferred such that all data bytes for the signal (including all elements of a wide signal) are from the same time step. However, from one transfer of data to the next, the relative sample time (delay) for which the data is transferred can vary. In this mode, the code to read/write the data is run more often than in the DetandInt mode. In the worst case, the delay is equivalent to the DetandInt mode, but the delay can be less which is important in some applications. Also, this mode supports data transfers to/from asynchronous rates which the DetandInt mode cannot support. Only ANSI-C code is used, no target specific 'critical section' protection is needed.

**No data consistency operations are performed (None)**: For this case, the Rate Transition block does not generate code. This mode is acceptable in some applications where atomic access of scalar data types is guaranteed and when the relative temporal values of the data is not important. This mode does not introduce any delay.

**Data Transfer Assumptions**

Basis of operation for data transfers between tasks:

- Data transitions occur between a single reading task and a single writing task.
- A read or write of a byte sized variable is atomic.
- When two tasks interact through a data transition, only one of them can preempt the other.
- For periodic tasks, the faster rate task has higher priority than the slower rate task; the faster rate task always preempts the slower rate task.
- All tasks run on a single processor. Time slicing is not allowed.
- Processes do not crash/restart (especially while data is being transferred between tasks)

**Model rtwdemo_ratetrans**

```matlab
open_system('rtwdemo_ratetrans')
```
This model shows the differences in the operation modes of the Rate Transition block when used in a multirate, multitasking model. The flexible options for the Rate Transition block allow you to select the mode that is best suited for your application. You can trade levels of determinism and data integrity to improve system performance.
Model `rtwdemo_ratetrans` shows the differences in the operation modes of the following Rate Transition blocks.

**Rate Transition block DetAndIntegF2S**

Determinism and data integrity (fast to slow transition):

- The block output is used as a persistent data buffer.
- Data is written to output at slower rate but done during the faster rate context.
- Data as seen by the slower rate is always the value when both the faster and slower rate last executed. Any subsequent steps by the faster rate (and associated data updates) while the slower rate is running are not seen by the slower rate.

**Rate Transition block DetAndIntegS2F**

Determinism and data integrity (slow to fast transition):

- Uses two persistent data buffers, an internal buffer and the blocks output.
- The internal buffer is copied to the output at the slower rate but done during the faster rate context.
- The internal buffer is written at the slower rate and during the slower rate context.
- The data that Fast rate sees is always delayed, i.e. data is from the previous step of the slow rate code.

**Rate Transition block IntegOnlyF2S**

Data integrity only (fast to slow transition):

- The block output is used as a persistent data buffer.
- Data is written to buffer during the faster rate context if a flag indicates it not in the process of being read.
- The flag is set and data is copied from the buffer to output at the slow rate, the flag is then cleared. This is an additional copy as compared to the deterministic case.
- Data as seen by the slower rate can be from a more recent step of the faster rate than from when the slower rate and faster rate both executed.

**Rate Transition block IntegOnlyS2F**

Data integrity only (slow to fast transition):
• Uses two persistent data buffers, both are internal buffers.
• One of the 2 buffers is always copied to the output at faster rate.
• One of the 2 buffers is written at the slower rate and during the slower rate context, then the active buffer is switched.
• The data as seen by the faster rate can be more recent than for the deterministic case. Specifically, when both the slower and faster rate have their hits, the faster rate will see a previous value from the slower rate. But, subsequent steps for the faster rate may see an updated value (when the slower rate updates the non-active buffer and switches the active buffer flag.

**Rate Transition block NoneF2S**

No code is generated for the Rate Transition block when determinism and data integrity is waived.

**Rate Transition block NoneS2F**

No code is generated for the Rate Transition block when determinism and data integrity is waived.

```matlab
bdclose('rtwdoc_rate_trans');
```

Asynchronous Events

Asynchronous Support

Normally, you time models from which you plan to generate code from a periodic interrupt source (for example, a hardware timer). Blocks in a periodically clocked single-rate model run at a timer interrupt rate (the base rate of the model). Blocks in a periodically clocked multirate model run at the base rate or at multiples of that rate.

Many systems must also support execution of blocks in response to events that are asynchronous with respect to the periodic timing source of the system. For example, a peripheral device might signal completion of an input operation by generating an interrupt. The system must service such interrupts, for example, by acquiring data from the interrupting device.

This chapter explains how to use blocks to model and generate code for asynchronous event handling, including servicing of hardware-generated interrupts, maintenance of timers, asynchronous read and write operations, and spawning of asynchronous tasks under a real-time operating system (RTOS). This block library demonstrates integration with an example RTOS (VxWorks). Although the blocks target an example RTOS, this chapter provides source code analysis and other information you can use to develop blocks that support asynchronous event handling for an alternative target RTOS.4

Block Library for Calls to an Example Real-Time Operating System

The next figure shows the blocks in the vxlib1 block library.

---

4. VxWorks is a registered trademark of Wind River Systems, Inc.
The key blocks in the library are the Async Interrupt and Task Sync blocks. These blocks are targeted for an example RTOS (VxWorks). You can use them, with modification, to support your RTOS applications.

**Note** You can use the blocks in the vxlib1 (Simulink Coder) library (Async Interrupt and Task Sync) for simulation and code generation. These blocks provide starting point examples to help you develop custom blocks for your target environment.

To implement asynchronous support for an RTOS other than the example RTOS, use the guidelines and example code are provided to help you adapt the vxlib1 library blocks to target your RTOS. This topic is discussed in “Create a Customized Asynchronous Library” on page 18-49.

The vxlib1 library includes blocks you can use to

- Generate interrupt-level code — Async Interrupt block
- Spawn an RTOS task that calls a function call subsystem — Task Sync block
- Enable data integrity when transferring data between blocks running as different tasks — Protected RT block
- Use an unprotected/nondeterministic mode when transferring data between blocks running as different tasks — Unprotected RT block

The use of protected and unprotected Rate Transition blocks in asynchronous contexts is discussed in “Rate Transitions and Asynchronous Blocks” on page 18-40. For general information on rate transitions, see “Time-Based Scheduling and Code Generation” on page 17-2.
Access the Block Library for RTOS Integration

To access the example RTOS (VxWorks) block library, enter the MATLAB command `vxlib1`.

Generate Code Using Library Blocks for RTOS Integration

To generate an example RTOS compatible application from a model containing `vxlib1` library blocks, use the following configuration parameter values for your model.

• Select system target file `ert.tlc` (requires an Embedded Coder license) from the browse menu for the **Code Generation > System target file** parameter (`SystemTargetFile`).
• Enable the **Configuration Parameters > Code Generation > Generate code only** parameter (`GenCodeOnly`).
• Enable the **Configuration Parameters > Code Generation > Templates > Custom templates > Generate an example main program** parameter (`GenerateSampleERTMain`).
• Select **VxWorksExample** from the menu for the **Configuration Parameters > Code Generation > Templates > Custom templates > Target operating system** parameter (`TargetOS`).

Examples and Additional Information

Additional information relevant to the topics in this chapter can be found in

• The `rtwdemo_async` model, which uses the `tornado.tlc` system target file and `vxlib1` block library. To open this example, type `rtwdemo_async` at the MATLAB command prompt.
• The `rtwdemo_async_mdlreftop` model, which uses the `tornado.tlc` system target file and `vxlib1` block library. To open this example, type `rtwdemo_async_mdlreftop` at the MATLAB command prompt.
• “Time-Based Scheduling and Code Generation” (Simulink Coder), discusses general multitasking and rate transition issues for periodic models.
• The Embedded Coder documentation discusses the `ert.tlc` system target file, including task execution and scheduling.
• For detailed information about the system calls to the example RTOS (VxWorks) mentioned in this chapter, see VxWorks system documentation on the Wind River website.

• “Asynchronous Support Limitations” (Simulink Coder)
Generate Interrupt Service Routines

To generate an interrupt service routine (ISR) associated with a specific VME interrupt level for the example RTOS (VxWorks), use the Async Interrupt block. The Async Interrupt block enables the specified interrupt level and installs an ISR that calls a connected function call subsystem.

You can also use the Async Interrupt block in a simulation. It provides an input port that can be enabled and connected to a simulated interrupt source.

**Note** The operating system integration techniques that are demonstrated in this section use one or more blocks the blocks in the `vxlib1` (Simulink Coder) library. These blocks provide starting point examples to help you develop custom blocks for your target environment.

Connecting the Async Interrupt Block

To generate an ISR, connect an output of the Async Interrupt block to the control input of

- A function call subsystem
- The input of a Task Sync block
- The input to a Stateflow chart configured for a function call input event

The next figure shows an Async Interrupt block configured to service two interrupt sources. The outputs (signal width 2) are connected to two function call subsystems.
Requirements and Restrictions

Note the following requirements and restrictions:

- The Async Interrupt block supports VME interrupts 1 through 7.
- The Async Interrupt block uses the following system calls to the example RTOS (VxWorks):
  - sysIntEnable
  - sysIntDisable
  - intConnect
  - intLock
  - intUnlock
  - tickGet

Performance Considerations

Execution of large subsystems at interrupt level can have a significant impact on interrupt response time for interrupts of equal and lower priority in the system. As a general rule, it is best to keep ISRs as short as possible. Connect only function call subsystems that contain a small number of blocks to an Async Interrupt block.
A better solution for large subsystems is to use the Task Sync block to synchronize the execution of the function call subsystem to a RTOS task. The Task Sync block is placed between the Async Interrupt block and the function call subsystem. The Async Interrupt block then installs the Task Sync block as the ISR. The ISR releases a synchronization semaphore (performs a semGive) to the task, and returns immediately from interrupt level. The task is then scheduled and run by the example RTOS (VxWorks). See “Spawn and Synchronize Execution of RTOS Task” on page 18-15 for more information.

**Using the Async Interrupt Block in Simulation and Code Generation**

This section describes a dual-model approach to the development and implementation of real-time systems that include ISRs. In this approach, you develop one model that includes a plant and a controller for simulation, and another model that only includes the controller for code generation. Using a Simulink library, you can implement changes to both models simultaneously. The next figure shows how changes made to the plant or controller, both of which are in a library, are propagated to the models.

**Dual-Model Use of Async Interrupt Block for Simulation and Code Generation**

A single-model approach is also possible. In this approach, the Plant component of the model is active only in simulation. During code generation, the Plant components are effectively switched out of the system and code is generated only for the interrupt block and controller parts of the model. For an example of this approach, see the rtwdemo_async model.
**Dual-Model Approach: Simulation**

The following block diagram shows a simple model that illustrates the dual-model approach to modeling. During simulation, the Pulse Generator blocks provide simulated interrupt signals.

The simulated interrupt signals are routed through the Async Interrupt block's input port. Upon receiving a simulated interrupt, the block calls the connected subsystem.

During simulation, subsystems connected to Async Interrupt block outputs are executed in order of their priority in the example RTOS (VxWorks). In the event that two or more interrupt signals occur simultaneously, the Async Interrupt block executes the downstream systems in the order specified by their interrupt levels (level 7 gets the highest priority). The first input element maps to the first output element.

You can also use the Async Interrupt block in a simulation without enabling the simulation input. In such a case, the Async Interrupt block inherits the base rate of the model and calls the connected subsystems in order of their priorities in the RTOS. (In this case, the Async Interrupt block behaves as if all inputs received a 1 simultaneously.)

**Dual-Model Approach: Code Generation**

In the generated code for the sample model,
Ground blocks provide input signals to the Environment Controller block
The Async Interrupt block does not use its simulation input

The Ground blocks drive control input of the Environment Controller block, so code is not generated for that signal path. The code generator does not produce code for blocks that drive the simulation control input to the Environment Controller block because that path is not selected during code generation. However, the sample times of driving blocks for the simulation input to the Environment Controller block contribute to the sample times supported in the generated code. To avoid including unnecessary sample times in the generated code, use the sample times of the blocks driving the simulation input in the model where generated code is intended.

Standalone functions are installed as ISRs and the interrupt vector table is as follows:

<table>
<thead>
<tr>
<th>Offset</th>
<th>Function Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>192</td>
<td>&amp;isr_num1_vec192()</td>
</tr>
<tr>
<td>193</td>
<td>&amp;isr_num2_vec193()</td>
</tr>
</tbody>
</table>

Consider the code generated from this model, assuming that the Async Interrupt block parameters are configured as shown in the next figure.
Initialization Code

In the generated code, the Async Interrupt block installs the code in the Subsystem blocks as interrupt service routines. The interrupt vectors for IRQ1 and IRQ2 are stored at locations 192 and 193 relative to the base of the interrupt vector table, as specified by the VME interrupt vector offset(s) parameter.

Installing an ISR requires two RTOS (VxWorks) calls, int_connect and sysInt_Enable. The Async Interrupt block inserts these calls in the model_initialize function, as shown in the following code excerpt.

```c
/* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
/* Connect and enable ISR function: isr_num1_vec192 */
if( intConnect(INUM_TO_IVEC(192), isr_num1_vec192, 0) != OK) {
  printf("intConnect failed for ISR 1.\n");
} sysIntEnable(1);
```
/* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
/* Connect and enable ISR function: isr_num2_vec193 */
if( intConnect(INUM_TO_IVEC(193), isr_num2_vec193, 0) != OK)
{
    printf("intConnect failed for ISR 2.\n");
} sysIntEnable(2);

The hardware that generates the interrupt is not configured by the Async Interrupt block. Typically, the interrupt source is a VME I/O board, which generates interrupts for specific events (for example, end of A/D conversion). The VME interrupt level and vector are set up in registers or by using jumpers on the board. You can use the mdlStart routine of a user-written device driver (S-function) to set up the registers and enable interrupt generation on the board. You must match the interrupt level and vector specified in the Async Interrupt block dialog to the level and vector set up on the I/O board.

**Generated ISR Code**

The actual ISR generated for IRQ1 in the RTOS (VxWorks) is listed below.

/* VxWorks Interrupt Block: '<Root>/Async Interrupt' */

```c
void isr_num1_vec192(void)
{
    int_T lock;
    FP_CONTEXT context;

    /* Use tickGet() as a portable tick counter example. 
       A much higher resolution can be achieved with a 
       hardware counter */
    Async_Code_M->Timing.clockTick2 = tickGet();

    /* disable interrupts (system is configured as non-ive) */
    lock = intLock();

    /* save floating point context */
    fppSave(&context);

    /* Call the system: <Root>/Subsystem A */
    Count(0, 0);

    /* restore floating point context */
    fppRestore(&context);

    /* re-enable interrupts */
```
intUnlock(lock);
}

There are several features of the ISR that should be noted:

- Because of the setting of the **Preemption Flag(s)** parameter, this ISR is locked; that is, it cannot be preempted by a higher priority interrupt. The ISR is locked and unlocked in the example RTOS (VxWorks) by the `int_lock` and `int_unlock` functions.

- The connected subsystem, `Count`, is called from within the ISR.

- The `Count` function executes algorithmic (model) code. Therefore, the floating-point context is saved and restored across the call to `Count`.

- The ISR maintains its own absolute time counter, which is distinct from other periodic base rate or subrate counters in the system. Timing data is maintained for the use of any blocks executed within the ISR that require absolute or elapsed time.

See “Timers in Asynchronous Tasks” on page 18-46 for details.

**Model Termination Code**

The model's termination function disables the interrupts in the RTOS (VxWorks):  

```c
/* Model terminate function */
void Async_Code_terminate(void)
{
    /* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
    /* Disable interrupt for ISR system: isr_num1_vec192 */
    sysIntDisable(1);

    /* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
    /* Disable interrupt for ISR system: isr_num2_vec193 */
    sysIntDisable(2);
}
```

Spawn and Synchronize Execution of RTOS Task

This example shows how to simulate and generate code for asynchronous events on a multitasking real-time operating system (VxWorks®). The model shows different techniques for handling asynchronous events depending on the size of the triggered subsystems.

About the Example Model

Open the example model `rtwdemo_async`. 

The model simulates an interrupt source and includes an Async Interrupt block, a Task Sync block, function-call subsystems Count and Algorithm, and Rate Transition blocks. The Async Interrupt block creates two Versa Module Eurocard (VME) interrupt service routines (ISRs) that pass interrupt signals to subsystem Count and the Task Sync block. You can place an Async Interrupt block between a simulated interrupt source and one of the following:
• Function call subsystem
• Task Sync block
• A Stateflow® chart configured for a function call input event
• A referenced model with an Inport block that connects to one of the preceding model elements

The Async Interrupt and Task Sync blocks enable the subsystems to execute asynchronously.

Count represents a simple interrupt service routine (ISR) that executes at interrupt level. It is best to keep ISRs as simple as possible. This subsystem includes only a Discrete-Time Integrator block.

Algorithm includes more substance. It includes multiple blocks and produces two output values. Execution of larger subsystems at interrupt level can significantly impact response time for interrupts of equal and lower priority in the system. A better solution for larger subsystems is to use the Task Sync block to represent the ISR for the function-call subsystem.

The Async Interrupt block generates calls to ISRs. Place the block between a simulated interrupt source and one of the following:

• Function call subsystem
• Task Sync block
• A Stateflow® chart configured for a function call input event

For each specified interrupt level, the block generates a Versa Module Eurocard (VME) ISR that executes the connected subsystem, Task Sync block, or chart.

In the example model, the Async Interrupt block is configured for VME interrupts 1 and 2, by using interrupt vector offsets 192 and 193. Interrupt 1 connects directly to subsystem Count. Interrupt 2 connects to a Task Sync block, which serves as the ISR for Algorithm. Place a Task Sync block in one of the following locations:

• Between an Async Interrupt block and a function-call subsystem or Stateflow® chart.
• At the output port of a Stateflow® chart that has an event, Output to Simulink, that you configure as a function call.

In the example model, the Task Sync block is between the Async Interrupt block and function-call subsystem Algorithm. The Task Sync block is configured with the task
name Task(), a priority of 50, a stack size of 8192, and data transfers of the task synchronized with the caller task. The spawned task uses a semaphore to synchronize task execution. The Async Interrupt block triggers a release of the task semaphore.

Four Rate Transition blocks handle data transfers between ports that operate at different rates. In two instances, Protected Rate Transition blocks protect data transfers (prevent them from being preempted and corrupted). In the other two instances, Unprotected Rate Transition blocks introduce no special behavior. Their presence informs Simulink® of a rate transition.

The code generated for the Async Interrupt and Task Sync blocks is tailored for the example RTOS (VxWorks®). However, you can modify the blocks to generate code specific to your run-time environment.

**Data Transfer Assumptions**

- Data transfers occur between one reading task and one writing task.
- A read or write operation on a byte-size variable is atomic.
- When two tasks interact, only one can preempt the other.
- For periodic tasks, the task with the faster rate has higher priority than the task with the slower rate. The task with the faster rate preempts the tasks with slower rates.
- Tasks run on a single processor. Time slicing is not allowed.
- Processes do not stop and restart, especially while data is being transferred between tasks.

**Simulate the Model**

Simulate the model. By default, the model is configured to show sample times in different colors. Discrete sample times for input and output appear red and green, respectively. Constants are reddish-blue. Asynchronous interrupts and tasks are purple. The Rate Transition Blocks, which are a hybrid rate (their input and output sample times can differ), are yellow.

**Generate Code and Report**

Generate code and a code generation report for the model. Generated code for the Async Interrupt and Task Sync blocks is for the example RTOS (VxWorks®). However, you can modify the blocks to generate code for another run-time environment.

1. Create a temporary folder for the build and inspection process.
2. Build the model.

```bash
### Starting build procedure for model: rtwdemo_async
Warning: Simulink Coder: The tornado.tlc target will be removed in a future release.

### Wrapping unrecognized make command (angle brackets added)
###    <make>
### in default batch file
### Successful completion of code generation for model: rtwdemo_async
```

**Review Initialization Code**

Open the generated source file `rtwdemo_async.c`. The initialization code:

1. Creates and initializes the synchronization semaphore `Task0_semaphore`.

   ```c
   *(SEM_ID *)rtwdemo_async_DW.SFunction_PWORK.SemID = semBCreate(SEM_Q_PRIORITY, SEM_EMPTY);
   if (rtwdemo_async_DW.SFunction_PWORK.SemID == NULL) {
       printf("semBCreate call failed for block Task0.\n");
   }
   
   2. Spawns task `task0` and assigns the task priority 50.

   ```c
   rtwdemo_async_DW.SFunction_IWORK.TaskID = taskSpawn("Task0", 50.0, VX_FP_TASK, 8192.0, (FUNCPTR)Task0, 0, 0, 0, 0, 0, 0, 0, 0);  
   if (rtwdemo_async_DW.SFunction_IWORK.TaskID == ERROR) {
       printf("taskSpawn call failed for block Task0.\n");
   }
   /* End of Start for S-Function (vxtask1): '<S5>/S-Function' */
   
   /* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
   /* Connect and enable ISR function: isr_num1_vec192 */
   if (intConnect(INUM_TO_IVEC(192), isr_num1_vec192, 0) != OK) {
       printf("intConnect failed for ISR 1.\n");
   }
   ```
sysIntEnable(1);

/* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
/* Connect and enable ISR function: isr_num2_vec193 */
if (intConnect(INUM_TO_IVEC(193), isr_num2_vec193, 0) != OK) {
    printf("intConnect failed for ISR 2.\n");
}

sysIntEnable(2);

3. Connects and enables ISR isr_num1_vec192 for interrupt 1 and ISR
   isr_num2_vec193 for interrupt 2.

return rtwdemo_async_M;
The order of these operations is important. Before the code generator enables the interrupt that activates the task, it must spawn the task.

**Review Task and Task Synchronization Code**

In the generated source file `rtwdemo_async.c`, review the task and task synchronization code.

The code generator produces the code for function `Task0` from the Task Sync block. That function includes a small amount of interrupt-level code and runs as an RTOS task.

The task waits in an infinite `for` loop until the system releases a synchronization semaphore. If the system releases the semaphore, the function updates its task timer and calls the code generated for the Algorithm subsystem.

In the example model, the **Synchronize the data transfer of this task with the caller task** parameter for the Task Sync block is set. This parameter setting updates the timer associated with the Task Sync block (`rtM->Timing.clockTick2`) with the value of the timer that the Async Interrupt block (`rtM->Timing.clockTick3`) maintains. As a result, code for blocks within the Algorithm subsystem use timer values that are based on the time of the most recent interrupt, rather than the most recent activation of `Task0`.

```c
{
    /* Wait for semaphore to be released by system: rtwdemo_async/Task Sync */
    for (;;) {
        if (semTake(*(SEM_ID *)rtwdemo_async_DW.SFunction_PWORK.SemID,NO_WAIT) !=
            ERROR) {
            logMsg("Rate for Task Task0() too fast.\n",0,0,0,0,0,0);

            #if STOPONOVERRUN
                logMsg("Aborting real-time simulation.\n",0,0,0,0,0,0);
                semGive(stopSem);
                return(ERROR);
            #endif
```
} else {
    semTake(*(SEM_ID *)rtwdemo_async_DW.SFunction_PWORK.SemID, WAIT_FOREVER);
}

/* Use the upstream clock tick counter for this Task. */

       rtwdemo_async_B.Sum[i];
}

rtwdemo_async_DW.ProtectedRT2_ActiveBufIdx = (int8_T)
   (rtwdemo_async_DW.ProtectedRT2_ActiveBufIdx == 0);

/* End of Update for RateTransition: '<Root>/Protected RT2' */
}
The code generator produces code for ISRs `isr_num1_vec192` and `isr_num2_vec293`. ISR `isr_num2_vec192`:

- Disables interrupts.
- Saves floating-point context.
- Calls the code generated for the subsystem that connects to the referenced model `Inport` block, which receives the interrupt.
- Restores floating-point context.
- Reenables interrupts.

```c
void isr_num1_vec192(void)
{
    int_T lock;
    FP_CONTEXT context;
    /* Use tickGet() as a portable tick
       counter example. A much higher resolution can
       be achieved with a hardware counter */
    rtwdemo_async_M->Timing.clockTick2 = tickGet();
    /* disable interrupts (system is configured as non-preemptive) */
    lock = intLock();
    /* save floating point context */
    fppSave(&context);
    /* Call the system: '<Root>/Count' */
    
    /* S-Function (vxinterrupt1): '<Root>/Async Interrupt' */
    
    /* Output and update for function-call system: '<Root>/Count' */
    
    uint32_T Count_ELAPS_T_tmp;
    Count_ELAPS_T_tmp = rtwdemo_async_M->Timing.clockTick2;
    rtwdemo_async_DW.Count_ELAPS_T = Count_ELAPS_T_tmp -
    rtwdemo_async_DW.Count_PREV_T;
    rtwdemo_async_DW.Count_PREV_T = Count_ELAPS_T_tmp;
    /* Outport: '<Root>/Out1' incorporates:
ISR isr_num2_vec293 maintains a timer that stores the tick count at the time that the interrupt occurs. After updating the timer, the ISR releases the semaphore that activates Task0.

```c
ISR isr_num2_vec193(void)
{
    /* Use tickGet() as a portable tick counter example. A much higher resolution can be achieved with a hardware counter */
    rtwdemo_async_M->Timing.clockTick3 = tickGet();

    /* Call the system: '<S4>/Subsystem' */
    {
        /* S-Function (vxinterrupt1): '<Root>/Async Interrupt' */
        /* Output and update for function-call system: '<S4>/Subsystem' */
        /* S-Function (vxtask1): '<S5>/S-Function' */
        /* VxWorks Task Block: '<S5>/S-Function' (vxtask1) */
        /* Release semaphore for system task: Task0 */
        semGive(*(SEM_ID *)rtwdemo_async_DW.SFunction_PWORK.SemID);
    }
}
```
Review Task Termination Code

The Task Sync block generates the following termination code.

```c
static void rtwdemo_async_terminate(void) {
    /* Terminate for S-Function (vxinterrupt1): '<Root>/Async Interrupt' */
    /* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
    /* Disable interrupt for ISR system: isr_num1_vec192 */
    sysIntDisable(1);
    /* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
    /* Disable interrupt for ISR system: isr_num2_vec193 */
    sysIntDisable(2);
    /* End of Terminate for S-Function (vxinterrupt1): '<Root>/Async Interrupt' */
    /* Terminate for S-Function (vxinterrupt1): '<Root>/Async Interrupt' incorporates:
        * SubSystem: '<S4>/Subsystem' */
    /* Termination for function-call system: '<S4>/Subsystem' */
    /* Terminate for S-Function (vxtask1): '<S5>/S-Function' */
    /* VxWorks Task Block: '<S5>/S-Function' (vxtask1) */
    /* Destroy task: Task0 */
    taskDelete(rtwdemo_async_DW.SFunction_IWORK.TaskID);
    /* End of Terminate for S-Function (vxtask1): '<S5>/S-Function' */
    /* End of Terminate for S-Function (vxinterrupt1): '<Root>/Async Interrupt' */
}

Pass Asynchronous Events in RTOS as Input To a Referenced Model

This example shows how to simulate and generate code for a model that triggers asynchronous events in an example RTOS (VxWorks®) that get passed as input to a referenced model.

Open Example Model

Open the example model rtwdemo_async_mdlreftop.

Warning: Undefined function 'LibraryBrowserCustomizer' for input arguments of type 'DAStudio.CustomizationManager'.

---

Event-Based Scheduling in Simulink Coder
The model simulates an interrupt source and includes an Async Interrupt block and referenced model. The Async Interrupt block creates two Versa Module Eurocard (VME) interrupt service routines (ISRs) that pass interrupt signals to Inport blocks 1 and 2 of the referenced model. You can place an Async Interrupt block between a simulated interrupt source and one of the following:

- Function call subsystem
- Task Sync block
- A Stateflow® chart configured for a function call input event
- A referenced model with an Inport block that connects to one of the preceding model elements
In this example model, the Async Interrupt block passes asynchronous events (function-call trigger signals), Interrupt1 and Interrupt2, to the referenced model through Inport blocks 1 and 2.

The code generated for the Async Interrupt block is tailored for the example real-time operating system (VxWorks). However, you can modify the block to generate code specific to your run-time environment.

Open the referenced model.

The referenced model includes the two Inport blocks that receive the interrupts, each connected to an Asynchronous Task Specification block, function-call subsystems Count and Algorithm, and Rate Transition blocks. The Asynchronous Task Specification block, in combination with a root-level Inport block, allows a reference model to receive asynchronous function-call input. To use the block:

1. Connect the Asynchronous Task Specification block to the output port of a root-level Inport block that outputs a function-call trigger.
2. Select the **Output function call** parameter of the Inport block to specify that it accepts function-call signals.
3. On the Asynchronous Task Specification parameters dialog box, set the task priority for the asynchronous task associated with an Inport block. Specify an integer or []. If you specify an integer, it must match the priority of the interrupt initiated by the Async Interrupt block in the parent model. If you specify [], the priorities do not have to match.

The Asynchronous Task Specification block for the higher priority interrupt, interrupt1, connects to function-call subsystem Count. Count represents a simple interrupt service routine (ISR). The second Asynchronous Task Specification block connects to the subsystem Algorithm, which includes more substance. It includes multiple blocks and produces two output values. Both subsystems execute at interrupt level.

For each interrupt level specified for the Async Interrupt block in the parent model, the block generates a VME ISR that executes the connected subsystem, Task Sync block, or chart.

In the example top model, the Async Interrupt block is configured for VME interrupts 1 and 2, using interrupt vector offsets 192 and 193. Interrupt 1 is wired to trigger subsystem Count. Interrupt 2 is wired to trigger subsystem Algorithm.
The Rate Transition blocks handle data transfers between ports that operate at different rates. In two instances, the blocks protect data transfers (prevent them from being preempted and corrupted). In the other instance, no special behavior occurs.

**Data Transfer Assumptions**

- Data transfers occur between one reading task and one writing task.
- A read or write operation on a byte-sized variable is atomic.
- When two tasks interact, only one can preempt the other.
- For periodic tasks, the task with the faster rate has higher priority than the task with the slower rate. The task with the faster rate preempts the tasks slower rates.
- Tasks run on a single processor. Time slicing is not allowed.
- Processes do not crash and restart, especially while data is being transferred between tasks.

**Simulate the Model**

Simulate the model. By default, the model is configured to show sample times in different colors. Discrete sample times for input and output appear red and green, respectively. Constants are magenta. Asynchronous interrupts are purple. The Rate Transition Blocks, which are hybrid (input and output sample times can differ), appear yellow.

**Generate Code and Report**

Generate code and a code generation report for the model. Async Interrupt block and Task Sync block generated code is for the example RTOS (VxWorks). However, you can modify the blocks to generate code for another run-time environment.

1. Create a temporary folder for the build and inspection process.

2. Build the model.

Warning: Simulink Coder: The tornado.tlc target will be removed in a future release.

```bash
### Wrapping unrecognized make command (angle brackets added)

```
### Wrapping unrecognized make command (angle brackets added)
###    <make>
### in default batch file
### Successful completion of code generation for model: rtwdemo_async_mdlreftop

**Review Initialization Code**

Open the generated source file `rtwdemo_async_mdlreftop.c`. The initialization code connects and enables ISR `isr_num1_vec192` for interrupt 1 and ISR `isr_num2_vec193` for interrupt 2.

```c
static void rtwdemo_async_mdlreftop_initialize(void)
{
    /* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
    /* Connect and enable ISR function: isr_num1_vec192 */
    if (intConnect(INUM_TO_IVEC(192), isr_num1_vec192, 0) != OK) {
        printf("intConnect failed for ISR 1.\n");
    }

    sysIntEnable(1);

    /* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
    /* Connect and enable ISR function: isr_num2_vec193 */
    if (intConnect(INUM_TO_IVEC(193), isr_num2_vec193, 0) != OK) {
        printf("intConnect failed for ISR 2.\n");
    }

    sysIntEnable(2);

    /* SystemInitialize for ModelReference: '<Root>/Model' */
    rtwdemo_async_mdlrefbot_Init(&rtwdemo_async_mdlreftop_Y.Out1);

    /* Enable for S-Function (vxinterrupt1): '<Root>/Async Interrupt' */
    /* Enable for ModelReference: '<Root>/Model' incorporates:
     * Enable for Inport: '<Root>/In1_60hz'
     * Enable for Inport: '<Root>/In2_60_hz'
     * Enable for Inport: '<Root>/In3_60hz'
    */
    rtwdemo_async_mdlrefbot_Interrupt1_Enable();
    rtwdemo_async_mdlrefbot_Interrupt2_Enable();

    /* End of Enable for S-Function (vxinterrupt1): '<Root>/Async Interrupt' */
}
```
Review ISR Code

In the generated source file rtwdemo_async_mdlreftop.c, review the code for ISRs isr_num1_vec192 and isr_num2_vec293. Each ISR:

- Disables interrupts.
- Saves floating-point context.
- Calls the code generated for the subsystem connected to the referenced model Inport block that receives the interrupt.
- Restores floating-point context.
- Reenables interrupts.

```c
void isr_num1_vec192(void)
{
    int_T lock;
    FP_CONTEXT context;

    /* disable interrupts (system is configured as non-preemptive) */
    lock = intLock();

    /* save floating point context */
    fppSave(&context);

    /* Call the system: '<Root>/Model' */
    {
        /* S-Function (vxinterrupt1): '<Root>/Async Interrupt' */

        /* ModelReference: '<Root>/Model' incorporates:
         * Inport: '<Root>/In1_60hz'
         * Inport: '<Root>/In2_60_hz'
         * Inport: '<Root>/In3_60hz'
         */
        rtwdemo_async_mdlrefbot_Interrupt1(&rtwdemo_async_mdlreftop_Y.Out1);

        /* End of Outputs for S-Function (vxinterrupt1): '<Root>/Async Interrupt' */
    }

    /* restore floating point context */
    fppRestore(&context);

    /* re-enable interrupts */
    intUnlock(lock);
}
```
void isr_num2_vec193(void)
{
  FP_CONTEXT context;

  /* save floating point context */
  fppSave(&context);

  /* Call the system: '<Root>/Model' */
  {
    /* S-Function (vxinterrupt1): '<Root>/Async Interrupt' */
    /* ModelReference: '<Root>/Model' incorporates:
      * Inport: '<Root>/In1_60hz'
      * Inport: '<Root>/In2_60_hz'
      * Inport: '<Root>/In3_60hz'
    */
    rtwdemo_async_mdlreftop_Interrupt2();

    /* End of Outputs for S-Function (vxinterrupt1): '<Root>/Async Interrupt' */
  }

  /* restore floating point context */
  fppRestore(&context);
}

Review Task Termination Code

The Task Sync block generates the following termination code.

static void rtwdemo_async_mdlreftop_terminate(void)
{
  /* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
  /* Disable interrupt for ISR system: isr_num1_vec192 */
  sysIntDisable(1);

  /* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
  /* Disable interrupt for ISR system: isr_num2_vec193 */
  sysIntDisable(2);
}

Rate Transitions and Asynchronous Blocks

Because an asynchronous function call subsystem can preempt or be preempted by other model code, an inconsistency arises when more than one signal element is connected to an asynchronous block. The issue is that signals passed to and from the function call subsystem can be in the process of being written to or read from when the preemption occurs. Thus, some old and some new data is used. This situation can also occur with scalar signals in some cases. For example, if a signal is a double (8 bytes), the read or write operation might require two machine instructions. The following sections describe these issues.

In this section...

| “About Rate Transitions and Asynchronous Blocks” on page 18-40 |
| “Handle Rate Transitions for Asynchronous Tasks” on page 18-42 |
| “Handle Multiple Asynchronous Interrupts” on page 18-42 |
| “Protect Data Integrity with volatile Keyword” on page 18-44 |

Note The operating system integration techniques that are demonstrated in this section use one or more blocks the blocks in the vxlib1 (Simulink Coder) library. These blocks provide starting point examples to help you develop custom blocks for your target environment.

About Rate Transitions and Asynchronous Blocks

The Simulink Rate Transition block is designed to deal with preemption problems that occur in data transfer between blocks running at different rates. These issues are discussed in “Time-Based Scheduling and Code Generation” (Simulink Coder).

You can handle rate transition issues automatically by selecting the Automatically handle rate transition for data transfer parameter on the Solver pane of the Configuration Parameters dialog box. This saves you from having to manually insert Rate Transition blocks to avoid invalid rate transitions, including invalid asynchronous-to-periodic and asynchronous-to-asynchronous rate transitions, in multirate models. For asynchronous tasks, the Simulink engine configures inserted blocks for data integrity but not determinism during data transfers.

For asynchronous rate transitions, the Rate Transition block provides data integrity, but cannot provide determinism. Therefore, when you insert Rate Transition blocks explicitly,
you must clear the **Ensure data determinism** check box in the Block Parameters dialog box.

When you insert a Rate Transition block between two blocks to maintain data integrity and priorities are assigned to the tasks associated with the blocks, the code generator assumes that the higher priority task can preempt the lower priority task and the lower priority task cannot preempt the higher priority task. If the priority associated with task for either block is not assigned or the priorities of the tasks for both blocks are the same, the code generator assumes that either task can preempt the other task.

Priorities of periodic tasks are assigned by the Simulink engine, in accordance with the options specified in the **Solver selection** section of the **Solver** pane of the Configuration Parameters dialog box. When the **Periodic sample time constraint** option field of **Solver selection** is set to **Unconstrained**, the model base rate priority is set to 40. Priorities for subrates then increment or decrement by 1 from the base rate priority, depending on the setting of the **Higher priority value indicates higher task priority option**.

You can assign priorities manually by using the **Periodic sample time properties** field. The Simulink engine does not assign a priority to asynchronous blocks. For example, the priority of a function call subsystem that connects back to an Async Interrupt block is assigned by the Async Interrupt block.

The **Simulink task priority** field of the Async Interrupt block specifies a priority level (required) for every interrupt number entered in the **VME interrupt number(s)** field. The priority array sets the priorities of the subsystems connected to each interrupt.

For the Task Sync block, if the example RTOS (VxWorks) is the target, the **Higher priority value indicates higher task priority option** should be deselected. The **Simulink task priority** field specifies the block priority relative to connected blocks (in addition to assigning an RTOS priority to the generated task code).

The vxlib1 library provides two types of rate transition blocks as a convenience. These are simply preconfigured instances of the built-in Simulink Rate Transition block:

- **Protected Rate Transition block**: Rate Transition block that is configured with the **Ensure data integrity during data transfers** on and **Ensure deterministic data transfer** off.
- **Unprotected Rate Transition block**: Rate Transition block that is configured with the **Ensure data integrity during data transfers** option off.
Handle Rate Transitions for Asynchronous Tasks

For rate transitions that involve asynchronous tasks, you can maintain data integrity. However, you cannot achieve determinism. You have the option of using the Rate Transition block or target-specific rate transition blocks.

Consider the following model, which includes a Rate Transition block.

You can use the Rate Transition block in either of the following modes:

- Maintain data integrity, no determinism
- Unprotected

Alternatively, you can use target-specific rate transition blocks. The following blocks are available for the example RTOS (VxWorks):

- Protected Rate Transition block (reader)
- Protected Rate Transition block (writer)
- Unprotected Rate Transition block

Handle Multiple Asynchronous Interrupts

Consider the following model, in which two functions trigger the same subsystem.
The two tasks must have equal priorities. When priorities are the same, the outcome depends on whether they are firing periodically or asynchronously, and also on a diagnostic setting. The following table and notes describe these outcomes:

**Supported Sample Time and Priority for Function Call Subsystem with Multiple Triggers**

<table>
<thead>
<tr>
<th>Async Priority</th>
<th>Async Priority 1</th>
<th>Async Priority 2</th>
<th>Async Priority Unspecified</th>
<th>Periodic Priority 1</th>
<th>Periodic Priority 2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Async Priority</td>
<td>Supported (1)</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Async Priority 1</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Async Priority</td>
<td>Supported (1)</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Async Priority 2</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Async Priority</td>
<td>Supported (2)</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Async Priority 3</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

1. Control these outcomes using the **Tasks with equal priority** option in the Diagnostics pane of the Configuration Parameters dialog box; set this diagnostic to none if tasks of equal priority cannot preempt each other in the target system.

2. For this case, the following warning message is issued unconditionally:

The function call subsystem <name> has multiple asynchronous triggers that do not specify priority. Data integrity will not be maintained if these triggers can preempt one another.
Empty cells in the above table represent multiple triggers with differing priorities, which are unsupported.

The code generator provides absolute time management for a function call subsystem connected to multiple interrupts in the case where timer settings for TriggerA and TriggerB (time source, resolution) are the same.

Assume that all of the following conditions are true for the model shown above:

- A function call subsystem is triggered by two asynchronous triggers (TriggerA and TriggerB) having identical priority settings.
- Each trigger sets the source of time and timer attributes by calling the functions ssSetTimeSource and ssSetAsyncTimerAttributes.
- The triggered subsystem contains a block that needs elapsed or absolute time (for example, a Discrete Time Integrator).

The asynchronous function call subsystem has one global variable, clockTick# (where # is the task ID associated with the subsystem). This variable stores absolute time for the asynchronous task. There are two ways timing can be handled:

- If the time source is set to SS_TIMESOURCE_BASERATE, the code generator produces timer code in the function call subsystem, updating the clock tick variable from the base rate clock tick. Data integrity is maintained if the same priority is assigned to TriggerA and TriggerB.
- If the time source is SS_TIMESOURCE_SELF, generated code for both TriggerA and TriggerB updates the same clock tick variable from the hardware clock.

The word size of the clock tick variable can be set directly or be established according to the Application lifespan (days) (Simulink) setting and the timer resolution set by the TriggerA and TriggerB S-functions (which must be the same). See “Timers in Asynchronous Tasks” on page 18-46 and “Control Memory Allocation for Time Counters” on page 56-11 for more information.

**Protect Data Integrity with volatile Keyword**

When you select **Ensure data integrity during data transfer**, the code generated for a Rate Transition block defines volatile global buffers and semaphores and uses them to protect the integrity of the transferred data. If necessary, for additional protection, or for protection without a Rate Transition block, you can explicitly apply volatile to the
transferred data. For more information, see “Protect Global Data with const and volatile Keywords” on page 30-17.

Timers in Asynchronous Tasks

An ISR can set a source for absolute time. This is done with the function ssSetTimeSource. The function ssSetTimeSource cannot be called before ssSetOutputPortWidth is called. If this occurs, the program will come to a halt and generate an error message. ssSetTimeSource has the following three options:

- **SS_TIMESOURCE_SELF**: Each generated ISR maintains its own absolute time counter, which is distinct from a periodic base rate or subrate counters in the system. The counter value and the timer resolution value (specified in the Timer resolution (seconds) parameter of the Async Interrupt block) are used by downstream blocks to determine absolute time values required by block computations.
- **SS_TIMESOURCE_CALLER**: The ISR reads time from a counter maintained by its caller. Time resolution is thus the same as its caller's resolution.
- **SS_TIMESOURCE_BASERATE**: The ISR can read absolute time from the model's periodic base rate. Time resolution is thus the same as its base rate resolution.

**Note** The operating system integration techniques that are demonstrated in this section use one or more blocks from the vxlib1 (Simulink Coder) library. These blocks provide starting point examples to help you develop custom blocks for your target environment.

By default, the counter is implemented as a 32-bit unsigned integer member of the Timing substructure of the real-time model structure. For a target that supports the rtModel data structure, when the time data type is not set by using ssSetAsyncTimeDataType, the counter word size is determined by the Application lifespan (days) (Simulink) model parameter. As an example (from ERT target code),

```c
/* Real-time Model Data Structure */
struct _RT_MODEL_elapseTime_exp_Tag {
    const char *errorStatus;

    /*
     * Timing:
     * The following substructure contains information regarding
     * the timing information for the model.
     */
    struct {
        uint32_T clockTick1;
    }
```
uint32_T clockTick2;
} Timing;
};

The example omits unused fields in the Timing data structure (a feature of ERT target code not found in GRT). For a target that supports the rtModel data structure, the counter word size is determined by the **Application lifespan (days)** (Simulink) model parameter.

By default, the vxlib1 library blocks for the example RTOS (VxWorks) set the timer source to **SS_TIMESOURCE_SELF** and update their counters by using the system call **tickGet**. **tickGet** returns a timer value maintained by the RTOS kernel. The maximum word size for the timer is **UINT32**. The following example shows a generated call to **tickGet**.

```c
/* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
void isr_num2_vec193(void)
{
    /* Use tickGet() as a portable tick counter example. A much higher resolution can be achieved with a hardware counter */
    rtM->Timing.clockTick2 = tickGet();
    ...
```

The **tickGet** call is supplied only as an example. It can (and in many instances should) be replaced by a timing source that has better resolution. If you are implementing a custom asynchronous block for an RTOS other than the example RTOS (VxWorks), you should either generate an equivalent call to the target RTOS, or generate code to read a timer register on the target hardware.

The default **Timer resolution (seconds)** parameter of your Async Interrupt block implementation should be changed to match the resolution of your target's timing source.

The counter is updated at interrupt level. Its value represents the tick value of the timing source at the most recent execution of the ISR. The rate of this timing source is unrelated to sample rates in the model. In fact, typically it is faster than the model's base rate. Select the timer source and set its rate and resolution based on the expected rate of interrupts to be serviced by the Async Interrupt block.

For an example of timer code generation, see “Async Interrupt Block Implementation” on page 18-50.

Create a Customized Asynchronous Library

This topic describes how to implement asynchronous blocks for use with your target RTOS, using the Async Interrupt and Task Sync blocks as a starting point. Rate Transition blocks are target-independent, so you do not need to develop customized rate transition blocks. The following sections provide implementation details.

<table>
<thead>
<tr>
<th>In this section...</th>

</tr>
</tbody>
</table>

Note The operating system integration techniques that are demonstrated in this section use one or more blocks the blocks in the vxlib1 (Simulink Coder) library. These blocks provide starting point examples to help you develop custom blocks for your target environment.

About Implementing Asynchronous Blocks

You can customize the asynchronous library blocks by modifying the block implementation. These files are

- The block’s underlying S-function MEX-file
- The TLC files that control code generation of the block

In addition, you need to modify the block masks to remove references specific to the example RTOS (VxWorks) and to incorporate parameters required by your target RTOS.

Custom block implementation is an advanced topic, requiring familiarity with the Simulink MEX S-function format and API, and with the Target Language Compiler (TLC). These topics are covered in the following documents:

- Simulink topics “What Is an S-Function?” (Simulink), “Use S-Functions in Models” (Simulink), “How S-Functions Work” (Simulink), and “Implementing S-Functions” (Simulink) describe MEX S-functions and the S-function API in general.
• The “Inlining S-Functions” (Simulink Coder), “Inline C MEX S-Functions” (Simulink Coder), and “S-Functions and Code Generation” (Simulink Coder) describe how to create a TLC block implementation for use in code generation.

The following sections discuss the C/C++ and TLC implementations of the asynchronous library blocks, including required SimStruct macros and functions in the TLC asynchronous support library (asynclib.tlc).

**Async Interrupt Block Implementation**

The source files for the Async Interrupt block are located in `matlabroot/rtw/c/tornado/devices` (open):

- `vxinterrupt1.c`: C MEX-file source code, for use in configuration and simulation
- `vxinterrupt1.tlc`: TLC implementation, for use in code generation
- `asynclib.tlc`: library of TLC support functions, called by the TLC implementation of the block. The library calls are summarized in “asynclib.tlc Support Library” on page 18-56.

**C MEX Block Implementation**

Most of the code in `vxinterrupt1.c` performs ordinary functions that are not related to asynchronous support (for example, obtaining and validating parameters from the block mask, marking parameters nontunable, and passing parameter data to the `model.rtw` file).

The `mdlInitializeSizes` function uses special SimStruct macros and `SS_OPTIONS` settings that are required for asynchronous blocks, as described below.

Note that the following macros cannot be called before `ssSetOutputPortWidth` is called:

- `ssSetTimeSource`
- `ssSetAsyncTimerAttributes`
- `ssSetAsyncTimerResolutionEl`
- `ssSetAsyncTimerDataType`
- `ssSetAsyncTimerDataTypeEl`
- `ssSetAsyncTaskPriorities`
• ssSetAsyncTaskPrioritiesEl

If one of the above macros is called before ssSetOutputPortWidth, the following error message appears:

SL_SfcnMustSpecifyPortWidthBfCallSomeMacro {
  S-function '%s' in '%<BLOCKFULLPATH>'
  must set output port %d width using
  ssSetOutputPortWidth before calling macro %s
}

ssSetAsyncTimerAttributes

ssSetAsyncTimerAttributes declares that the block requires a timer, and sets the resolution of the timer as specified in the **Timer resolution (seconds)** parameter.

The function prototype is

ssSetAsyncTimerAttributes(SimStruct *S, double res)

where

• S is a Simstruct pointer.
• res is the **Timer resolution (seconds)** parameter value.

The following code excerpt shows the call to ssSetAsyncTimerAttributes.

/* Setup Async Timer attributes */
ssSetAsyncTimerAttributes(S,mxGetPr(TICK_RES)[0]);

ssSetAsyncTaskPriorities

ssSetAsyncTaskPriorities sets the Simulink task priority for blocks executing at each interrupt level, as specified in the block's **Simulink task priority** field.

The function prototype is

ssSetAsyncTaskPriorities(SimStruct *S, int numISRs,
                        int *priorityArray)

where

• S is a SimStruct pointer.
• numISRs is the number of interrupts specified in the **VME interrupt number(s)** parameter.
• `priorityarray` is an integer array containing the interrupt numbers specified in the **VME interrupt number(s)** parameter.

The following code excerpt shows the call to `ssSetAsyncTaskPriorities`:

```c
/* Setup Async Task Priorities */
priorityArray = malloc(numISRs*sizeof(int_T));
for (i=0; i<numISRs; i++) {
    priorityArray[i] = (int_T)(mxGetPr(ISR_PRIORITIES)[i]);
}
ssSetAsyncTaskPriorities(S, numISRs, priorityArray);
free(priorityArray);
priorityArray = NULL;
```

**SS_OPTION Settings**

The code excerpt below shows the **SS_OPTION** settings for `vxinterrupt1.c`. **SS_OPTION ASYNCHRONOUS_INTERRUPT** should be used when a function call subsystem is attached to an interrupt. For more information, see the documentation for **SS_OPTION** and **SS_OPTION ASYNCHRONOUS** in `matlabroot/simulink/include/simstruc.h`.

```c
ssSetOptions( S, (SS_OPTION_EXCEPTION_FREE_CODE |
                SS_OPTION_DISALLOW_CONSTANT_SAMPLE_TIME |
                SS_OPTION_ASYNCHRONOUS_INTERRUPT |
```

If an S-function specifies the **SS_OPTION_DISALLOW_CONSTANT_SAMPLE_TIME** option and inherits a sample time of `Inf`, the code generator determines how to produce code for the block based on whether the block is invariant. A block is invariant if its port signals are invariant. A signal is invariant if it has a constant value during the entire simulation. A Constant block sample time does not guarantee that the port signals are invariant. For more information, see “Inline Invariant Signals” (Simulink Coder). If the block is not invariant, the code generator produces code only in the initialize entry-point function. If the block is invariant, the code generator does not produce code for the block.

**TLC Implementation**

This section discusses each function of `vxinterrupt1.tlc`, with an emphasis on target-specific features that you will need to change to generate code for your target RTOS.

**Generate #include Directives**

`vxinterrupt1.tlc` begins with the statement
%include "vxlib.tlc"

vxlib.tlc is a target-specific file that generates directives to include header files for the example RTOS (VxWorks). You should replace this with a file that generates includes for your target RTOS.

BlockInstanceSetup Function

For each connected output of the Async Interrupt block, BlockInstanceSetup defines a function name for the corresponding ISR in the generated code. The functions names are of the form

isr_num_vec_offset

where num is the ISR number defined in the VME interrupt number(s) block parameter, and offset is an interrupt table offset defined in the VME interrupt vector offset(s) block parameter.

In a custom implementation, this naming convention is optional.

The function names are cached for use by the Outputs function, which generates the actual ISR code.

Outputs Function

Outputs iterates over the connected outputs of the Async Interrupt block. An ISR is generated for each such output.

The ISR code is cached in the "Functions" section of the generated code. Before generating the ISR, Outputs does the following:

- Generates a call to the downstream block (cached in a temporary buffer).
- Determines whether the ISR should be locked or not (as specified in the Preemption Flag(s) block parameter).
- Determines whether the block connected to the Async Interrupt block is a Task Sync block. (This information is obtained by using the asynclib calls LibGetFcnCallBlock and LibGetBlockAttribute.) If so,
  - The preemption flag for the ISR must be set to 1. An error results otherwise.
  - The RTOS (VxWorks) calls to save and restore floating-point context are generated, unless the user has configured the model for integer-only code generation.
When generating the ISR code, `Outputs` calls the `asynclib` function `LibNeedAsyncCounter` to determine whether a timer is required by the connected subsystem. If so, and if the time source is set to be `SS_TIMESOURCE_SELF` by `ssSetTimeSource`, `LibSetAsyncCounter` is called to generate an RTOS (VxWorks) `tickGet` function call and update the counter. In your implementation, you should generate either an equivalent call to the target RTOS, or generate code to read the timer register on the target hardware.

**Start Function**

The `Start` function generates the required RTOS (VxWorks) calls (`int_connect` and `sysInt_Enable`) to connect and enable each ISR. You should replace this with calls to your target RTOS.

**Terminate Function**

The `Terminate` function generates the call `sysIntDisable` to disable each ISR. You should replace this with calls to your target RTOS.

**Task Sync Block Implementation**

The source files for the Task Sync block are located in `matlabroot/rtw/c/tornado/devices (open)`. They are:

- `vxtask1.cpp`: MEX-file source code, for use in configuration and simulation.
- `vxtask1.tlc`: TLC implementation, for use in code generation.
- `asynclib.tlc`: library of TLC support functions, called by the TLC implementation of the block. The library calls are summarized in “asynclib.tlc Support Library” on page 18-56.

**C MEX Block Implementation**

Like the Async Interrupt block, the Task Sync block sets up a timer, in this case with a fixed resolution. The priority of the task associated with the block is obtained from the Simulink task priority parameter. The `SS_OPTION` settings are the same as those used for the Async Interrupt block.

```c
ssSetAsyncTimerAttributes(S, 0.01);

priority = (int_T) (*(mxGetPr(PRIORITY)));
ssSetAsyncTaskPriorities(S,1,&priority);
```
ssSetOptions(S, (SS_OPTION_EXCEPTION_FREE_CODE | 
    SS_OPTIONASYNCHRONOUS | 
    SS_OPTION_DISALLOW_CONSTANT_SAMPLE_TIME | 
} 

TLC Implementation

Generate #include Directives

vxtask1.tlc begins with the statement

%include "vxlib.tlc"

vxlib.tlc is a target-specific file that generates directives to include header files for the example RTOS (VxWorks). You should replace this with a file that generates includes for your target RTOS.

BlockInstanceSetup Function

The BlockInstanceSetup function derives the task name, block name, and other identifiers used later in code generation. It also checks for and warns about unconnected block conditions, and generates a storage declaration for a semaphore (stopSem) that is used in case of interrupt overflow conditions.

Start Function

The Start function generates the required RTOS (VxWorks) calls to define storage for the semaphore that is used in management of the task spawned by the Task Sync block. Depending on the value of the CodeFormat TLC variable of the target, either a static storage declaration or a dynamic memory allocation call is generated. This function also creates a semaphore (semBCreate) and spawns an RTOS task (taskSpawn). You should replace these with calls to your target RTOS.

Outputs Function

The Outputs function generates an example RTOS (VxWorks) task that waits for a semaphore. When it obtains the semaphore, it updates the block's tick timer and calls the downstream subsystem code, as described in “Spawn and Synchronize Execution of RTOS Task” on page 18-15. Outputs also generates code (called from interrupt level) that grants the semaphore.
**Terminate Function**

The `Terminate` function generates the example RTOS (VxWorks) call `taskDelete` to end execution of the task spawned by the block. You should replace this with calls to your target RTOS.

Note also that if the target RTOS has dynamically allocated memory associated with the task, the `Terminate` function should deallocate the memory.

**asynclib.tlc Support Library**

`asynclib.tlc` is a library of TLC functions that support the implementation of asynchronous blocks. Some functions are specifically designed for use in asynchronous blocks. For example, `LibSetAsyncCounter` generates a call to update a timer for an asynchronous block. Other functions are utilities that return information required by asynchronous blocks (for example, information about connected function call subsystems).

The following table summarizes the public calls in the library. For details, see the library source code and the `vxinterrupt1.tlc` and `vxtask1.tlc` files, which call the library functions.
## Summary of asynclib.tlc Library Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LibBlockExecuteFcnCall</td>
<td>For use by inlined S-functions with function call outputs. Generates code to execute a function call subsystem.</td>
</tr>
<tr>
<td>LibGetBlockAttribute</td>
<td>Returns a field value from a block record.</td>
</tr>
<tr>
<td>LibGetFcnCallBlock</td>
<td>Given an S-Function block and call index, returns the block record for the downstream function call subsystem block.</td>
</tr>
<tr>
<td>LibGetCallerClockTickCounter</td>
<td>Provides access to the time counter of an upstream asynchronous task.</td>
</tr>
<tr>
<td>LibGetCallerClockTickCounterHighWord</td>
<td>Provides access to the high word of the time counter of an upstream asynchronous task.</td>
</tr>
<tr>
<td>LibManageAsyncCounter</td>
<td>Determines whether an asynchronous task needs a counter and manages its own timer.</td>
</tr>
<tr>
<td>LibNeedAsyncCounter</td>
<td>If the calling block requires an asynchronous counter, returns TLC_TRUE, otherwise returns TLC_FALSE.</td>
</tr>
<tr>
<td>LibSetAsyncClockTicks</td>
<td>Returns code that sets clockTick counters that are to be maintained by the asynchronous task.</td>
</tr>
<tr>
<td>LibSetAsyncCounter</td>
<td>Generates code to set the tick value of the block's asynchronous counter.</td>
</tr>
<tr>
<td>LibSetAsyncCounterHighWord</td>
<td>Generates code to set the tick value of the high word of the block's asynchronous counter</td>
</tr>
</tbody>

Import Asynchronous Event Data for Simulation

Capabilities

You can import asynchronous event data into a function-call subsystem via an Inport block. For standalone fixed-step simulations, you can specify:

- The time points at which each asynchronous event occurs
- The number of asynchronous events at each time point

Input Data Format

You can enter your asynchronous data at the MATLAB command line or on the Data Import/Export pane of the Configuration Parameters dialog box. In either case, a number of restrictions apply to the data format.

- The expression for the parameter Data Import/Export > Input must be a comma-separated list of tables.
- The table corresponding to the input port outputting asynchronous events must be a column vector containing time values for the asynchronous events.
  - The time vector of the asynchronous events must be of double data type and monotonically increasing.
  - All time data must be integer multiples of the model step size.
  - To specify multiple function calls at a given time step, you must repeat the time value accordingly. In other words, if you wish to specify three asynchronous events at \( t = 1 \) and two events at \( t = 9 \), then you must list 1 three times and 9 twice in your time vector. (\( t = [1 \ 1 \ 1 \ 9 \ 9]' \))
- The table corresponding to normal data input port can be of any other supported format.

See “Load Data to Root-Level Input Ports” (Simulink) for more information.

Example

In this model, a function-call subsystem is used to track the total number of asynchronous events and to multiply a set of inputs by 2.
To input data via the Configuration Parameters dialog box,

a. Select Simulation > Configuration Parameters > Data Import/Export.

b. Select the Input parameter.

c. For this example, enter the following command in the MATLAB window:

```matlab
>> t = [1 1 5 9 9 9]', u = [1:10]' [1:10]'
```

Alternatively, you can enter the data as $t, tu$ in the Data Import/Export pane:
Here, $t$ is a column vector containing the times of asynchronous events for Inport block In1 while $tu$ is a table of input values versus time for Inport block In2.

2 By default, the **Time** and **Output** options are selected and the output variables are named $tout$ and $yout$.

3 Simulate the model.

4 Display the output by entering `[tout yout]` at the MATLAB command line and obtain:

   
   ```
   ans =
   
   0 0 -1
   1 2 2
   2 2 2
   3 2 2
   4 2 2
   5 3 10
   6 3 10
   7 3 10
   8 3 10
   9 6 18
   10 6 18
   ```

   Here the first column contains the simulation times.

   The second column represents the output of Out1 — the total number of asynchronous events. Since the function-call subsystem is triggered twice at $t = 1$, the output is 2. It is not called again until $t = 5$, and so does not increase to 3 until then. Finally, it is called three times at 9, so it increases to 6.
The third column contains the output of Out2 obtained by multiplying the input value at each asynchronous event time by 2. At any other time, the output is held at its previous value.

Asynchronous Support Limitations

In this section...

“Asynchronous Task Priority” on page 18-63
“Convert an Asynchronous Subsystem into a Model Reference” on page 18-63

Asynchronous Task Priority

The Simulink product does not simulate asynchronous task behavior. Although you can specify a task priority for an asynchronous task represented in a model with the Task Sync block, the priority setting is for code generation purposes only and is not honored during simulation.

Convert an Asynchronous Subsystem into a Model Reference

You can use the Asynchronous Task Specification block to specify an asynchronous function-call input to a model reference. However, you must convert the Async Interrupt and Function-Call blocks into a subsystem and then convert the subsystem into a model reference.

Following is an example with step-by-step instructions for conversion.

1 Convert the Async Interrupt and Count blocks into a subsystem. Select both blocks and right-click Count. From the menu, select Subsystem & Model Reference > Create Subsystem from Selection.
To prepare for converting the new subsystem to a Model block, set the following configuration parameters in the top model. Open the Configuration Parameters dialog box.

- Under Diagnostics, navigate to the Sample Time pane. Then set Multitask rate transition to error and Multitask conditionally executed subsystem to error.
- Under Diagnostics, navigate to the Connectivity pane. Set Bus signal treated as vector, and Invalid function-call connection to error. Also set Context-dependent inputs to Enable All.
- Under Diagnostics, navigate to the Data Validity pane and set the Multitask data store option to error.
- Set the Configuration Parameters > Diagnostics > Data Validity > Advanced parameters > Underspecified initialization detection parameter to Simplified.
- If your model is large or complex, run the Model Advisor checks in the folder “Migrating to Simplified Initialization Mode Overview” (Simulink) and make the suggested changes.

Convert the subsystem to an atomic subsystem. Select Edit > Subsystem Parameters > Treat as atomic unit.
4 Convert the subsystem to a Model block. Right-click the subsystem and select **Subsystem & Model Reference > Convert Subsystem to > Referenced Model.** A window opens with a model reference block inside of it.

5 Replace the subsystem in the top model with the new model reference block.

6 Move the Async Interrupt block from the model reference to the top model, before the model reference block.
7 Insert an Asynchronous Task Specification block in the model reference. Set the priority of the Asynchronous Task Specification block. (For more information on setting the priority, see Asynchronous Task Specification.)

8 In the model reference, double-click the input port to open its Source Block Parameters dialog box. Click the **Signal Attributes** tab and select the **Output function call** option. Click **OK**.
Save your model and then perform **Simulation > Update Diagram** to verify your settings.

Use Discrete and Continuous Time

**In this section...**

| “Support for Discrete and Continuous Time Blocks” on page 19-2 |
| “Support for Continuous Solvers” on page 19-2 |
| “Support for Stop Time” on page 19-2 |

**Support for Discrete and Continuous Time Blocks**

The ERT target supports code generation for discrete and continuous time blocks. If the `Support: continuous time` option is selected on the `Code Generation > Interface` pane, you can use these blocks in your models, without restriction.

Note that use of certain blocks is not recommended for production code generation for embedded systems. The Simulink Block Data Type Support table summarizes characteristics of blocks in the Simulink and Fixed-Point Designer block libraries, including whether or not they are recommended for use in production code generation. To view this table, execute the following command and see the “Code Generation Support” column of the table that appears:

```
showblockdatatypetable
```

**Support for Continuous Solvers**

The ERT target supports continuous solvers. In the `Solver` options dialog, you can select an available solver in the `Solver` menu. (Note that the solver `Type` must be `fixed-step` for use with the ERT target.)

**Note** Custom targets must be modified to support continuous time. The required modifications are described in “Customize System Target Files” (Simulink Coder).

**Support for Stop Time**

The ERT target supports the stop time for a model. When generating host-based executables, the stop time value is honored if one of the following is true:
• **External mode** is selected on the **Code Generation > Interface** pane

• **MAT-file logging** is selected

• **Classic call interface** is selected

Otherwise, the executable runs indefinitely.

**Note** The ERT target provides both generated and static examples of the `ert_main.c` file. The `ert_main.c` file controls the overall model code execution by calling the `model_step` function and optionally checking the `ErrorStatus/StopRequested` flags to terminate execution. For a custom target, if you provide your own custom static `main.c`, you should consider including support for checking these flags.

Optimize Multirate Multitasking Execution for RTOS Run-Time Environments

Using the `rtmStepTask` macro, run-time environments that employ task management mechanisms of an real-time operating system (RTOS)—for example, VxWorks—can improve performance of generated code by eliminating redundant scheduling calls during the execution of tasks in a multirate, multitasking model. The following sections describe implementation details.

**Use rtmStepTask**

The `rtmStepTask` macro is defined in `model.h` and its syntax is as follows:

```c
boolean task_ready = rtmStepTask(rtm, idx);
```

The arguments are:

- `rtm`: pointer to the real-time model structure (`rtM`)
- `idx`: task identifier (`tid`) of the task whose scheduling counter is to be tested

`rtmStepTask` returns `TRUE` if the task's scheduling counter equals zero, indicating that the task should be scheduled for execution on the current time step. Otherwise, it returns `FALSE`.

If your target supports the **Generate an example main program** parameter, you can generate calls to `rtmStepTask` using the TLC function `RTMTaskRunsThisBaseStep`.

**Schedule Code for Real-time Model without an RTOS**

To understand the optimization that is available for an RTOS target, consider how the ERT target schedules tasks for bareboard targets (where RTOS is not present). The ERT target maintains scheduling counters and event flags for each subrate task. The scheduling counters are implemented within the real-time model (`rtM`) data structure as arrays, indexed on task identifier (`tid`).

The scheduling counters are updated by the base-rate task. The counters are clock rate dividers that count up the sample period associated with each subrate task. When a given subrate counter reaches a value that indicates it has a hit, the sample period for that rate has elapsed and the counter is reset to zero. When this occurs, the subrate task must be scheduled for execution.
The event flags indicate whether or not a given task is scheduled for execution. For a multirate, multitasking model, the event flags are maintained by code in the main program for the model. For each task, the code maintains a task counter. When the counter reaches 0, indicating that the task's sample period has elapsed, the event flag for that task is set.

On each time step, the counters and event flags are updated and the base-rate task executes. Then, the scheduling flags are checked in tid order, and tasks whose event flag is set is executed. Therefore, tasks are executed in order of priority.

For bareboard targets that cannot rely on an external RTOS, the event flags are mandatory to allow overlapping task preemption. However, an RTOS target uses the operating system itself to manage overlapping task preemption, making the maintenance of the event flags redundant.

### Schedule Code for Multirate Multitasking on an RTOS

The following task scheduling code, from ertmainlib.tlc, is designed for multirate multitasking operation on an example RTOS (VxWorks) target. The example uses the TLC function RTMTaskRunsThisBaseStep to generate calls to the rtmStepTask macro. A loop iterates over each subrate task, and rtmStepTask is called for each task. If rtmStepTask returns TRUE, the RTOS semGive function is called, and the RTOS schedules the task to run.

```tcl
%assign ifarg = RTMTaskRunsThisBaseStep("i")
for (i = 1; i < %<FcnNumST>; i++) {
   if (%<ifarg>) {
      semGive(taskSemList[i]);
      if (semTake(taskSemList[i],NO_WAIT) != ERROR) {
         logMsg("Rate for SubRate task %d is too fast.\n",i,0,0,0,0,0);
         semGive(taskSemList[i]);
      }
   }
}
```

### Suppress Redundant Scheduling Calls

Redundant scheduling calls are still generated by default for backward compatibility. To change this setting and suppress them, add the following TLC variable definition to your system target file before the %include "codegenentry.tlc" statement:

```tcl
%assign SuppressSetEventsForThisBaseRateFcn = 1
```

- “Migrate Memory Section and Shared Utility Settings from Configuration Parameters to Code Mapping Editor” on page 20-21
Define Storage Classes, Memory Sections, and Function Templates for Software Architecture

In a team or large organization, to enable multiple users to generate code that conforms to a standard architecture, you can create and share code generation definitions, such as storage classes, with those users. When configuring code generation settings for different models, the users can apply the definitions to data and function elements in the models, generating standardized code.

Create Code Definitions for Use as Default Code Generation Settings

To control the default appearance of model elements in the generated code, you apply settings to categories of elements, such as data and functions, by using the Code Mapping Editor. For more information, see “Configure Default Code Generation for Categories of Model Data and Functions” on page 21-7.

To create definitions that you and other users can use in the Code Mapping Editor, use an Embedded Coder Dictionary.

When you create definitions in an Embedded Coder Dictionary, you must decide where to store the definitions.

- If you need to use the definitions only in one model, create the definitions in the Embedded Coder Dictionary of the model. If the model is not linked to a Simulink data dictionary (see “What Is a Data Dictionary?” (Simulink)), open the Embedded Coder Dictionary for the model as described in Embedded Coder Dictionary.

  If you link the model to a data dictionary, you must store the definitions in the Embedded Coder Dictionary of that data dictionary, or of a referenced data dictionary, as described in “Share Embedded Coder Dictionary Definition Between Models” on page 20-6.

- If you need to use the definitions in multiple models, including the models in a model reference hierarchy, store the definitions in the Embedded Coder Dictionary of a Simulink data dictionary. For general information about data dictionaries, see “What Is a Data Dictionary?” (Simulink).

  To use an Embedded Coder Dictionary, and for limitations with respect to code generation definitions in an Embedded Coder Dictionary, see Embedded Coder Dictionary.
Create Code Definitions to Override Default Settings

To override the default settings that you specify in the Code Mapping Editor, you apply code generation settings to individual model elements by using other tools such as the Model Data Editor and the Property Inspector. For general information, see “Environment for Configuring Model Data and Functions for Code Generation” on page 21-2.

To create code definitions that you can apply through these other tools, use the Custom Storage Class Designer. You can define storage classes and memory sections, which you can apply only to data elements. For more information, see “Create Custom Storage Classes by Using the Custom Storage Class Designer” on page 26-26 and “Control Data and Function Placement in Memory by Inserting Pragmas” on page 30-2.

Avoid Maintaining Duplicate Definitions in Packages and Dictionaries

If you want to use the same code generation definition as a default setting and for direct application to individual model elements, you do not need to store one copy of the definition in an Embedded Coder Dictionary and another copy in a package. Instead, store the definition in a package (by using the Custom Storage Class Designer). Then, configure one or more Embedded Coder Dictionaries to refer to the definition in the package. With this technique, when you want to make changes to the definition, you make the changes in only one place, the package.

However, if you create a custom storage class by using the Custom Storage Class Designer and set Type to FlatStructure, as described in “Generate Structured Data” on page 26-33, or to Other, as described in “Finely Control Data Representation by Writing TLC Code for a Custom Storage Class” on page 26-39, you cannot configure an Embedded Coder Dictionary to refer to the package. Therefore, you cannot use the storage class in the Code Mapping Editor.

To create a code generation definition in a package by using the Custom Storage Class Designer, see “Create Custom Storage Classes by Using the Custom Storage Class Designer” on page 26-26. Then, to configure an Embedded Coder Dictionary to refer to the package, see “Refer to Code Generation Definitions in a Package”.

Deploy Code Generation Definitions to Users

In a large organization with multiple models and users, you can share code generation definitions by storing them in a mutually accessible location. The process of sharing code
definitions is called deployment. For more information, see “Deploy Code Generation Definitions” on page 20-6.

**Maintain Code Generation Definitions**

In a model, you apply a code definition to a model element by selecting the name of the definition in a drop-down list, for example, in the Model Data Editor or in the Code Mapping Editor. Also, you can associate a memory section with a storage class or function template by using a drop-down list in the Custom Storage Class Designer or in an Embedded Coder Dictionary.

Depending on the storage location of the code definition, changing or deleting the definition can break these usage points, requiring you to take action.

**Package Definitions**

If you created the code definition in a package, changing the name or deleting the definition can break usage points, which you must fix manually.

- To fix usage points for individual data elements in a model, you can optionally write a script. See the interactive and programmatic examples in “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 26-19.
- To fix usage points in a package (for example, when you change the name of a memory section that a storage class uses), you must use the Custom Storage Class Designer. You cannot write a script.

If you loaded the package into one or more Embedded Coder Dictionaries (see “Refer to Code Generation Definitions in a Package”), when you make any changes to the code definition (including to properties other than the name) or delete the definition, you must:

1. **Reload the package.** In each dictionary, use the **Manage Package** button to unload, and then reload the package.

   Reloading the package breaks usage points in the Code Mapping Editor for affected models, which you must fix manually.

2. **Fix usage points in the Code Mapping Editor for affected models.** To write a script that fixes Code Mapping Editor usage points, see “Configure Default Data and Function Code Generation Programmatically” on page 21-22.
Embedded Coder Dictionary Definitions

If you created the code definition in an Embedded Coder Dictionary:

- Changing the name of the code definition does not break usage points. Simulink propagates the new name to the usage points.
- Deleting the code definition breaks usage points in the Code Mapping Editor for affected models. In the Editor, drop-down lists display Unresolved. You must fix these usage points manually. To fix them by writing a script, see “Configure Default Data and Function Code Generation Programmatically” on page 21-22.

Interact with Code Generation Definitions Programmatically

You cannot create code generation definitions programmatically. However, for Embedded Coder Dictionary definitions, you can delete, copy, and move code definitions between models and data dictionaries by using these functions:

- `coder.dictionary.copy`
- `coder.dictionary.move`
- `coder.dictionary.remove`

Deploy Code Generation Definitions

As described in “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 20-2, you can create code generation definitions that you and other users can apply to model elements such as data and functions. The code definitions control the appearance of those elements in the generated code.

In a large organization with multiple models and users, you can share code generation definitions by storing them in a mutually accessible location. The process of sharing code definitions is called deployment.

Share Code Generation Definitions Between Multiple Models and Users

When you create custom code generation definitions, to share the definitions between models and other users:

- When you create definitions in a package by using the Custom Storage Class Designer, for each user, place the folder containing the package folder on the MATLAB path. For more information, see “What Is the MATLAB Search Path?” (MATLAB).
- When you create definitions in an Embedded Coder Dictionary, store the definitions in a Simulink data dictionary. Then, link each model to a separate data dictionary. Configure each separate dictionary to refer to the dictionary that contains the code generation definitions. For an example, see “Share Embedded Coder Dictionary Definition Between Models” on page 20-6.

Share Embedded Coder Dictionary Definition Between Models

This example shows how to create a storage class that yields separate global variables in the generated code and share the storage class between two models, rtwdemo_roll and rtwdemo_advsc. Then, you configure each model to use the storage class as the default code generation setting for internal data, which includes block states.

It is a best practice to store shared code generation definitions in a standalone data dictionary, which means that no models are linked directly to the dictionary. Then, you can link the target models to one or more additional, intermediate dictionaries, which you configure to refer to the standalone dictionary. With this modular dictionary hierarchy, each model can store other data, such as design data, separately from the code generation definitions.
The figure shows an example dictionary hierarchy. In the figure:

- `modelOne.slx` and `modelTwo.slx` are different model files.
- `dataForModelOne.sldd` and `dataForModelTwo.sldd` are data dictionaries. Each dictionary stores design data, such as numeric MATLAB variables, for one of the models.
- `coderDefs.sldd` is a shared data dictionary that stores code generation definitions for both models. The other dictionaries reference `coderDefs.sldd`.

### Create Code Generation Definition in Standalone Data Dictionary

Create a data dictionary. Then, create the storage class in the dictionary.

1. At the command prompt, open the Model Explorer.
   
   `daexplr`

2. In the Model Explorer, select **File > New > Data Dictionary**.
3. Name the dictionary `coderDefs.sldd`.
4. In the Model Explorer **Model Hierarchy** pane, right-click `coderDefs` and select **Show Empty Sections**.
5. In the **Model Hierarchy** pane, select the **Embedded Coder Dictionary** node.
6 In the Dialog pane (the right pane), click Open Embedded Coder Dictionary.
7 In the Embedded Coder Dictionary dialog box, click Add.
8 For the new storage class, set these property values:

- **Name** to `internalsInFile`.
- **Header File** to `$R_internal.h`.
- **Definition File** to `$R_internal.c`.
9 In the Model Explorer **Model Hierarchy** pane, right-click `coderDefs` and select **Save Changes**.

### Link Models to Data Dictionaries

Link each model to a separate data dictionary. Then, configure each dictionary to refer to the standalone dictionary (`coderDefs.sldd`).

1 Open the models.

   
   rtwdemo_advsc
   rtwdemo_roll

2 In `rtwdemo_roll`, select **File > Model Properties > Link to Data Dictionary**.
3 In the Model Properties dialog box, select **Data Dictionary** and click **New**.
4 Use the Create a new Data Dictionary dialog box to create a dictionary named `rtwdemo_roll_data.sldd`.
5 In the Model Properties dialog box, click **OK**.
6 In the Link Model to Data Dictionary dialog box, click **OK**.

Simulink links the model to the new dictionary and attempts to migrate design data from the base workspace to the dictionary. However, the model does not use data in the base workspace, so the dictionary does not contain any data.

7 In the lower-left corner of the model, click the data dictionary badge, which opens the dictionary in the Model Explorer.
8 In the Dialog pane, under **Referenced Dictionaries**, click **Add**.
9 In the Open Data Dictionary dialog box, double-click `coderDefs.sldd`.
10 Use the **Model Hierarchy** pane to save the changes you made to `rtwdemo_roll_data.sldd`.
11 Link `rtwdemo_advsc` to a dictionary named `rtwdemo_advsc_data.sldd` and configure the new dictionary to refer to `coderDefs.sldd`.

   `rtwdemo_advsc` uses a variable in the base workspace, so Simulink migrates the variable into the dictionary.
Apply Code Generation Definition in Models

Confirm that the shared definition is available for use in the models by applying it as a default setting for internal data and inspecting the generated code.

2. Under Code Mappings > Data Defaults, for the Internal data row, set Storage Class to internalsInFile.
3. In rtwdemo_advsc, use the Code Perspective to set Storage Class to internalsInFile for the Internal data row.
4. Generate code from rtwdemo_roll.
5. In the code generation report, inspect the generated file rtwdemo_roll_internal.c. The file defines global variables that correspond to state data in the model, such as the state of the Integrator block in the BasicRollMode subsystem.

```c
/* Storage class 'internalsInFile' */
real32_T rtwdemo__FixPtUnitDelay1_DSTATE;
real32_T rtwdemo_roll_Integrator_DSTATE;
int8_T rtwde_Integrator_PrevResetState;
```

6. Optionally, generate code from rtwdemo_advsc and confirm that the code appears as expected.

Migrate Definitions from Model File to Shared Data Dictionary

If you create code generation definitions in the Embedded Coder Dictionary of a model, the definitions are stored in the model file. If you want to share the definitions between models:

1. Create a shared data dictionary as shown in “Share Embedded Coder Dictionary Definition Between Models” on page 20-6. Before you proceed to the next step, make sure all of the target models have access to the shared dictionary.
2. Use the coder.dictionary.move function to migrate the definitions from the source model file to the shared data dictionary.
3. Optionally, copy Code Mapping Editor settings from the source model to other models by using the programmatic interface of the Code Mapping Editor (see “Configure Default Data and Function Code Generation Programmatically” on page 21-22).

In this example, you create a storage class in the Embedded Coder Dictionary of a model and use the storage class in the Code Mapping Editor. Then, you convert a subsystem to a
referenced model. To use the same Code Mapping Editor settings for the first model and for the referenced model, you must extract the storage class into a shared data dictionary (.sldd).

**Create and Apply Storage Class**

1. Open the example model `rtwdemo_roll`.

    `rtwdemo_roll`

2. In the model, select **Code > C/C++ Code > Configure Model in Code Perspective.**

3. Underneath the block diagram, in the Code Mapping Editor, click the **Embedded Coder Dictionary** button.

4. In the Embedded Coder Dictionary dialog box, on the **Storage Classes** tab, click **Add.**

5. For the new storage class, set these property values:

   - **Name** to `internalsInFile`.
   - **Header File** to `$R_internal.h`.
   - **Definition File** to `$R_internal.c`.

6. In the model, in the Code Mapping Editor, for the **Data Defaults > Internal data** row, set **Storage Class** to `internalsInFile`.

**Create Referenced Model**

1. In the model, right-click the `BasicRollMode` subsystem and select **Subsystem & Model Reference > Convert to > Referenced Model.**

2. In the Model Reference Conversion Advisor, click **Convert.**

The new referenced model, `BasicRollMode`, opens. The model file is in your current folder.

By default, the referenced model cannot access the code generation definitions in the Embedded Coder Dictionary of the parent model. Now, move the storage class out of the parent model and into a shared data dictionary.

**Move Storage Class to Shared Data Dictionary**

As a best practice, link each model to a separate data dictionary (.sldd), create a shared, standalone data dictionary to store the code generation definition (the storage class), and
To link the models to separate dictionaries:

1. In the `rtwdemo_roll` model, select **File > Model Properties > Link to Data Dictionary**.
2. In the Model Properties dialog box, select the **Data Dictionary** option and click **New**.
3. Use the Create a new Data Dictionary dialog box to create a dictionary named `rtwdemo_roll_data.sldd`.
4. In the Model Properties dialog box, click **OK**.
5. In the Link Model to Data Dictionary dialog box, click **OK**.
6. Click **OK** in response to the message about importing data from the base workspace.
7. In the `BasicRollMode` model, use the Model Properties dialog box to link the model to a new data dictionary named `basicRollMode_data.sldd`. In response to the message about changing dictionaries or moving data, click **Move Data**.

Selecting **Move Data** causes Simulink to configure the dictionary of the parent model, `rtwdemo_roll_data.sldd`, to refer to `basicRollMode_data.sldd`. To simulate and generate code from the model reference hierarchy, this reference must be in place.

To create the shared, standalone dictionary and store the code generation definition in it:

1. In both models, at the lower-left corner of the block diagram, click the data dictionary badge to open each dictionary in the Model Explorer.
2. In the Model Explorer, select **File > New > Data Dictionary**.
3. Create a data dictionary named `coderDefs.sldd`.
4. In the Model Explorer **Model Hierarchy** pane, select the `rtwdemo_roll_data` node.
5. In the Dialog pane (the right pane), under **Referenced Dictionaries**, click **Add**.
6. Add a reference to `coderDefs.sldd`.
7. Configure `basicRollMode_data.sldd` to refer to `coderDefs.sldd`.
8. In the **Model Hierarchy** pane, right-click the `rtwdemo_roll_data` node and select **Save Changes**.
9. At the command prompt, move the code generation definitions from the `rtwdemo_roll` model file to the `coderDefs.sldd` data dictionary.

```python
    coder.dictionary.move('rtwdemo_roll', 'coderDefs.sldd')
```

Now, both models have access to the storage class `internalsInFile`.

 configure dictionary referencing so that all of the models can use the code generation definition.

Selecting **Move Data** causes Simulink to configure the dictionary of the parent model, `rtwdemo_roll_data.sldd`, to refer to `basicRollMode_data.sldd`. To simulate and generate code from the model reference hierarchy, this reference must be in place.

To create the shared, standalone dictionary and store the code generation definition in it:

1. In both models, at the lower-left corner of the block diagram, click the data dictionary badge to open each dictionary in the Model Explorer.
2. In the Model Explorer, select **File > New > Data Dictionary**.
3. Create a data dictionary named `coderDefs.sldd`.
4. In the Model Explorer **Model Hierarchy** pane, select the `rtwdemo_roll_data` node.
5. In the Dialog pane (the right pane), under **Referenced Dictionaries**, click **Add**.
6. Add a reference to `coderDefs.sldd`.
7. Configure `basicRollMode_data.sldd` to refer to `coderDefs.sldd`.
8. In the **Model Hierarchy** pane, right-click the `rtwdemo_roll_data` node and select **Save Changes**.
9. At the command prompt, move the code generation definitions from the `rtwdemo_roll` model file to the `coderDefs.sldd` data dictionary.

```python
    coder.dictionary.move('rtwdemo_roll', 'coderDefs.sldd')
```

Now, both models have access to the storage class `internalsInFile`. 
Copy Code Mapping Editor Settings from Parent Model to Referenced Model

By default, the new referenced model does not use the Code Mapping Editor settings that the parent model uses. To copy the settings from the parent model to the referenced model, use the programmatic interface of the Code Mapping Editor.

At the command prompt, copy the storage class setting for `Internal data` from `rtwdemo_roll` to `BasicRollMode`.

```matlab
roll_sc = coder.mapping.defaults.get('rtwdemo_roll','InternalData','StorageClass');
coder.mapping.create('BasicRollMode');
coder.mapping.defaults.set('BasicRollMode','InternalData','StorageClass',roll_sc);
```

Now, both models use the same Code Mapping Editor settings. For more information about the programmatic interface of the Code Mapping Editor, see “Configure Default Data and Function Code Generation Programmatically” on page 21-22.

Definitions in Shared Dictionary Do Not Appear in Code Mapping Editor

If a model file contains Embedded Coder Dictionary definitions, and the model is linked to a data dictionary that also contains Embedded Coder Dictionary definitions, the Code Mapping Editor uses the definitions in the model file. To resolve this issue so that you can use the definitions in the data dictionary, remove the definitions from the model file. Use one or more of these functions:

- `coder.dictionary.remove`, which deletes all of the code generation definitions in a model file or data dictionary.
- `coder.dictionary.move`, which moves all of the code generation definitions from a model or data dictionary to a different model or data dictionary.

Make Shared Definitions in a Data Dictionary Available to New Models

A model that you create from the Simulink Start Page or by using the `new_system` function is not linked to a Simulink data dictionary. The new model cannot access code generation definitions that you store in a data dictionary.

To make code definitions available to a new model out of the box, write callbacks and other code that immediately links the model to a data dictionary.
• For a simple example that shows how to link a model to a data dictionary programmatically and for information about configuring dictionary referencing programmatically, see “Store Data in Dictionary Programmatically” (Simulink).

• If you use Simulink projects, consider creating a project shortcut that creates a model and immediately links the new model to a data dictionary. For information about projects and project shortcuts, see “What Are Simulink Projects?” (Simulink).

Use Data Dictionary to Store Code Definitions but Not Design Data

A Simulink data dictionary can store design data such as MATLAB variables and Simulink.AliasType objects (see “Global and Shared Data: Data Dictionary” (Simulink)). However, migrating the design data of a large model or of multiple models from the base workspace to a data dictionary can take time and careful planning.

If you want to store shared code generation definitions in a data dictionary but do not want to migrate the design data of a model, in the data dictionary to which the model is linked, select the Allow access to base workspace property. The model can use design data from the base workspace and code generation definitions from the dictionary or from a referenced dictionary. For more information about Allow access to base workspace, see “Continue to Use Shared Data in the Base Workspace” (Simulink).

Opening Code Perspective Generates Error

In a hierarchy of referenced data dictionaries (see “Dictionary Referencing” (Simulink)), only one dictionary can store code generation definitions in an Embedded Coder Dictionary. When you open the Code Perspective in a model that has access to multiple Embedded Coder Dictionaries through referenced data dictionaries, Simulink generates an error. To resolve the error, use coder.dictionary.move and coder.dictionary.remove to transfer and delete Embedded Coder Dictionaries until only one exists in the dictionary hierarchy. If necessary, store the Embedded Coder Dictionary in a standalone, shared data dictionary as described in “Share Embedded Coder Dictionary Definition Between Models” on page 20-6.

Limitations for Definitions in a Simulink Data Dictionary

When you store code generation definitions in a data dictionary, these limitations apply:
• In a hierarchy of referenced data dictionaries (see “Dictionary Referencing” (Simulink)), only one dictionary can store code generation definitions in an Embedded Coder Dictionary. You cannot partition the definitions by storing them in multiple referenced dictionaries.

• When you link a model to a data dictionary, if the model file contains code generation definitions in an Embedded Coder Dictionary, you cannot use code generation definitions that the data dictionary provides. To use code generation definitions from the data dictionary, use `coder.dictionary.move` or `coder.dictionary.remove` to remove the Embedded Coder Dictionary from the model file.

You and other users can configure default code generation settings for categories of model data and functions by using the Code Mapping Editor (see “Configure Default Code Generation for Categories of Model Data and Functions” on page 21-7). You can also configure other model-wide code generation settings through configuration parameters. With these broad, general settings, you can make models generate code that conforms to a general software architecture by default.

As projects expand and you and other users create more models, manually configuring the default settings for each new model takes time. To reduce this manual data entry, you can write scripts and create templates that apply these default settings to new models.

You can copy settings between models, enabling each model to later change the settings independently of each other. Alternatively, you can share settings, enabling you to change the settings for multiple models at once with minimal effort.

</tr>
</tbody>
</table>

**Techniques to Share Settings**

- To share configuration parameter settings, create a configuration set object. Create a template model that refers to the object through a configuration reference.

  Consider storing the object in a data dictionary. Because you cannot create a template model that is linked to a data dictionary, you must configure dictionary linking and referencing for each new model.

- You cannot share default data and function settings that you specify in the Code Mapping Editor.

• “Partition Data for Model Reference Hierarchy Using Data Dictionaries” (Simulink)
Migrate Memory Section and Shared Utility Settings from Configuration Parameters to Code Mapping Editor

Starting in R2018a, for new models:

- To apply model-wide memory section settings, you do not use the model configuration parameters under **Code Generation > Advanced parameters > Memory Sections**. Instead, you use the Code Mapping Editor in the Code Perspective. To define the memory sections, you can continue to use packages or you can use the new Embedded Coder Dictionary.

- To set a naming rule for shared utility functions, you do not use the model configuration parameter **Code Generation > Symbols > Advanced parameters > Shared utilities identifier format**. Instead, you use the Embedded Coder Dictionary to create a function customization template that specifies the naming rule, then apply the template by using the Code Mapping Editor.

For general information about the Code Perspective, the Code Mapping Editor, and the Embedded Coder Dictionary, see “Environment for Configuring Model Data and Functions for Code Generation” on page 21-2.

In a model that you created in a release before R2018a, when you or another user opens the Code Perspective, Simulink migrates memory section and shared utility settings from the configuration parameters to the Code Mapping Editor of the model. If necessary, as part of this migration, Simulink configures the Embedded Coder Dictionary that the model uses:

- To refer to the package that defines the memory sections, as described in “Refer to Code Generation Definitions in a Package”.

- To contain a function customization template that specifies the naming rule and, if applicable, memory section settings that you specified for shared utilities.

Also, if you use the `coder.mapping.create` function on such a model, Simulink migrates memory section and shared utility settings in this manner.

**Effects of Migration**

- The migration process makes changes to the model file, which you must save. The changes include:
• Translating the configuration parameter settings into Code Mapping Editor settings.

• If the model is not linked to a data dictionary, configuring the Embedded Coder Dictionary in the model file to refer to the memory section package and to contain a function customization template.

• If the model is linked to a data dictionary, the migration process makes changes to the dictionary, which you must save. The changes include:

• If the configuration parameters are stored in the model file (the model does not refer to a Simulink.ConfigSet object), configuring the Embedded Coder Dictionary of the data dictionary to refer to the memory section package and to contain a function customization template.

If the data dictionary references other dictionaries, the migration process configures the dictionary at the bottom of the reference hierarchy so other models and dictionaries in the hierarchy can use the memory section and function template definitions.

• If the model refers to a Simulink.ConfigSet object, configuring the Embedded Coder Dictionary of the data dictionary that stores the object.

Considerations Before Migrating

• Typically, when you open the Code Perspective, it executes the migration process without prompting you. Do not open the Code Perspective unless you are ready to migrate memory section and shared utility naming settings.

The Code Perspective prompts you to accept the migration if your model meets either of these conditions:

• The model has multiple configuration sets (one active and one or more inactive).
• The model refers to a Simulink.ConfigSet object.

If you do not accept, you cannot use the Code Perspective.

• If you use Simulink data dictionaries, before you or other users open the Code Perspective in any models, consider creating and configuring the dictionaries first.

In a hierarchy of referenced data dictionaries (for example, a dictionary hierarchy that parallels a model hierarchy), only one dictionary can contain an Embedded Coder Dictionary. Setting up data dictionaries before migrating associated models enables
you to control where the Embedded Coder Dictionary resides in the dictionary hierarchy. Create or identify a data dictionary at the bottom of the hierarchy so that all of the models can access the memory section and function template definitions. Then, when you initiate migration by opening the Code Perspective in a model, Simulink configures that data dictionary.

For information about sharing an Embedded Coder Dictionary between models by using referenced dictionaries, see “Share Embedded Coder Dictionary Definition Between Models” on page 20-6.

- The migration process makes changes based on the active configuration set of the model (see “Manage a Configuration Set” (Simulink)) at the time that you open the Code Perspective. Before you open the Code Perspective, activate the configuration set whose settings you want the migration process to use.

The process ignores settings in inactive configuration sets. If different configuration sets of the model specify different settings, you must choose one set to migrate.

**Considerations After Migrating**

- In a branching hierarchy of referenced models and referenced data dictionaries, after you or other users migrate referenced models in different branches, opening the Code Perspective in a parent model can generate an error due to the presence of multiple Embedded Coder Dictionaries in the data dictionary hierarchy. To resolve these errors, use `coder.dictionary.move` and `coder.dictionary.remove` to transfer and delete Embedded Coder Dictionaries until only one dictionary remains. Place the remaining Embedded Coder Dictionary in a data dictionary at the bottom of the hierarchy so that all of the models can access the memory section and function template definitions.

For information about sharing an Embedded Coder Dictionary between models by using referenced dictionaries, see “Share Embedded Coder Dictionary Definition Between Models” on page 20-6.

- After you migrate a model, Embedded Coder ignores memory section and shared utility settings in the configuration parameters. If you use `set_param` or `get_param` to access these configuration parameter settings programmatically, the functions generate warnings. To change or set these settings, use the Code Mapping Editor or the equivalent programmatic interface as described in “Configure Default Code Generation for Categories of Model Data and Functions” on page 21-7.
However, if a model contains atomic subsystems that have nondefault memory section settings, the model continues to depend on the `Package` setting in the configuration parameters. See “Override Default Memory Placement for Subsystem Functions and Data” on page 30-12.

- If a model refers to a `Simulink.ConfigSet` object, after migration, the model no longer uses the memory section and shared utility settings in the object. If you used the object to set the configuration parameters of multiple models:
  
  - Changing memory section and shared utility settings in the object affects only models that you have not migrated.
  - Migrated models no longer acquire memory section and shared utility settings from a single location (the `Simulink.ConfigSet` object). To change these settings for these models, you must use the Code Mapping Editor of each individual model.

- “Configure Default Code Generation for Categories of Model Data and Functions” on page 21-7
Environment for Configuring Model Data and Functions for Code Generation

When you generate code from a model, the code includes:

- Entry-point functions such as `model_step`, which your application code calls to execute the model algorithm.
- Data such as signals, states, and parameters, which your application code can read and write to.

To control the names and representation of the data and functions in the code, follow the iterative paradigm shown in the diagram.
In this paradigm:

- A software engineer directly interacts with and generates code from production models.
- A system architect helps multiple engineers and multiple projects generate code that conforms to the standards of a department or organization. The architect achieves this
standardization by customizing the Simulink development environment that engineers use.

To access tools such as the Code Mapping Editor, consider placing your model in the Code Perspective. In the model, select Code > C/C++ Code > Configure Model in Code Perspective.

**Software Engineer: Configure Default Settings**

For each category of data and functions in a model, such as root-level inputs, parameters, and execution functions, you can specify default code generation settings. For example, you can configure the generated code to conform to these objectives by default:

- Read root-level input data from global variables defined by your external code.
- Store state data in structures whose placement in memory you can control.
- Name functions according to a rule that you specify.

The default settings can help you to reduce manual data entry.

- As you add blocks and signals to a model, the new data elements and functions inherit the default settings.
- To change code generation settings for many data elements or functions at once, you make the changes in one place—the default settings.
- You can use naming rules and other parameterized, abstract schemes to avoid additional duplication of effort as you make changes elsewhere in the model.

For some categories of data, code generation optimizations can eliminate the data from the code. For your default settings to apply, you must identify individual data elements that you want to preserve against the optimizations. For more information, see “Elimination of Parameters and Other Internal Data by Optimizations” on page 21-32.

To configure default settings, use the Code Mapping Editor.

**Software Engineer: Override Default Settings**

After using the Code Mapping Editor to configure model-wide default settings, you can override the defaults for individual data elements and functions.
<table>
<thead>
<tr>
<th>Override Defaults For</th>

**System Architect: Create Code Generation Definitions**

Using the Code Mapping Editor and the Model Data Editor, application developers apply code generation definitions, such as the built-in storage class `ExportedGlobal`, to model data elements and functions. To standardize the code that you and your users generate from multiple models, you can create and share custom definitions with meaningful names. Creating custom definitions also enables you to achieve code generation objectives that the built-in definitions cannot satisfy.

- To create definitions that you want to appear in the **Code Mapping Editor**, use the **Embedded Coder Dictionary**. See Embedded Coder Dictionary.

  If you plan to use your Embedded Coder Dictionary definitions in one model, you can store the definitions in the model file. Alternatively, to share the definitions between models and projects, store the definitions in a Simulink data dictionary. With a data dictionary, to modify a shared definition, you change a definition in one place—the dictionary.

- To create definitions that you want to appear in other tools, such as the Model Data Editor, use the Custom Storage Class Designer. See “Create Custom Storage Classes by Using the Custom Storage Class Designer” on page 26-26.

  For some definitions that you create by using the Custom Storage Class Designer, you can make the definitions appear in the Code Mapping Editor by configuring an Embedded Coder Dictionary to refer to them.

Configure Default Code Generation for Categories of Model Data and Functions

Reduce the effort of preparing a model for code generation by specifying default configurations for categories of data elements and functions across a model. Applying default configurations can save time and reduce the risk of introducing errors in code, especially for larger models and models from which you generate multi-instance code.

You can set a default code generation configuration for:

• Categories of model data. When producing code for the data, the code generator uses a storage class that you specify to determine properties, such as whether the data is structured, naming rules for definition and header files, and whether the data is stored in a memory section.

• Categories of functions. When producing code for the functions, the code generator uses a function customization template that you specify to determine properties, such as a function naming rule and whether the function code is stored in a memory section.

You can specify the default configurations interactively in the Simulink model editing environment from the Code Mapping Editor or programmatically by using an API.

Configure Default Data and Function Configurations in Model Editing Environment

To specify default code generation configurations for model data and functions interactively in Simulink model editing environment, use the Code Mapping Editor and Property Inspector. When a model is in Code Perspective mode, the editor and inspector are accessible. After preparing the model for code generation, the Embedded Coder Quick Start tool places a model in Code Perspective mode. Alternatively, you can enable Code Perspective mode from the Simulink Editor by doing one of the following:

• Click the perspective control in the lower-right corner and select Code.

• Select Code > C/C++ Code > Configure Model in Code Perspective.

The Code Mapping Editor appears below the model diagram. The editor display consists of two tabbed tables: Data Defaults and Function Defaults. Use the tables to associate categories of model data elements with storage classes and functions with function customization templates. When you select a row in one of the tables, the Code section of
the Property Inspector shows the property settings for that data element category or function category.

If you close the Code Mapping Editor, the Model Editor window remains in Code Perspective mode. To reopen the Code Mapping Editor, select View > Code Mappings.

After you open the Code Perspective or use the default mapping programmatic interface to configure one or more categories of data and functions for a model, setting memory section and Shared utilities identifier format model configuration parameters has no effect. Also, when you open the Perspective, Simulink migrates the model configuration parameter settings to the Code Mapping Editor. If necessary, as part of the migration, Simulink configures the Embedded Coder Dictionary that the model uses as described in “Migrate Memory Section and Shared Utility Settings from Configuration Parameters to Code Mapping Editor” on page 20-21.

### Configure Default Code Generation for Data

You configure default code generation for categories of data elements in a model by associating the categories with storage classes and memory sections. Data elements are grouped into these categories.

<table>
<thead>

The **Code Mapping Editor** presents valid storage class options for a given category. The options can include:

- Unspecified storage class (**Default**). The code generator places the code for the category of data elements in standard structures, such as B_, ExtY_, ExtU_, DW_, and P_. See “Standard Data Structures in the Generated Code” on page 22-26.
- Relevant built-in storage class, such as ExportedGlobal.
- Relevant storage class in an available package, such as ImportFromFile.
- Storage class defined in an Embedded Coder Dictionary.

This example shows how to use the **Code Mapping Editor** to specify code generation requirements for model data. The model uses multiple execution rates and is configured for single-instance usage.

In this example, the code generation requirements for data:

- Use project type definition `DBL_FLOAT` defined in header file `exDblFloat.h`.
- Get data element `ex_input1` from header file `exInDataMem.h`. The data is used for computing a value stored in memory, and then used in an if-else condition of a Switch block.
- Get data elements `ex_input2`, `ex_input3`, and `ex_input4` from header file `exInDataLut.h`. The data is used in lookup tables `Table1` and `Table2`.
- Data imported into the model from header files `exInDataMem.h` and `exInDataLut.h` is of type `DBL_FLOAT`, a project standard.
• Parameter K1 must be tunable to enable calibration.
• Data store mode defines data that is shared within the model. The Logical Operator block writes to the data store and a Rate Transition block reads from the data store.
• Data element X represents the delay for the Unit Delay block.
• Store data that is internal to the model, such as delay X, in a section of memory labeled internalDataMem.
• Export output data declarations to header file exSysOut.h and definitions to exSysOut.c.

To configure default code generation mappings for the model data, use the Code Mapping Editor. Although the model uses single instances of some data, the example configures default settings to demonstrate different types of mappings. As you add blocks to the model, new data elements acquire the default code generation mappings.

Set Up Example Environment

1 Copy these external source and header files from matlabroot/toolbox/rtw/rtwdemos to a writable working folder. These files define and declare the external data type and data that the generated code uses.

<table>
<thead>
<tr>
<th>File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>exDblFloat.h</td>
<td>Defines the project data type alias for double, DBL_FLOAT. Simulink uses the PreLoadFcn callback specified for the model to parse this header file and create a corresponding Simulink.AliasType object.</td>
</tr>
<tr>
<td>exInDataMem.c</td>
<td>Includes exInDataMem.h and defines variable ex_input1.</td>
</tr>
<tr>
<td>exInDataMem.h</td>
<td>Includes exDblFloat.h and declares variable ex_input1.</td>
</tr>
<tr>
<td>exInDataLut.c</td>
<td>exInDataLut.c includes exInDataLut.h and defines variables ex_input2, ex_input3, and ex_input4.</td>
</tr>
<tr>
<td>exInDataLut.h</td>
<td>Includes exDblFloat.h and declares variables ex_input2, ex_input3, and ex_input4.</td>
</tr>
<tr>
<td>rtwdemo_configdefault.slx</td>
<td>Example model.</td>
</tr>
</tbody>
</table>
2  Open your copy of example model rtwdemo_configdefaults.

3  To gain access to the Code Mapping Editor, open the Code Perspective. Click Code > C/C++ Code > Configure Model in Code Perspective.

Configure Default Settings for Inport Data

Specify an external header file that declares input data. Three of the four root inports read input from variables declared in header file exInDataLut.h. Set that header file as the default.

1  Under Code Mappings - C, in the Data Defaults tab, select category Inports and set the storage class to ImportFromFile.

2  In the Property Inspector, set Header File to exInDataLut.h.

The default mappings for a model are stored as part of the model.

Override Default Settings for Inport In1

Override the default external header file setting for In1. That inport reads data from a variable declared in header file exInDataMem.h.
1 Open the Model Data Editor.
2 In the Source column, select In1.
3 Set the storage class for In1 to ImportFromFile.
4 Set Header File to inDataMem.h.
5 Return to the Code Mappings Editor by clicking the Code Mappings - C tab.

Configure Default Settings for Local Parameters

Configure parameters UPPER, LOWER, K1, and K2. Those parameters are local parameters for which parameter objects are stored in the model workspace. Map category Local parameters to storage class ExportedGlobal, which makes the parameter objects appear in the generated code as tunable global variables.

Prevent Optimizations From Eliminating Parameter From Generated Code

Prevent code generator optimizations from eliminating K1 from the generated code. The data requirements indicate that K1 must be tunable. To prevent potential elimination of the variable from the generated code, in the Code view of the Model Data Editor, find the model workspace parameter for K1. Set the storage class to Model default. For more information, see “Elimination of Parameters and Other Internal Data by Optimizations” on page 21-32.

Define Memory Section for Internal Data

Define a memory section for storing the unit delay X, data that is internal to the model.
1 Return to the Code Mappings Editor.
2 Open the Embedded Coder Dictionary by clicking .
3 Click the Memory Sections tab.
4 Click Add.
5 In the new row at the bottom of the table, name the new memory section internalDataMem. Also set:
   • Pre Statement to #pragma start INTERNALDATA
   • Post Statement to #pragma end INTERNALDATA
   • Statements Surround to Group of variables
6 Close the dictionary.
Configure Default Memory Section for Internal Data

In the Code Mapping Editor, configure the code generator to place internal data in memory section internalDataMem.

1. Select category **Internal data**.
2. In the Property Inspector, set **Memory Section** to internalDataMem.

Configure Default Settings for Outport Data

Specify the default external header and definition files for variables to which the generated code writes output. Map category **Outports** to storage class ExportToFile. In the Property Inspector, set **Header File** to exSysOut.h and **Definition File** to exSysOut.c. Save the model.

Generate and Verify Code

- Use the code generation report to verify the following code:
  - `rtwdemo_configdefaults_private.h` includes header files that declare external input data:
    ```
    #include "exInDataMem.h"
    #include "exInDataLut.h"
    ```
  - `rtwdemo_configdefaults.c` initializes the gain variable K1 and uses the variable in the model step function `exFast_step1`.
    ```
    DBL_FLOAT K1 = 2.0;
    ...
    void exFast_step1(void)
    {
      DBL_FLOAT rtb_Gain;
      ...
      rtb_Gain = K1 * look1_binlc(ex_input2, rtCP_Table1_bp01Data,
                                  rtCP_Table1_tableData, 10U);
      ...
    }
    ```
  - `rtwdemo_configdefaults.c` includes `pragma` control lines that define memory sections for the local data store, unit delay, and constants.
    ```
    #pragma start INTERNALDATA
    BlockIO_rtwdemo_configdefaults B;
    #pragma end INTERNALDATA
    ```
#pragma start INTERNALDATA
D_Work_rtwdemo_configdefaults DWork;
#pragma end INTERNALDATA

#pragma start INTERNALDATA
RT_MODEL_rtwdemo_configdefaults M_;  
#pragma end INTERNALDATA

#pragma start INTERNALDATA
RT_MODEL_rtwdemo_configdefaults *const M = &M_;  
#pragma end INTERNALDATA

• exSysOut.c includes an exported data definition for Out1.

    #include "rtwtypes.h"  
    #include "rtwdemo_dataconfig_types.h"

    DBL_FLOAT Out1;

• Shared file exSysOut.h declares Out1. To gain access to Out1, external code can include this header file.

    extern DBL_FLOAT Out1;

## Configure Default Code Generation for Functions

Configure default code generation for a category of functions by using the **Code Mapping Editor** to associate the category with a function customization template.

<table>
<thead>
<tr>
<th>Model Function Category</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Initialize/Terminate</td>
<td>Initialization and termination function code, such as <code>model_initial</code> and <code>model_terminate</code>.</td>
</tr>
<tr>
<td>Execution</td>
<td>Execution code for a model, such as <code>model_step</code> and <code>model_reset</code>.</td>
</tr>
<tr>
<td>Shared utility</td>
<td>Code for shared utility functions.</td>
</tr>
</tbody>
</table>

A function customization template defines how the code generator produces code for a category of functions. For a function category, you can define:

- A rule for naming functions
- A location in memory for function definitions (memory section)

By default, the code generator uses the identifier naming rule `$R$N` to name entry-point functions. `$R` is the name of the root model. `$N` is the default code generator name of the
function, for example, `initialize`, `step`, and `terminate`. To integrate generated code with existing external code or to comply with naming standards or guidelines, you can adjust the default naming rule. Adjusting the default naming rule can save time, especially for multirate models for which the code generator produces a unique `step` function for each rate.

Unless someone has defined function customization templates for a model, the Code Mapping Editor presents `Default` as the only template option. To define a template, use the Embedded Coder Dictionary. You can open the dictionary by clicking .

Before configuring default code generation settings for functions, consider these questions.

<table>
<thead>
<tr>
<th>Consideration</th>
<th>See</th>
</tr>
</thead>
<tbody>
<tr>
<td>What categories are relevant to your model?</td>
<td>“Configure Code Generation for Model Entry-Point Functions” on page 28-2</td>
</tr>
<tr>
<td>Do you have function naming requirements? If the answer is yes, what are they? To which categories do the requirements apply?</td>
<td>“Configure Code Generation for Model Entry-Point Functions” on page 28-2 and “Identifier Format Control” on page 39-22</td>
</tr>
<tr>
<td>Does the model use several instances of functions that are in a category? If the answer is yes, applying default mappings is beneficial. If the answer is no, consider configuring code generation for each function separately by using function-prototype control options as described in the cited topics.</td>
<td>“Customize Generated C Function Interfaces” on page 29-2 and “Customize Generated Function Interfaces for Simulink Function and Function Caller Blocks” on page 29-24</td>
</tr>
<tr>
<td>Does your application require the code generator to store function code in a specific area of memory?</td>
<td>“Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 20-2 and “Control Data and Function Placement in Memory by Inserting Pragmas” on page 30-2</td>
</tr>
<tr>
<td>Do you need to define new function customization templates to include as options in the Code Mapping Editor?</td>
<td>“Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 20-2</td>
</tr>
</tbody>
</table>
This example shows how to use the Code Mapping Editor to specify code generation requirements for model functions. The model uses multiple execution rates and is configured for single-instance usage. The code generator produces initialize, execution, and terminate entry-point functions. Because the model uses multiple rates, the code generator produces an execution function for each rate.

In this example, code generation requirements for entry-point functions:

- Store generated initialize and terminate functions in memory section functionSlowMem and execution functions in memory section functionFastMem.
- Use the naming rule exSlow_$N to name initialize and terminate entry-point functions. Use the naming rule exFast_$N to name execution functions.

To configure default code generation settings for the functions, use the Embedded Coder Dictionary and Code Mapping Editor.

Open Model

Open the copy of example model rtwdemo_configdefaults that you previously created.

Define Memory Sections

Define the two memory sections: functionSlowMem for initialize and terminate functions and functionFastMem for execution functions.

2. Click the Memory Sections tab.
3. Click Add.
4. In the new row at the bottom of the table, name the new memory section functionFastMem. Then, set:

   - **Pre Statement** to #pragma start FASTMEM
Define Function Customization Templates

To configure categories of functions, define function customization templates. Unless you define templates in the Embedded Coder Dictionary that are associated with a model, the only available template is Default. Based on the requirements, in the dictionary, define two function customization templates: one to specify the naming rule and memory section for initialize and terminate functions and one to specify the naming rule and memory section for execution functions.

1. In the Embedded Coder Dictionary, click the Function Customization Templates tab.
2. Click Add.
3. In the new row of the table, name the new template exFastFunction. Then, set:
   - Function Name to exFast_$N. This naming rule applies the prefix exFast_ to the name that identifies the default code generator name of the function (for example, initialize or step).
   - Memory Section to functionFastMem. This mapping associates the memory section that you defined in step 2 with the new template.
4. Click Add again. Name the template exSlowFunction. Then, set:
   - Function Name to exSlow_$N.
   - Memory Section to functionSlowMem.

Configure Default Settings for Functions

1. To access the Code Mapping Editor, open the Code Perspective.
2. In the Code Mapping Editor, click the Function Defaults tab.
3. Configure the initialize and terminate entry-point functions. For category Initialize/Terminate, from the template menu, exSlowFunction.
4. Configure the execution entry-point functions. For category Execution, select template exFastFunction.
The default mappings for a model are stored as part of the model.

**Generate and Verify Code**

Use the code generation report to verify the following code:

- The Code Interface Report section documents the generated entry-point functions:
  - `exSlow_initialize`
  - `exFast_step` (called periodically, every 0.5 seconds)
  - `exFast_step1` (called periodically, every 1 second)
  - `exFast_step2` (called periodically, every 1.5 seconds)
  - `exSlow_terminate`

- To gain access to the entry-point function code in `rtwdemo_configdefaults.c`, use the function name file links in the Code Interface Report. Verify that the correct `pragma` control statements surround the function code. For example:

```c
#pragma start FASTMEM
void exFast_step2(void)                /* Sample time: [1.5s, 0.0s] */
{
    DWork.RateTransition1_Buffer0 = ((ex_input1 > 10.0) || (ex_input1 < -10.0));
}
#pragma end FASTMEM
```

- To gain access to the entry-point function declarations in `rtwdemo_configdefaults.h`, use the header file links in the report. Verify that the correct `pragma` control statements surround the declarations. For example:

```c
#pragma start SLOWMEM
void exSlow_initialize(void)
{
    /* (no initialization code required) */
}
#pragma end SLOWMEM
```
Configure Default Data and Function Code Generation with Definitions Stored in Shared Data Dictionary

You have the option of configuring default data and function code generation with definitions that are set up in a Simulink data dictionary. A data dictionary enables sharing of code definitions between models. Using definitions in a data dictionary, configure default mappings:

1. If not already defined, define code definitions (storage classes, function customization templates, and memory sections) in a data dictionary. For this example, use definitions defined in the existing data dictionary `exSharedCodeDefs.sldd`. See “Share Code Generation Definitions Between Multiple Models and Users” on page 20-6.

2. Link the model to the data dictionary.

3. Map data and function default categories to code definitions in the dictionary.

This example shows how to link model model `rtwdemo_configdefaults` to data dictionary `exSharedCodeDefs.sldd`. That data dictionary includes Embedded Coder Dictionary definitions for:

- Memory section `internalDataMem` with **Pre Statement** set to `#pragma start INTERNALDATA` and **Post Statement** set to `#pragma end INTERNALDATA`.
- Memory section function `fastMem` with **Pre Statement** set to `#pragma start FASTMEM` and **Post Statement** set to `#pragma end FASTMEM`.
- Memory section function `slowMem` with **Pre Statement** set to `#pragma start SLOWMEM` and **Post Statement** set to `#pragma end SLOWMEM`.
- Function customization template `exFastFunction` with function naming rule `exFast_$N` and memory section `functionFastMem`.
- Function customization template `exSlowFunction` with function naming rule `exSlow_$N` and memory section `functionSlowMem`.

```c
#pragma start SLOWMEM
extern void exSlow_initialize(void);
#pragma end SLOWMEM

#pragma start FASTMEM
extern void exFast_step0(void);
#pragma end FASTMEM

# */
Then, use the Code Mapping Editor to map data and function categories to code definitions in the data dictionary.

**Link Model to Data Dictionary**

1. Open model `rtwdemo_configdefaults`.
2. In the model window, select **File > Model Properties > Link to Data Dictionary**.
3. In the Model Properties dialog box, select **Data Dictionary** and click **Browse**.
4. Open the dictionary `exSharedCodeDefs.sldd` through the Open Data Dictionary dialog box.
5. In the Model Properties dialog box, click **OK**. The Link Model to Data Dictionary dialog box appears. Leave the option **Migrate reference variables from base workspace to dictionary 'sharedCodeDefs.sldd'** selected. Click **OK**. Simulink links the model to the dictionary and migrates design data from the base workspace to the dictionary.
6. In the lower-left corner of the model, click the data dictionary badge. The dictionary opens in Model Explorer.
7. In the **Model Hierarchy** pane, under `exSharedCodeDefs`, select **Embedded Coder Dictionary**.
8. In the **Dialog** pane, click **Open Embedded Coder Dictionary**.
9. Verify that the dictionary includes the required code definitions.

**Configure Default Categories for Code Generation**

1. In the model window for `rtwdemo_config_defaults`, select **Code > C/C++ Code > Configure Model in Code Perspective**.
2. In the Code Mapping Editor, in the **Data Defaults** tab, select category **Internal data**.
3. In the Property Inspector, set **Memory Section** to `internalDataMem`.
4. In the **Function Defaults** tab, for the **Initialize/Terminate** category, select the function customization template `exSlowFunction`. For the **Execution** category, select template `exFastFunction`.
5. Save the model.
6. Generate and review code.
For more information about setting up an Embedded Coder Dictionary, see “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 20-2.

Configure Default Data and Function Code Generation Programmatically

This example shows how to configure default data and function code generation for example model rtwdemo_configdefaults. The example uses the default mapping programming interface to specify code generation requirements for model data and functions. Use that interface to automate the configuration, or if you prefer to configure models programmatically. For information about configuring the default data and function code generation by using the Code Mapping Editor, see “Configure Default Code Generation for Categories of Model Data and Functions” on page 21-7.

Open the Model

The model rtwdemo_configdefaults uses multiple execution rates and is configured for single-instance usage.

```
open_system('rtwdemo_configdefaults')
```
**Code Generation Requirements**

For this example, the code generation requirements:

- Import project type definition for data of type `double`, `DBL_FLOAT`, from header file `exDbfFloat.h`.
- Import signal `ex_input1` for computing a value stored in memory and used in an if-else condition in the Switch block. Import the signal data from header file `exInDataMem.h`.
- Import signals `ex_input2`, `ex_input3`, and `ex_input4` for lookup tables `Table1` and `Table2`. Import the signal data from header file `exInDataLut.h`.
- Data imported into the model from header files `exInDataMem.h` and `exInDataLut.h` is of type `DBL_FLOAT`, a project standard.
- Parameters `UPPER`, `LOWER`, `K1`, and `K2` are parameter objects stored in the model workspace. `K1` must be tunable to enable calibration.
- Data store mode defines data that is shared within the model.
- Data element `X` represents the delay for the Unit Delay block.
- Store data that is internal to the model in memory section `internalDataMem`.
- Store generated initialize and terminate functions in memory section `functionSlowMem` and execution functions in memory section `functionFastMem`.
- Use the identifier naming rule `exSlow_$N` to name initialize and terminate entry-point functions. Use the naming rule `exFast_$N` to name execution functions.
- Export output data declarations to header file `exSysOut.h` and definitions to `exSysOut.c`.

For this example someone, such as a system architect, has previously created these code definitions in an Embedded Coder Dictionary that is part of Simulink data dictionary `ex_configdefault.sldd`:

- Memory sections `internalDataMem`, `functionFastMem`, and `functionSlowMem`.
- Function customization templates `exFastFunction` and `exSlowFunction`.

**Create Environment for Configuring Code Generation for Data and Functions**

Create an environment for configuring code generation for data and functions associated with model `rtwdemo_configdefaults` by calling the function `coder.mapping.create`. You can skip this step if you previously opened the model in Code Perspective mode.
coder.mapping.create('rtwdemo_configdefaults');

**Identify Category, Property, and Value Combinations To Set As Data Defaults**

Align the code generation requirements for data with available data categories. Each category has a set of properties that you can configure. Each property has a set of possible values. Use calls to `coder.mapping.defaults.dataCategories`, `coder.mapping.defaults.allowedProperties`, and `coder.mapping.defaults.allowedValues` to review the list of names for categories, properties, and values of interest.

For this example, you need to configure default settings for inports, outports, and parameter objects stored in the model workspace. Get a list of the available data categories by calling `coder.mapping.defaults.dataCategories`.

```
coder.mapping.defaults.dataCategories()
ans = 1x8 cell array
    Columns 1 through 4
    {'Inports'}    {'Outports'}    {'GlobalParameters'}    {'LocalParameters'}
    Columns 5 through 7
    {'SharedLocalDat...'}    {'GlobalDataStores'}    {'InternalData'}
    Column 8
    {'Constants'}
```

For data categories `Inports`, `Outports`, `LocalParameters`, and `InternalData` identify the properties that you can set with calls to `coder.mapping.defaults.allowedProperties`.

```
coder.mapping.defaults.allowedProperties('rtwdemo_configdefaults', 'Inports')
ans = 2x1 cell array
    {'StorageClass'}
    {'HeaderFile' }
```

```
coder.mapping.defaults.allowedProperties('rtwdemo_configdefaults', 'Outports')
ans = 4x1 cell array
    {'StorageClass' }
```
coder.mapping.defaults.allowedProperties('rtwdemo_configdefaults', 'LocalParameters')
ans = 1x1 cell array
    {'StorageClass'}

coder.mapping.defaults.allowedProperties('rtwdemo_configdefaults', 'InternalData')
ans = 2x1 cell array
    {'StorageClass'}
    {'MemorySection'}

For data category and property combinations that you want to set, identify possible values with calls to coder.mapping.defaults.allowedValues. Based on requirements and the results of step b, specify:

- **StorageClass** with categories Inports, Outports, LocalParameters, and InternalData
- **MemorySection** with InternalData

You do not need to determine values for properties **HeaderFile** (for Inports and Outports) and **DefinitionFile** (Outports). The values that you set for those properties are known strings.

coder.mapping.defaults.allowedValues('rtwdemo_configdefaults', 'Inports', 'StorageClass')
ans = 9x1 cell array
    {'Default'    }
    {'ExportedGlobal' }
    {'ImportedExtern' }
    {'ImportedExternPointer'}
    {'Volatile'    }
    {'ExportToFile' }
    {'ImportFromFile' }
    {'AutoScope'    }
    {'GetSet'    }

coder.mapping.defaults.allowedValues('rtwdemo_configdefaults', 'Outports', 'StorageClass')
ans = 9x1 cell array
{'Default'   }
{'ExportedGlobal' }
{'ImportedExtern' }
{'ImportedExternPointer'}
{'Volatile'   }
{'ExportToFile'  }
{'ImportFromFile' }
{'AutoScope'   }
{'GetSet'     }

coder.mapping.defaults.allowedValues('rtwdemo_configdefaults', 'LocalParameters', 'StorageClass')
ans = 14x1 cell array
{'Default'   }
{'ExportedGlobal' }
{'ImportedExtern' }
{'ImportedExternPointer'}
{'Const'    }
{'Volatile' }
{'ConstVolatile' }
{'Define'   }
{'ImportedDefine' }
{'ExportToFile'  }
{'ImportFromFile' }
{'FileScope'   }
{'GetSet'     }
{'CompilerFlag'

coder.mapping.defaults.allowedValues('rtwdemo_configdefaults', 'InternalData', 'StorageClass')
ans = 10x1 cell array
{'Default'   }
{'ExportedGlobal' }
{'ImportedExtern' }
{'ImportedExternPointer'}
{'Volatile'   }
{'ExportToFile'  }
{'ImportFromFile' }
{'FileScope'   }
{'AutoScope'   }
{'GetSet'     }

21 Configuring Data and Functions in the Generated Code
Identify Category, Property, and Value Combinations To Set As Function Defaults

Align the code generation requirements for functions with available function categories. For this example, you need to configure default settings for initialize, execution, and terminate functions. Get a list of the available function categories by calling `coder.mapping.defaults.functionCategories`.

```matlab
coder.mapping.defaults.functionCategories()
ans = 1x3 cell array
    {'InitializeTermi...'    {'Execution'}    {'SharedUtility'}
```

The categories that apply are InitializeTerminate and Execution.

For function categories InitializeTerminate and Execution, identify the properties that you can set with calls to `coder.mapping.defaults.allowedProperties`.

```matlab
coder.mapping.defaults.allowedProperties('rtwdemo_configdefaults', 'InitializeTerminate')
an = 1x1 cell array
    {'FunctionCustomizationTemplate'}
```

You get the same output for category Execution.

For function category and property combinations that you want to set, identify possible values with calls to `coder.mapping.defaults.allowedValues`. Based on requirements and the results of calling `coder.mapping.defaults.allowedProperties`, specify `FunctionCustomizationTemplate` with categories InitializeTerminate and Execution.

```matlab
coder.mapping.defaults.allowedValues('rtwdemo_configdefaults', 'InitializeTerminate', 'FunctionCustomizationTemplate')
ans = 3x1 cell array
   {'Default'      }
   {'exSlowFunction'}
   {'exFastFunction'}

The list of templates is the same for InitializeTerminate and Execution.

**Set Relevant Category, Property, and Value Combinations**

Set relevant category, property, and value combinations with calls to `coder.mapping.defaults.set`.

```matlab
coder.mapping.defaults.set('rtwdemo_configdefaults', 'Inports',...   'Storageclass', 'ImportFromFile',...   'HeaderFile', 'exInDataLut.h');
coder.mapping.defaults.set('rtwdemo_configdefaults', 'Outports',...   'Storageclass', 'ExportToFile',...   'HeaderFile', 'exSysOut.h',...   'DefinitionFile', 'exSysOut.c');
coder.mapping.defaults.set('rtwdemo_configdefaults', 'LocalParameters',...   'Storageclass', 'ExportedGlobal');
coder.mapping.defaults.set('rtwdemo_configdefaults', 'InternalData',...   'MemorySection', 'internalDataMem');
coder.mapping.defaults.set('rtwdemo_configdefaults', 'InitializeTerminate',...   'FunctionCustomizationTemplate', 'exSlowFunction');
coder.mapping.defaults.set('rtwdemo_configdefaults', 'Execution',...   'FunctionCustomizationTemplate', 'exFastFunction');
```

**Verify Default Mappings**

Verify default mappings with calls to `coder.mapping.defaults.get`.

```matlab
coder.mapping.defaults.get('rtwdemo_configdefaults', 'Inports', 'StorageClass')
anst =
   'ImportFromFile'
coder.mapping.defaults.get('rtwdemo_configdefaults', 'Inports', 'HeaderFile')
ans = 'exInDataLut.h'
coder.mapping.defaults.get('rtwdemo_configdefaults', 'Outports', 'StorageClass')
ans = 'ExportToFile'
coder.mapping.defaults.get('rtwdemo_configdefaults', 'Outports', 'HeaderFile')
ans = 'exSysOut.h'
coder.mapping.defaults.get('rtwdemo_configdefaults', 'Outports', 'DefinitionFile')
ans = 'exSysOut.c'
coder.mapping.defaults.get('rtwdemo_configdefaults', 'LocalParameters',... 'StorageClass')
ans = 'ExportedGlobal'
coder.mapping.defaults.get('rtwdemo_configdefaults', 'InternalData',... 'MemorySection')
ans = 'internalDataMem'
coder.mapping.defaults.get('rtwdemo_configdefaults', 'InitializeTerminate',... 'FunctionCustomizationTemplate')
ans = 'exSlowFunction'
coder.mapping.defaults.get('rtwdemo_configdefaults', 'Execution',... 'FunctionCustomizationTemplate')
ans = 'exFastFunction'

**Override Header File Setting**

Override the header file setting for input signal `ex_input1`. Previously, you set the default header file for data in the `Inports` category to `exInDataLut.h`. The
requirements specify that you import data for that signal from header file 
exInDataMem.h.

Create a handle to the output port of block In1.

```matlab
portHandles = get_param('rtwdemo_configdefaults/In1', 'PortHandles');
outH = portHandles.Outport;
```

In the base workspace, create a temporary signal object.

```matlab
temp_Obj = Simulink.Signal
```

```matlab
temp_Obj =
   Signal with properties:
     CoderInfo: [1x1 Simulink.CoderInfo]
       Description: ''
       DataType: 'auto'
         Min: []
         Max: []
        Unit: ''
     Dimensions: -1
     DimensionsMode: 'auto'
       Complexity: 'auto'
      SampleTime: -1
     InitialValue: ''
```

In the nested Simulink.CoderInfo object, set the StorageClass property to CIn step 3, youustom. Then, use the CustomStorageClass property to specify the storage class ImportFromFile.

```matlab
temp_Obj.CoderInfo.StorageClass = 'Custom';
temp_Obj.CoderInfo.CustomStorageClass = 'ImportFromFile';
```

Define the instance-specific header file, exDataInMem.h, in the nested Simulink.CoderInfo object by using the CustomAttributes property.

```matlab
temp_Obj.CoderInfo.CustomAttributes.HeaderFile= 'exInDataMem.h';
```

Embed the signal object in the target signal line by attaching a copy of the temporary workspace object.

```matlab
set_param(outH, 'SignalObject', temp_Obj);
```
Clear the object from the base workspace. The signal now uses an embedded copy of the object.

clear tempObj

Unresolved Storage Classes, Function Customization Templates, and Memory Sections

If someone removes the definition for a storage class, function customization template, or memory section from the Embedded Coder Dictionary associated with a model, the Code Mapping Editor identifies the definition as Unresolved. For example, this figure shows that the function customization template for execution entry-point functions was removed from the dictionary associated with the model.

To fix the unresolved code definition, do one of the following:

• In the second column of the Code Mapping Editor, select a different definition from the Storage Classes, Function Customization Templates, or Memory Sections list.
• Replace or add an appropriate definition to the Embedded Coder Dictionary. Then, update the mapping.
• Consult with someone else, such as the system architect for your project, about adding an appropriate definition to the Embedded Coder Dictionary. Then, update the mapping.

Elimination of Parameters and Other Internal Data by Optimizations

Code generation optimizations can eliminate data from the code, which means your application code cannot interact with the data. For general information about data elimination by optimizations, see “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 22-50.

The optimizations can eliminate data in these categories:

• Global parameters
• Local parameters
• Internal data

The optimizations cannot eliminate:

• Data in other categories.
• Data that the code needs for numeric accuracy, including most block states, which are in the Internal data category.

After eliminating data with optimizations, the code generator applies the default code generation settings in the Code Mapping Editor to the remaining data. For parameters and signal lines, optimizations can eliminate data for an entire category. If this happens, default settings that you specify for that category do not apply to data.

To prevent optimizations from eliminating individual data elements, explicitly apply a storage class to the element by using the Model Data Editor. The storage class controls the appearance of the data in the generated code. To force a data element to use the default storage class that you specify in the Code Mapping Editor, explicitly apply the storage class Model default. See “Choose a Storage Class for Controlling Data Representation in the Generated Code” on page 22-69.
Limitations

- For a referenced model, map data element categories **Inports** and **Outports** to Default, a built-in storage class other than ParamStruct or SignalStruct, or a package storage class.
- For these categories, use the built-in storage class SignalStruct or create your own structured storage class in an Embedded Coder Dictionary.
  - **Inport**
  - **Outport**
  - **Internal data**
- For these categories, set up default mappings to a storage class defined with property **Const** selected or property **Data Initialization** set to Dynamic or None:
  - **Inports**
  - **Outports**
  - Data store categories
  - **Internal data**
- Map parameter categories to storage classes defined with the **Data Initialization** property set to Static or None.
- Map categories **Inport**, **Outport**, and **Internal data**, where at least one data element in the category is specified with symbolic dimensions (see “Define Variable-Size Data for Code Generation” (Simulink)), to a storage class defined with the **Data Scope** property set to Imported.
- Map data element categories **Global parameters** and **Global data stores** to Default, a built-in storage class other than ParamStruct or SignalStruct, or a package storage class.
- If a model includes a reusable subsystem (subsystem with block parameter **Function packaging** set to Reusable function) that contains a shared local data store, map the category **Shared local data stores** to a storage class that is defined in the Embedded Coder Dictionary for that model. For more information, see “Generate Reentrant Code from Subsystems” on page 6-42.
- For top and referenced models configured for multi-instance usage (see “Generate Reentrant Code from Top Models” on page 6-24 and “Generate Reentrant Code from Simulink Function Blocks” on page 6-30), map data element categories to storage classes that have the **Storage Type** property set to **Structured**.
• If a model uses data object alignment, do not configure default data mappings for the model. For more information, see Simulink.CoderInfo.

• If you configure a model with a code replacement library that includes a data alignment specification, you cannot configure default code mappings that involve storage classes defined in an Embedded Coder Dictionary. For more information, see “Data Alignment for Code Replacement” on page 54-136.

• When evaluating storage class settings for variant control variables, the code generator ignores default mappings. For more information, see “Represent Subsystem and Model Variants in Generated Code” on page 15-23.

• Default mappings for global data categories must be the same across model reference hierarchies.

• You cannot set up default mappings to:

  • Structure-based built-in storage classes, Struct and BitField
  • Package storage classes of type FlatStructure or Other (requires you to write TLC code), which you create with the Custom Storage Class Designer

• When a model is configured for compact file packaging, you cannot map a data element category to a storage class defined with the Data Scope property set to Exported and the Header File property set to a naming rule other than $N.h.

• Storage classes defined in an Embedded Coder Dictionary are not compatible with models that contain nonreusable subsystems with separate data or are configured to generate a C++ class interface.

• If a model contains a tunable, nonfinite parameter (for example, with a value of inf):

  • If you specify the nonfinite value directly in the model, without using a MATLAB variable or parameter object (such as Simulink.Parameter), in the generated code, the parameter appears as a field of the default parameter data structure (see “Standard Data Structures in the Generated Code” on page 22-26). The parameter does not use the storage class that you specify for the corresponding category of parameter data in the Code Mapping Editor.

  • If you store the nonfinite value in a variable or parameter object, for the corresponding category of parameter data in the Code Mapping Editor, you cannot use a storage class that you create in an Embedded Coder Dictionary. When you try to generate code, the model generates an error. Choose one of these workarounds:
• Apply a storage class other than `Auto` or `Model default` directly to the nonfinite parameter as described in “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 22-81.

• If only one block uses the variable or object, instead of using the variable or object, specify the nonfinite value directly in the model, in the block parameter.

Configure Data Accessibility for Rapid Prototyping

As you iteratively develop a model, you capture the values of signals and states that model execution generates. You also tune parameter values during execution to observe the effect on the signals and states. You can then base your design decisions upon analysis of these outputs. To access signal, state, and parameter data in a rapid prototyping environment, you can configure the generated code to store the data in addressable memory.

Depending on the system target file that you use (such as `grt.tlc`), by default, optimization settings can make the generated code more efficient by:

- Eliminating unnecessary global and local storage for signals and some states.
  
  However, the optimizations do not eliminate storage for root-level Inport and Outport blocks, which represent the primary inputs and outputs of a system. To access this data, you do not need to take optimizations into consideration.

- Inlining the numeric values of block parameters. The code does not store the parameters in memory, so you cannot interact with the parameters during code execution.

To generate code that instead allocates addressable memory for this data, you can disable the optimizations, or override the optimizations by specifying code generation settings for individual data items.

Access Signal, State, and Parameter Data During Execution

For an example that shows how to configure data accessibility for rapid prototyping, see “Access Signal, State, and Parameter Data During Execution” on page 22-7.
## Configure Data Accessibility

<table>
<thead>
<tr>
<th>Goal</th>
<th>Considerations and More Information</th>
</tr>

<tbody>
<tr>
<td>Configure signals as accessible and parameters as tunable by default</td>
<td>Clear the model configuration parameter <strong>Signal storage reuse</strong> and set the configuration parameter <strong>Default parameter behavior</strong> to Tunable. These settings prevent the elimination of storage for signals and prevent parameter inlining. Each block parameter and signal line appears in the generated code as a field of a structure. For more information about these data structures, see “How Generated Code Exchanges Data with an Environment” on page 22-33 and “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 22-50. For more information about <strong>Default parameter behavior</strong>, see “Default parameter behavior” (Simulink Coder). For more information about optimizations that eliminate storage for signals, see “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 22-50 and “Minimize Computations and Storage for Intermediate Results at Block Outputs” (Simulink Coder).</td>
</tr>
</tbody>
</table>
| Preserve accessibility and tunability of a data item after you select optimizations | You can generate more efficient code by selecting optimizations such as **Signal storage reuse**, but the code generator eliminates storage for as many data items as possible. To exclude individual data items from the optimizations:  
  - Configure a signal as a test point (see “Configure Signals as Test Points” (Simulink)) or apply a storage class such as **ExportedGlobal** to the signal (see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 22-81). If you use test points, when you later configure the model for efficient production code, you can subject all of the test-point signals to optimizations by selecting the model configuration parameter **Ignore test point signals**. Apply a storage class only when you need to control the representation of the signal in the code.  
  - Apply a storage class, such as **ExportedGlobal**, to states and parameters. See “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 22-81. |

Access Signal, State, and Parameter Data During Execution

As you iteratively develop a model, you capture output signal and state data that model execution generates. You also tune parameter values during execution to observe the effect on the outputs. You can then base your design decisions upon analysis of these outputs. To access this signal, state, and parameter data in a rapid prototyping environment, you can configure the generated code to store the data in addressable memory.

By default, optimization settings make the generated code more efficient by eliminating unnecessary signal storage and inlining the numeric values of block parameters. To generate code that instead allocates addressable memory for this data, you can disable the optimizations or specify code generation settings for individual data items.

**Explore Example Model**

Run a script that prepares the model `rtwdemo_basicsc` for this example.

```
run(fullfile(matlabroot,'examples','simulinkcoder','main','prepare_rtwdemo_basicsc'));
```

Open the example model, `rtwdemo_basicsc`.

```
rtwdemo_basicsc
```
The model loads numeric MATLAB variables into the base workspace. The workspace variables set some block parameters in the model. However, The Gain block in the model uses the literal value 2.

**Disable Optimizations**

In the model, clear the model configuration parameter **Signal storage reuse**. When you clear this optimization and other optimizations such as **Eliminate superfluous local variables (expression folding)**, the generated code allocates memory for signal lines. Clearing **Signal storage reuse** disables most of the other optimizations.

```matlab
set_param('rtwdemo_basicsc','OptimizeBlockIOStorage','off')
```

Set the optimization **Configuration Parameters > Optimization > Default parameter behavior** to Tunable. When set to Tunable, this configuration parameter causes the generated code to allocate memory for block parameters and workspace variables.

```matlab
set_param('rtwdemo_basicsc','DefaultParameterBehavior','Tunable')
```

Generate code from the model.
rtwbuild('rtwdemo_basicsc')

### Starting build procedure for model: rtwdemo_basicsc
### Successful completion of build procedure for model: rtwdemo_basicsc

In the code generation report, view the file `rtwdemo_basicsc.h`. This header file defines a structure type that contains signal data. The structure contains fields that each represent a signal line in the model. For example, the output signal of the Gain block, whose name is Gain, appears as the field Gain.

```c
file = fullfile('rtwdemo_basicsc_grt_rtw','rtwdemo_basicsc.h');
rtwdemodbtype(file,'/* Block signals (default storage) */', 'B_rtwdemo_basicsc_T;',1,1)
/* Block signals (default storage) */
typedef struct {
    real32_T Table1;                /* '<Root>/Table1' */
    real32_T Gain;                  /* '<Root>/Gain' */
    real32_T Delay;                 /* '<Root>/Delay' */
    real32_T Table2;                /* '<Root>/Table2' */
    boolean_T RelOp1;               /* '<Root>/RelOp1' */
    boolean_T RelOp2;               /* '<Root>/RelOp2' */
    boolean_T LogOp;                /* '<Root>/LogOp' */
} B_rtwdemo_basicsc_T;
```

The file defines a structure type that contains block parameter data. For example, the **Gain** parameter of the Gain block appears as the field **Gain_Gain**. The other fields of the structure represent other block parameters and workspace variables from the model, including initial conditions for signals and states.

```c
rtwdemodbtype(file,'/* Parameters (default storage) */', ' /* Real-time Model Data Structure */',1,0)
/* Parameters (default storage) */
struct P_rtwdemo_basicsc_T_ {
    real_T K2;                        /* Variable: K2
        * Referenced by: '<Root>/Stateflow Chart'
        */

    real32_T LOWER;                   /* Variable: LOWER
        * Referenced by: '<Root>/Constant2'
        */

    real32_T T1Break[11];            /* Variable: T1Break
        * Referenced by: '<Root>/Table1'
        */
} P_rtwdemo_basicsc_T;
```
real32_T T1Data[11];                 /* Variable: T1Data
   * Referenced by: '<Root>/Table1'
   */
real32_T T2Break[3];                 /* Variable: T2Break
   * Referenced by: '<Root>/Table2'
   */
real32_T T2Data[9];                  /* Variable: T2Data
   * Referenced by: '<Root>/Table2'
   */
real32_T UPPER;                      /* Variable: UPPER
   * Referenced by: '<Root>/Constant1'
   */
real32_T Gain_Gain;                  /* Computed Parameter: Gain_Gain
   * Referenced by: '<Root>/Gain'
   */
real32_T Delay_InitialCondition;     /* Computed Parameter: Delay_InitialCondition
   * Referenced by: '<Root>/Delay'
   */
uint32_T Table2_maxIndex[2];         /* Computed Parameter: Table2_maxIndex
   * Referenced by: '<Root>/Table2'
   */
boolean_T DataStoreMemory_InitialValue;/* Computed Parameter: DataStoreMemory_InitialValue
   * Referenced by: '<Root>/Data Store Memory'
   */
}

View the file rtwdemo_basicsc_data.c. This source file allocates global memory for a parameter structure and initializes the field values based on the parameter values in the model.

View the source file rtwdemo_basicsc.c. The code allocates global memory for a structure variable that contains signal data.

```c
file = fullfile('rtwdemo_basicsc_grt_rtw','rtwdemo_basicsc.c');
rtwdemodbtype(file,'/* Block signals (default storage) */','...
   'B_rtwdemo_basicsc_T rtwdemo_basicsc_B;',1,1)

/* Block signals (default storage) */
B_rtwdemo_basicsc_T rtwdemo_basicsc_B;
```

The code algorithm in the model step function calculates the signal values. It then assigns these values to the fields of the signal structure. To perform the calculations, the algorithm uses the parameter values from the fields of the parameter structure.
Exclude Data Items from Optimizations

When you want to select code generation optimizations such as **Signal storage reuse**, you can preserve individual data items from the optimizations. The generated code then allocates addressable memory for the items.

Select the optimizations that you previously cleared.

```matlab
set_param('rtwdemo_basicsc','OptimizeBlockIOStorage','on')
set_param('rtwdemo_basicsc','LocalBlockOutputs','on')
set_param('rtwdemo_basicsc','DefaultParameterBehavior','Inlined')
```

In the model, select **View > Model Data Editor**.

In the Model Data Editor, inspect the **Signals** tab.

Set the **Change view** drop-down list to **Instrumentation**.

In the model, select the output signal of the Gain block.

In the Model Data Editor, select the check box in the **Test Point** column.

```matlab
portHandle = get_param('rtwdemo_basicsc/Gain','PortHandles');
portHandle = portHandle.Outport;
set_param(portHandle,'TestPoint','on')
```

Inspect the **Parameters** tab.

In the model, select the Gain block.

In the Model Data Editor, use the **Value** column to set the gain value to **K1**.

Next to **K1**, click the action button (with three vertical dots) and select **Create**.

In the Create New Data dialog box, set **Value** to `Simulink.Parameter(2)` and click **Create**. A `Simulink.Parameter` object named **K1**, with value 2, appears in the base workspace.

In the property dialog box for **K1**, apply a storage class other than **Auto** by using **Storage class**. For example, use the storage class **Model default** to represent the parameter object as a field of the global parameters structure.
set_param('rtwdemo_basicsc/Gain','Gain','K1');
K1 = Simulink.Parameter(2);
K1.StorageClass = 'Model default';

Generate code from the model.

rtwbuild('rtwdemo_basicsc')

### Starting build procedure for model: rtwdemo_basicsc
### Successful completion of build procedure for model: rtwdemo_basicsc

In the code generation report, view the file rtwdemo_basicsc.h. The structure that contains signal data now defines only one field, Gain, which represents the test-pointed output of the Gain block.

file = fullfile('rtwdemo_basicsc_grt_rtw','rtwdemo_basicsc.h');
rtwdemodbtype(file,'/* Block signals (default storage) */',
'Module signals (default storage) *',1,1)

/* Block signals (default storage) */
typedef struct {
    real32_T Gain;                       /* '<Root>/Gain' */
} B_rtwdemo_basicsc_T;

The structure that contains block parameter data defines one field, K1, which represents the parameter object K1.

rtwdemodbtype(file,'/* Parameters (default storage) */',
'/* Real-time Model Data Structure */',1,0)

/* Parameters (default storage) */
struct P_rtwdemo_basicsc_T {
    real32_T K1;                         /* Variable: K1
                                 * Referenced by: '<Root>/Gain'
    */
};

**Access Data Through Generated Interfaces**

You can configure the generated code to contain extra code and files so that you can access model data through standardized interfaces. For example, use the C API to log signal data and tune parameters during execution.

Copy this custom source code into a file named ex_myHandCode.c in your current folder.
#include "ex_myHandHdr.h"

#define paramIdx 0 /* Index of the target parameter, determined by inspecting the array of structures generated by the C API. */
#define sigIdx 0 /* Index of the target signal, determined by inspecting the array of structures generated by the C API. */

void tuneFcn(rtwCAPI_ModelMappingInfo *mmi, time_T *tPtr)
{
    /* Take action with the parameter value only at the beginning of simulation and at the 5-second mark. */
    if (*tPtr == 0 || *tPtr == 5) {

        /* Local variables to store information extracted from the model mapping information (mmi). */
        void** dataAddrMap;
        const rtwCAPI_DataTypeMap *dataTypeMap;
        const rtwCAPI_ModelParameters *params;
        int_T addrIdx;
        uint16_T dTypeIdx;
        uint8_T slDataType;

        /* Use built-in C API macros to extract information. */
        dataAddrMap = rtwCAPI_GetDataAddressMap(mmi);
        dataTypeMap = rtwCAPI_GetDataTypeMap(mmi);
        params = rtwCAPI_GetModelParameters(mmi);
        addrIdx = rtwCAPI_GetModelParameterAddrIdx(params, paramIdx);
        dTypeIdx = rtwCAPI_GetModelParameterDataTypeIdx(params, paramIdx);
        slDataType = rtwCAPI_GetDataTypeSLId(dataTypeMap, dTypeIdx);

        /* Handle data types 'double' and 'int8'. */
        switch (slDataType) {
            case SS_DOUBLE: {
                real_T* dataAddress;
                dataAddress = dataAddrMap[addrIdx];
                /* At the 5-second mark, increment the parameter value by 1. */
                if (*tPtr == 5) {
                    (*dataAddress)++;
                }
                printf("Parameter value is \%f\n", *dataAddress);
                break;
            }
        }
    }
}
case SS_INT8: {
    int8_T* dataAddress;
dataAddress = dataAddrMap[addrIdx];
    if (*tPtr == 5) {
        (*dataAddress)++;
    }
    printf("Parameter value is %i\n", *dataAddress);
    break;
}
}

void logFcn(rtwCAPI_ModelMappingInfo *mmi, time_T *tPtr)
{
    /* Take action with the signal value only when 
    the simulation time is an integer value. */
    if (*tPtr-(int_T)*tPtr == 0) {

        /* Local variables to store information extracted from 
        the model mapping information (mmi). */
        void** dataAddrMap;
        const rtwCAPI_DataTypeMap *dataTypeMap;
        const rtwCAPI_Signals *sigs;
        int_T addrIdx;
        uint16_T dTypeIdx;
        uint8_T slDataType;

        /* Use built-in C API macros to extract information. */
        dataAddrMap = rtwCAPI_GetDataAddressMap(mmi);
        dataTypeMap = rtwCAPI_GetDataTypeMap(mmi);
        sigs = rtwCAPI_GetSignals(mmi);
        addrIdx = rtwCAPI_GetSignalAddrIdx(sigs,sigIdx);
        dTypeIdx =  rtwCAPI_GetSignalDataTypeIdx(sigs,sigIdx);
        slDataType = rtwCAPI_GetDataTypeSLId(dataTypeMap, dTypeIdx);

        /* Handle data types 'double' and 'single'. */
        switch (slDataType) {
            case SS_DOUBLE: {
                real_T* dataAddress;
dataAddress = dataAddrMap[addrIdx];
                printf("Signal value is %f\n", *dataAddress);
            } 
        }
    }
break;
}

case SS_SINGLE: {
    real32_T* dataAddress;
    dataAddress = dataAddrMap[addrIdx];
    printf("Signal value is %f\n", *dataAddress);
    break;
}
}

Copy this custom header code into a file named `ex_myHandHdr.h` in your current folder.

```c
#include <stdio.h>
#include <string.h>
#include <math.h>
/* Include rtw_modelmap.h for definitions of C API macros. */
#include "rtw_modelmap.h"
#include "builtin_typeid_types.h"
#include "rtwtypes.h"
void tuneFcn(rtwCAPI_ModelMappingInfo *mmi, time_T *tPtr);
void logFcn(rtwCAPI_ModelMappingInfo *mmi, time_T *tPtr);
```

These files use the C API to access signal and parameter data in the code that you generate from the example model.

In the model, set **Configuration Parameters > Code Generation > Custom Code > Insert custom C code in generated > Header file** to `#include "ex_myHandHdr.h"`. In the same pane in the Configuration Parameters dialog box, set **Additional Build Information > Source files** to `ex_myHandCode.c`.

```matlab
set_param('rtwdemo_basicsc','CustomHeaderCode','#include "ex_myHandHdr.h"
set_param('rtwdemo_basicsc','CustomSource','ex_myHandCode.c')
```

Select **Configuration Parameters > MAT-file Logging**. The generated executable runs only until the simulation stop time (which you set in the model configuration parameters).

```matlab
set_param('rtwdemo_basicsc','MatFileLogging','on')
```

Select all of the options under **Configuration Parameters > Code Generation > Interface > Generate C API for**.
set_param('rtwdemo_basicsc','RTWCAPIParams','on')
set_param('rtwdemo_basicsc','RTWCAPISignals','on')
set_param('rtwdemo_basicsc','RTWCAPIStates','on')
set_param('rtwdemo_basicsc','RTWCAPIRootIO','on')

Load the Custom Code block library.

custcode

Add a System Outputs block to the model.

add_block('custcode/System Outputs','rtwdemo_basicsc/System Outputs')

In the System Outputs block dialog box, set **System Outputs Function Execution Code** to this code:

```
{ 
  rtwdemo_basicsc_U.input2++;
  rtwCAPI_ModelMappingInfo *MMI = &(rtmGetDataMapInfo(rtwdemo_basicsc_M).mmi);
  tuneFcn(MMI, rtmGetTPtr(rtwdemo_basicsc_M));
}
```

In the block dialog box, set **System Outputs Function Exit Code** to this code:
Alternatively, to configure the System Outputs block, at the command prompt, use these commands:

```matlab
temp.TLCFile = 'custcode';
temp.Location = 'System Outputs Function';
temp.Middle = sprintf(['{
rtwdemo_basicsc_U.input2++;'
    '\nrtwCAPI_ModelMappingInfo *MMI = &
    '(rtmGetDataMapInfo(rtwdemo_basicsc_M).mmi);
    '\ntuneFcn(MMI, rtmGetTPtr(rtwdemo_basicsc_M));
}']);
temp.Bottom = sprintf(['{
rtwCAPI_ModelMappingInfo *MMI = &
    '(rtmGetDataMapInfo(rtwdemo_basicsc_M).mmi);
    '\nlogFcn(MMI, rtmGetTPtr(rtwdemo_basicsc_M));
}']);
set_param('rtwdemo_basicsc/System Outputs','RTWdata',temp)
```

Generate code from the model.

```matlab
rtwbuild('rtwdemo_basicsc')
```

### Starting build procedure for model: rtwdemo_basicsc
### Successful completion of build procedure for model: rtwdemo_basicsc

In the code generation report, view the interface file `rtwdemo_basicsc_capi.c`. This file initializes the arrays of structures that you can use to interact with data items through the C API. For example, in the array of structures `rtBlockSignals`, the first structure (index 0) describes the test-pointed output signal of the Gain block in the model.

```c
/* Block output signal information */
static const rtwCAPI_Signals rtBlockSignals[] = {
    /* addrMapIndex, sysNum, blockPath, */
    * signalName, portNumber, dataTypeIndex, dimIndex, fxpIndex, sTimeIndex
    *
    { 0, 0, TARGET_STRING("rtwdemo_basicsc/Gain"),
        TARGET_STRING(""), 0, 0, 0, 0 },

    { 0, 0, TARGET_STRING(""), 0, 0, 0, 0, 0 },

    /* Individual block tuning */
    1, 0)
```
The fields of the structure, such as `addrMapIndex`, indicate indices into other arrays of structures, such as `rtDataAddrMap`, that describe the characteristics of the signal. These characteristics include the address of the signal data (a pointer to the data), the numeric data type, and the dimensions of the signal.

In the file `rtwdemo_basicsc.c`, view the code algorithm in the model `step` function. The algorithm first executes the code that you specified in the System Outputs block.

```c
file = fullfile('rtwdemo_basicsc_grt_rtw','rtwdemo_basicsc.c');
rtdemodbtype(file,'/* user code (Output function Body) */',...'/* Logic: ''<Root>/LogOp'' incorporates:',1,0)

/* user code (Output function Body) */

/* System '<Root>' */
{
    rtwdemo_basicsc_U.input2++;  
    rtwCAPI_ModelMappingInfo *MMI = &(rtmGetDataMapInfo(rtwdemo_basicsc_M).mmi);
    tuneFcn(MMI, rtmGetTPtr(rtwdemo_basicsc_M));
}

/* DataStoreWrite: '<Root>/DSWrite' incorporates:
 * Constant: '<Root>/Constant1'
 * Constant: '<Root>/Constant2'
 * Inport: '<Root>/In1'
 * Logic: '<Root>/LogOp'
 * RelationalOperator: '<Root>/RelOp1'
 * RelationalOperator: '<Root>/RelOp2'
 */
rtwdemo_basicsc_DW.mode = ((rtwdemo_basicsc_U.input1 > 10.0F) ||
                          (rtwdemo_basicsc_U.input1 < -10.0F));

/* Gain: '<Root>/Gain' incorporates:

/* Start for DataStoreMemory: '<Root>/Data Store Memory' */
rtwdemo_basicsc_DW.mode = false;
This code first perturbs the input signal input2 by incrementing the value of the signal each time the step function executes. The code then uses the built-in macro rtmGetDataMapInfo to extract model mapping information from the model data structure rtwdemo_basicsc_M. The pointer MMI points to the extracted mapping information, which allows the functions tuneFcn and logFcn to access the information contained in the arrays of structures that the C API file rtwdemo_basicsc_capi.c defines.

View the function tuneFcn in the file ex_myHandCode.c. This function uses the C API (through the model mapping information mmi) and a pointer to the simulation time to print the value of the parameter K1 at specific times during code execution. When the simulation time reaches 5 seconds, the function changes the parameter value in memory. By using a switch case block, the function can access the parameter data whether the data type is int8 or double.

View the code algorithm in the model step function again. Near the end of the function, the algorithm executes the code that you specified in the System Outputs block. This code calls the function logFcnc.

rtwdemodbtype(file,'/* user code (Output function Trailer) */','/* Matfile logging */',1,0)

/* user code (Output function Trailer) */

/* System '<Root>' */
{
    rtwCAPI_ModelMappingInfo *MMI = &(rtmGetDataMapInfo(rtwdemo_basicsc_M).mmi);
    logFcn(MMI, rtmGetTPtr(rtwdemo_basicsc_M));
}

View the function logFcn in the file ex_myHandCode.c. The function uses the C API to print the value of the test-pointed signal. The function can access the signal data whether the data type is single or double.
At the command prompt, run the generated executable `rtwdemo_bascisc.exe`.

```matlab
system('rtwdemo_basicsc')
```

The parameter and signal values appear in the Command Window output.

For more information about data interfaces, including the C API, see “Data Exchange Interfaces” (Simulink Coder).

Standard Data Structures in the Generated Code

By default, signal lines, block parameters, states, and other model data appear in the generated code as fields of standard structures. For general information, see “How Generated Code Stores Internal Signal, State, and Parameter Data” (Simulink Coder).

The table shows some common data structures in the generated code. The name of the structure type and, if applicable, structure variable in the code that you generate from a model depends on the model settings. Regardless of the settings, the name of the structure type in the code contains the short name from the Short Name of Structure Type column in the table.

For additional structures, see “System-generated identifiers” (Simulink Coder).

You can exclude data from appearing in these structures by using:

- Direct application of storage classes. For example, you can use storage classes to represent signals, tunable parameters, and states as individual global variables. For more information, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 22-81.

- Configuration parameters, such as those on the Optimization pane in the Configuration Parameters dialog box. You can adjust these configuration parameters to control the default representation of data. For more information, see “Optimization Pane” (Simulink Coder).
Control Characteristics of Data Structures (Embedded Coder)

To control the characteristics of the standard data structures, use the information in the table.

Use the Real-Time Model Data Structure

The code generator uses the real-time model (RT_MODEL) data structure. This structure is also referred to as the rtModel data structure. You can access rtModel data by using a set of macros analogous to the ssSetxxx and ssGetxxx macros that S-functions use to access SimStruct data, including noninlined S-functions compiled by the code generator.

You need to use the set of macros rtmGetxxx and rtmSetxxx to access the real-time model data structure. The rtModel is an optimized data structure that replaces SimStruct as the top level data structure for a model. The rtmGetxxx and rtmSetxxx macros are used in the generated code as well as from the main.c or main.cpp module. If you are customizing main.c or main.cpp (either a static file or a generated file), you need to use rtmGetxxx and rtmSetxxx instead of the ssSetxxx and ssGetxxx macros.

Usage of rtmGetxxx and rtmSetxxx macros is the same as for the ssSetxxx and ssGetxxx versions, except that you replace SimStruct S by real-time model data structure rtM. The following table lists rtmGetxxx and rtmSetxxx macros that are used in grt_main.c and grt_main.cpp.
## Macros for Accessing the Real-Time Model Data Structure

How Generated Code Exchanges Data with an Environment

To use the code that you generate from a model, you call the generated entry-point functions such as `step` and `initialize`. The environment in which you call these functions must provide input signal data and, depending on your application, scheduling information. The generated algorithm then calculates output data that the calling environment can use. The environment and the algorithm can exchange this data through global variables or through formal parameters (arguments).

The set of input and output data and the exchange mechanisms constitute the interfaces of the entry-point functions. When you understand the default interfaces and how to control them, you can:

- Write code that calls the generated code.
- Generate reusable (reentrant) code that you can call multiple times in a single application.
- Integrate the generated code with other, external code in your application.

In a model, root-level Inport and Outport blocks represent the primary inputs and outputs of the block algorithm. By default, the code generator aggregates these blocks into standard structures that store input and output data.

For information about how the generated code stores internal data, which does not participate in the model interface, see “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 22-50.

Data Interfaces in the Generated Code

This example shows how the generated code exchanges data with an environment.

Explore Example Model

Open the example model `rtwdemo_roll`.

```plaintext
open_system('rtwdemo_roll')
```
At the root level, the model has a number of Inport blocks and one Outport block.

In the model, set Configuration Parameters > Code Generation > System target file to grt.tlc.

set_param('rtwdemo_roll','SystemTargetFile','grt.tlc')

Inspect the setting for Configuration Parameters > Code Generation > Interface > Code interface packaging. The setting Nonreusable function means that the generated code is not reusable (not reentrant).

For this example, to generate simpler code, clear the Configuration Parameters > Code Generation > Interface > Advanced parameters > Mat-file logging.

set_param('rtwdemo_roll','MatFileLogging','off')

**Generate Nonreusable Code**

Generate code from the model.

rtwbuild('rtwdemo_roll')

### Starting build procedure for model: rtwdemo_roll
### Successful completion of build procedure for model: rtwdemo_roll
Inspect the file `rtwdemo_roll.h`. The file defines a structure type that represents input data and a type that represents output data.

```c
file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.h');
rtwdemodbtype(file,'/* External inputs (root inport signals with default storage) */',...}' ExtY_rtwdemo_roll_T;',1,1)

typedef struct {
    real32_T Phi;                        /* '<Root>/Phi' */
    real32_T Psi;                        /* '<Root>/Psi' */
    real32_T Rate_FB;                    /* '<Root>/Rate_FB' */
    real32_T TAS;                        /* '<Root>/TAS' */
    boolean_T AP_Eng;                    /* '<Root>/AP_Eng' */
    boolean_T HDG_Mode;                  /* '<Root>/HDG_Mode' */
    real32_T HDG_Ref;                    /* '<Root>/HDG_Ref' */
    real32_T Turn_Knob;                  /* '<Root>/Turn_Knob' */
} ExtU_rtwdemo_roll_T;

typedef struct {
    real32_T Ail_Cmd;                    /* '<Root>/Ail_Cmd' */
} ExtY_rtwdemo_roll_T;
```

Each field corresponds to an Inport or Outport block at the root level of the model. The name of each field derives from the name of the block.

The file also defines a structure type, the real-time model data structure, whose single field stores a run-time indication of whether the generated code has encountered an error during execution.

```c
rtwdemodbtype(file,'/* Real-time Model Data Structure */',...}' /* Block states (default storage) */',1,0)

/* Real-time Model Data Structure */
struct tag_RTM_rtwdemo_roll_T {
    const char_T *errorStatus;
};
```

When you modify model configuration parameters to suit your application, this structure can also contain other data that pertain to the entire model, such as scheduling information.
For the structure type that represents the real-time model data structure, the file \texttt{rtwdemo_roll_types.h} creates an alias (\texttt{typedef}) that the generated code later uses to allocate memory for the structure.

\begin{verbatim}
file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll_types.h');
rtwdemodbtype(file,'/* Forward declaration for rtModel */',...
     'RT_MODEL_rtwdemo_roll_T;',1,1)

/* Forward declaration for rtModel */
typedef struct tag_RTM_rtwdemo_roll_T RT_MODEL_rtwdemo_roll_T;
\end{verbatim}

Using these structure types, the file \texttt{rtwdemo_roll.c} defines (allocates memory for) global structure variables that store input and output data for the generated algorithm. The file also defines variables that represent the real-time model data structure and a pointer to the structure.

\begin{verbatim}
file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.c');
rtwdemodbtype(file,...
   '/* External inputs (root inport signals with default storage) */',...
   '= &rtwdemo_roll_M_;',1,1)

/* External inputs (root inport signals with default storage) */
ExtU_rtwdemo_roll_T rtwdemo_roll_U;

/* External outputs (root outports fed by signals with default storage) */
ExtY_rtwdemo_roll_T rtwdemo_roll_Y;

/* Real-time model */
RT_MODEL_rtwdemo_roll_T rtwdemo_roll_M;
RT_MODEL_rtwdemo_roll_T *const rtwdemo_roll_M = &rtwdemo_roll_M;
\end{verbatim}

The file \texttt{rtwdemo_roll.h} declares these structure variables. Your external code can include (\texttt{#include}) this file, whose general name is \texttt{model.h} where \texttt{model} is the name of the model, to access data that participate in the model interface.

In \texttt{rtwdemo_roll.c}, the model step function, which represents the primary model algorithm, uses a \texttt{void} interface (with no arguments).

\begin{verbatim}
rtwdemodbtype(file,...
   '/* Model step function */','void rtwdemo_roll_step(void)',1,1)
\end{verbatim}
/* Model step function */
void rtwdemo_roll_step(void)

In the function definition, the algorithm reads input data and writes output data by
directly accessing the global structure variables. For example, near the end of the
algorithm, the code for the EngSwitch block reads the value of the AP_Eng field (which
represents an input) and, based on that value, conditionally writes a constant value to the
Ail_Cmd field (which represents an output).

rtwdemodbtype(file,'if (rtwdemo_roll_U.AP_Eng) {','    }',1,1)

if (rtwdemo_roll_U.AP_Eng) {
    /* Outputs for Atomic SubSystem: '<Root>/BasicRollMode' */
    /* Saturate: '<S1>/CmdLimit' */
    if (rtwdemo_roll_Y.Ail_Cmd > 15.0F) {
        /* Sum: '<S1>/Sum2' incorporates:
         *  Outport: '<Root>/Ail_Cmd'
        */
        rtwdemo_roll_Y.Ail_Cmd = 15.0F;
    } else {
        if (rtwdemo_roll_Y.Ail_Cmd < -15.0F) {
            /* Sum: '<S1>/Sum2' incorporates:
             *  Outport: '<Root>/Ail_Cmd'
            */
            rtwdemo_roll_Y.Ail_Cmd = -15.0F;
        }
    }
}

Due to the void interface and the direct data access, the function is not reentrant.
If you call the function multiple times in an application, each call reads and writes input
and output data to the same global structure variables, resulting in data corruption and
unintentional interaction between the calls.

The model initialization function, rtwdemo_roll_initialize, initializes all of the input
and output data to zero. The function also initializes the error status. The function directly
accesses the global variables, which means the function is not reentrant.

rtwdemodbtype(file,'/* Model initialize function */',...'
    'rtmSetErrorStatus(rtwdemo_roll_M, (NULL));',1,1)

/* Model initialize function */
void rtwdemo_roll_initialize(void)
{  
    /* Registration code */
    
    /* initialize error status */
    rtmSetErrorStatus(rtwdemo_roll_M, (NULL));

    rtwdemodbtype(file,' /* external inputs */','/* SystemInitialize for Atomic SubSystem:','1,0)

    /* external inputs */
    (void)memset((void *)&rtwdemo_roll_U, 0, sizeof(ExtU_rtwdemo_roll_T));

    /* external outputs */
    rtwdemo_roll_Y.Ail_Cmd = 0.0F;

**Generate Reusable Code**

You can configure the generated code as reentrant, which means that you can call the entry-point functions multiple times in an application. With this configuration, instead of directly accessing global variables, the entry-point functions exchange input, output, and other model data through formal parameters (pointer arguments). With these pointer arguments, each call can read inputs and write outputs to a set of separate global variables, preventing unintentional interaction between the calls.

In the model, set **Configuration Parameters > Code Generation > Interface > Code interface packaging** to **Reusable function**.

`set_param('rtwdemo_roll','CodeInterfacePackaging','Reusable function')`

Generate code from the model.

`rtwbuild('rtwdemo_roll')`

### Starting build procedure for model: rtwdemo_roll
### Successful completion of build procedure for model: rtwdemo_roll

Now, in `rtwdemo_roll.h`, the real-time model data structure contains pointers to the error indication, the input data, the output data, and additional data in the form of a DWork substructure (which stores, for example, block states such as the state of a Discrete-Time Integrator block).

`file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.h');
rtwdemodbtype(file,' /* Real-time Model Data Structure */','/* External data declarations for dependent source files */',1,0)`
/* Real-time Model Data Structure */
struct tag_RTM_rtwdemo_roll_T {
    const char_T *errorStatus;
    ExtU_rtwdemo_roll_T *inputs;
    ExtY_rtwdemo_roll_T *outputs;
    DW_rtwdemo_roll_T *dwork;
};

To call the generated code multiple times in an application, your code must allocate memory for a real-time model data structure per call. The file rtwdemo_roll.c defines a specialized function that allocates memory for a new real-time model data structure and returns a pointer to the structure. The function also allocates memory for the substructures that the fields in the model data structure point to, such as the input and output structures.

file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.c');
rtwedemodbtype(file,/* Model data allocation function */,...'
    'RT_MODEL_rtwdemo_roll_T *rtwdemo_roll(void)',1,1)

/* Model data allocation function */
RT_MODEL_rtwdemo_roll_T *rtwdemo_roll(void)

In rtwdemo_roll.c, the model step function accepts an argument that represents the real-time model data structure.

file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.c');
rtwedemodbtype(file,...'
    '/* Model step function */','void rtwdemo_roll_step',1,1)

/* Model step function */
void rtwdemo_roll_step(RT_MODEL_rtwdemo_roll_T *const rtwdemo_roll_M)

In the function definition, the algorithm first extracts each pointer from the real-time model data structure into a local variable.

rtwedemodbtype(file,...
    '*rtwdemo_roll_DW =','rtwdemo_roll_M->outputs;',1,1)

    DW_rtwdemo_roll_T *rtwdemo_roll_DW = ((DW_rtwdemo_roll_T *)
        rtwdemo_roll_M->dwork);
    ExtU_rtwdemo_roll_T *rtwdemo_roll_U = (ExtU_rtwdemo_roll_T *)
Then, to access the input and output data stored in global memory, the algorithm interacts with these local variables.

```c
rtwdemodbtype(file,'  if (rtwdemo_roll_U->AP_Eng) {',...
  /* End of Switch: ''<Root>/EngSwitch'' */',1,1)

if (rtwdemo_roll_U->AP_Eng) {
  /* Outputs for Atomic SubSystem: '<Root>/BasicRollMode' */
  /* Saturate: '<S1>/CmdLimit' */
  if (rtwdemo_roll_Y->Ail_Cmd > 15.0F) {
    /* Sum: '<S1>/Sum2' incorporates:
     *  Outport: '<Root>/Ail_Cmd'
    */
    rtwdemo_roll_Y->Ail_Cmd = 15.0F;
  } else {
    if (rtwdemo_roll_Y->Ail_Cmd < -15.0F) {
      /* Sum: '<S1>/Sum2' incorporates:
       *  Outport: '<Root>/Ail_Cmd'
      */
      rtwdemo_roll_Y->Ail_Cmd = -15.0F;
    }
  }
  /* End of Saturate: '<S1>/CmdLimit' */
  /* End of Outputs for SubSystem: '<Root>/BasicRollMode' */
} else {
  /* Sum: '<S1>/Sum2' incorporates:
   *  Constant: '<Root>/Zero'
   *  Outport: '<Root>/Ail_Cmd'
  */
  rtwdemo_roll_Y->Ail_Cmd = 0.0F;
}

/* End of Outputs for SubSystem: '<Root>/BasicRollMode' */
```

Similarly, the model initialization function accepts the real-time model data structure as an argument.

```c
rtwdemodbtype(file,...
  /* Model initialize function */','void rtwdemo_roll_initialize',1,1)
```

22-40
void rtwdemo_roll_initialize(RT_MODEL_rtwdemo_roll_T *const rtwdemo_roll_M)

Because each call that you make to an entry-point function interacts with a separate real-time model data structure, you avoid unintentional interaction between the calls.

**Configure Data Interface**

To control the characteristics of the data interface in the generated code, see “Control Data and Function Interface in Generated Code” on page 22-42.

**See Also**

**Related Examples**

- “Standard Data Structures in the Generated Code” on page 22-26
- “Use the Real-Time Model Data Structure” on page 22-29

- “Control Data and Function Interface in Generated Code” on page 22-42
- “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 22-50
Control Data and Function Interface in Generated Code

To use the code that you generate from a model, you call the generated entry-point functions such as `step` and `initialize`. The calling environment and the generated functions can exchange input and output data through global variables or through formal parameters (arguments). This data and the exchange mechanisms constitute the interfaces of the entry-point functions. For information about the default interfaces for reentrant and nonreentrant models in the generated code, see “How Generated Code Exchanges Data with an Environment” on page 22-33.

By controlling the interfaces that appear in the generated code, you can:

- Minimize the modifications that you must make to your existing code.
- Generate stable interfaces that do not change or minimally change when you make changes to the model.
- Generate code that exchanges data more efficiently (for example, by using pointers and pass-by-reference arguments for nonscalar data).

Control Type Names, Field Names, and Variable Names of Standard I/O Structures (Embedded Coder)

By default, for nonreentrant code, Inport blocks at the root level of the model appear in the generated code as fields of a global structure variable. Similarly, Outport blocks appear in a different structure. For reentrant code, depending on your setting for `Configuration Parameters > Code Generation > Interface > Pass root-level I/O as`, the code can also package input and output data into standard structures.

With Embedded Coder, you can control these names. See “Control Characteristics of Data Structures (Embedded Coder)” (Simulink Coder).

Control Names of Generated Entry-Point Functions (Embedded Coder)

To use the generated code, you write code that calls generated entry-point functions. For example, entry-point functions include `model_step`, `model_initialize`, and top-level functions generated from an export-function model. To control the names of the model entry-point functions, choose one or both of these techniques, which require Embedded Coder:
• Specify a default naming rule for categories of entry-point functions by applying function customization templates in the Code Mapping Tool. With this technique, the naming rule applies to all of the functions in each category. For more information, see “Configure Default Code Generation for Functions” on page 21-15.

• Apply function prototype control to individual functions. With this technique:
  • You can specify a literal name for a function, which overrides the default naming rule that you specify with a function customization template in the Code Mapping Editor.
  • You can control the names of only step functions, initialization functions, and Simulink functions.

You use different tools and dialog boxes to apply function prototype control based on the kind of target function. For more information, see “Control Generation of Function Interfaces” on page 53-2.

Control Data Interface for Nonreentrant Code

When you set Configuration Parameters > Code Generation > Interface > Code interface packaging to Nonreusable function (the default), the generated entry-point functions are not reentrant. Typically, the functions exchange data with the calling environment through direct access to global variables.

Configure Inport or Outport Block as Separate Global Variable

To remove the block from the standard I/O structures by creating a separate global variable, apply a storage class, such as ExportedGlobal or ExportToFile, to the signal that the block represents.

  • To specify a default storage class for Inport blocks and a different default for Outport blocks, use the Code Mapping Tool. As you add such blocks to the model, they acquire the storage class that you specify. You do not need to configure each individual block.

    For this technique, you must have Embedded Coder.

  • To override the default for an individual block, apply a different storage class by using other tools such as the Model Data Editor or the Property Inspector. See “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder).
For an example, see “Design Data Interface by Configuring Inport and Outport Blocks” (Simulink Coder). For general information about storage classes, see “Choose a Storage Class for Controlling Data Representation in the Generated Code” (Simulink Coder).

**Configure Generated Code to Read or Write to Global Variables Defined by External Code**

If your calling code already defines a global variable that you want the generated code to use as input data or use to store output data, you can reuse the variable by preventing the code generator from duplicating the definition. Apply a storage class to the corresponding Inport or Outport block in the model. Choose a storage class that specifies an imported data scope, such as `ImportedExtern` or `ImportFromFile`. For information about applying storage classes, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder) and “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 26-19.

**Package Multiple Inputs or Outputs into Custom Structure**

You can configure a single Inport or Outport block to appear in the generated code as a custom structure that contains multiple input or output signals. You can also configure the block to appear as a substructure of the default I/O structures or as a separate structure variable.

Configure the block as a nonvirtual bus by using a `Simulink.Bus` object as the data type of the block. If your external code defines the structure type, consider using the `Simulink.importExternalCTypes` function to generate the bus object.

- To generate the bus signal as a substructure in the standard I/O structures, leave the block storage class at the default setting, `Auto`. If you have Embedded Coder, in the Code Mapping Editor, leave **Data Defaults > Inports** and **Data Defaults > Outports** at the default setting, `Default`.
- To generate the bus signal as a separate global structure variable, apply a storage class such as `ExportedGlobal` or `ExportToFile`.

For more information about grouping signals into custom structures in the generated code, see “Organize Data into Structures in Generated Code” on page 22-177.

**Configure Inport or Outport Block as Function Call (Embedded Coder)**

If your external code defines a function that returns input data for the generated code or accepts output data that the generated code produces, you can configure an Inport or
Outport block so that the generated code calls the function instead of accessing a global variable. Apply the Embedded Coder storage class GetSet. For more information, see “Access Data Through Functions with Custom Storage Class GetSet” on page 26-42.

**Pass Inputs and Outputs Through Function Arguments (Embedded Coder)**

With Embedded Coder, you can optionally configure the model execution function to access inputs and outputs through arguments instead of directly reading and writing to global variables. Completely control the argument characteristics such as name, order, and passing mechanism (by reference or by value). This configuration can help to integrate the generated code with your external code.

To pass inputs and outputs through arguments, apply function prototype control to the model. Then, each Inport and Outport block at the root level of the model appears in the code as an argument of the execution function. For more information, see “Customize Generated C Function Interfaces” on page 29-2.

**Configure Referenced Model Inputs and Outputs as Global Variables (void-void)**

By default, for a nonreentrant referenced model, the generated code passes root-level inputs and outputs through function arguments. A nonreentrant referenced model is one in which you set Configuration Parameter **Total number of instances allowed per top model** to One.

To pass this data through global variables instead (for a void-void interface), in the referenced model, apply storage classes such as ExportedGlobal and ExportToFile to root-level Inport and Outport blocks.

- To apply a default storage class to all such blocks, use the Code Mapping Editor, which requires Embedded Coder. With this technique, as you add such blocks to the model, the blocks acquire the default storage class, preserving the void-void interface. For more information, see “Configure Default Code Generation for Data” on page 21-8.
- To override the default storage class, apply storage classes directly to individual blocks by using the Model Data Editor. See “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 22-81.
- For an example that requires Embedded Coder, see “Establish Data Ownership in a System of Components” on page 23-15.
Control Data Interface for Reentrant Code

When you set Configuration Parameters > Code Generation > Interface > Code interface packaging to Reusable function, the generated entry-point functions are reentrant. The functions exchange data with the calling environment through formal parameters (arguments). By default, each root-level Inport and Outport block appears in the generated code as a separate argument instead of a field of the standard I/O structures.

• To reduce the number of arguments, see “Reduce Number of Arguments by Using Structures” (Simulink Coder).
• To control the data types of the arguments, see “Control Data Types of Arguments” (Simulink Coder).

Prevent Unintended Changes to the Interface

Some changes that you make to a model change the signatures of the entry-point functions in the generated code. For example, if you change the name of the model, the names of the functions can change. If you configure the model code to exchange data through arguments, when you add or remove Inport or Outport blocks or change the names of the blocks, the corresponding arguments can change.

For easier maintenance of your calling code, prevent changes to the interfaces of the entry-point functions.

• If you exchange input and output data through arguments, configure the generated code to package Inport and Outport blocks into structures instead of allowing each block to appear as a separate argument (the default). Then, when you add or remove Inport or Outport blocks, or change their properties such as name and data type, the fields of the structures change, but the signatures of the entry-point functions do not change. See “Reduce Number of Arguments by Using Structures” on page 22-47.
• Set the data types of Inport and Outport blocks explicitly instead of using an inherited data type setting (which these blocks use by default). Inherited data type settings can cause the blocks to use different data types depending on the data types of upstream and downstream signals. For more information about configuring data types, see “Control Signal Data Types” (Simulink).
• With Embedded Coder, specify function names that do not depend on the model name. If you specify a naming rule with a function customization template, do not use the token $R in the rule. See “Control Names of Generated Entry-Point Functions (Embedded Coder)” (Simulink Coder).
Reduce Number of Arguments by Using Structures

Reducing the number of arguments of a function can improve the readability of the code and reduce consumption of stack memory. To create a structure argument that can pass multiple pieces of data at one time, use any of these techniques:

- Manually combine multiple Inport or Outport blocks so that they appear in the generated code as fields of a structure or substructure of a standard data structure. The generated entry-point function or functions accept the address of the structure either as a separate argument or as a substructure (field) of the standard I/O structures.

Replace the Inport or Outport blocks with a single block, and configure the new block as a nonvirtual bus by using a Simulink.Bus object as the data type of the block. If your external code defines the structure type, consider using the Simulink.importExternalCTypes function to generate the bus object. See “Organize Data into Structures in Generated Code” on page 22-177 and Simulink.importExternalCTypes.

- When you generate reentrant code with Embedded Coder, configure Inport and Outport blocks to appear in aggregated structures by default. Set Configuration Parameters > Code Generation > Interface > Pass root-level I/O as to a setting other than Individual arguments.

- To package all of the Inport and Outport blocks into the real-time model data structure, select Part of model data structure. The code generator aggregates the blocks into the default I/O structures, which the real-time model data structure points to. The generated entry-point function or functions accept the real-time model data structure as a single argument. If you choose this setting, the function has the smallest number of arguments.

- To aggregate all Inport blocks into a structure and all Outport blocks into a different structure, select Structure reference. The generated entry-point function or functions accept the address of each structure as an argument. Another argument accepts the real-time model data structure. If you choose this setting, the inputs and outputs are more identifiable in the function signatures.

With this setting, if you remove all root-level Inport blocks or all root-level Outport blocks, the function signature can change. Similarly, the signature can change if you add a root-level Inport or Outport block to a model that does not have any such blocks.
• For additional control over the characteristics of the structures, set **Pass root-level I/O as** to **Part of model data structure**. Then, set the default storage class for Inport and Outport blocks to a structured storage class that you create. With this technique:
  
  • You can create a single structure for all of the blocks or create two separate structures.
  • You can control the names of the structure types.
  • The structures appear as substructures of the real-time model data structure.
    You must set **Pass root-level I/O as** to **Part of model data structure**.

  Create the storage class by using the Embedded Coder Dictionary (see “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 20-2). Apply the storage class by using the Code Mapping Editor (see “Configure Default Code Generation for Data” on page 21-8).

  For more information about **Pass root-level I/O as**, see “Pass root-level I/O as” (Simulink Coder).

**Control Data Types of Arguments**

You can configure the generated entry-point functions to exchange data through arguments. For a scalar or array argument, to control the name of the primitive data type, use a `Simulink.AliasType` object to either set the data type of the corresponding block or to configure data type replacements for the entire model. These techniques require Embedded Coder. For more information, see “Control Data Type Names in Generated Code” on page 24-2.

**Promote Data Item to the Interface**

By default, the code generator assumes that Inport and Outport blocks at the root level of the model constitute the data interface of the model. You can promote an arbitrary signal, block parameter, or block state to the interface so that other systems and components can access it. See “Promote Internal Data to the Interface” on page 22-63.

How Generated Code Stores Internal Signal, State, and Parameter Data

To calculate outputs from inputs, the generated code stores some internal data in global memory. A signal that does not connect to a root-level input or output (Inport or Outport block) is internal data.

Internal data can also include:

- A block state such as the state of a Unit Delay block. The algorithm must retain the state value between execution cycles, so the generated code typically stores states in global memory (for example, as a global variable or a field of a global structure variable).
- A block parameter, such as the Gain parameter of a Gain block, whose value the code generator cannot inline in the code. For example, the code generator cannot inline the value of a nonscalar parameter.
- The status indicator of a conditionally executed subsystem such as an enabled subsystem.

For more efficient code, you can configure optimizations such as Configuration Parameters > Default parameter behavior and Configuration Parameters > Signal storage reuse that attempt to eliminate storage for internal data. However, the optimizations cannot eliminate storage for some data, which consume memory in the generated code.

When you understand the default format in which the generated code stores internal data, you can:

- Make signals accessible and parameters tunable by default. You can then interact with and monitor the code during execution.
- Generate efficient production code by eliminating storage for internal data and, depending on your hardware and build toolchain, controlling the placement in memory of data that the optimizations cannot eliminate.
- Promote pieces of internal data to the model interface so that other components and systems can access that data.

For information about how the generated code exchanges data with a calling environment through interfaces, see “How Generated Code Exchanges Data with an Environment” on page 22-33.
Internal Data in the Generated Code

This example shows how the generated code stores internal data such as block states.

Explore Example Model

Open the example model `rtwdemo_roll`.

```matlab
open_system('rtwdemo_roll')
```

The model contains internal signals that do not connect to root-level Inport or Outport blocks. Some of the signals have a name, such as the `phiCmd` signal.

The model also contains some blocks that maintain state data. For example, in the `BasicRollMode` subsystem, a Discrete-Time Integrator block labeled `Integrator` maintains a state.

In the model, set **Configuration Parameters > Code Generation > System target file** to `grt.tlc`.

```matlab
set_param('rtwdemo_roll','SystemTargetFile','grt.tlc')
```
Inspect the setting for **Configuration Parameters > Code Generation > Interface > Code interface packaging**. The setting Nonreusable function means that the generated code is not reusable (reentrant).

For this example, generate simpler code by clearing **Configuration Parameters > Code Generation > Interface > Advanced parameters > Mat-file logging**.

```matlab
set_param('rtwdemo_roll','MatFileLogging','off')
```

**Generate Nonreusable Code**

Set these configuration parameters:

- Set **Default parameter behavior** to Tunable.
- Clear **Signal storage reuse**.

```matlab
set_param('rtwdemo_roll','DefaultParameterBehavior','Tunable',... 'OptimizeBlockIOStorage','off')
```

Generate code from the model.

```matlab
rtwbuild('rtwdemo_roll')
```

The file `rtwdemo_roll.h` defines several structure types that represent internal data. For example, the block input and output structure defines one field for each internal signal in the model. Each field name derives from the name of the block that generates the signal or, if you specify a name for the signal, from the name of the signal.

```matlab
file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.h');
rtwdemodbtype(file,... '/* Block signals (default storage) */','} B_rtwdemo_roll_T;',1,1)
```

```c
typedef struct {
    real32_T phiCmd;         /* '<Root>/ModeSwitch' */
    real32_T Abs;            /* '<S3>/Abs' */
    real32_T FixPtUnitDelay1; /* '<S7>/FixPt Unit Delay1' */
    real32_T Xnew;           /* '<S7>/Enable' */
    real32_T TKSwitch;       /* '<S3>/TKSwitch' */
    real32_T RefSwitch;      /* '<S3>/RefSwitch' */
} rtwdemo_roll_T;
```
real32_T Integrator;  /* '<S1>/Integrator' */
real32_T DispLimit;  /* '<S1>/DispLimit' */
real32_T Sum;  /* '<S1>/Sum' */
real32_T DispGain;  /* '<S1>/DispGain' */
real32_T RateLimit;  /* '<S1>/RateLimit' */
real32_T Sum1;  /* '<S1>/Sum1' */
real32_T RateGain;  /* '<S1>/RateGain' */
real32_T Sum2;  /* '<S1>/Sum2' */
real32_T CmdLimit;  /* '<S1>/CmdLimit' */
real32_T IntGain;  /* '<S1>/IntGain' */
real32_T hdgError;  /* '<S2>/Sum' */
real32_T DispGain_a;  /* '<S2>/DispGain' */
real32_T Product;  /* '<S2>/Product' */
boolean_T NotEngaged;  /* '<S3>/NotEngaged' */
boolean_T TKThreshold;  /* '<S3>/TKThreshold' */
boolean_T RefThreshold2;  /* '<S3>/RefThreshold2' */
boolean_T RefThreshold1;  /* '<S3>/RefThreshold1' */
boolean_T Or;  /* '<S3>/Or' */
boolean_T NotEngaged_e;  /* '<S1>/NotEngaged' */
} B_rtwdemo_roll_T;

The file defines a structure type, the DWork structure, to represent block states such as the state of the Discrete-Time Integrator block.

rtwdemodbtype(file,...
    '/* Block states (default storage) for system','} DW_rtwdemo_roll_T;',1,1)

/* Block states (default storage) for system '<Root>' */
typedef struct {
    real32_T FixPtUnitDelay1_DSTATE;  /* '<S7>/FixPt Unit Delay1' */
    real32_T Integrator_DSTATE;  /* '<S1>/Integrator' */
    int8_T Integrator_PrevResetState;  /* '<S1>/Integrator' */
} DW_rtwdemo_roll_T;

The file defines a structure type to represent parameter data. Each tunable block parameter in the model, such as the Gain parameter of a Gain block, appears as a field of this structure. If a block parameter acquires its value from a MATLAB variable or a Simulink.Parameter object, the variable or object appears as a field, not the block parameter.

The file also defines a structure type, the real-time model data structure, whose single field represents a run-time indication of whether the generated code has encountered an error during execution.
/* Real-time Model Data Structure */
struct tag_RTM_rtwdemo_roll_T {
    const char_T *errorStatus;
};

For the structure type that represents the real-time model data structure, the file rtwdemo_roll_types.h creates an alias that the generated code later uses to allocate memory for the structure.

file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll_types.h');
rtwdemodbtype(file,'/* Forward declaration for rtModel */',
    'RT_MODEL_rtwdemo_roll_T;',1,1)

/* Forward declaration for rtModel */
typedef struct tag_RTM_rtwdemo_roll_T RT_MODEL_rtwdemo_roll_T;

Using these structure types, the file rtwdemo_roll.c defines (allocates memory for) global structure variables that store internal data for the generated algorithm. The file also defines variables that represent the real-time model data structure and a pointer to the structure.

file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.c');
rtwdemodbtype(file,'/* Block signals (default storage) */',
    '= &rtwdemo_roll_M_;',1,1)

/* Block signals (default storage) */
B_rtwdemo_roll_T rtwdemo_roll_B;

/* Block states (default storage) */
DW_rtwdemo_roll_T rtwdemo_roll_DW;

/* External inputs (root inport signals with default storage) */
ExtU_rtwdemo_roll_T rtwdemo_roll_U;

/* External outputs (root outports fed by signals with default storage) */
ExtY_rtwdemo_roll_T rtwdemo_roll_Y;

/* Real-time model */
The model step function, which represents the primary model algorithm, uses a void void interface (with no arguments).

In the function definition, the algorithm performs calculations and stores intermediate results in the signal and state structures by directly accessing the global variables. The algorithm also reads parameter data from the corresponding global variable. For example, in the BasicRollMode subsystem, the code generated for the Integrator block reads and writes signal, state, and parameter data from the structures.

Due to the void void interface and the direct data access, the function is not reentrant. If you call the function multiple times in an application, each call writes data to the global structure variables and the subsequent call can read that data, resulting in unintentional interference between the calls.
The model initialization function `rtwdemo_roll_initialize` initializes all of the internal data to zero. The function also initializes the error status by calling a specialized macro function. The initialization function directly accesses the global variables, which means that the function is not reentrant.

```c
/* Model initialize function */
void rtwdemo_roll_initialize(void) {
    /* Registration code */
    /* initialize error status */
    rtmSetErrorStatus(rtwdemo_roll_M, (NULL));
    /* block I/O */
    (void) memset(((void *) &rtwdemo_roll_B), 0, sizeof(B_rtwdemo_roll_T));
    /* states (dwork) */
    (void) memset((void *)&rtwdemo_roll_DW, 0, sizeof(DW_rtwdemo_roll_T));
}
```

The function then initializes the block states in the DWork structure to the initial values that the block parameters in the model specify. Two of the three states in the model have tunable initial values, so the code initializes them by reading data from the parameters structure.

```c
/* SystemInitialize for Atomic SubSystem: '<Root>/RollAngleReference' */
/* InitializeConditions for UnitDelay: '<S7>/FixPt Unit Delay1' */
rtwdemo_roll_DW.FixPtUnitDelay1_DSTATE = rtwdemo_roll_PLatchPhi_vinit;
/* End of SystemInitialize for SubSystem: '<Root>/RollAngleReference' */
/* SystemInitialize for Atomic SubSystem: '<Root>/BasicRollMode' */
/* InitializeConditions for DiscreteIntegrator: '<S1>/Integrator' */
rtwdemo_roll_DW.Integrator_DSTATE = rtwdemo_roll_P.Integrator_IC;
rtwdemo_roll_DW.Integrator_PrevResetState = 0;
```
Generate Reusable Code

You can configure the generated code as reentrant, which means you can call the entry-point functions multiple times in an application. With this configuration, instead of directly accessing global variables, the entry-point functions accept internal data through formal parameters (pointer arguments). With these pointer arguments, each call can maintain internal data in a set of separate global variables, preventing unintentional interaction between the calls.

In the model, set Configuration Parameters > Code Generation > Interface > Code interface packaging to Reusable function.

```matlab
set_param('rtwdemo_roll','CodeInterfacePackaging','Reusable function')
```

Generate code from the model.

```matlab
rtwbuild('rtwdemo_roll')
```

Now, in `rtwdemo_roll.h`, the real-time model data structure contains pointers to the error indication, the internal data, and primary input and output data in the form of ExtU and ExtY substructures (the fields of which represent Inport and Outport blocks at the root level of the model).

```c
/* Real-time Model Data Structure */
struct tag_RTM_rtwdemo_roll_T {
    const char_T *errorStatus;
    B_rtwdemo_roll_T *blockIO;
    P_rtwdemo_roll_T *defaultParam;
    ExtU_rtwdemo_roll_T *inputs;
    ExtY_rtwdemo_roll_T *outputs;
    boolean_T paramIsMalloced;
    DW_rtwdemo_roll_T *dwork;
};
```

How Generated Code Stores Internal Signal, State, and Parameter Data

22-57
To call the generated code multiple times in an application, your code must allocate memory for a real-time model data structure per call. The file `rtwdemo_roll.c` defines a specialized function that allocates memory for a new real-time model data structure and returns a pointer to the structure. The function also allocates memory for the substructures that the fields in the model data structure point to, such as the DWork structure.

```c
file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.c');
rtwdemdobjtype(file,'/* Model data allocation function */',... 
   'RT_MODEL_rtwdemo_roll_T *rtwdemo_roll(void)',1,1)
/* Model data allocation function */
RT_MODEL_rtwdemo_roll_T *rtwdemo_roll(void)

The model step function accepts an argument that represents the real-time model data structure.

```c
rtwdemdobjtype(file,'/* Model step function */','void rtwdemo_roll_step',1,1)
/* Model step function */
void rtwdemo_roll_step(RT_MODEL_rtwdemo_roll_T *const rtwdemo_roll_M)

In the function definition, the algorithm first extracts each pointer from the real-time model data structure into a local variable.

```c
rtwdemdobjtype(file,'*rtwdemo_roll_P_e =','rtwdemo_roll_M->outputs;',1,1)
P_rtwdemo_roll_T *rtwdemo_roll_P_e = ((P_rtwdemo_roll_T *)
   rtwdemo_roll_M->defaultParam);
B_rtwdemo_roll_T *rtwdemo_roll_B = ((B_rtwdemo_roll_T *)
   rtwdemo_roll_M->blockIO);
DW_rtwdemo_roll_T *rtwdemo_roll_DW = ((DW_rtwdemo_roll_T *)
   rtwdemo_roll_M->dwork);
ExtU_rtwdemo_roll_T *rtwdemo_roll_U = (ExtU_rtwdemo_roll_T *)
   rtwdemo_roll_M->inputs;
ExtY_rtwdemo_roll_T *rtwdemo_roll_Y = (ExtY_rtwdemo_roll_T *)
   rtwdemo_roll_M->outputs;
```

Then, to access the internal data stored in global memory, the algorithm interacts with these local variables.
rtwdemodbtype(file,'/* DiscreteIntegrator: ''<S1>/Integrator'' */',...  
'/* End of DiscreteIntegrator: ''<S1>/Integrator'' */',1,1)

/* DiscreteIntegrator: '<S1>/Integrator' */
if (rtwdemo_roll_B->NotEngaged_e ||
    (rtwdemo_roll_DW->Integrator_PrevResetState != 0)) {
    rtwdemo_roll_DW->Integrator_DSTATE = rtwdemo_roll_P_e->Integrator_IC;
}

if (rtwdemo_roll_DW->Integrator_DSTATE >= rtwdemo_roll_P_e->intLim) {
    rtwdemo_roll_DW->Integrator_DSTATE = rtwdemo_roll_P_e->intLim;
} else {
    if (rtwdemo_roll_DW->Integrator_DSTATE <=
        rtwdemo_roll_P_e->Integrator_LowerSat) {
        rtwdemo_roll_DW->Integrator_DSTATE = rtwdemo_roll_P_e->Integrator_LowerSat;
    }
}

rtwdemo_roll_B->Integrator = rtwdemo_roll_DW->Integrator_DSTATE;

Similarly, the model initialization function accepts the real-time model data structure as an argument.

rtwdemodbtype(file,...
   '/* Model initialize function */','void rtwdemo_roll_initialize',1,1)

/* Model initialize function */
void rtwdemo_roll_initialize(RT_MODEL_rtwdemo_roll_T *const rtwdemo_roll_M)

Because each call that you make to an entry-point function interacts with a separate real-time model data structure, you avoid unintentional interaction between the calls.

Eliminate Internal Data with Code Generation Optimizations

For more efficient code that consumes less memory, select the optimizations, such as Default parameter behavior, that you cleared earlier.

set_param('rtwdemo_roll','DefaultParameterBehavior','Inlined',...
  'OptimizeBlockI0Storage','on',...
  'LocalBlockOutputs','on')
In this example, for simpler code, set **Code interface packaging** to **Nonreusable function**.

```matlab
set_param('rtwdemo_roll','CodeInterfacePackaging','Nonreusable function')
```

Generate code from the model.

```bash
rtwbuild('rtwdemo_roll')
```

### Starting build procedure for model: rtwdemo_roll
### Successful completion of build procedure for model: rtwdemo_roll

Now, `rtwdemo_roll.h` does not define a structure for block inputs and outputs. For all of the internal signals in the model, the optimizations either eliminated storage or created local function variables instead of global structure fields.

The optimizations were not able to eliminate storage for the three block states, so the file continues to define the DWork structure type.

```matlab
file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.h');
rtwdemodbtype(file,...
    '/* Block states (default storage) for system','} DW_rtwdemo_roll_T;',1,1)
```

```c
/* Block states (default storage) for system 'rtwdemo_roll' */
typedef struct {
    float32_T FixPtUnitDelay1_DSTATE;     /* '<S7>/FixPt Unit Delay1' */
    float32_T Integrator_DSTATE;          /* '<S1>/Integrator' */
    int8_T Integrator_PrevResetState;    /* '<S1>/Integrator' */
} DW_rtwdemo_roll_T;
```

The code generated for the Discrete-Time Integrator block now stores state and output data only in the DWork structure.

```matlab
file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.c');
rtwdemodbtype(file,'/* Update for DiscreteIntegrator: '<S1>/Integrator'...',
    '/End of Update for DiscreteIntegrator: '<S1>/Integrator' */',1,1)
```

```c
/* Update for DiscreteIntegrator: '<S1>/Integrator' incorporates:
 * Gain: '<S1>/IntGain'
 */
rtwdemo_roll_DW.Integrator_DSTATE += 0.5F * rtb_TKSwitch * 0.025F;
if (rtwdemo_roll_DW.Integrator_DSTATE >= 5.0F) {
    rtwdemo_roll_DW.Integrator_DSTATE = 5.0F;
}```
The optimizations also eliminated storage for the block parameters in the model. For example, in the Discrete-Time Integrator block, the **Upper saturation limit** and **Lower saturation limit** parameters are set to intLim and -intLim. intLim is a Simulink.Parameter object that stores the value 5. In the code generated for the Discrete-Time Integrator, these block parameters and intLim appear as inlined literal numbers 5.0F and -5.0F.

If a model contains a parameter that the code generator cannot inline directly (for example, an array parameter), the code defines a structure type that represents the data. This constant parameters structure uses the **const** storage type qualifier, so some build toolchains can optimize the assembly code further.

### Local Variables in the Generated Code

When you select the optimization **Configuration Parameters > Enable local block outputs**, the code generator attempts to yield more efficient code by representing internal signals as local variables instead of fields of a global structure. If the memory consumed by local variables risks exceeding the stack space available on your target hardware, consider indicating the maximum stack size by setting **Configuration Parameters > Maximum stack size (bytes)**. For more information, see “Maximum stack size (bytes)” (Simulink Coder).

### Appearance of Test Points in the Generated Code

A **test point** is a signal that is stored in a unique memory location. For information about including test points in your model, see “Test Points” (Simulink).

When you generate code for models that include test points, the build process allocates a separate memory buffer for each test point. By default, test points are stored as members of an appropriate standard data structure such as `model_B`.

If you have Embedded Coder:
• You can control the default representation of test points by specifying code generation settings for the **Internal data** category of data in the Code Mapping Editor (see “Configure Default Code Generation for Data” on page 21-8).

• You can specify that the build process ignore test points in the model, allowing optimal buffer allocation, by using the “Ignore test point signals” (Simulink Coder) parameter. Ignoring test points facilitates transitioning from prototyping to deployment and avoids accidental degradation of generated code due to workflow artifacts. See “Ignore test point signals” (Simulink Coder).

Virtual buses do not appear in generated code, even when associated with a test point. To display a bus in generated code, use a nonvirtual bus or a virtual bus converted to a nonvirtual bus by a Signal Conversion block.

### Appearance of Workspace Variables in the Generated Code

Workspace variables are variables that you use to specify block parameter values in a model. Workspace variables include numeric MATLAB variables and `Simulink.Parameter` objects that you store in a workspace, such as the base workspace, or in a data dictionary.

When you set **Default parameter behavior** to **Tunable**, by default, workspace variables appear in the generated code as tunable fields of the global parameters structure. If you use such a variable to specify multiple block parameter values, the variable appears as a single field of the global parameters structure. The code does not create multiple fields to represent the block parameters. Therefore, tuning the field value during code execution changes the mathematical behavior of the model in the same way as tuning the value of the MATLAB variable or parameter object during simulation.

If you have Embedded Coder, you can control the default representation of workspace variables by specifying code generation settings for categories of parameter data in the Code Mapping Editor (see “Configure Default Code Generation for Data” on page 21-8).

• The **Local parameters** category applies to variables that you store in a model workspace.

• The **Global parameters** category applies to variables that you store in the base workspace or a data dictionary.
**Promote Internal Data to the Interface**

By default, the code generator assumes that other systems and components in your application do not need to access internal data. For example, internal data are subject to optimizations that can eliminate them from the generated code. For prototyping and testing purposes, you can access internal data by clearing the optimizations or by configuring test points and applying storage classes (see “Configure Data Accessibility for Rapid Prototyping” on page 22-3). For optimized production code, configure individual data items to appear in the generated code as part of the model interface.

**Data That You Can Promote**

Depending on the reentrancy of the generated code, that is, the setting that you choose for **Code interface packaging**, you can configure each data item in a model to participate in the interface by appearing in the code as one of these entities:

- A global symbol, such as a global variable or a call to a specialized function
- A formal parameter (argument) of the generated entry-point functions

The table shows the mechanisms that each category of data can use to participate in the interface.

<table>
<thead>
<tr>
<th>Category of Data</th>
<th>Appear as Global Symbol</th>
<th>Appear as Argument of Entry-Point Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>Root-level Inport or Outport block</td>
<td>Only for a nonreentrant model.</td>
<td>Yes.</td>
</tr>
<tr>
<td>Signal connecting two blocks</td>
<td>Only for a nonreentrant model.</td>
<td>Only for a reentrant model and only as a field of a structure. Alternatively, connect the signal to a root-level Outport block.</td>
</tr>
<tr>
<td>Block state</td>
<td>Only for a nonreentrant model.</td>
<td>Only for a reentrant model and only as a field of a structure.</td>
</tr>
<tr>
<td>Category of Data</td>
<td>Appear as Global Symbol</td>
<td>Appear as Argument of Entry-Point Function</td>
</tr>
<tr>

<td>Only for a reentrant model and only as a field of a structure.</td>
</tr>
<tr>
<td>Block parameter or parameter object such as Simulink.Parameter</td>
<td>Yes.</td>
<td>Only as a field of a structure.</td>
</tr>
</tbody>
</table>

**Single-Instance Algorithm**

For a single-instance algorithm (you set **Code interface packaging** to **Nonreusable function**), apply storage classes directly to individual data items by using the Model Data Editor or the Property Inspector. With a directly applied storage class, a data item appears in the code as a global symbol such as a global variable. The storage class also prevents optimizations from eliminating storage for the data item.

You can apply storage classes to signals, block states, and block parameters. (For block parameters, you apply storage classes indirectly through parameter objects such as Simulink.Parameter). However, for a signal, consider connecting the signal to an Outport block at the root level of the model. Then, optionally, you can apply a storage class to the block. In the block diagram, the Outport block shows that the signal represents a system output.

For more information about storage classes, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 22-81.

**Reentrant Algorithm**

For a reentrant algorithm (you set **Code interface packaging** to **Reusable function**), use different techniques to configure data items to appear in the code as formal parameters (arguments) of the generated entry-point functions.

- For an internal signal, directly apply the storage class **Model default** (see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 22-81). If you have Embedded Coder, in the Code Mapping Editor, for the **Internal data** category, set the default storage class to **Default** or to a structured storage class that you define in an Embedded Coder Dictionary (see “Create Code Definitions for Use as Default Code Generation Settings” on page 20-2). Alternatively, configure the signal as a test point (see “Appearance of Test Points in the Generated Code” on
By default, the signal appears as a field of one of the standard data structures (see “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 22-50). If you do not want the signal to appear in production code, use a test point so that you can later select the model configuration parameter Ignore test point signals.

Alternatively, connect the signal to an Outport block at the root level of the model. Connecting the signal to a root-level Outport block prevents optimizations from eliminating the signal from the code. To help with signal routing in a large model, use Goto and From blocks.

• For a block parameter, create a parameter object such as Simulink.Parameter and directly apply a storage class other than Auto to the object. The storage class prevents optimizations from inlining the parameter value in the code.

With the storage class, the parameter is shared between all instances of the model, which are calls to the entry-point functions. The functions access the parameter data directly, as a global symbol, not an argument. You cannot configure a parameter to appear in the code as an argument, so you cannot enable each instance of the model to use a different value for the parameter.

For information about applying storage classes, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder).

**Control Default Representation of Internal Data (Embedded Coder)**

By default, the code generator aggregates internal data that optimizations cannot eliminate, such as most state data, into standard structures such as the DWork structure. With Embedded Coder, you can control how the generated code stores this data.

**Control Placement of Data in Memory by Inserting Pragmas**

Use the Code Mapping Editor to specify a default memory section for each category of data such as states and signals (Internal data). In the generated code, your custom pragmas or other decorations surround the data definitions and declarations.

You can also partition the structures according to atomic subsystems in your model so that you can specify different default memory sections for the data of subroutines and other algorithmic subcomponents.
For more information, see “Control Data and Function Placement in Memory by Inserting Pragmas” on page 30-2.

Control Names of Types, Fields, and Global Variables for Standard Data Structures

You can control some characteristics of the standard data structures. For more information, see “Control Characteristics of Data Structures (Embedded Coder)” (Simulink Coder).

For additional control over structure characteristics, such as placement in generated code files, create your own structured storage class by using the Embedded Coder Dictionary. Then, apply the storage class to categories of data by using the Code Mapping Editor. The storage class removes the data from the standard structures, creating other structures that you can more finely control. For more information about applying default storage classes to categories of data, see “Configure Default Code Generation for Data” on page 21-8. For more information about creating a storage class, see “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 20-2.

Organize Data into Structures According to Subcomponents

- In the standard data structures, to create substructures that contain the data for a single-instance (nonreentrant) subroutine or subcomponent, use an atomic subsystem to encapsulate the corresponding blocks. In the subsystem parameters, set Function packaging to Reusable function. For more information, see “Generate Modular Function Code” on page 29-65.

  Alternatively, encapsulate the blocks in a model and use a Model block. In the referenced model, set Configuration Parameters > Model Referencing > Total number of instances allowed per top model to Multiple. For more information, see “Code Generation of Referenced Models” on page 4-2.

- To create separate, standalone structures that contain the data for a multi-instance (reentrant) subroutine or subcomponent, in the model, use an atomic subsystem to encapsulate the corresponding blocks. In the subsystem parameters, set Function packaging to Nonreusable function and select Function with separate data.

  For more information, see “Generate Modular Function Code” on page 29-65.

  Alternatively, encapsulate the blocks in a model and use a Model block. In the referenced model, choose one of these techniques:
• Set **Configuration Parameters > Model Referencing > Total number of instances allowed per top model** to One. For more information, see “Code Generation of Referenced Models” on page 4-2.

• Set **Total number of instances allowed per top model** to Multiple and create a structured storage class by using an Embedded Coder Dictionary. Then, apply the storage class to categories of data by using the Code Mapping Editor. To create a storage class, see “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 20-2. To apply the storage class to categories of data, see “Configure Default Code Generation for Data” on page 21-8.

**Organize Signal and Parameter Data into Meaningful, Custom Structures and Substructures**

To organize arbitrary signals and parameters into custom structures and substructures, create nonvirtual bus signals and parameter structures. Optionally, to prevent optimizations from eliminating the data from the code, set the storage class of a bus signal or parameter structure to a value other than **Auto** (the default setting).

As you add blocks to the model, you must explicitly place each new signal and parameter into a bus or a structure.

For more information, see “Organize Data into Structures in Generated Code” on page 22-177.

**Create Separate Global Variables Instead of Structure Fields**

To make a category of internal data appear in the generated code as separate, unstructured global variables instead of fields of a standard data structure, apply an unstructured storage class to the data category by using the Code Mapping Editor. For example, apply the storage class **ExportedGlobal**. However, if you generate multi-instance, reentrant code by setting the configuration parameter **Code interface packaging** to a value other than **Nonreusable function**, you cannot use this technique for some categories of data (see “Use Storage Classes in Reentrant, Multi-Instance Models and Components” (Simulink Coder)).

To apply default storage classes to categories of data by using the Code Mapping Editor, see “Configure Default Code Generation for Data” on page 21-8. To choose a storage class, see “Choose a Storage Class for Controlling Data Representation in the Generated Code” (Simulink Coder).

Choose a Storage Class for Controlling Data Representation in the Generated Code

A storage class is a code generation setting that you apply to model data, such as signals, block parameters, and states. Use storage classes to control the appearance of data elements in the generated code.

The table shows built-in storage classes that you can choose. These storage classes come with Simulink Coder.
<table>
<thead>
<tr>
<th>Storage Class Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Auto</td>
<td>Auto is the default storage class setting for each data element in a model. The data element is subject to code generation optimizations, which can eliminate the element from the code or change the representation of the element. For information about these optimizations, such as those on the Configuration Parameters &gt; Code Generation &gt; Optimization pane, see “How Generated Code Stores Internal Signal, State, and Parameter Data” (Simulink Coder). Optimizations cannot eliminate some data, such as most block states, from the code. This remaining data acquire the appropriate default storage class that you specify with the Code Mapping Editor (see “Configure Default Code Generation for Data“ on page 21-8—requires Embedded Coder). If you leave the storage class setting in the Code Mapping Editor at the default value, Default, the data element appears as a field of the appropriate standard data structure (see “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 22-50). If optimizations cannot eliminate the data element, the name of the element in the code is based on naming rules that you specify with model configuration parameters (see “Identifier Format Control” on page 39-22—requires Embedded Coder). Use this storage class to enable optimizations to operate on the data</td>
</tr>
<tr>
<td>Storage Class Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>element, potentially generating more efficient code.</td>
<td></td>
</tr>
<tr>
<td>Model default</td>
<td>The data element acquires the corresponding default storage class that you specify with the Code Mapping Editor. The name of the data element in the code is the same as the name in the model. Use this storage class to prevent optimizations from eliminating storage for a data element (see “How Generated Code Stores Internal Signal, State, and Parameter Data” (Simulink Coder)).</td>
</tr>
<tr>
<td>ExportedGlobal</td>
<td>Generate a global variable definition and declaration. The name of the variable is the name of the data element. The code declares the variable in the generated file model.h, which you can include (#include) in your external code.</td>
</tr>
<tr>
<td>ImportedExtern</td>
<td>Generate code that reads from and writes to a global variable defined by your external code. The generated code declares the variable in the generated file model_private.h so that the model entry-point functions can read and write to the variable. Use this storage class to make a data element in a model represent a global variable that your external code defines. The generated algorithmic code uses the variable without defining it.</td>
</tr>
</tbody>
</table>
Storage Class Name | Description
---|---
ImportedExternPointer | Generate code that reads from and writes to a global pointer variable defined by your external code. The generated code declares the variable in the generated file `model_private.h` and reads and writes to the data by dereferencing the pointer. Use this storage class when your external code defines a data element and provides a pointer for accessing that data.

If you have Embedded Coder, you can choose additional built-in storage classes, shown in the next table.

<table>
<thead>
<tr>
<th>Storage Class Name</th>
<th>Description</th>
<th>Use for Signal or State Data</th>
<th>Use for Parameter Data</th>

<td>Generate code that interacts with data by calling your custom accessor functions. Your external code defines the data and provides the function definitions. For examples, see “Access Data Through Functions with Custom Storage Class GetSet” on page 26-42.</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>ImportedDefine</td>
<td>Generate code that uses a macro (#define directive) defined in a header file in your external code. For an example, see “Macro Definitions (#define)” on page 14-71.</td>
<td>No</td>
<td>Yes</td>
</tr>
<tr>
<td>ImportFromFile</td>
<td>Generate code that reads from and writes to a global variable defined by your external code. Similar to ExportToFile, but the generated code does not define the variable.</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Storage Class Name</td>
<td>Description</td>
<td>Use for Signal or State Data</td>
<td>Use for Parameter Data</td>
</tr>
<tr>
<td>--------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-----------------------------</td>
<td>------------------------</td>
</tr>
<tr>
<td>Reusable</td>
<td>Generate more efficient code that stores intermediate calculations of a data path (a series of connected blocks) in a single, reused global variable. For an example, see “Specify Buffer Reuse by Using Simulink.Signal Objects” on page 58-19. You can apply this storage class only to a Simulink.Signal object that represents multiple signal lines in a model.</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Struct</td>
<td>Generate a global structure whose name you can specify. For examples, see “Organize Parameter Data into a Structure by Using the Struct Custom Storage Class” on page 26-23 and “Structures of Signals” on page 14-81. You cannot use this storage class in the Code Mapping Editor.</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Volatile</td>
<td>Generate a global variable definition and declaration with the volatile type qualifier.</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>ParamStruct</td>
<td>Generate global structures that contain parameter data. In a hierarchy of components (referenced models or atomic subsystems), you can use this storage class to create a corresponding hierarchy of parameter structures. This storage class appears only in the Code Mapping Editor for the data category called Local parameters.</td>
<td>No</td>
<td>Yes</td>
</tr>
<tr>
<td>Storage Class Name</td>
<td>Description</td>
<td>Use for Signal or State Data</td>
<td>Use for Parameter Data</td>
</tr>
<tr>
<td>--------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-----------------------------</td>
<td>------------------------</td>
</tr>
<tr>
<td>SignalStruct</td>
<td>Generate global structures that contain signal or state data. In a hierarchy of components (referenced models or atomic subsystems), you can use this storage class to create a corresponding hierarchy of signal and state structures. This storage class appears only in the Code Mapping Editor.</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Localizable</td>
<td>For signals, if possible, generate variables that are local to functions rather than in global storage. Generating local variables prevents the code generator from implementing optimizations that remove the variables from the generated code. For an example, see “Generate Local Variables with Localizable Custom Storage Class” on page 26-94.</td>
<td>Yes (signals not states)</td>
<td>No</td>
</tr>
</tbody>
</table>

When you generate reentrant, multi-instance code, limitations and restrictions apply if you want to use storage classes. See “Use Storage Classes in Reentrant, Multi-Instance Models and Components” (Simulink Coder).

**Specify File Names and Other Data Attributes With Storage Class (Embedded Coder)**

After you apply some storage classes, such as ExportToFile, you can specify additional settings such as declaration (header) and definition file names. In the Code Mapping Editor, to access these additional settings, you use the Property Inspector.

With other storage classes, you cannot specify additional settings.

- These built-in Simulink Coder storage classes do not allow you to specify additional settings:
• ExportedGlobal
• ImportedExtern
• ImportedExternPointer

• The built-in Embedded Coder storage classes typically allow you to specify declaration and definition file names.

• When you create a storage class with the Custom Storage Class Designer, you can choose whether the user of the storage class can specify additional settings. See “Allow Users of Custom Storage Class to Specify Property Value” on page 26-32.

Specify Default #include Syntax for Header Files That Declare Data (Embedded Coder)

To control the file placement of a data item, such as a signal line or block state, in the generated code, you can apply a storage class to the data item (see “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 26-19). You then use the Header file custom attribute to specify the generated or external header file that contains the declaration of the data.

To reduce maintenance effort and data entry, when you specify Header file, you can omit delimiters (" or <>) and use only the file name. You can then control the default delimiters that the generated code uses for the corresponding #include directives. To use angle brackets by default, set Configuration Parameters > Code Generation > Code Placement > #include file delimiters to #include `<header.h>`.

Storage Class Limitations

• When you use storage classes in the Code Mapping Editor (Embedded Coder), some limitations apply. See “Limitations” on page 21-33.

• Data objects cannot use an Embedded Coder storage class and a multiword data type.

• The Fcn block does not support parameters with an Embedded Coder storage class in code generation.

• For Embedded Coder storage classes in models that use referenced models:
  • If you apply a grouped storage class to multiple data items, the storage class Data scope property must be set to Imported and you must provide the data declaration in an external header file. Grouped storage classes use a single variable in the generated code to represent multiple data objects. For example, the storage classes BitField and Struct are grouped storage classes.
• If a parameter object exists in the base workspace or a data dictionary, and a referenced model uses the object, you cannot apply the storage class `FileScope`. As a workaround, move the object into the model workspace of the referenced model. Then, you can use `FileScope`.

• You cannot apply the storage class `FileScope` to data items used by a data exchange interface (C API, external mode, or ASAP2) or MAT-file logging. File-scoped data is not externally accessible.

• “How Generated Code Stores Internal Signal, State, and Parameter Data” (Simulink Coder)
Use Storage Classes in Reentrant, Multi-Instance Models and Components

The code that you generate from a model or component (referenced model or subsystem) is multi-instance code if it allows your application to maintain multiple independent instances of the component during execution. For example, you can generate reentrant, multi-instance code from an entire model by setting the model configuration parameter Code interface packaging to Reusable function. For general information about multi-instance models and components, see “Code Reuse” (Simulink Coder).

Under some circumstances, applying storage classes can:

- Prevent you from generating multi-instance code.
- Cause some data elements to appear in the generated code as singletons, which means that each instance of the model or component directly accesses the same shared, global data, creating dependencies between the instances.

To avoid errors and unexpected generation of single-instance code and singleton data, observe the guidelines and limitations below.

Directly Applied Storage Classes

When you apply a storage class directly to a data element (see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder)):

- To generate multi-instance code, you must apply the storage class only to parameter objects, global data stores, and shared local data stores.
- The storage class yields only singleton data.

Storage Classes Applied by Default

When you apply a default storage class by using the Code Mapping Editor (see “Configure Default Code Generation for Data” on page 21-8—requires Embedded Coder):

- For these data categories, you can generate only singleton data:
  - Local parameters
  - Global parameters
• Global data stores
• Shared local data stores
• For these data categories, you can generate only instance-specific data, which means each instance of the model or component operates on a separate copy of the data:
  • Inports
  • Outports
  • Internal data

For these categories, you must use the built-in storage class `SignalStruct` or create your own structured storage class by using an Embedded Coder Dictionary.

Apply Storage Classes to Individual Signal, State, and Parameter Data Elements

A storage class is a code generation setting that you apply to a data item (signal, block parameter, or state) in a model. When you directly apply it to a data item, a storage class:

- Causes the data item to appear in the generated code as a global symbol, typically a global variable.
- Prevents optimizations such as Default parameter behavior and Signal storage reuse from eliminating the data item from the generated code.
- With Embedded Coder, you can configure the format in which the generated code stores or otherwise defines the data item. For example, you can apply the storage type qualifiers const or volatile or configure a parameter data item to appear as a macro (#define).

Directly apply storage classes to individual data items to:

- Tune parameters and monitor signals and states during execution.
- Configure data placement in memory through memory sections.
- Generate code that exchanges data (for example, global variables) with your external code.

For information about applying storage classes to categories of data by default, by using the Code Mapping Editor, see “Configure Default Code Generation for Data” on page 21-8.

Apply Storage Classes to Data Items

This example shows how to apply storage classes to a signal, a block state, and a block parameter in a model.

Explore Example Model

Open the example model rtwdemo_roll.

open_system('rtwdemo_roll')
Navigate into the BasicRollMode subsystem.

open_system('rtwdemo_roll/BasicRollMode')

The subsystem contains an Integrator block, which maintains a piece of state data.

From the root level of the model, navigate into the RollAngleReference subsystem.

open_system('rtwdemo_roll/RollAngleReference')
The subsystem contains a Constant block labeled UpThr.

In this example, you configure the state and output signal of the Integrator block and the Constant value parameter of the Constant block to appear in the generated code as separate global variables.

**Apply Storage Classes**

Navigate to the root level of the model.

Select View > Model Data Editor.

To see the data items in the subsystems, activate the Change scope button.

Select the Signals tab.

Set the Change view drop-down list to Code.

In the Filter contents box, enter integrator.

Optionally, use the Name column to specify a name for the output signal of the Integrator block, such as mySignal.

Use the Storage Class column to apply the storage class ExportedGlobal.
Select the **States** tab.

Optionally, use the **Name** column to specify a name for the state, such as `myState`.

Use the **Storage Class** column to apply the storage class `ExportedGlobal`.

Select the **Parameters** tab. You cannot apply a storage class directly to a block parameter. Instead, you must create a parameter object, such as `Simulink.Parameter`, use the object to set the value of the block parameter, and apply the storage class to the object.

Set the **Change view** drop-down list to **Design**.

In the **Filter contents** box, enter `UpThr`.

Use the **Value** column to change the parameter value from 6 to `UpThr`.

While editing the parameter value, next to `UpThr`, click the action button (with three vertical dots) and select **Create**.

In the **Create New Data** dialog box, set **Value** to `Simulink.Parameter` and click **OK**. A `Simulink.Parameter` object named `UpThr` appears in the base workspace.

In the `UpThr` property dialog box, set **Value** to 6 and **Storage class** to `ExportedGlobal`. Click **OK**.

Alternatively, you can use these commands at the command prompt to configure the signal, state, and parameter data.

```matlab
% Configure signal
portHandles = get_param('rtwdemo_roll/BasicRollMode/Integrator',...
    'PortHandles');
outportHandle = portHandles.Outport;
set_param(outportHandle,'Name','mySignal')
set_param(outportHandle,'StorageClass','ExportedGlobal')

% Configure state
set_param('rtwdemo_roll/BasicRollMode/Integrator',...
    'StateName','myState')
set_param('rtwdemo_roll/BasicRollMode/Integrator',...
    'StateStorageClass','ExportedGlobal')

% Configure parameter
set_param('rtwdemo_roll/RollAngleReference/UpThr','Value','UpThr')
```
UpThr = Simulink.Parameter(6);
UpThr.StorageClass = 'ExportedGlobal';

**Generate and Inspect Code**

Generate code from the model.

```matlab
set_param('rtwdemo_roll','SystemTargetFile','grt.tlc')
rtwbuild('rtwdemo_roll')
```

```matlab
### Starting build procedure for model: rtwdemo_roll
### Successful completion of build procedure for model: rtwdemo_roll
```

Inspect the file `rtwdemo_roll.c`. The file defines the global variables.

```matlab
file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.c');
rtwdemodbtype(file,'/* Exported block signals */','real32_T myState;',1,1)
```

```matlab
/* Exported block signals */
real32_T mySignal;            /* '<S1>/Integrator' */

/* Exported block parameters */
real32_T UpThr = 6.0F;        /* Variable: UpThr
   * Referenced by: '<S3>/UpThr'

/* Exported block states */
real32_T myState;             /* '<S1>/Integrator' */
```

The file `rtwdemo_roll.h` declares the variables. To access these variables, your external code can include (`#include`) this header file.

In `rtwdemo_roll.c`, search the file for the names of the variables, such as `UpThr`. The model algorithm in the `rtwdemo_roll_step` function reads and writes to the variables.

**Built-In Storage Classes You Can Choose**

The default storage class setting for a data item is Auto, which means the code generator determines how the item appears in the code. For a list of built-in storage classes that you can choose, see “Choose a Storage Class for Controlling Data Representation in the Generated Code” (Simulink Coder).
Decide Where to Store Storage Class Specification

For each individual signal or state data item (including Data Store Memory blocks) to which you directly apply a storage class, Simulink stores your storage class specification either in the model file or in the properties of a signal data object (Simulink.Signal), which you create in the base workspace, a model workspace, or a data dictionary. To apply a storage class to a block parameter, you must create a parameter data object (such as Simulink.Parameter) and specify the storage class in the object.

- When you apply a storage class to a signal or state in a model, for example, by using the Model Data Editor or the Property Inspector, you store the storage class specification in the model file.

  If you use this technique, you cannot control other characteristics of the data item, such as data type, by using an external signal data object.

- When you create a signal or parameter data object, you apply the storage class by using the CoderInfo property of the object. The value of the property is a Simulink.CoderInfo object, whose StorageClass property you use to specify the storage class. After you associate the data item in the model with the object, the data item acquires the storage class from the object.

For signals, states, and Data Store Memory blocks, to decide whether to store the storage class specification in the model or in a data object, see “Store Design Attributes of Signals and States” (Simulink).

Apply Storage Classes to Outport Blocks by Using the Model Data Editor

You can use the Model Data Editor to apply a storage class directly to a root-level Outport block or to the input signal that drives the block.

- To store the storage class specification in the Outport block, use the Inports/Outports tab in the Model Data Editor. When you use this technique, the specification remains after you delete the input signal that drives the block. Use this technique to configure the model interface before you develop the internal algorithm.

- To store the specification in the input signal that drives the block, use the Signals tab in the Model Data Editor.
Techniques to Apply Storage Classes Interactively

To apply storage classes to multiple data items in a list that you can search, sort, and filter, use the Model Data Editor (View > Model Data Editor) as shown in “Apply Storage Classes to Data Items” on page 22-81.

To apply a storage class while focusing on a single signal, block state, or parameter, use the Property Inspector (View > Property Inspector), the Signal Properties dialog box (for a signal), or the block dialog box (for a state or parameter). Under Code Generation, apply the storage class.

- For a parameter, first set the value of the parameter to the name that you want to use for the required parameter object. Then, create and configure the parameter object as shown in “Create Tunable Calibration Parameter in the Generated Code” on page 22-121.

- For a signal, state, or Data Store Memory block, first give the signal or state a name, which the code generator uses as the name of the corresponding global symbol. Then, either specify a storage class using Storage class (in which case the model file stores the specification) or create a signal data object as shown in “Use Data Objects in Simulink Models” (Simulink) and apply a storage class to the object.

Techniques to Apply Storage Classes Programmatically

- For a block parameter, use set_param to set the value of the parameter. Use other commands to create and configure the properties of the required parameter object. For an example, see “Create Tunable Calibration Parameter in the Generated Code” on page 22-121.

- For a signal, use get_param or find_system to return a handle to the block port that generates the signal. Use the parameters of the handle to name the signal, then apply the storage class directly (see “Apply Storage Class Directly to Signal Line” (Simulink Coder)) or configure the signal to acquire settings, including the storage class, from a signal object (see “Use Data Objects in Simulink Models” (Simulink)).

- For an Inport block, configure the signal line that exits the block. For an Outport block, configure the block or the signal line that enters the block. For an example, see “Design Data Interface by Configuring Inport and Outport Blocks” on page 22-206.

- For a block state, use set_param to interact with the block. Name the state, then apply the storage class directly (see “Apply Storage Class Directly to Block State” (Simulink Coder)) or configure the state to acquire the storage class from a signal object (see “Use Data Objects in Simulink Models” (Simulink)).
For a Data Store Memory block, use set_param to interact with the block. Because the data store already has a name, you do not need to specify a name. Apply the storage class directly by using the StateStorageClass parameter or configure the data store to acquire the storage class from a signal object.

To interact with a signal or parameter data object that you store in a model workspace or data dictionary, use the programmatic interface of the workspace or dictionary. See “Interact With Variables Programmatically” (Simulink).

**Apply Storage Class Directly to Signal Line**

This example shows how to programmatically apply a storage class directly to a signal line.

1. Open the example model rtwdemo_secondOrderSystem.
   ```matlab
   rtwdemo_secondOrderSystem
   ```

2. Get a handle to the output of the block named Force: f(t).
   ```matlab
   portHandles = ... 
   get_param('rtwdemo_secondOrderSystem/Force: f(t)','PortHandles'); 
   outportHandle = portHandles.Outport;
   ```

3. Set the name of the corresponding signal to ForceSignal.
   ```matlab
   set_param(outportHandle,'Name','ForceSignal')
   ```

4. Set the storage class of the signal to ExportedGlobal.
   ```matlab
   set_param(outportHandle,'StorageClass','ExportedGlobal')
   ```

5. Generate code from the model. The code declares and defines a global variable ForceSignal to represent the signal.

**Apply Storage Class Directly to Block State**

This example shows how to programmatically apply a storage class to a block state.

1. Open the example model rtwdemo_basicsc.
   ```matlab
   rtwdemo_basicsc
   ```

2. Name the state of the Delay block as myState.
   ```matlab
   set_param('rtwdemo_basicsc/Delay','StateName','myState')
   ```
3 Set the storage class of the state to `ExportedGlobal`.

```matlab
set_param('rtwdemo_basicsc/Delay', ...
    'StateStorageClass','ExportedGlobal')
```

4 Generate code from the model. The code declares and defines a global variable `myState` to represent the state.

## Parameter Object Configuration Quick Reference Diagram

This diagram shows the code generation and storage class options that control the representation of parameter objects in the generated code.

### Enumerated Data Types

Enumerated data is data that is restricted to a finite set of values. An enumerated data type is a MATLAB class that defines a set of enumerated values. Each enumerated value consists of an enumerated name and an underlying integer which the software uses internally and in generated code. The following is a MATLAB class definition for an enumerated data type named BasicColors, which is used in the examples in this section.

```matlab
classdef BasicColors < Simulink.IntEnumType
    enumeration
        Red(0)
        Yellow(1)
        Blue(2)
    end
end
```

For basic information about enumerated data types and their use in Simulink models, see “Use Enumerated Data in Simulink Models” (Simulink). For information about enumerated data types in Stateflow charts, see “Define Enumerated Data Types” (Stateflow).

### Specify Integer Data Type for Enumeration

When you specify a data type for your enumeration, you can:

- Control the size of enumerated data types in the generated code by specifying a superclass.
• Reduce RAM/ROM usage.
• Improve code portability.
• Improve integration with legacy code.

You can specify any of these integer data types:

• int8
• uint8
• int16
• uint16
• int32
• Simulink.IntEnumType. Specify values in the range of the signed integer for your hardware platform.

**Use a Class Definition in a MATLAB File**

To specify an integer data type size, derive your enumeration class from the integer data type.

```matlab
classdef Colors < int8
    enumeration
        Red(0)
        Green(1)
        Blue(2)
    end
end
```

The code generator generates this code:

```
typedef int8_T Colors;

#define Red      ((Colors)0)
#define Green ((Colors)1)
#define Blue     ((Colors)2)
```

**Use the Function Simulink.defineIntEnumType**

To specify an integer data type size, specify the name-value pair `StorageType` as the integer data type.

```matlab
Simulink.defineIntEnumType('Colors',{'Red','Green','Blue'},... [0;1;2],'StorageType','int8')
```
The code generator generates this code:

```c
typedef int8_T Colors;
#define Red ((Colors)0)
#define Green ((Colors)1)
#define Blue ((Colors)2)
```

**Customize Enumerated Data Type**

When you generate code from a model that uses enumerated data, you can implement these static methods to customize the behavior of the type during simulation and in generated code:

- `getDefaultValue` — Specifies the default value of the enumerated data type.
- `getDescription` — Specifies a description of the enumerated data type.
- `getHeaderFile` — Specifies a header file where the type is defined for generated code.
- `getDataScope` — Specifies whether generated code exports or imports the enumerated data type definition to or from a separate header file.
- `addClassNameToEnumNames` — Specifies whether the class name becomes a prefix in generated code.

The first of these methods, `getDefaultValue`, is relevant to both simulation and code generation, and is described in “Specify a Default Enumerated Value” (Simulink). The other methods are relevant only to code generation. To customize the behavior of an enumerated type, include a version of the method in the `methods(Static)` section of the enumeration class definition. If you do not want to customize the type, omit the `methods(Static)` section. The table summarizes the methods and the data to supply for each one.
<table>
<thead>
<tr>
<th>Static Method</th>
<th>Purpose</th>
<th>Default Value Without Implementing Method</th>
<th>Custom Return Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>getDefaultValue</code></td>
<td>Specifies the default enumeration member for the class.</td>
<td>First member specified in the enumeration definition</td>
<td>A character vector containing the name of an enumeration member in the class (see “Instantiate Enumerations” (Simulink)).</td>
</tr>
<tr>
<td><code>getDescription</code></td>
<td>Specifies a description of the enumeration class.</td>
<td>''</td>
<td>A character vector containing the description of the type.</td>
</tr>
<tr>
<td><code>getHeaderFile</code></td>
<td>Specifies the name of a header file. The method <code>getDataScope</code> determines the significance of the file.</td>
<td>''</td>
<td>A character vector containing the name of the header file that defines the enumerated type.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>By default, the generated <code>#include</code> directive uses the preprocessor delimiter &quot; instead of <code>&lt; and &gt;</code>. To generate the directive <code>#include &lt;myTypes.h&gt;</code>, specify the custom return value as '&lt;myTypes.h&gt;'.</td>
</tr>
</tbody>
</table>
### Specify a Description

To specify a description for an enumerated data type, include this method in the `methods(Static)` section of the enumeration class:

```matlab
function retVal = getDescription()
    % GETDESCRIPTION  Optional description of the data type.
    retVal = 'description';
end
```

Substitute a MATLAB character vector for `description`. The generated code that defines the enumerated type includes the specified description.

### Import Type Definition in Generated Code

To prevent generated code from defining an enumerated data type, which allows you to provide the definition in an external file, include these methods in the `methods(Static)` section of the enumeration class:

```matlab
function retVal = getHeaderFile()
    % GETHEADERFILE Specifies the file that defines this type in generated code.
    % The method getDataScope determines the significance of the specified file.
    retVal = 'imported_enum_type.h';
end
```
function retVal = getDataScope()
    % GETDATASCOPE Specifies whether generated code imports or exports this type.
    % Return one of:
    % 'Auto':     define type in model_types.h, or import if header file specified
    % 'Exported': define type in a generated header file
    % 'Imported': import type definition from specified header file
    % If you do not define this method, DataScope is 'Auto' by default.
    retVal = 'Imported';
end

Instead of defining the type in model_types.h, which is the default behavior, generated code imports the definition from the specified header file using a #include statement like:

#include "imported_enum_type.h"

Generating code does not create the imported header file. You must provide the header file, using the file name specified by the method getHeaderFile, that defines the enumerated data type.

To create a Simulink enumeration that corresponds to your existing C-code enumeration, use the Simulink.importExternalCTypes function.

Export Type Definition inGenerated Code

To generate a separate header file that defines an enumerated data type, include these methods in the methods(Static) section of the enumeration class:

function retVal = getDataScope()
    % GETDATASCOPE Specifies whether generated code imports or exports this type.
    % Return one of:
    % 'Auto':     define type in model_types.h, or import if header file specified
    % 'Exported': define type in a generated header file
    % 'Imported': import type definition from specified header file
    % If you do not define this method, DataScope is 'Auto' by default.
    retVal = 'Exported';
end

function retVal = getHeaderFile()
    % GETHEADERFILE Specifies the file that defines this type in generated code.
    % The method getDataScope determines the significance of the specified file.
    retVal = 'exported_enum_type.h';
end

Generated code exports the enumerated type definition to the generated header file exported_enum_type.h.
Add Prefixes To Class Names

By default, enumerated values in generated code have the same names that they have in the enumeration class definition. Alternatively, your code can prefix every enumerated value in an enumeration class with the name of the class. You can use this technique to prevent identifier conflicts or to improve the readability of the code. To specify class name prefixing, include this method in the methods(Static) section of an enumeration class:

```matlab
function retVal = addClassNameToEnumNames()
    % ADDCLASSNAMETOENUMNAMES Specifies whether to add the class name
    % as a prefix to enumeration member names in generated code.
    % Return true or false.
    % If you do not define this method, no prefix is added.
    retVal = true;
end
```

Specify the return value as `true` to enable class name prefixing or as `false` to suppress prefixing. If you specify `true`, each enumerated value in the class appears in generated code as `EnumTypeName_EnumName`. For the example enumeration class `BasicColors` in “Enumerated Data Types” on page 22-90, the data type definition in generated code might look like this:

```c
#ifndef _DEFINED_TYPEDEF_FOR_BasicColors_
#define _DEFINED_TYPEDEF_FOR_BasicColors_

typedef enum {
    BasicColors_Red = 0,       /* Default value */
    BasicColors_Yellow = 1,
    BasicColors_Blue = 2,
} BasicColors;

#endif
```

The enumeration class name `BasicColors` appears as a prefix for each of the enumerated names.

Control Enumerated Type Implementation in Generated Code

Suppose that you define an enumerated type `BasicColors`. You can specify that the generated code implement the type definition using:

- An `enum` block. The native integer type of your hardware is the underlying integer type for the enumeration members.
- A `typedef` statement and a series of `define` macros. The `typedef` statement bases the enumerated type name on a specific integer data type, such as `int8`. The macros associate the enumeration members with the underlying integer values.
Implement Enumerated Type Using enum Block

To implement the type definition using an enum block:

- In Simulink, define the enumerated type using a classdef block in a script file. Derive the enumeration from the type Simulink.IntEnumType.
- Alternatively, use the function Simulink.defineIntEnumType. Do not specify the property StorageType.

When you generate code, the type definition appears in an enum block.

```c
#ifndef _DEFINED_TYPEDEF_FOR_BasicColors_
#define _DEFINED_TYPEDEF_FOR_BasicColors_

typedef enum {
    Red = 0,          /* Default value */
    Yellow,
    Blue,
} BasicColors;

#endif
```

Implement Enumerated Type Using a Specific Integer Type

To implement the type definition using a typedef statement and #define macros:

- In Simulink, define the enumerated type using a classdef block in a script file. Derive the enumeration from a specific integer type such as int8.
- Alternatively, use the function Simulink.defineIntEnumType. Specify the property StorageType using a specific integer type such as int8.

When you generate code, the type definition appears as a typedef statement and a series of #define macros.

```c
#ifndef _DEFINED_TYPEDEF_FOR_BasicColors_
#define _DEFINED_TYPEDEF_FOR_BasicColors_

typedef int8_T BasicColors;

#define Red ((BasicColors)0)  /* Default value */
#define Yellow ((BasicColors)1)
#define Blue ((BasicColors)2)
```
By default, the generated file `model_types.h` contains enumerated type definitions.

**Type Casting for Enumerations**

**Safe Casting**

A Simulink Data Type Conversion block accepts a signal of integer type. The block converts the input to one of the underlying values of an enumerated type.

If the input value does not match any of the underlying values of the enumerated type values, Simulink inserts a safe cast to replace the input value with the enumerated type default value.

**Enable and Disable Safe Casting**

You can enable or disable safe casting for enumerations during code generation for a Simulink Data Type Conversion block or a Stateflow block.

To control safe casting, enable or disable the **Saturate on integer overflow** block parameter. The parameter works as follows:

- **Enabled**: Simulink replaces a nonmatching input value with the default value of the enumerated values during simulation. The software generates a safe cast function during code generation.
- **Disabled**: For a nonmatching input value, Simulink generates an error during simulation. The software omits the safe cast function during code generation. In this case, the code is more efficient. However, the code may be more vulnerable to run-time errors.

**Safe Cast Function in Generated Code**

This example shows how the safe cast function `int32_T ET08_safe_cast_to_BasicColors` for the enumeration `BasicColors` appears in generated code when generated for 32-bit hardware.

```c
static int32_T ET08_safe_cast_to_BasicColors(int32_T input)
{
    int32_T output;
    /* Initialize output value to default value for BasicColors (Red) */
```
```c
output = 0;
if ((input >= 0) && (input <= 2)) {
    /* Set output value to input value if it is a member of BasicColors */
    output = input;
}
return output;
}
```

Through this function, the enumerated type’s default value is used if the input value does not match one of underlying values of the enumerated type’s values.

If the block’s **Saturate on integer overflow** parameter is disabled, this function does not appear in generated code.

**Enumerated Type Limitations**

- Generated code does not support logging enumerated data.

| “Data Stores Shared by Instances of a Reusable Model” on page 22-106 |
| “Structures in Generated Code Using Data Stores” on page 22-107 |

About Data Stores

A data store contains data that is accessible in a model hierarchy at or below the level in which the data store is defined. Data stores can allow subsystems and referenced models to share data without having to use I/O ports to pass the data from level to level. See “Data Stores with Data Store Memory Blocks” (Simulink) for information about data stores in Simulink. This section provides additional information about data store code generation.

Generate Code for Data Store Memory Blocks

To control the code generated for a Data Store Memory block, apply a storage class to the data store. You can associate a Data Store Memory block with a signal object that you store in a workspace or data dictionary, and control code generation for the block by applying the storage class to the object:

1. In the model, select View > Model Data Editor.
2. In the Model Data Editor, select the Data Stores tab.
3. Begin editing the name of the target Data Store Memory block by clicking the corresponding row in the Name column.
4. Next to the name, click the button ☰ and select Create and Resolve.
5. In the Create New Data dialog box, set Value to Simulink.Signal. Optionally, use the Location drop-down list to choose a workspace for storing the resulting Simulink.Signal object.
6 Click **Create**. The `Simulink.Signal` object, which has the same name as the data store, appears in the target workspace. Simulink selects the block parameter **Data store name must resolve to Simulink signal object**.

The property dialog box for the object opens.

7 Use the **Storage class** drop-down list to apply the target storage class.

---

**Note** When a Data Store Memory block is associated with a signal object, the mapping between the **Data store name** and the signal object name must be one-to-one. If two or more identically named entities map to the same signal object, the name conflict is flagged as an error at code generation time. See “Resolve Conflicts in Configuration of Signal Objects for Code Generation” (Simulink) for more information.

---

### Storage Classes for Data Store Memory Blocks

You can control how Data Store Memory blocks in your model are stored and represented in the generated code by assigning storage classes and type qualifiers. You do this in almost exactly the same way you assign storage classes and type qualifiers for block states.

Data Store Memory blocks, like block states, have Auto storage class by default, and their memory is stored within the `DWork` vector. The symbolic name of the storage location is based on the data store name.

You can generate code from multiple Data Store Memory blocks that have the same data store name, subject to the following restriction: _at most one_ of the identically named blocks can have a storage class other than Auto. An error is reported if this condition is not met.

For blocks with Auto storage class, the code generator produces a unique symbolic name for each block to avoid name clashes. For Data Store Memory blocks with storage classes other than Auto, the generated code uses the data store name as the symbol.

In the following model, a Data Store Write block writes to memory declared by the Data Store Memory block `myData`:
To control the storage declaration for a Data Store Memory block, use the Code Generation > Signal object class and Code Generation > Storage class drop-down lists of the Data Store Memory block dialog box. Set Signal object class to Simulink.Signal (the default), and choose a storage class from the Storage class drop-down list. The next figure shows the Data Store Memory block dialog box for the preceding model.

To apply storage classes to data stores, you can alternatively use the Data Stores tab in the Model Data Editor (in the model, View > Model Data Editor).
Data Store Memory blocks are nonvirtual because code is generated for their initialization in `.c` and `.cpp` files and their declarations in header files. The following table shows how the code generated for the Data Store Memory block in the preceding model differs for different storage classes. The table gives the variable declarations and `MdlOutputs` code generated for the `myData` block.

<table>
<thead>

For information about applying storage classes, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 22-81.

**Data Store Buffering in Generated Code**

A Data Store Read block is a nonvirtual block that copies the value of the data store to its output buffer when it executes. Since the value is buffered, downstream blocks connected to the output of the data store read utilize the same value, even if a Data Store Write block updates the data store in between execution of two of the downstream blocks.
The next figure shows a model that uses blocks whose priorities have been modified to achieve a particular order of execution:

The following execution order applies:

1. The block Data Store Read buffers the current value of the data store A at its output.
2. The block Abs1 uses the buffered output of Data Store Read.
3. The block Data Store Write updates the data store.
4. The block Abs uses the buffered output of Data Store Read.
Because the output of Data Store Read is a buffer, both Abs and Abs1 use the same value: the value of the data store at the time that Data Store Read executes.

The next figure shows another example:

```
real_T rtb_DataStoreRead;

/* DataStoreWrite: '<Root>/Data Store Write' incorporates:
* Constant: '<Root>/Constant'
*/
A = DoBufferDSMRead2_P.Constant_Value;

/* DataStoreRead: '<Root>/Data Store Read' */
rtb_DataStoreRead = A; /* Buffer the value of A */

/* Outputs for Atomic SubSystem: '<Root>/Atomic SubSystem' */
DoBufferDSMRead.AtomicSubsystem(); /* We don't do a global analysis to
detect if this function writes to A */

/* Output: '<Root>/Out1' incorporates:
* Sum: '<Root>/Sum'
*/
DoBufferDSMRead2_Y.Out1 = rtb_DataStoreRead + DoBufferDSMRead2_B.Abs;
```

In this example, the following execution order applies:

1. The block Data Store Read buffers the current value of the data store A at its output.
2. Atomic Subsystem executes.
3. The Sum block adds the output of Atomic Subsystem to the output of Data Store Read.
Simulink assumes that Atomic Subsystem might update the data store, so Simulink buffers the data store. Atomic Subsystem executes after Data Store Read buffers its output, and the buffer provides a way for the Sum block to use the value of the data store as it was when Data Store Read executed.

In some cases, the code generator determines that it can optimize away the output buffer for a Data Store Read block, and the generated code refers to the data store directly, rather than a buffered value of it. The next figure shows an example:

In the generated code, the argument of the \texttt{fabs()} function is the data store \( A \) rather than a buffered value.

**Data Stores Shared by Instances of a Reusable Model**

You can use a data store to share a piece of data between the instances of a reusable referenced model (see “Specify Reusability of Referenced Models” (Simulink)) or a model that you configure to generate reentrant code (by setting the configuration parameter
**Code interface packaging** to Reusable function. If you implement the data store as a Data Store Memory block and select the **Share across model instances** parameter:

- By default, the data store appears in the generated code as a separate global symbol.
- If you have Embedded Coder, to restrict access such that only the code generated from the model can use the data store, configure the data store to appear as **static** by applying the custom storage class **FileScope**. For more information about **FileScope** and other custom storage classes, see “Choose a Storage Class for Controlling Data Representation in the Generated Code” on page 22-69.

**Structures in Generated Code Using Data Stores**

If you use more than one data store to provide global access to multiple signals in generated code, you can combine the signals into a single structure variable by using one data store. This combination of signal data can help you integrate the code generated from a model with other existing code that requires the data in a structure format.

This example shows how to store several model signals in a structure in generated code using a single data store. To store multiple signals in a data store, you configure the data store to accept a composite signal, such as a nonvirtual bus signal or an array of nonvirtual bus signals.

**Explore Example Model**

1. Open the example model `ex_bus_struct_in_code`.
   
   The model contains three subsystems that perform calculations on the inputs from the top level of the model. In each subsystem, a Data Store Memory block stores an intermediate calculated signal.

2. Generate code with the model. In the code generation report, view the file `ex_bus_struct_in_code.c`. The code defines a global variable for each data store.

   ```c
   real_T BioBTURate;
   real_T CoalBTURate;
   real_T GasBTURate;
   ```

Suppose that you want to integrate code generated from the example model with other existing code. Suppose also that the existing code requires access to all of the data from the three data stores in a single structure variable. You can use a data store to assemble all of the target data in a structure in generated code.
Configure Data Store

Configure a data store to contain multiple signals by creating a bus type to use as the data type of the data store. Define the bus type using the same hierarchy of elements as the structure that you want to appear in generated code.

1. Open the Bus Editor tool.

   `buseditor`

2. Define a new bus type `Raw_BTU_Rate` with one element for each of the three target signals. Name the elements `BioBTU`, `GasBTU`, and `CoalBTU`.

   ![Base Workspace](image)
   ![Raw_BTU_Rate](image)
   - BioBTU
   - GasBTU
   - CoalBTU

3. At the top level of the example model, add a Data Store Memory block.

4. In the Simulink Editor, select **View > Model Data Editor**.

5. In the Model Data Editor, inspect the **Data Stores** tab.

6. For the new Data Store Memory block, use the **Name** column to set the data store name to `Raw_BTU_Data`.

7. Use the **Data Type** column to set the data type of the data store to `Bus: Raw_BTU_Rate`.

8. Set the **Change view** drop-down list to **Code**.

9. Use the **Storage Class** column to apply the storage class `ExportedGlobal`.

Write to Data Store Elements

To write to a specific element of a data store, use a Data Store Write block. On the **Element Assignment** tab in the dialog box, you can specify to write to a single element, a collection of elements, or the entire contents of a data store.

1. Open the **Biomass Calc** subsystem.

2. Delete the Data Store Memory block `BioBTURate`.

3. In the block dialog box for the Data Store Write block, set **Data store name** to `Raw_BTU_Data`. 
4 On the **Element Assignment** tab, under **Signals in the bus**, expand the contents of the data store `Raw_BTU_Data`. Click the element `BioBTU`, and then click **Select**. Click **OK**.

5 Modify the **Gas Calc** and **Coal Calc** subsystems similarly.

- Delete the Data Store Memory block in each subsystem.
- In each Data Store Write block dialog box, set **Data store name** to `Raw_BTU_Data`.
- In the **Gas Calc** subsystem, use the Data Store Write block to write to the data store element `GasBTU`. In the **Coal Calc** subsystem, write to the element `CoalBTU`.  

22-109
Generate Code with Data Store Structure

1. Generate code for the example model.

2. In the code generation report, view the file `ex_bus_struct_in_code_types.h`. The code defines a structure that corresponds to the bus type `Raw_BTU_Rate`.

   ```c
   typedef struct {
     real_T BioBTU;
     real_T GasBTU;
     real_T CoalBTU;
   } Raw_BTU_Rate;
   ```

3. View the file `ex_bus_struct_in_code.c`. The code represents the data store with a global variable `Raw_BTU_Data` of the structure type `Raw_BTU_Rate`. In the model step function, the code assigns the data from the calculated signals to the fields of the global variable `Raw_BTU_Data`.

Specify Single-Precision Data Type for Embedded Application

When you want code that uses only single precision, such as when you are targeting a single-precision processor, you can use model configuration parameters and block parameters to prevent the introduction of double in the model.

To design and validate a single-precision model, see “Validate a Floating-Point Embedded Model” (Simulink). If you have Fixed-Point Designer, you can use the Single Precision Converter app (see “Single-Precision Design for Simulink” (Fixed-Point Designer)).

Use single Data Type as Default for Underspecified Types

This example shows how to avoid introducing a double-precision data type in code generated for a single-precision hardware target.

If you specify an inherited data type for signals, but data type propagation rules cannot determine data types for the signals, the signal data types default to double. You can use a model configuration parameter to specify the default data type as single.

Explore Example Model

Open the example model rtwdemo_underspecified_datatype and configure it to show the generated names of blocks.

```matlab
model = 'rtwdemo_underspecified_datatype';
load_system(model)
set_param(model,'HideAutomaticNames','off')
open_system(model);
```
The root imports In2, In3, and In4 specify Inherit: Auto for the Data type block parameter. The downstream blocks also use inherited data types.

**Generate Code with double as Default Data Type**

The model starts with the configuration parameter System target file set to ert.tlc, which requires Embedded Coder. Set System target file to grt.tlc instead.

```matlab
generateCode('model', 'SystemTargetFile', 'grt.tlc');
generateCode('model', 'CodeGenerationArguments', '-o rtwdemo_underspecified_datatype_rtwbuild');
```

Generate code from the model.

```matlab
rtwbuild(model)
```
In the code generation report, view the file `rtwdemo_underspecified_datatype.h`. The code uses the double data type to define the variables In2, In3, and In4 because the Inport data types are underspecified in the model.

cfile = fullfile('rtwdemo_underspecified_datatype_grt_rtw',...
   'rtwdemo_underspecified_datatype_h');
rtwdemodbtype(cfile,...
   /* External inputs (root inport signals with default storage) */',...'
   /* External outputs (root outports fed by signals with default storage) */',...
   1, 0);

/* External inputs (root inport signals with default storage) */
typedef struct {
    int8_T In1;                          /* '<Root>/In1' */
    real_T In2;                          /* '<Root>/In2' */
    real_T In3;                          /* '<Root>/In3' */
    real_T In4;                          /* '<Root>/In4' */
} ExtU_rtwdemo_underspecified_d_T;

Generate Code with single as Default Data Type

Open the Configuration Parameters dialog box. On the Math and Data Types pane, select single in the Default for underspecified data type drop-down list.

Alternatively, enable the optimization at the command prompt.

set_param(model, 'DefaultUnderspecifiedDataType', 'single');

Generate code from the model.

rtwbuild(model)

### Starting build procedure for model: rtwdemo_underspecified_datatype
### Successful completion of build procedure for model: rtwdemo_underspecified_datatype

In the code generation report, view the file `rtwdemo_underspecified_datatype.h`. The code uses the single data type to define the variables In2, In3, and In4.

rtwdemodbtype(cfile,...
   /* External inputs (root inport signals with default storage) */',...'
   /* External outputs (root outports fed by signals with default storage) */',...
   1, 0);

/* External inputs (root inport signals with default storage) */
typedef struct {
    int8_T In1;                        /* '<Root>/In1' */
    real32_T In2;                      /* '<Root>/In2' */
    real32_T In3;                      /* '<Root>/In3' */
    real32_T In4;                      /* '<Root>/In4' */
} ExtU_rtwdemo_underspecified_d_T;

Tune Phase Parameter of Sine Wave Block During Code Execution

Under certain conditions, you cannot configure the Phase parameter of a Sine Wave block to appear in the generated code as a tunable global variable (for more information, see the block reference page). This example shows how to generate code so that you can tune the phase during execution.

Create the model `ex_phase_tunable` by using a Digital Clock block.

```matlab
open_system('ex_phase_tunable')
```

Set Default parameter behavior to Tunable so that the parameters of the Sine Wave block appear in the generated code as tunable fields of the global parameter structure.

```matlab
set_param('ex_phase_tunable','DefaultParameterBehavior','Tunable')
```

Generate code from the model.

```matlab
rtwbuild('ex_phase_tunable')
```

### Starting build procedure for model: ex_phase_tunable
### Successful completion of code generation for model: ex_phase_tunable

In the code generation report, view the file `ex_phase_tunable.c`. The code algorithm in the model step function calculates the Sine Wave block output. The parameters of the block, including Phase, appear in the code as tunable structure fields.

```plaintext
/* Outport: '<Root>/Out1' incorporates:
 *  DigitalClock: '<Root>/Digital Clock'
 *  Sin: '<Root>/Sine Wave'
 */
```
ex_phase_tunable_Y.Out1 = sin(ex_phase_tunable_P.SineWave_Freq *
  (((ex_phase_tunable_M->Timing.clockTick1 +
    ex_phase_tunable_M->Timing.clockTickH1* 4294967296.0)) * 1.0) +
  ex_phase_tunable_P.SineWave_Phase) * ex_phase_tunable_P.SineWave_Amp +
  ex_phase_tunable_P.SineWave_Bias;

During code execution, you can assign new values to the structure field that corresponds
to the Phase parameter.

Switch Between Output Waveforms During Code Execution for Waveform Generator Block

This example shows how to generate code that enables you to switch between stimulus waveforms during code execution.

For a Waveform Generator block, you cannot make the parameters of a waveform, such as amplitude and phase shift, tunable in the generated code. Instead, you can generate code that enables you to choose an active waveform from a set of waveform variants that you specify in the block. During execution of the code, you activate a variant by adjusting the value of a global structure field.

You must set the model configuration parameter Default parameter behavior to Tunable. Then, by default, block parameters in the model appear tunable in the generated code. These parameters can consume large amounts of memory for a large model.

Create the model ex_switch_waveform.

open_system('ex_switch_waveform')

In the Waveform Generator block, configure this waveform:

square(amp,10,0,dutyCycle)

In the base workspace, create the variables amp and dutyCycle.

amp = 2.71;
dutyCycle = 50;

This waveform represents the baseline stimulus that you want the application to use at the start of execution.
Suppose that, during execution, you want to observe the effects of changing the waveform frequency from 10 to 15 and the phase shift from 0 to 0.5. In the Waveform Generator block, add these waveform variants:

```matlab
square(amp,10,0.5,dutyCycle)
square(amp,15,0,dutyCycle)
square(amp,15,0.5,dutyCycle)
```

Set the model configuration parameter **Default parameter behavior** to Tunable.

```matlab
set_param('ex_switch_waveform','DefaultParameterBehavior','Tunable')
```

Generate code from the model.

```matlab
rtwbuild('ex_switch_waveform')
```

### Starting build procedure for model: ex_switch_waveform
### Successful completion of code generation for model: ex_switch_waveform

The generated file `ex_switch_waveform.h` defines the standard structure type that stores tunable parameter data for the model. The structure contains a field whose value represents the active waveform.

```matlab
file = fullfile('ex_switch_waveform_grt_rtw','ex_switch_waveform.h');
rtwdemodbtype(file,'/* Parameters (default storage) */',...'
  /* Real-time Model Data Structure */',1,0)

/* Parameters (default storage) */
struct P_ex_switch_waveform_T_ {
  real_T WaveformGeneratorStimulus_Selec; /* Mask Parameter: WaveformGeneratorStimulus_Selec */
    /* Referenced by: '<S1>/Switch' */
  real_T GainControlSystem_Gain;       /* Expression: 3.5 */
    /* Referenced by: '<Root>/Gain (Control System)' */
};
```

The file `ex_switch_waveform_data.c` defines a global structure variable and initializes the field value to 1. This value represents the baseline waveform.

```matlab
file = fullfile('ex_switch_waveform_grt_rtw','ex_switch_waveform_data.c');
rtwdemodbtype(file,'/* Block parameters (default storage) */',1,1)

/* Block parameters (default storage) */
```
The file `ex_switch_waveform.c` defines the model execution function. The function uses a switch statement to determine the value of the active waveform, and then calculates the value of the root-level Outport block, Out1.

```c
switch ((int32_T)ex_switch_waveform_P.WaveformGeneratorStimulus_Selec) {
    case 1:
        temp = temp - floor(temp) <= 0.5 ? 2.71 : -2.71;
        break;
    case 2:
        temp = (temp - 0.79577471545947676) - floor(temp - 0.79577471545947676) <=
            0.5 ? 2.71 : -2.71;
        break;
    case 3:
        temp = temp_tmp_tmp - floor(temp_tmp_tmp) <= 0.5 ? 2.71 : -2.71;
        break;
    default:
        temp = (temp_tmp_tmp - 1.1936620731892151) - floor(temp_tmp_tmp -
            1.1936620731892151) <= 0.5 ? 2.71 : -2.71;
        break;
}
```

/* End of MultiPortSwitch: '<S1>/MultiportSwitch' */

/* Outport: '<Root>/Out1' incorporates:
   * Gain: '<Root>/Gain (Control System)'
ex_switch_waveform_Y.Out1 = ex_switch_waveform_P.GainControlSystem_Gain * temp;

During code execution, to change the active waveform, adjust the value of the structure field in the global parameters structure.

Create Tunable Calibration Parameter in the Generated Code

A calibration parameter is a value stored in global memory that an algorithm reads for use in calculations but does not write to. Calibration parameters are tunable because you can change the stored value during algorithm execution. You create calibration parameters so that you can:

- Determine an optimal parameter value by tuning the parameter and monitoring signal values during execution.
- Efficiently adapt an algorithm to different execution conditions by overwriting the parameter value stored in memory. For example, you can use the same control algorithm for multiple vehicles of different masses by storing different parameter values in each vehicle’s engine control unit.

In Simulink, create a Simulink.Parameter object to represent a calibration parameter. You use the parameter object to set block parameter values, such as the Gain parameter of a Gain block. To control the representation of the parameter object in the generated code, you apply a storage class to the object.

To make block parameters accessible in the generated code by default, for example for rapid prototyping, set Default parameter behavior (see “Default parameter behavior” (Simulink Coder)) to Tunable. For more information, see “Configure Data Accessibility for Rapid Prototyping” on page 22-3.

Represent Block Parameter as Tunable Global Variable

This example shows how to create tunable parameter data by representing block parameters as global variables in the generated code.

Configure Block Parameter by Using Parameter Object

Open the example model rtwdemo_paraminline and configure it to show the generated names of blocks.

```matlab
load_system('rtwdemo_paraminline')
set_param('rtwdemo_paraminline','HideAutomaticNames','off')
open_system('rtwdemo_paraminline')
```
In the model, select **View > Model Data Editor**.

In the Model Data Editor, inspect the **Parameters** tab.

In the model, click the **G1** Gain block. The Model Data Editor highlights the row that corresponds to the **Gain** parameter of the block.

In the Model Data Editor **Value** column, change the gain value from 2 to **myGainParam**.

Next to **myGainParam**, click the action button (with three vertical dots) and select **Create**.

In the Create New Data block dialog box, set **Value** to `Simulink.Parameter(2)`. Click **Create**. A `Simulink.Parameter` object **myGainParam** stores the parameter value, 2, in the base workspace.

In the **myGainParam** dialog box, set **Storage class** to `ExportedGlobal` and click **OK**. This storage class causes the parameter object to appear in the generated code as a tunable global variable.

Alternatively, to create the parameter object and configure the model, use these commands at the command prompt:
set_param('rtwdemo_paraminline/G1','Gain','myGainParam')
myGainParam = Simulink.Parameter(2);
myGainParam.CoderInfo.StorageClass = 'ExportedGlobal';

Use the Model Data Editor to create a parameter object, myOtherGain, for the G2 Gain block. Apply the storage class ExportedGlobal.

Alternatively, use these commands at the command prompt:
set_param('rtwdemo_paraminline/G2','Gain','myOtherGain')
myOtherGain = Simulink.Parameter(-2);
myOtherGain.CoderInfo.StorageClass = 'ExportedGlobal';

**Generate and Inspect Code**

Generate code from the model.

rtwbuild('rtwdemo_paraminline')

### Starting build procedure for model: rtwdemo_paraminline
### Successful completion of build procedure for model: rtwdemo_paraminline

The generated file `rtwdemo_paraminline.h` contains `extern` declarations of the global variables `myGainParam` and `myOtherGain`. You can include (`#include`) this header file so that your code can read and write the value of the variable during execution.

file = fullfile('rtwdemo_paraminline_grt_rtw','rtwdemo_paraminline.h');
rtwdemodbtype(file,...

  'extern real_T myGainParam;','Referenced by: '<Root>/G2''',1,1)

extern real_T myGainParam;       /* Variable: myGainParam
                                 * Referenced by: '<Root>/G1'
                                 */

extern real_T myOtherGain;       /* Variable: myOtherGain
                                 * Referenced by: '<Root>/G2'
                                 */

The file `rtwdemo_paraminline.c` allocates memory for and initializes `myGainParam` and `myOtherGain`.

file = fullfile('rtwdemo_paraminline_grt_rtw','rtwdemo_paraminline.c');
rtwdemodbtype(file,...

  '/* Exported block parameters */','Referenced by: '<Root>/G2''',1,1)

  /* Exported block parameters */
real_T myGainParam = 2.0; /* Variable: myGainParam
   * Referenced by: '<Root>/G1'
   */
real_T myOtherGain = -2.0;  /* Variable: myOtherGain
   * Referenced by: '<Root>/G2'
   */

The generated code algorithm in the model step function uses myGainParam and myOtherGain for calculations.

rtwdemodbtpe(file,...
   /* Model step function */','/* Model initialize function */',1,0)

/* Model step function */
void rtwdemo_paraminline_step(void)
{
   /* Outport: '<Root>/Out1' incorporates:
      * Gain: '<Root>/G1'
      * Gain: '<Root>/G2'
      * Inport: '<Root>/In1'
      * Sum: '<Root>/Sum'
      */
   rtwdemo_paraminline_Y.Out1 = myGainParam * rtwdemo_paraminline_U.In1 +
                              myOtherGain * -75.0;
}

**Apply Storage Class When Block Parameter Refers to Numeric MATLAB Variable**

If you use a numeric variable to set the value of a block parameter, you cannot apply a storage class to the variable. As a workaround, you can convert the variable to a parameter object, and then apply a storage class to the object. To convert the variable to a parameter object, choose one of these techniques:

- On the Model Data Editor **Parameters** tab, with **Change view** set to Code, find the row that corresponds to the variable. In the **Storage Class** column, from the drop-down list, select **Convert to parameter object**. The Model Data Editor converts the variable to a parameter object. Then, use the **Storage Class** column to apply a storage class to the object.

  You can also use this technique in the Model Explorer.

- Use the Data Object Wizard (see “Create Data Objects for a Model Using Data Object Wizard” (Simulink)). In the Wizard, select the **Parameters** check box. The Wizard
converts variables to objects. Then, apply storage classes to the objects, for example, by using the Model Data Editor or the Model Explorer.

Create Storage Class That Represents Calibration Parameters

Create Storage Class That Represents Calibration Parameters (Embedded Coder)

This example shows how to create a storage class that yields a calibration parameter in the generated code. The storage class causes each parameter object (Simulink.Parameter) to appear as a global variable with special decorations such as keywords and pragmas.

In the generated code, the calibration parameters must appear as global variables defined in a file named calPrms.c and declared in calPrms.h. The variable definitions must look like these definitions:

```c
#pragma SEC(CALPRM)
const volatile float param1 = 3.0F;
const volatile float param2 = 5.0F;
const volatile float param3 = 7.0F;
#pragma SEC()
```

The variables use the keywords const and volatile. The pragma `#pragma SEC(CALPRM)` controls the placement of the variables in memory. To implement the pragma, all of the variable definitions must appear in a contiguous block of code.

Also, the generated code must include an ASAP2 (a2l) description of each parameter.

Create Package for Storing Storage Class and Memory Section Definitions

Now, create a package in your current folder by copying the example package +SimulinkDemos. The package stores the definitions of Parameter and Signal classes that you later use to apply the storage class to data elements in models. Later, the package also stores the definitions of the storage class and an associated memory section.

1. Set your current MATLAB folder to a writable location.
2. Copy the +SimulinkDemos package folder into your current folder. Name the copy +myPackage.
copyfile(fullfile(matlabroot,...
   'toolbox','simulink','simdemos','dataclasses','+SimulinkDemos'),...
   '+myPackage','f')

3 Navigate inside the +myPackage folder to the file Signal.m to edit the definition of the Signal class.

4 Uncomment the methods section that defines the method setupCoderInfo. In the call to the function useLocalCustomStorageClasses, replace 'packageName' with 'myPackage'. When you finish, the section looks like this:

\begin{verbatim}
methods
    function setupCoderInfo(h)
        % Use custom storage classes from this package
        useLocalCustomStorageClasses(h, 'myPackage');
    end
end % methods
\end{verbatim}

5 Save and close the file.

6 Navigate inside the +myPackage folder to the file Parameter.m to edit the definition of the Parameter class. Uncomment the methods section that defines the method setupCoderInfo and replace 'packageName' with 'myPackage'.

7 Save and close the file.

**Create Storage Class and Memory Section**

1 Set your current folder to the folder that contains the package folder +myPackage.

2 Open the Custom Storage Class Designer.

\begin{verbatim}
cscdesigner('myPackage')
\end{verbatim}

3 In the Custom Storage Class Designer, on the **Memory Sections** tab, click **New**.

4 For the new memory section, set properties according to the table.

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>CalMem</td>
</tr>
<tr>
<td>Statements Surround</td>
<td>Group of variables</td>
</tr>
<tr>
<td>Pre Statement</td>
<td>#pragma SEC(CALPRM)</td>
</tr>
<tr>
<td>Post Statement</td>
<td>#pragma SEC()</td>
</tr>
<tr>
<td>Is const</td>
<td>Select</td>
</tr>
<tr>
<td>Is volatile</td>
<td>Select</td>
</tr>
</tbody>
</table>

5 Click **Apply**.

6 On the **Custom Storage Class** tab, click **New**.
For the new storage class, set properties according to the table.

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>CalParam</td>
</tr>
<tr>
<td>For signals</td>
<td>Clear</td>
</tr>
<tr>
<td>Data scope</td>
<td>Exported</td>
</tr>
<tr>
<td>Header File</td>
<td>calPrms.h</td>
</tr>
<tr>
<td>Definition File</td>
<td>calPrms.c</td>
</tr>
<tr>
<td>Memory Section</td>
<td>CalMem</td>
</tr>
</tbody>
</table>

Click OK. In response to the message about saving changes, click Yes.

Set Default Parameter Object to myPackage.Parameter

To make applying the storage class easier, use the Model Explorer to change the default parameter object from Simulink.Parameter to myPackage.Parameter.

1. At the command prompt, open the Model Explorer.

   \[
   \text{daexplr}
   \]

2. In the Model Explorer Model Hierarchy pane, select Base Workspace.
3. In the Model Explorer toolbar, click the arrow next to the Add Simulink Parameter button. In the drop-down list, select Customize class lists.
4. In the Customize class lists dialog box, under Parameter classes, select the check box next to myPackage.Parameter. Click OK.
5. In the Model Explorer toolbar, click the arrow next to the Add Simulink Parameter button. In the drop-down list, select myPackage Parameter.

A myPackage.Parameter object appears in the base workspace. You can delete this object.

Now, when you use tools such as the Model Data Editor to create parameter objects, Simulink creates myPackage.Parameter objects instead of Simulink.Parameter objects.

Apply Storage Class

In the example model rtwdemo_roll, the BasicRollMode subsystem represents a PID controller. Configure the P, I, and D parameters as calibration parameters.
Open the model.

```
rtwdemo_roll
```

In the model, navigate into the BasicRollMode subsystem.

3. Select **Code > C/C++ Code > Configure Model in Code Perspective**.

4. Underneath the block diagram, open the Model Data Editor by selecting the **Model Data Editor** tab.

5. In the Model Data Editor, select the **Parameters** tab and update the block diagram.

Now, the data table contains rows that correspond to workspace variables used by the Gain blocks (which represent the P, I, and D parameters of the controller).

6. In the Model Data Editor, next to the **Filter contents** box, activate the **Filter using selection** button.

7. In the model, select the three Gain blocks.

8. In the **Filter contents** box, enter **model workspace**.

The variables that the Gain blocks use are in the model workspace.

9. In the data table, select the three rows and, in the **Storage Class** column for any of the rows, select **Convert to parameter object**.

The Model Data Editor converts the workspace variables to **myPackage.Parameter** objects. Now, you can apply a storage class to the objects.

10. In the **Storage Class** column for any of the rows, select **CalParam**.

**Configure Generation of ASAP2 Interface**

Configure the model to generate a2l files. Select **Configuration Parameters > Code Generation > Interface > ASAP2 interface**.

**Generate and Inspect Code**

1. Generate code from the model.

2. In the code generation report, inspect the calPrms.c file. The file defines the calibration parameters.

```
/* Exported data definition */
#pragma SEC(CALPRM)

/* Definition for custom storage class: CalParam */
const volatile real32_T dispGain = 0.75F;
const volatile real32_T intGain = 0.5F;
const volatile real32_T rateGain = 2.0F;
```
The file calPrms.h declares the parameters.

3 Inspect the interface file rtwdemo_roll.a2l. The file contains information about each parameter, for example, for dispGain.

/begin CHARACTERISTIC
/* Name */ dispGain
/* Long Identifier */ 
/* Type */ VALUE
/* ECU Address */ 0x0000 /* @ECU_Address@dispGain@ */
/* Record Layout */ Scalar_FLOAT32_IEEE
/* Maximum Difference */ 0
/* Conversion Method */ rtwdemo_roll_CM_single
/* Lower Limit */ -3.4E+38
/* Upper Limit */ 3.4E+38
/end CHARACTERISTIC

Initialize Parameter Value From System Constant or Other Macro (Embedded Coder)

You can generate code that initializes a tunable parameter with a value calculated from some system constants (macros). For example, you can generate this code, which initializes a tunable parameter totalVol with a value calculated from macros numVessels and vesInitVol:

#define numVessels 16
#define vesInitVol 18.2

double totalVol = numVessels * vesInitVol;

This initialization technique preserves the mathematical relationship between the tunable parameter and the system constants, which can make the generated code more readable and easier to maintain. To generate this code:

1 Create parameter objects that represent the system constants.

    numVessels = Simulink.Parameter(16);
    vesInitVol = Simulink.Parameter(18.2);

2 Configure the objects to use the storage class Define, which yields a macro in the generated code.
3 Create another parameter object that represents the tunable parameter. Configure the object to use the storage class `ExportedGlobal`, which yields a global variable in the generated code.

```matlab
totalVol = Simulink.Parameter;
totalVol.CoderInfo.StorageClass = 'ExportedGlobal';
```

4 Set the value of `totalVol` by using the expression `numVessels * vesInitVol`. To specify that the generated code preserve the expression, use the `slexpr` function.

```matlab
totalVol.Value = slexpr('numVessels * vesInitVol');
```

5 Use `totalVol` to set block parameter values in your model. The code that you generate from the model initializes the tunable parameter with a value based on the system constants.

For more information and limitations about using an expression to set the value of a `Simulink.Parameter` object, see “Set Variable Value by Using a Mathematical Expression” (Simulink).

**Code Generation Impact of Storage Location for Parameter Objects**

You can create a parameter object in the base workspace, a model workspace, or a data dictionary. However, when you end your MATLAB session, variables in the base workspace are deleted. To determine where to store parameter objects and other variables that a model uses, see “Determine Where to Store Variables and Objects for Simulink Models” (Simulink).

The location of a parameter object can impact the file placement of the corresponding data definition in the generated code.

- If you place a parameter object in the base workspace or a data dictionary, the code generator assumes that the corresponding parameter data (for example, a global variable) belongs to the system from which you generate code, not to any specific component in the system. For example, if a model in a model reference hierarchy uses a parameter object with a storage class other than `Auto`, the data definition appears in...
the code generated for the top model in the hierarchy, not in the code generated for
the model that uses the object.

However, if you have Embedded Coder, some custom storage classes enable you to
specify the name of the model that owns a piece of data. When you specify an owner
model, the code generated for that model defines the data. For more information about
data ownership, see “Control Placement of Global Data Definitions and Declarations in
Generated Files” on page 23-2.

• If you place a parameter object in a model workspace, the code generator assumes
that the model owns the data. If you generate code from a reference hierarchy that
includes the containing model, the data definition appears in the code generated for
the containing model.

For more information about data ownership, see “Control Placement of Global Data
Definitions and Declarations in Generated Files” on page 23-2.

• If you apply a storage class other than Auto to a parameter object, the object appears
in the generated code as a global symbol. Therefore, in a model reference hierarchy,
two such objects in different model workspaces or dictionaries cannot have the same
name. The name of each object must be unique throughout the model hierarchy.

However, if you have Embedded Coder, you can use the storage class FileScope to
prevent name clashes between parameter objects in different model workspaces. See
“Apply Custom Storage Classes to Individual Signal, State, and Parameter Data
Elements” on page 26-19.

If you store an AUTOSAR.Parameter object in a model workspace, the code generator
ignores the storage class that you specify for the object.

**Configure Accessibility of Signal Data**

When you tune the value of a parameter during algorithm execution, you monitor or
capture output signal values to analyze the effect of the tuning. To represent signals in
the generated code as accessible data, you can use techniques such as test points and
storage classes. See “Configure Data Accessibility for Rapid Prototyping” on page 22-3.

**Programmatic Interfaces for Tuning Parameters**

You can configure the generated code to include:
• A C application programming interface (API) for tuning parameters independent of external mode. The generated code includes extra code so that you can write your own code to access parameter values. See “Exchange Data Between Generated and External Code Using C API” on page 46-2.

• A Target Language Compiler API for tuning parameters independently of external mode. See “Parameter Functions” (Simulink Coder).

Set Tunable Parameter Minimum and Maximum Values

It is a best practice to specify minimum and maximum values for tunable parameters.

You can specify these minimum and maximum values:

• In the block dialog box that uses the parameter object. Use this technique to store the minimum and maximum information in the model.

• By using the properties of a Simulink.Parameter object that you use to set the parameter value. Use this technique to store the minimum and maximum information outside the model.

For more information, see “Specify Minimum and Maximum Values for Block Parameters” (Simulink).

Limitations for Block Parameter Tunability in the Generated Code

A block parameter, MATLAB variable, or Simulink.Parameter object is tunable if it appears in the generated code as data stored in memory, such as a global variable. For example, when you apply the storage class ExportedGlobal to a parameter object, the parameter object appears tunable in the generated code. When you set Default parameter behavior to Tunable, MATLAB variables and parameter objects appear tunable in the generated code. By definition, model arguments also appear tunable.

Under certain conditions, the code generator cannot maintain tunability of a parameter, variable, object, or expression. In this case, the code generator inlines the numeric value, preventing you from changing the value during code execution.

To detect these conditions in your model, set the model configuration parameter Detect loss of tunability (see “Detect loss of tunability” (Simulink)) to warning or error.

Tunable Expression Limitations

You can specify block parameter values as expressions that use Simulink.Parameter objects or workspace variables. For example, you can use the expression 5 * gainParam. For general information about using expressions to set block parameter values, see “Use Mathematical Expressions, MATLAB Functions, and Custom Functions” (Simulink). For limitations with respect to expressions that you use to set the values of Simulink.Parameter objects, see “Code Generation of Parameter Objects With Expression Values” (Simulink Coder).

A tunable workspace variable is a Simulink.Parameter object or workspace variable that appears tunable in the generated code. For example, an object or variable is tunable if you apply a storage class other than Auto or if you set Default parameter behavior to Tunable.

An expression that contains one or more tunable workspace variables, model arguments, or tunable mask parameters is called a tunable expression. The expression is tunable because the code generator attempts to preserve the expression in the code. Because the code generator preserves the expression, you can change the values of the parameter data during code execution.
The code generator reduces certain expressions to an inlined numeric value in the generated code. The inlining renders workspace variables in the expression nontunable. To avoid loss of tunability due to unsupported expressions, observe these guidelines:

- Expressions involving complex (i) workspace variables or parameter objects are not supported.
- Certain operators and functions cause the code generator to reduce expressions and remove tunability. To determine whether an operator or function causes loss of tunability, use the information in this table.

<table>
<thead>
<tr>
<th>Category</th>
<th>Operators or Functions</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>+ - .* ./ &lt; &gt; &lt;= &gt;= == ~= &amp;</td>
</tr>
<tr>
<td>2</td>
<td>* /</td>
</tr>
<tr>
<td>3</td>
<td>abs, acos, asin, atan, atan2, boolean, ceil, cos, cosh, exp, floor, log, log10, sign, sin, sinh, sqrt, tan, tanh, single, int8, int16, int32, uint8, uint16, uint32</td>
</tr>
<tr>
<td>4</td>
<td>: .^ ^ [] {} . \ . \ ' . ' , ;</td>
</tr>
</tbody>
</table>

- Use operators from category 1 without loss of tunability.
- Use operators from category 2 in expressions as long as at least one operand is a scalar. For example, scalar/scalar and scalar/matrix operand combinations are supported, but matrix/matrix combinations are not supported.
- You can use tunable workspace variables as arguments for the functions in category 3. If you use other functions, the code generator removes the tunability of the arguments.
- The operators in category 4 are not supported.
- The Fcn and If blocks do not support tunable expressions for code generation or in referenced models.
- You can write mask initialization code that creates and modifies variables. If you use those variables in an expression, the expression is not tunable.
- You can specify any data type for the Simulink.Parameter objects or workspace variables that makeup expressions. As long as the data type of these variables and objects and the data type of the corresponding block parameters are the same or double, the code generator can preserve tunability.
Linear Block Parameter Tunability

These blocks have a Realization parameter that affects the tunability of their numeric parameters:

- Transfer Fcn
- State-Space
- Discrete State-Space

To set the Realization parameter, you must use the command prompt:

```matlab
set_param(gcb,'Realization','auto')
```

For the Realization parameter, you can choose these options:

- **general**: The block's numeric parameters appear tunable in the generated code.
- **sparse**: The generated code represents the block's parameters as transformed values that increase efficiency. The parameters are not tunable.
- **auto**: The default. If one or more of the block’s parameters are tunable (for example, because you use a tunable parameter object to set a parameter value), then the block uses the general realization. Otherwise, the block uses the sparse realization.

To tune the parameter values of one of these blocks during an external mode simulation, the block must use the general realization.

Parameter Structures

As described in “Organize Data into Structures in Generated Code” on page 22-177, you can create structures of parameter data in the generated code.

- If a parameter structure is tunable, the numeric fields of the structure are tunable in the generated code. However, if any field contains a nontunable entity, such as a multidimensional array, none of the structure fields are tunable.
- You cannot declare individual substructures or fields within a parameter structure as tunable. You cannot use a Simulink.Parameter object as the value of a structure field. Instead, you must store the entire structure in the parameter object.

## Code Generation of Parameter Objects With Expression Values

As described in “Set Variable Value by Using a Mathematical Expression” (Simulink), you can set the value of a Simulink.Parameter object to an expression involving other MATLAB variables or parameter objects. When you generate code from a model that uses such a parameter object, to achieve your goal, use the information in the table.

<table>
<thead>
<tr>
<th>Goal</th>
<th>Technique and More Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>Generate code without Embedded Coder.</td>
<td>For the parameter object that uses the expression, apply any available storage class (see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder)). For the parameter objects used in the expression, apply only the storage class Auto.</td>
</tr>
<tr>
<td>Generate code that defines a global variable and initializes it by using an expression involving system constants and other macros (requires Embedded Coder).</td>
<td>See “Initialize Parameter Value From System Constant or Other Macro (Embedded Coder)” on page 22-129.</td>
</tr>
<tr>
<td>Generate code that defines a macro whose value is an expression involving other macros (requires Embedded Coder).</td>
<td>For the parameter object that uses the expression, apply a storage class that yields a macro in the generated code, such as Define (see “Macro Definitions (#define)” on page 14-71). For the parameter objects used in the expression, apply storage classes that yield imported macros. For example, use the storage class ImportedDefine. Your external code must define these macros.</td>
</tr>
</tbody>
</table>

### Considerations and Limitations

- To avoid errors that prevent code generation, if you apply a storage class other than Auto to the dependent parameter object (which uses the expression as its value), the
parameter objects used in the expression must use either Auto or a storage class that yields a macro in the generated code.

- You cannot set the value of a parameter object that represents a symbolic dimension (see “Implement Dimension Variants for Array Sizes in Generated Code” on page 15-2) to an expression.
- With Embedded Coder, you can generate code that preserves the expression, but only for the purpose of statically initializing the value of a global variable or macro that corresponds to the dependent parameter object. Follow the guidelines in “Expression Preservation” (Simulink Coder).

**Expression Preservation**

If you want Embedded Coder to preserve expressions in the generated code, adhere to these restrictions and guidelines.

- The dependent parameter object must use a storage class other than Auto. For example, to generate a global variable and initialize it by using the expression, use ExportedGlobal or ExportToFile.
- The parameter objects used in the expression must:
  - Use a storage class that yields a macro in the generated code, such as Define.
  - Have scalar, real values if the expression uses operators.
- The expression can use only these operators (in MATLAB syntax):
  - Mathematical: +, -, *
  - Relational: ==, ~=, <, >, <=, >=
- These data typing guidelines apply:
  - If possible, for a parameter object used in an expression, leave the **DataType** property at the default value, **auto**.
    
    To use a value other than **auto**, you must set the **DataType** property of the object that uses the expression to the same value. Otherwise, the code generator does not preserve the expression.
  - If you want to use a parameter object in multiple different expressions, and the dependent parameter objects have different data types, leave the **DataType** property of the independent object at the default value, **auto**. In the generated code, the value of the macro is expressed as a floating-point number (with effective
data type `double`), and the code initializes the dependent parameters by typecasting the result of each expression.

Simulink.Parameter

**Related Examples**

- “Create Tunable Calibration Parameter in the Generated Code” (Simulink Coder)
- “Share and Reuse Block Parameter Values by Creating Variables” (Simulink)
Specify Instance-Specific Parameter Values for Reusable Referenced Model

When you use model referencing to break a large system into components, each component is a separate model. You can reuse a component by referring to it with multiple Model blocks. Each Model block is an instance of the component. You can then configure a block parameter (such as the Gain parameter of a Gain block) to use either the same value or a different value for each instance of the component. To use different values, create and use a model argument to set the value of the block parameter.

When you generate code from a model hierarchy that uses model arguments, the arguments appear in the code as formal parameters of the referenced model entry-point functions, such as the output (step) function. The generated code then passes the instance-specific parameter values, which you specify in each Model block, to the corresponding function calls.

Whether you use or do not use model arguments, you can use storage classes to configure block parameters to appear in the generated code as tunable global variables. You can also use storage classes to generate tunable model argument values, which the generated code stores in memory and passes to the function calls. You can then change the values during execution.

Pass Parameter Data to Referenced Model Entry-Point Functions as Arguments

Configure a referenced model to accept parameter data through formal parameters of the generated model entry-point function. This technique enables you to specify a different parameter value for each instance (Model block) of the referenced model.

Configure Referenced Model to Use Model Arguments

Create the model ex_arg_code_ref. This model represents a reusable algorithm.

open_system('ex_arg_code_ref')
In the model, select **View > Model Data Editor**.

In the Model Data Editor, in the data table, use the **Data Type** column to set the data type of the Inport block to **single**. Due to data type inheritance, the other signals in the model use the same data type.

Select the **Parameters** tab.

In the model, select the Gain block.

In the Model Data Editor, use the **Value** column to set the value of the **Gain** parameter to **gainArg**.

Next to **gainArg**, click the action button `:` and select **Create**.

In the Create New Data dialog box, set **Value** to **Simulink.Parameter** and **Location** to **Model Workspace**. Click **Create**.

In the property dialog box, set **Value** to a number, for example, **3.17**. Click **OK**.

Use the Model Data Editor to set the **Numerator** parameter by using a **Simulink.Parameter** object named **coeffArg** whose value is **1.05**. As with **gainArg**, store the parameter object in the model workspace.

In the Model Data Editor, click the **Show/refresh additional information** button.

Use the **Filter contents** box to find each parameter object (**gainArg** and **coeffArg**). For each object, select the check box in the **Argument** column.
Save the `ex_arg_code_ref` model.

Alternatively, at the command prompt, you can use these commands to configure the blocks and the parameter objects:

```matlab
set_param('ex_arg_code_ref/In1','OutDataTypeStr','single')
set_param('ex_arg_code_ref/Gain','Gain','gainArg')
modelWorkspace = get_param('ex_arg_code_ref','ModelWorkspace');
assignin(modelWorkspace,'gainArg',Simulink.Parameter(3.17));
set_param('ex_arg_code_ref/Discrete Filter','Numerator','coeffArg')
assignin(modelWorkspace,'coeffArg',Simulink.Parameter(1.05));
set_param('ex_arg_code_ref','ParameterArgumentNames','coeffArg,gainArg')
save_system('ex_arg_code_ref')
```

**Specify Instance-Specific Parameter Values in Model Blocks**

Create the model `ex_arg_code_ref`. This model uses multiple instances (Model blocks) of the reusable algorithm.

```matlab
open_system('ex_arg_code')
```
In the model, open the Model Data Editor **Parameters** tab (**View > Model Data Editor**). The Model Data Editor shows four rows that correspond to the model arguments, `coeffArg` and `gainArg`, that you can specify for the two Model blocks.

Use the Model Data Editor to set values for the model arguments. For example, use the values in the figure.

Alternatively, at the command prompt, you can use these commands to set the values:

```matlab
set_param('ex_arg_code/Model','ParameterArgumentValues',...    
          struct('coeffArg','0.98','gainArg','2.98'))

set_param('ex_arg_code/Model1','ParameterArgumentValues',...    
          struct('coeffArg','1.11','gainArg','3.34'))
```

Generate code from the top model.

```bash
rtwbuild('ex_arg_code')
```
The file `ex_arg_code_ref.c` defines the referenced model entry-point function, `ex_arg_code_ref`. The function has two formal parameters, `rtp_coeffArg` and `rtp_gainArg`, that correspond to the model arguments, `coeffArg` and `gainArg`. The formal parameters use the data type `real32_T`, which corresponds to the data type `single` in Simulink.

```c
/* Output and update for referenced model: */
' ex_arg_code_ref' */
void ex_arg_code_ref(const real32_T *rtu_In1,
   real32_T *rty_Out1,
   DW_ex_arg_code_ref_f_T *localDW,
   real32_T rtp_coeffArg,
   real32_T rtp_gainArg)
```

The file `ex_arg_code.c` contains the definition of the top model entry-point function `ex_arg_code`. This function calls the referenced model entry-point function `ex_arg_code_ref` and uses the model argument values that you specified (such as 1.11 and 3.34) as the values of `rtp_coeffArg` and `rtp_gainArg`.

```c
/* ModelReference: '<Root>/Model' incorporates:
 *      Inport: '<Root>/In1'
 *      Outport: '<Root>/Out1'
 */
ex_arg_code_ref(&ex_arg_code_U.In1, &ex_arg_code_Y.Out1,
   &(ex_arg_code_DW.Model_InstanceData.rtdw), 0.98F, 2.98F);

/* ModelReference: '<Root>/Model1' incorporates:
 *      Inport: '<Root>/In1'
 *      Outport: '<Root>/Out2'
 */
ex_arg_code_ref(&ex_arg_code_U.In1, &ex_arg_code_Y.Out2,
   &(ex_arg_code_DW.Model1_InstanceData.rtdw), 1.11F, 3.34F);
```

The formal parameters use the data type `real32_T` (single).

- The block parameters in `ex_arg_code_ref` determine their data types through internal rules. For example, in the Gain block dialog box, on the Parameter Attributes tab, Parameter data type is set to Inherit: Inherit via internal rule (the default). In this case, the internal rule chooses the same data type as the input and output signals, single.

- The model arguments in the model workspace use context-sensitive data typing because the value of the DataType property is set to auto (the default). With this setting, the model arguments use the same data type as the block parameters, single.

- The formal parameters in the generated code use the same data type as the model arguments, single.
Generate Tunable Argument Values

You can configure the instance-specific values in the Model blocks to appear in the generated code as tunable global variables. This technique enables you to store the parameter values for each instance in memory and tune the values during code execution.

In the top model `ex_arg_code`, select the Model Data Editor **Parameters** tab.

Use the Model Data Editor to set the values of the model arguments according to this figure.

```
set_param('ex_arg_code/Model','ParameterArgumentValues',...  
struct('coeffArg','coeffForInst1','gainArg','gainForInst1'))
set_param('ex_arg_code/Model1','ParameterArgumentValues',...  
struct('coeffArg','coeffForInst2','gainArg','gainForInst2'))
```

View the contents of the `ex_arg_code_ref` model workspace in Model Explorer by selecting **View > Model Explorer > Model Explorer**.

Copy `gainArg` and `coeffArg` from the `ex_arg_code_ref` model workspace to the base workspace.

Rename `gainArg` as `gainForInst1`. Rename `coeffArg` as `coeffForInst1`.

```
gainForInst1 = getVariable(modelWorkspace,'gainArg');
gainForInst1 = copy(gainForInst1);
coeffForInst1 = getVariable(modelWorkspace,'coeffArg');
coeffForInst1 = copy(coeffForInst1);
```

Copy `gainForInst1` and `coeffForInst1` as `gainForInst2` and `coeffForInst2`.

```
gainForInst2 = copy(gainForInst1);
coeffForInst2 = copy(coeffForInst1);
```
Set the instance-specific parameter values by using the Value property of the parameter objects in the base workspace.

```matlab
gainForInst1.Value = 2.98;
coeffForInst1.Value = 0.98;

gainForInst2.Value = 3.34;
coeffForInst2.Value = 1.11;
```

In the Model Data Editor for the top model `ex_arg_code`, click the **Show/refresh additional information** button.

Set the **Change view** drop-down list to **Code**.

For the new parameter objects, set the value in the **Storage Class** column to **ExportedGlobal**. This setting causes the parameter objects to appear in the generated code as tunable global variables.

```matlab
gainForInst1.StorageClass = 'ExportedGlobal';
coeffForInst1.StorageClass = 'ExportedGlobal';
gainForInst2.StorageClass = 'ExportedGlobal';
coeffForInst2.StorageClass = 'ExportedGlobal';
```

Generate code from the top model.

```matlab
rtwbuild('ex_arg_code')
```

The file `ex_arg_code.c` defines the global variables that correspond to the parameter objects in the base workspace.

```c
/* Exported block parameters */
real32_T coeffForInst1 = 0.98F;  /* Variable: coeffForInst1
   * Referenced by: '<Root>/Model'
*/

real32_T coeffForInst2 = 1.11F;  /* Variable: coeffForInst2
   * Referenced by: '<Root>/Model1'
*/

real32_T gainForInst1 = 2.98F;   /* Variable: gainForInst1
   * Referenced by: '<Root>/Model'
*/

real32_T gainForInst2 = 3.34F;   /* Variable: gainForInst2
   * Referenced by: '<Root>/Model1'
*/
```
In each call to `ex_arg_code_ref`, the top model algorithm uses the global variables to set the values of the formal parameters.

```c
/* ModelReference: '<Root>/Model' incorporates:
 *  Inport: '<Root>/In1'
 *  Outport: '<Root>/Out1'
*/
ex_arg_code_ref(&ex_arg_code_U.In1, &ex_arg_code_Y.Out1,
               &ex_arg_code_DW.Model_InstanceData.rtdw), coeffForInst1,
               gainForInst1);

/* ModelReference: '<Root>/Model1' incorporates:
 *  Inport: '<Root>/In1'
 *  Outport: '<Root>/Out2'
*/
ex_arg_code_ref(&ex_arg_code_U.In1, &ex_arg_code_Y.Out2,
               &ex_arg_code_DW.Model1_InstanceData.rtdw), coeffForInst2,
               gainForInst2);
```

The global variables in the generated code use the data type `real32_T` (single).

- The parameter objects in the base workspace use context-sensitive data typing because the `DataType` property is set to `auto` (the default). With this setting, the parameter objects in the base workspace use the same data type as the model arguments, `single`.
- The global variables in the generated code use the same data type as the parameter objects in the base workspace.

**Group Multiple Model Arguments into Single Structure**

Use the Model Explorer to copy `gainArg` and `coeffArg` from the `ex_arg_code_ref` model workspace into the base workspace.

```matlab
temp = getVariable(modelWorkspace,'gainArg');
gainArg = copy(temp);
temp = getVariable(modelWorkspace,'coeffArg');
coeffArg = copy(temp);
```

At the command prompt, combine these two parameter objects into a structure, `structArg`.

```matlab
structArg = Simulink.Parameter(struct('gain',gainArg.Value,...
                              'coeff',coeffArg.Value));
```

Use the Model Explorer to move `structArg` into the model workspace.

```matlab
assignin(modelWorkspace,'structArg',copy(structArg));
clear structArg gainArg coeffArg
```
In the Contents pane, configure structArg as the only model argument.

```matlab
set_param('ex_arg_code_ref','ParameterArgumentNames','structArg')
```

In the ex_arg_code_ref model, select the Model Data Editor Parameters tab.

Use the Model Data Editor to set the value of the Gain parameter to structArg.gain and the value of the Numerator parameter to structArg.coeff. Save the model.

```matlab
set_param('ex_arg_code_ref/Gain','Gain','structArg.gain')
set_param('ex_arg_code_ref/Discrete Filter',...    
    'Numerator','structArg.coeff')
save_system('ex_arg_code_ref')
```

At the command prompt, combine the four parameter objects in the base workspace into two structures. Each structure stores the parameter values for one instance of ex_arg_code_ref.

```matlab
structForInst1 = Simulink.Parameter(struct('gain',gainForInst1.Value,...    
    'coeff',coeffForInst1.Value));

structForInst2 = Simulink.Parameter(struct('gain',gainForInst2.Value,...    
    'coeff',coeffForInst2.Value));
```

In the top model ex_arg_code, set the Change view drop-down list to Design. Use the Model Data Editor to set the argument values according to this figure.
set_param('ex_arg_code/Model','ParameterArgumentValues',...
  struct('structArg','structForInst1'))
set_param('ex_arg_code/Model1','ParameterArgumentValues',...
  struct('structArg','structForInst2'))

Click the **Show/refresh additional information** button.

For the new parameter objects `structForInst1` and `structForInst2`, use the Model Data Editor to apply the storage class `ExportedGlobal`.

`structForInst1.StorageClass = 'ExportedGlobal';
structForInst2.StorageClass = 'ExportedGlobal';`

At the command prompt, use the function `Simulink.Bus.createObject` to create a `Simulink.Bus` object. The hierarchy of elements in the object matches the hierarchy of the structure fields. The default name of the object is `slBus1`.

`Simulink.Bus.createObject(structForInst1.Value);`

Rename the bus object as `myParamStructType` by copying it.

`myParamStructType = copy(slBus1);`

In the Model Data Editor for `ex_arg_code`, set **Change view** to **Design**. Use the **Data Type** column to set the data type of `structForInst1` and `structForInst2` to `Bus: myParamStructType`.

`structForInst1.DataType = 'Bus: myParamStructType';
structForInst2.DataType = 'Bus: myParamStructType';`

In the Model Data Editor for `ex_arg_code_ref`, use the Model Data Editor to set the data type of `structArg` to `Bus: myParamStructType`. 
temp = getVariable(modelWorkspace,'structArg');
temp = copy(temp);
temp.DataType = 'Bus: myParamStructType';
assignin(modelWorkspace,'structArg',copy(temp));

Save the ex_arg_code_ref model.

save_system('ex_arg_code_ref')

When you use structures to group parameter values, you cannot take advantage of context-sensitive data typing to control the data types of the fields of the structures (for example, the fields of structForInst1). However, you can use the properties of the bus object to control the field data types.

At the command prompt, set the data type of the elements in the bus object to single. The corresponding fields in the structures (such as structForInst1 and structArg) use the same data type.

myParamStructType.Elements(1).DataType = 'single';
myParamStructType.Elements(2).DataType = 'single';

Generate code from the top model ex_arg_code.

rtwbuild('ex_arg_code')

The file ex_arg_code_types.h defines the structure type myParamStructType, which corresponds to the Simulink.Bus object.

typedef struct {
    real32_T gain;
    real32_T coeff;
} myParamStructType;

In the file ex_arg_code_ref.c, the referenced model entry-point function has a formal parameter, rtp_structArg, that corresponds to the model argument structArg.

/* Output and update for referenced model: 
   'ex_arg_code_ref' */
void ex_arg_code_ref(const real32_T *rtu_In1,
The file `ex_arg_code.c` defines the global structure variables that correspond to the parameter objects in the base workspace.

```c
/* Exported block parameters */
myParamStructType structForInst1 = {
    2.98F,
    0.98F
} ;                                    /* Variable: structForInst1
 * Referenced by: '<Root>/Model'
 */

myParamStructType structForInst2 = {
    3.34F,
    1.11F
} ;                                    /* Variable: structForInst2
 * Referenced by: '<Root>/Model1'
 */
```

The top model algorithm in the file `ex_arg_code.c` passes the addresses of the structure variables to the referenced model entry-point function.

```c
ex_arg_code_ref(&ex_arg_code_U.In1, &ex_arg_code_Y.Out1,
    &(ex_arg_code_DW.Model_InstanceData.rtdw), &structForInst1);

ex_arg_code_ref(&ex_arg_code_U.In1, &ex_arg_code_Y.Out2,
    &(ex_arg_code_DW.Model1_InstanceData.rtdw), &structForInst2);
```

### Control Data Types of Model Arguments and Argument Values

When you use model arguments, you can apply a data type to:

- The block parameters that use the arguments (for certain blocks, such as those in the Discrete library).
- The arguments in the referenced model workspace.
• The argument values that you specify in Model blocks.

To generate efficient code by eliminating unnecessary typecasts and C shifts, consider using inherited and context-sensitive data typing to match the data types.

• In the model workspace, use a MATLAB variable whose data type is double or a parameter object whose DataType property is set to auto. In this case, the variable or object uses the same data type as the block parameter.

• When you set the argument values in Model blocks, take advantage of context-sensitive data typing. To set an argument value, use an untyped value.

  • A literal number such as 15.23. Do not use a typed expression such as single(15.23).
  • A MATLAB variable whose data type is double.
  • A Simulink.Parameter object whose DataType property is set to auto.

In these cases, the number, variable, or object uses the same data type as the model argument in the referenced model workspace. If you also configure the model argument to use context-sensitive data typing, you can control the data types of the block parameter, the argument, and the argument value by specifying the type only for the block parameter.

For basic information about controlling parameter data types, see “Parameter Data Types in the Generated Code” on page 22-156.

Use Model Argument in Different Data Type Contexts

If you use a model argument to set multiple block parameter values, and the data types of the block parameters differ, you cannot use context-sensitive data typing (double or auto) for the argument in the model workspace. You must explicitly specify a data type for the argument. For example, if the argument in the model workspace is a parameter object (such as Simulink.Parameter), set the DataType property to a value other than auto. For more information about this situation, see “Reuse Parameter Data in Different Data Type Contexts” on page 22-173.

In this case, you can continue to take advantage of context-sensitive data typing to control the data type of the argument values that you specify in Model blocks. Each argument value uses the data type that you specify for the corresponding argument in the model workspace.

Parameter Data Types in the Generated Code

The data type of a block parameter (such as the Gain parameter of a Gain block), numeric MATLAB variable, or Simulink.Parameter object determines the data type that the corresponding entity in the generated code uses (for example, a global variable or an argument of a function). To generate more efficient code, you can match parameter data types with signal data types or store parameters in smaller data types.

For basic information about setting block parameter data types in a model, see “Control Block Parameter Data Types” (Simulink).

Significance of Parameter Data Types

The data type that a block parameter, MATLAB variable, or parameter object uses determines the data type that the generated code uses to store the parameter value in memory. For example:

- If you set the model configuration parameter Default parameter behavior (see “Default parameter behavior” (Simulink Coder)) to Tunable, the Gain parameter of a Gain block appears in the generated code as a field of a global structure that stores parameter data. If you apply the data type single to the block parameter in the model, the structure field in the code uses the corresponding data type, real32_T.

- If you apply the storage class ExportedGlobal to a Simulink.Parameter object, the object appears in the generated code as a separate global variable. If you set the DataType property of the object to int8, the global variable in the code uses the corresponding data type, int8_T.

- If you configure a Simulink.Parameter object in a model workspace as a model argument, the object appears in the generated code as a formal parameter (argument) of a model entry-point function, such as the step function. The DataType property of the object determines the data type of the formal parameter.

Other than determining the data type that the generated code uses to store parameter values in memory, the data type of a parameter, variable, or object can also:

- Cause the block to cast the value of the parameter prior to code generation. The cast can result in overflow, underflow, or quantization.

- Cause the generated code to include extra code, for example saturation code.
Typecasts Due to Parameter Data Type Mismatches

When the data types of block parameters, workspace variables, and signals differ, blocks can use typecasts to reconcile the data type mismatches. These typecasts can cause the generated code algorithm, including the model step function, to include explicit casts to reconcile mismatches in storage data type and C bit shifts to reconcile mismatches in fixed-point scaling.

Parameter data type mismatches can occur when:

• The data type that you specify for a MATLAB variable or parameter object (Simulink.Parameter) differs from the data type of a block parameter. The block parameter typecasts the value of the variable or object.
• The data type that you specify for an initial value differs from the data type of the initialized signal or state.
• The data type that you specify for a block parameter differs from the data type of the signal or signals that the parameter operates on. Some blocks typecast the parameter to perform the operation. For example, the Gain block performs this typecast.

If you configure a variable or object to use bias or fractional fixed-point slope, the block parameter cannot perform the typecast. In this case, you must match the data type of the variable or parameter object with the data type of the block parameter. Use one of these techniques:

• Use context-sensitive data typing for the variable or parameter object. For a MATLAB variable, use a double number to set the value of the variable. For a parameter object, set the DataType property to auto.
• Use a Simulink.AliasType or Simulink.NumericType object to set the data type of the block parameter and the data type of a parameter object.

Use this technique when you cannot rely on context-sensitive data typing, for example, when you use the field of a structure to set the value of the block parameter.

• Manually specify the same data type for the block parameter and the variable or parameter object.

Use this technique to reduce the dependence of the model on inherited and context-sensitive data types and on external variables and objects.

For blocks that access parameter data through pointer or reference in the generated code, if you specify different data types for the workspace variable and the block...
parameter, the generated code implicitly casts the data type of the variable to the data type of the block parameter. Note, that an implicit cast requires a data copy which could significantly increase RAM consumption and slow down code execution speed for large data sets. For example, Lookup Table blocks often access large vectors or matrices through pointer or reference in the generated code.

For information about matching parameter data types when you use model arguments, see “Control Data Types of Model Arguments and Argument Values” on page 22-153.

**Detect Downcast and Loss of Precision due to Data Type Mismatches**

You can configure diagnostic configuration parameters to detect unintentional data type mismatches that result in quantization and loss of parameter precision. See “Model Configuration Parameters: Data Validity Diagnostics” (Simulink).

**Considerations for Other Modeling Patterns**

When you use specific modeling patterns and constructs such as fixed-point data types, parameter structures, and lookup table objects, use different techniques to control parameter data types.

- “Tunable Parameters and Best-Precision Fixed-Point Scaling” on page 22-158
- “Control Data Types of Structure Fields” on page 22-159
- “Control Data Types of Lookup Table Objects” on page 22-159
- “Data Typing for Expressions in Parameter Objects” on page 22-160

**Tunable Parameters and Best-Precision Fixed-Point Scaling**

To apply best-precision fixed-point scaling to a tunable block parameter or parameter object, you can use the Fixed-Point Tool to autoscale an entire system or use the Data Type Assistant to configure individual parameters or objects. See “Calculate Best-Precision Fixed-Point Scaling for Tunable Block Parameters” (Simulink).

If a tunable parameter uses best-precision fixed-point scaling, Simulink chooses a data type based on the minimum and maximum values that you specify for the parameter (see “Specify Minimum and Maximum Values for Block Parameters” (Simulink)). You can specify these values in the block dialog box that uses the parameter or in the properties of a Simulink.Parameter object.

If you do not specify a minimum or maximum, Simulink chooses a data type based on the value of the parameter. The chosen scaling might restrict the range of possible tuning
values. Therefore, it is a best practice to specify minimum and maximum values for each tunable parameter.

A tunable parameter can use best-precision scaling even if you do not specify it in the parameter data type. For example, the Gain block can choose a best-precision scaling if the **Parameter data type** in the block dialog box is set to *Inherit: Inherit via internal rule*. This setting is the default for the block.

**Control Data Types of Structure Fields**

When you use a structure as the value of a block parameter (for example to initialize a bus signal), or when you organize multiple block parameter values into a single structure, you can create a Simulink.Bus object to use as the data type of a Simulink.Parameter object. You can then control the data types of individual fields in the structure. See “Control Field Data Types and Characteristics by Creating Parameter Object” (Simulink) and “Control Data Types of Initial Condition Structure Fields” (Simulink).

**Control Data Types of Lookup Table Objects**

When you use Simulink.LookupTable and Simulink.Breakpoint objects to store table and breakpoint data for a lookup table block, to control the data types of the table and breakpoint data, use one of these techniques:

- Set the Value property of the embedded Simulink.lookuptable.Table and Simulink.lookuptable.Breakpoint objects by using untyped expressions such as `[1 2 3]`, which returns a double vector. To control the data type, set the **DataType** property to a value other than auto.

  Use this technique to separate the value of the table or breakpoint data from the data type, which can improve readability and understanding of your design. You can then use a Simulink.NumericType or Simulink.AliasType object to:

  - Customize the name of the data type in the generated code.
  - Match the data type of the table or breakpoint data with the data type of a signal in the model.
  - Set the Value property of the embedded objects by using typed expressions such as `single([1 2 3])`. To use a fixed-point data type, set the Value property with an `fi` object.
Set the **DataType** property of the embedded objects to the default value, `auto`. The table and breakpoint data then acquire the data type that you use to set the **Value** property.

Use this technique to store the data type information in the **Value** property, which can simplify the way you interact with the `Simulink.LookupTable` and `Simulink.Breakpoint` objects. You can leave the **DataType** property at the default value.

When you later change the breakpoint or table data in the **Value** property, preserve the data type information by using a typed expression. Alternatively, if you use a command at the command prompt or a script to change the data, to avoid using a typed expression, use subscripted assignment, `(:)`.

```matlab
myLUTObject.Table.Value(:) = [4 5 6];
```

When you change the data stored in the **Value** property, if you do not use a typed expression or subscripted assignment, you lose the data type information.

When blocks in a subsystem use `Simulink.LookupTable` or `Simulink.Breakpoint` objects, you cannot set data type override (see “Control Fixed-Point Instrumentation and Data Type Override” (Simulink)) only on the subsystem. Instead, set data type override on the entire model.

**Data Typing for Expressions in Parameter Objects**

You can use an expression to set the value of a parameter object (such as `Simulink.Parameter`). The expression encodes mathematical relationships between different objects. When you use this technique, different data typing rules apply. See “Set Variable Value by Using a Mathematical Expression” (Simulink).

Generate Efficient Code by Specifying Data Types for Block Parameters

To generate more efficient code, match the data types of block parameters (such as the Gain parameter of a Gain block) with signal data types. Alternatively, you can store parameters in smaller data types.

Eliminate Unnecessary Typecasts and Shifts by Matching Data Types

These examples show how to generate efficient code by configuring a block parameter to use the same data type as a signal that the block operates on.

Store Data Type Information in Model

Open the example model rtwdemo_basicsc and configure it to show the generated names of blocks.

```matlab
load_system('rtwdemo_basicsc')
set_param('rtwdemo_basicsc','HideAutomaticNames','off')
open_system('rtwdemo_basicsc')
```
Identify the Gain block in the model, which uses the base workspace variable K1 to set the value of the Gain parameter. The input signal of this block uses the data type single.

In the model, select View > Model Data Editor.

In the Model Data Editor, select the Parameters tab.

In the model, select the Gain block. In the Model Data Editor, the Data Type column shows that the data type of the Gain parameter of the block is set to Inherit: Same as input. With this setting, the Gain parameter of this block uses the same data type as the input signal.

In the Model Data Editor, set the Change view drop-down list to Code.

Update the block diagram. Now, in the Model Data Editor, the data table shows rows that correspond to workspace variables that the model uses, including K1.

In the Model Data Editor, find the row that corresponds to K1. For that row, in the Storage Class column, select Convert to parameter object. Simulink converts K1 to a Simulink.Parameter object.
Use the **Storage Class** column to apply the storage class **ExportedGlobal**. With this setting, the object appears in the generated code as a global variable.

In the Model Data Editor, set **Change view** to **Design**.

In the data table, for the row that represents **K1**, in the **Data Type** column, select **auto**. With this setting, the parameter object acquires its data type from the block parameters that use the object (in this case, the **Gain** block parameter).

Alternatively, to create and configure the object, use these commands at the command prompt:

```matlab
K1 = Simulink.Parameter(2);
K1.CoderInfo.StorageClass = 'ExportedGlobal';
```

Generate code from the model.

```bash
rtwbuild('rtwdemo_basicsc')
```

The generated file `rtwdemo_basicsc.c` defines the global variable **K1** by using the data type `real32_T`, which corresponds to the data type `single` in Simulink.

```bash
file = fullfile('rtwdemo_basicsc_grt_rtw','rtwdemo_basicsc.c');
rtwedmodbtype(file,'/* Exported block parameters */','real32_T K1 = 2.0F;',1,1)
```

```bash
/* Exported block parameters */
real32_T K1 = 2.0F;                    /* Variable: K1
```

The generated code algorithm in the model **step** function uses **K1** directly without typecasting.

```bash
rtwedmodbtype(file,' rtwdemo_basicsc_DW.X = K1',...
   ' rtCP_Table1_bp01Data, rtCP_Table1_tableData','1,1)
```

```bash
rtwdemo_basicsc_DW.X = K1 * look1_iflf_binlx(rtwdemo_basicsc_U.input2,
rtCP_Table1_bp01Data, rtCP_Table1_tableData, 10U);
```

On the Model Data Editor **Parameters** tab, you can optionally set the data type of the **Gain** block parameter to **Inherit: Inherit via internal rule** (the default). In this case, the block parameter chooses the same data type as the input signal, **single**.
However, when you use Inherit: Inherit via internal rule, under other circumstances (for example, when you use fixed-point data types), the block parameter might choose a different data type.

**Store Data Type Information in Parameter Object**

When you use a Simulink.Parameter object to export or import parameter data from the generated code to your external code, for example by applying the storage class ImportedExtern, you can specify data type information in the parameter object. To match the data type of the parameter object with a signal data type, create a Simulink.NumericType or Simulink.AliasType object. You can strictly control the data type that the parameter object uses in the generated code, eliminating the risk that Simulink chooses a different data type when you make changes to the model.

At the command prompt, create a Simulink.NumericType object that represents the data type single.

```matlab
myType = Simulink.NumericType;
myType.DataTypeMode = 'Single';
```

Use the Model Data Editor **Data Type** column to set these data types to `myType`:

- The parameter object. Use the **Parameters** tab.
- The Inport block named `In2`. Use the **Inports/Outports** tab. Due to data type propagation, the input signal of the Gain block also uses `myType`.

Use the Model Data Editor **Parameters** tab to set the data type of the Gain block parameter to Inherit: Inherit from 'Gain'. Use this data type object as the data type of the parameter object.

Alternatively, to configure the object and the blocks, use these commands at the command prompt:

```matlab
K1.DataType = 'myType';
set_param('rtwdemo_basicsc/In2','OutDataTypeStr','myType')
set_param('rtwdemo_basicsc/Gain','ParamDataTypeStr','Inherit: Inherit from ''Gain''')
```

Generate code from the model.

```matlab
rtwbuild('rtwdemo_basicsc')
```

### Starting build procedure for model: rtwdemo_basicsc
### Successful completion of build procedure for model: rtwdemo_basicsc

22-165
The global variable K1 continues to use the data type `real32_T`.

```matlab
file = fullfile('rtwdemo_basicsc_grt_rtw','rtwdemo_basicsc.c');
rtwdemodbtype(file,'/* Exported block parameters */','real32_T K1 = 2.0F;',1,1)

/* Exported block parameters */
real32_T K1 = 2.0F;                /* Variable: K1 */
```

**Reduce Memory Consumption by Storing Parameter Value in Small Data Type**

When you use a parameter object (for example, `Simulink.Parameter`) to set block parameter values, you can configure the object to appear in the generated code as a tunable global variable. By default, the parameter object and the corresponding global variable typically uses the same data type as the signal or signals on which the block operates. For example, if the input signal of a Gain block uses the data type `int16`, the parameter object typically use the same data type. To reduce the amount of memory that this variable consumes, specify that the variable use a smaller integer data type such as `int8`.

**Store Parameter Value in Integer Data Type**

Run the script `prepare_rtwdemo_basicsc_2`, which prepares the model `rtwdemo_basicsc` for this example.

```matlab
run(fullfile(matlabroot,'examples','simulinkcoder',... 'main','prepare_rtwdemo_basicsc_2'))
```
Many of the signals in the model use the data type single.

In the model, select **View > Model Data Editor**.

In the Model Data Editor, inspect the **Parameters** tab.

Click the **Show/refresh additional information** button.

Next to the **Filter contents** box, activate the **Filter using selection** button.

In the model, click the Gain block. The Model Data Editor shows one row that corresponds to the **Gain** parameter of the block and one row that corresponds to the MATLAB variable K1, which sets the parameter value to 2. K1 resides in the base workspace.

In the Model Data Editor, set the **Change view** drop-down list to Code.

In the data table, for the row that corresponds to K1, in the **Storage Class** column, from the drop-down list, select **Convert to parameter object**. Simulink converts K1 to a Simulink.Parameter object.
K1 = Simulink.Parameter(K1);

Use the **Storage Class** column to apply the storage class `ExportedGlobal` to K1. With this setting, K1 appears in the generated code as a global variable.

K1.CoderInfo.StorageClass = 'ExportedGlobal';

In the Model Data Editor, set Change view to Design and use the **Data Type** column to apply the data type `int8` to K1.

K1.DataType = 'int8';

For the row that represents the **Gain** block parameter, in the **Data Type** column, set the drop-down list to Inherit: Inherit from 'Gain'. With this setting, the **Gain** parameter of the block inherits the `int8` data type from the parameter object.

```matlab
set_param('rtwdemo_basicsc/Gain','ParamDataTypeStr',
    'Inherit: Inherit from ''Gain''')
```

Generate code from the model.

```matlab
rtwbuild('rtwdemo_basicsc')
```

### Starting build procedure for model: rtwdemo_basicsc
### Successful completion of build procedure for model: rtwdemo_basicsc

The generated file `rtwdemo_basicsc.c` defines the global variable K1 by using the data type `int8_T`, which corresponds to the data type `int8` in Simulink.

```c
file = fullfile('rtwdemo_basicsc_grt_rtw','rtwdemo_basicsc.c');
rtwdemodbtype(file,'/* Exported block parameters */','int8_T K1 = 2;',1,1)
```

```c
/* Exported block parameters */
int8_T K1 = 2;                         /* Variable: K1

The code algorithm in the model step function uses K1 to calculate the output of the Gain block. The algorithm casts K1 to the data type `real32_T` (single) because the signals involved in the calculation use the data type `real32_T`.

```c
rtwdemodbtype(file,' rtwdemo_basicsc DW.X =','10U);',1,1)
```

```c
rtwdemo_basicsc DW.X = (real32_T)K1 * look1_iflf_binlx
(rtwdemo_basicsc_U.input2, rtCP_Table1_bp01Data, rtCP_Table1_tableData,
 10U);
```
Store Fixed-Point Parameter Value in Smaller Integer Data Type

Suppose you configure the signals in your model to use fixed-point data types. You want a gain parameter to appear in the generated code as a tunable global variable. You know the range of real-world values that you expect the parameter to assume (for example, between 0 and 4). If you can meet your application requirements despite reduced precision, you can reduce memory consumption by configuring the parameter to use a different data type than the input and output signals of the block.

Open the example model *fxpdemo_direct_form2* and configure it to show the generated names of blocks.

```matlab
load_system('fxpdemo_direct_form2')
set_param('fxpdemo_direct_form2','HideAutomaticNames','off')
open_system('fxpdemo_direct_form2')
```
Update the block diagram. Signals in this model use signed fixed-point data types with a word length of 16 and binary-point-only scaling.

Open the Gain5 block dialog box. The Gain parameter is set to 1.85. Suppose you want to configure this parameter.

Set Gain to myGainParam and click Apply.

Click the action button (with three vertical dots) next to the parameter value. Select Create.

In the Create New Data dialog box, set Value to Simulink.Parameter(1.85) and click Create. The Simulink.Parameter object myGainParam appears in the base workspace.

In the myGainParam property dialog box, set Storage class to ExportedGlobal and click OK. With this setting, myGainParam appears in the generated code as a global variable.

In the block dialog box, on the Parameter Attributes tab, set Parameter minimum to 0 and Parameter maximum to 4.

Set Parameter data type to fixdt(0,8) and click Apply.

Click the Show Data Type Assistant button. The Data Type Assistant shows that the expression fixdt(0,8) specifies an unsigned fixed-point data type with a word length of 8 and best-precision scaling. When you simulate or generate code, the block parameter chooses a fraction length (scaling) that enables the data type to represent values between the parameter minimum and maximum (0 and 4) with the best possible precision.

In the Data Type Assistant, set Scaling to Binary point. Click Calculate Best-Precision Scaling, Fixed-point details, and Refresh Details. The information under Fixed-point details shows that a fraction length of 5 can represent the parameter values with a precision of 0.03125.

Set Scaling back to Best precision and click OK. In this example, when you simulate or generate code, the block parameter chooses a fraction length of 5.

Alternatively, you can use these commands at the command prompt to create the object and configure the block:

```matlab
myGainParam = Simulink.Parameter(1.85);
myGainParam.CoderInfo.StorageClass = 'ExportedGlobal';
```
set_param('fxpdemo_direct_form2/Gain5','Gain','myGainParam')
set_param('fxpdemo_direct_form2/Gain5','ParamMin','0','ParamMax','4')
set_param('fxpdemo_direct_form2/Gain5','ParamDataTypeStr','fixdt(0,8)')

Configure the model to produce a code generation report. To reduce clutter in the Command Window, clear the configuration parameter **Verbose build**.

set_param('fxpdemo_direct_form2','GenerateReport','on',
   'LaunchReport','on','RTWVerbose','off')

Generate code from the model.

evalc('rtwbuild(''fxpdemo_direct_form2'')');

The generated file `fxpdemo_direct_form2.c` defines the global variable `myGainParam` by using the data type `uint8_T`, which corresponds to the specified word length, 8. The code initializes the variable by using an integer value that, given the fraction length of 5, represents the real-world parameter value 1.85.

```c
file = fullfile('fxpdemo_direct_form2_grt_rtw','fxpdemo_direct_form2.c');
rtwdemodbtype(file,'/* Exported block parameters */','uint8_T myGainParam = 59U;',1,1)

/* Exported block parameters */
uint8_T myGainParam = 59U;                        /* Variable: myGainParam */
```

The code algorithm uses `myGainParam` to calculate the output of the Gain5 block. The algorithm uses a C shift to scale the result of the calculation.

```c
rtwdemodbtype(file,'/* Gain: '<Root>/Gain5' */,'
   /* Gain: '<Root>/Gain'' incorporates:',1,0)

   /* Gain: '<Root>/Gain5' */
   fxpdemo_direct_form2_B.Gain5 = (int16_T)((myGainParam *
      fxpdemo_direct_form2_B.UnitDelay1) >> 5);
```

Reuse Parameter Data in Different Data Type Contexts

When you use a Simulink.Parameter object or a numeric MATLAB variable to set two or more block parameter values, if the block parameters have different data types, you must explicitly specify the data type of the object or variable. For example, you cannot leave the data type of the parameter object at the default value, auto.

Create and Configure Example Model

Create the model ex_paramdt_contexts.

ex_paramdt_contexts

In the model, select View > Model Data Editor.

In the Model Data Editor, on the Inports/Outports tab, use the Data Type column to set the data type of the In1 Inport block to single and the data type of the In2 block to int8.

On the Signals tab, set the data types of the Gain block outputs to Inherit: Same as input.

On the Parameters tab, for the Gain parameters of the Gain blocks, set Data Type to Inherit: Same as input.

For the Gain parameters, set Value to myGainParam.

Alternatively, to configure the blocks, use these commands at the command prompt:
In the Model Data Editor, for either Gain block parameter, click the cell in the Value column. Next to myGainParam, click the action button (with three vertical dots) and select Create.

In the Create New Data dialog box, set Value to Simulink.Parameter(3) and click Create. A Simulink.Parameter object with value 3 appears in the base workspace.

In the myGainParam property dialog box, set Data type to int8 and Storage class to ExportedGlobal. With the storage class ExportedGlobal, the object appears in the generated code as a global variable.

Alternatively, to create and configure the parameter object, use these commands at the command prompt:

```Matlab
myGainParam = Simulink.Parameter(3);
myGainParam.CoderInfo.StorageClass = 'ExportedGlobal';
myGainParam.DataType = 'int8';
```

In this model, you use the parameter object myGainParam to set two block parameter values. The block parameters inherit different data types from the block input signals (single or int8). To use myGainParam in these different data type contexts, you explicitly specify the data type of the parameter object by setting the DataType property to int8.

**Match Parameter Object Data Type with Signal Data Type**

Optionally, use a Simulink.NumericType or Simulink.AliasType object to set the parameter object data type and one of the signal data types. This technique eliminates unnecessary typecasts and shifts in the generated code due to a mismatch between the parameter object data type and the signal data type.

At the command prompt, create a Simulink.NumericType object to represent the data type int8.

```Matlab
sharedType_int8 = fixdt('int8');
```
In the Model Data Editor, on the **Imports/Outports** tab, set the data type of the In2 Inport block to *sharedType_int8*.

On the **Parameters** tab, update the block diagram. The data table now contains a row that represents the parameter object, *myGainParam*.

Use the **Data Type** column to set the data type of the parameter object to *sharedType_int8*.

Alternatively, to configure the block and the object, use these commands at the command prompt:

```matlab
myGainParam.DataType = 'sharedType_int8';
set_param('ex_paramdt_contexts/In2','OutDataTypeStr','sharedType_int8')
```

The parameter object and the signal use the data type *int8*. To change this data type, adjust the properties of the data type object *sharedType_int8*.

**Generate and Inspect Code**

Generate code from the model.

```bash
rtwbuild('ex_paramdt_contexts')
```

### Starting build procedure for model: ex_paramdt_contexts
### Successful completion of build procedure for model: ex_paramdt_contexts

The generated file *ex_paramdt_contexts.c* defines the global variable *myGainParam* by using the data type *int8_T*, which corresponds to the data type *int8* in Simulink.

```c
int8_T myGainParam = 3;
/* Variable: myGainParam */
```

The generated code algorithm in the model step function uses *myGainParam* to calculate the outputs of the two Gain blocks. In the case of the Gain block whose input signal uses the data type *single*, the code algorithm casts *myGainParam* to the data type *real32_T*, which corresponds to the data type *single* in Simulink.

```c
/* Variable: myGainParam */
int8_T myGainParam = 3;
/* Model step function */
rtwdemodbtype(file,'/* Model initialize function */',1,0)
/ * Model step function */
void ex_paramdt_contexts_step(void)
{
    /* Outport: '<Root>/Out1' incorporates:
    * Gain: '<Root>/Gain - single'
    * Inport: '<Root>/In1'
    */
    ex_paramdt_contexts_Y.Out1 = (real32_T)myGainParam * ex_paramdt_contexts_U.In1;

    /* Outport: '<Root>/Out2' incorporates:
    * Gain: '<Root>/Gain - int8'
    * Inport: '<Root>/In2'
    */
    ex_paramdt_contexts_Y.Out2 = (int8_T)(myGainParam * ex_paramdt_contexts_U.In2);
}

Organize Data into Structures in Generated Code

In C code, you use structures (struct) to store data in contiguous locations in memory. You can organize data, such as signals and states, by using meaningful names. Each structure acts as a namespace, so you can reuse a name to designate multiple data items. Like arrays, with structures, you can write code that efficiently transfers and operates on large amounts of data by using pointers.

By default, the code generator aggregates data into standard structures (see “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 22-50). To control the characteristics of these structures or to override this default behavior by creating different structures, use the information in the table.

| Reduce the number of arguments (formal parameters) for generated functions. | • To reduce the number of arguments for the entry-point functions of the model from which you generate code, such as `model_step`, see “Reduce Number of Arguments by Using Structures” on page 22-47.  
  • To reduce the number of arguments for the entry-point functions of a referenced model, in the referenced model:  
    • Configure root-level Inport and Outport blocks to appear in the code as structure fields. Replace multiple such blocks with a single block that you configure as a nonvirtual bus signal. With this technique, you have the greatest control over the structure characteristics. As you add blocks to the model, you must manually modify the bus definitions. See “Nonvirtual Buses and Parameter Structures” on page 22-183.  
    • Organize model arguments into a custom structure (see “Specify Instance-Specific Parameter Values for Reusable Referenced Model” on page 22-142).  
    • To reduce the number of arguments for the entry-point functions of a masked, reentrant subsystem, aggregate mask parameters into a custom structure. |
| Organize lookup table data into a structure. | Use `Simulink.LookupTable` and `Simulink.Breakpoint` objects. See `Simulink.LookupTable`. |
To create structures in the generated code, you can use any of these techniques:

- Apply a structured storage class to categories of data by using the Code Mapping Editor. As you add blocks and signals to a model, new data elements acquire this storage class by default.
- Apply a structured storage class, such as the built-in custom storage class `Struct`, directly to individual data items by using the Model Data Editor.
- Create custom nonvirtual buses and parameter structures.

To decide which techniques to use, use the information in the table.

### Default Application of Structured Storage Class

You can apply a default storage class to a category of model data. As you add blocks and signals to the model, the associated data acquire the default storage class that you specify. To aggregate new data into structures by default, you can apply structured storage classes. You must use the built-in storage classes `ParamStruct` and `SignalStruct` or create your own storage class by using an Embedded Coder Dictionary.

You cannot use default application to aggregate global data stores or global parameters (parameter objects that you store in the base workspace or a data dictionary).
To apply default storage classes, use the Code Mapping Editor. In a model window, select `Code > C/C++ Code > Configure Model in Code Perspective`. Then, under `Code Mappings > Data Defaults`, apply storage classes by using the `Storage Class` column.

For more information about the Code Mapping Editor, see “Configure Default Code Generation for Categories of Model Data and Functions” on page 21-7. To create your own storage class by using an Embedded Coder Dictionary, see “Create Code Definitions for Use as Default Code Generation Settings” on page 20-2.

**Direct Application of Structured Storage Class**

You can apply a structured storage class to individual data items. The direct application prevents code generation optimizations, such as `Default parameter behavior` and `Signal storage reuse`, from eliminating each data item from the generated code. The direct application also overrides the default storage classes that you specify with `Code Mappings > Data Defaults`.

To directly apply a storage class, use the Model Data Editor (`View > Model Data Editor`). Set `Change view` to `Code` and apply the storage class by using the `Storage Class` column.

For an example that shows how to use `Struct`, see “Organize Parameter Data into a Structure by Using the Struct Custom Storage Class” on page 26-23. For more information about applying storage classes, see “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 26-19.

**Nonvirtual Buses and Parameter Structures**

- To create a nonvirtual bus signal, use a Bus Creator block to organize multiple signal lines into a single bus, or configure an Inport block or Outport block as a nonvirtual bus. You must create a `Simulink.Bus` object that represents the structure type. For an example, see “Structures of Signals” on page 22-187. For general information about nonvirtual buses, see “Getting Started with Buses” (Simulink).

- To create a parameter structure, use MATLAB commands or the Variable Editor to organize the values of multiple block parameters into a MATLAB structure. Optionally, create a `Simulink.Bus` object so that you can control the name of the structure type and other characteristics such as the data type and dimensions of each field. For an example, see “Structures of Parameters” on page 22-184. For general information about parameter structures, see “Organize Related Block Parameter Definitions in Structures” (Simulink).
**Structures of Parameters**

Create a structure in the generated code. The structure stores parameter data.

**C Construct**

```
typedef struct {
    double G1;
    double G2;
} myStructType;
```

```
myStructType myStruct = {
    2.0,
    -2.0
} ;
```

**Procedure**

Open the example model `rtwdemo_paraminline`.

`rtwdemo_paraminline`
Select **View > Model Data Editor**.

In the Model Data Editor, select the **Parameters** tab.

In the model, click the Gain block labeled $G_1$.

In the Model Data Editor, use the **Value** column to set the value of the **Gain** parameter to `myStruct.G1`.

Use the Model Data Editor to set the value of the **Gain** parameter in the $G_2$ block to `myStruct.G2`.

Next to `myStruct.G2`, click the action button (with three vertical dots) and select **Create**.

In the Create New Data dialog box, set **Value** to `Simulink.Parameter(struct)` and click **Create**. A `Simulink.Parameter` object named `myStruct` appears in the base workspace.

In the `Simulink.Parameter` property dialog box, next to the **Value** property, click the action button and select **Open Variable Editor**.

In the Variable Editor, right-click the white space under the **Field** column and select **New**. Name the new structure field $G1$. Use the **Value** column to set the value of the field to 2.

Use the Variable Editor to add a field $G2$ whose value is -2 and then close the Variable Editor.

In the `Simulink.Parameter` property dialog box, set **Storage class** to `ExportedGlobal`. With this setting, the structure `myStruct` appears in the generated code as a global variable.

Alternatively, use these commands to configure the blocks and create `myStruct`.

```matlab
rtwdemo_paraminline
set_param('rtwdemo_paraminline/G1','Gain','myStruct.G1')
set_param('rtwdemo_paraminline/G2','Gain','myStruct.G2')

myStruct.G1 = 2;
myStruct.G2 = -2;
myStruct = Simulink.Parameter(myStruct);
myStruct.CoderInfo.StorageClass = 'ExportedGlobal';
```
**Results**

Generate code from the model.

```matlab
codegen('rtwdemo_paraminline')
```

### Starting build procedure for model: rtwdemo_paraminline  
### Successful completion of build procedure for model: rtwdemo_paraminline

The generated header file `rtwdemo_paraminline_types.h` defines a structure type with a random name.

```matlab
file = fullfile('rtwdemo_paraminline_grt_rtw', 'rtwdemo_paraminline_types.h');
rtwdemodbtype(file, 'typedef struct {', '}
struct_6h72eH5WFuEiyQr5YrdGuB;','
1,1)
```

typedef struct {
    real_T G1;
    real_T G2;
} struct_6h72eH5WFuEiyQr5YrdGuB;

The source file `rtwdemo_paraminline.c` defines and initializes the structure variable `myStruct`.

```matlab
file = fullfile('rtwdemo_paraminline_grt_rtw', 'rtwdemo_paraminline.c');
rtwdemodbtype(file, 'struct_6h72eH5WFuEiyQr5YrdGuB myStruct',
'/* Variable: myStruct',1,1)
```

```matlab
struct_6h72eH5WFuEiyQr5YrdGuB myStruct = {
    2.0,
    -2.0
} ; /* Variable: myStruct
```

### Specify Name of Structure Type

Optionally, specify a name to use for the structure type definition (struct).

At the command prompt, use the function `Simulink.Bus.createObject` to create a `Simulink.Bus` object that represents the structure type.

```matlab
Simulink.Bus.createObject(myStruct.Value);
```
The default name of the object is slBus1. Change the name by copying the object into a new MATLAB variable.

```matlab
myStructType = copy(slBus1);
```

In the Model Data Editor, click the **Show/refresh additional information** button.

In the data table, find the row that corresponds to `myStruct`. Use the **Data Type** column to set the data type of `myStruct` to `Bus: myStructType`.

Alternatively, at the command prompt, use this command to set the data type of `myStruct`.

```matlab
myStruct.DataType = 'Bus: myStructType';
```

Generate code from the model.

```matlab
rtwbuild('rtwdemo_paraminline')
```

### Starting build procedure for model: rtwdemo_paraminline
### Successful completion of build procedure for model: rtwdemo_paraminline

The code generates the definition of the structure type `myStructType` and uses this type to define the global variable `myStruct`.

```matlab
rtwdemodbtype(file,'myStructType myStruct = {','/* Variable: myStruct',...
1,1)
```

```matlab
myStructType myStruct = {
  2.0,
  -2.0
} ; /* Variable: myStruct
```

**Structures of Signals**

This example shows how to create a structure of signal data in the generated code.

**C Construct**

```c
typedef struct {
  double signal1;
  double signal2;
  double signal3;
} my_signals_type;
```
**Procedure**

To represent a structure type in a model, create a Simulink.Bus object. Use the object as the data type of bus signals in your model.

Create the `ex_signal_struct` model with Gain blocks, a Bus Creator block, and a Unit Delay block. The Gain and Unit Delay blocks make the structure more identifiable in the generated code.

To configure the Bus Creator block to accept three inputs, in the block dialog box, set **Number of inputs** to 3.

In the model, select **Edit > Bus Editor**.

Use the Bus Editor to create a Simulink.Bus object named `my_signals_type` that contains three signal elements: `signal1`, `signal2`, and `signal3`. To create bus objects with the Bus Editor, see “Create Bus Objects with the Bus Editor” (Simulink).

This bus object represents the structure type that you want the generated code to use.
In the Bus Creator block dialog box, set **Output data type** to **Bus: my_signals_type**.

Select **Output as nonvirtual bus**. Click **OK**. A nonvirtual bus appears in the generated code as a structure.

In the model, select **View > Model Data Editor**.

In the Model Data Editor, on the **Signals** tab, from the **Change view** drop-down list, select **Code**.

In the model, click the output signal of the Bus Creator block.

In the Model Data Editor, for the output of the Bus Creator block, set **Name** to **sig_struct_var**.

Set **Storage Class** to **ExportedGlobal**. With this setting, the output of the Bus Creator block appears in the generated code as a separate global structure variable named **sig_struct_var**.

Generate code from the model.

**Results**

The generated header file **ex_signal_struct_types.h** defines the structure type **my_signals_type**.

```c
typedef struct {
    real_T signal1;
    real_T signal2;
    real_T signal3;
} my_signals_type;
```

The source file **ex_signal_struct.c** allocates memory for the global variable **sig_struct_var**, which represents the output of the Bus Creator block.

```c
/* Exported block signals */
my_signals_type sig_struct_var;        /* '<Root>/Bus Creator' */
```
In the same file, in the model step function, the algorithm accesses `sig_struct_var` and the fields of `sig_struct_var`.

**Nested Structures of Signals**

You can create nested structures of signal data in the generated code.

**C Construct**

```c
typedef struct {
    double signal1;
    double signal2;
    double signal3;
} B_struct_type;

typedef struct {
    double signal1;
    double signal2;
} C_struct_type;

typedef struct {
    B_struct_type subStruct_B;
    C_struct_type subStruct_C;
} A_struct_type;
```

**Procedure**

To represent a structure type in a model, create a `Simulink.Bus` object. Use the object as the data type of bus signals in your model.

To nest a structure inside another structure, use a bus object as the data type of a signal element in another bus object.

Create the `ex_signal_nested_struct` model with Gain blocks, Bus Creator blocks, and a Unit Delay block. The Gain and Unit Delay blocks make the structure more identifiable in the generated code.
To configure a Bus Creator block to accept three inputs, in the block dialog box, set **Number of inputs** to 3.

In the model, select **Edit > Bus Editor**.

Use the Bus Editor to create a Simulink.Bus object named `A_struct_type` that contains two signal elements: `subStruct_B` and `subStruct_C`. To create bus objects with the Bus Editor, see “Create Bus Objects with the Bus Editor” (Simulink). This bus object represents the top-level structure type that you want the generated code to use.

For the `subStruct_B` element, set **DataType** to `Bus: B_struct_type`. Use a similar type name for `subStruct_C`. 

---

Organize Data into Structures in Generated Code

22-191
Each signal element in `A_struct_type` uses another bus object as a data type. Now, these elements represent substructures.

Use the Bus Editor to create the `Simulink.Bus` objects `B_struct_type` (with three signal elements) and `C_struct_type` (with two signal elements).

In the dialog box of the Bus Creator block that collects the three Gain signals, set **Output data type** to `Bus: B_struct_type`. Click **Apply**.

Select **Output as nonvirtual bus** and click **OK**.

In the dialog box of the other subordinate Bus Creator block, set **Output data type** to `Bus: C_struct_type` and select **Output as nonvirtual bus**. Click **OK**.

In the last Bus Creator block dialog box, set **Output data type** to `Bus: A_struct_type` and select **Output as nonvirtual bus**. Click **OK**.

In the model, select **View > Model Data Editor**.

In the Model Data Editor, on the **Signals** tab, from the **Change view** drop-down list, select **Code**.
In the model, click the output signal of the `A_struct_type` Bus Creator block, which feeds the Unit Delay block.

In the Model Data Editor, for the output of the Bus Creator block, set Name to `sig_struct_var`.

Set Storage Class to ExportedGlobal. With this setting, the output of the Bus Creator block appears in the generated code as a separate global structure variable named `sig_struct_var`.

Generate code from the model.

**Results**

The generated header file `ex_signal_nested_struct_types.h` defines the structure types. Each structure type corresponds to a Simulink.Bus object.

```c
typedef struct {
    real_T signal1;
    real_T signal2;
    real_T signal3;
} B_struct_type;

typedef struct {
    real_T signal1;
    real_T signal2;
} C_struct_type;

typedef struct {
    B_struct_type subStruct_B;
    C_struct_type subStruct_C;
} A_struct_type;

The generated source file `ex_signal_nested_struct.c` allocates memory for the global structure variable `sig_struct_var`. By default, the name of the `A_struct_type` Bus Creator block is Bus Creator2.

```c
/* Exported block signals */
A_struct_type sig_struct_var;          /* '<Root>/Bus Creator2' */
```
In the same file, in the model step function, the algorithm accesses `sig_struct_var` and the fields of `sig_struct_var`.

**Combine Techniques to Work Around Limitations**

To work around some of the limitations of each technique, you can combine structured custom storage classes with nonvirtual buses and parameter structures. For example, you can:

- Include a structure of signal data and a structure of parameter data in the same parent structure.
- Nest structures while aggregating new data by default.

In the generated code, a flat parent structure, which corresponds to the structured custom storage class, contains substructures, which correspond to each bus and parameter structure. Choose one of these combined techniques:

- Apply the structured custom storage class directly to each bus and parameter structure. For example, set the storage class of two nonvirtual bus signals to `Struct`. Each bus appears in the generated code as a field (substructure) of a single structure.
- Leave the storage class of each bus and parameter structure at the default setting, `Auto`, or at `Model default`, which prevents code generation optimizations from eliminating the bus or parameter structure. Then, configure default storage classes such that signal data and parameter data use the structured custom storage class by default.

**Arrays of Structures**

You can further package multiple consistent bus signals or parameter structures into an array. The array of buses or parameter structures appears in the generated code as an array of structures. To create arrays of buses, see “Combine Buses into an Array of Buses” (Simulink). To create arrays of parameter structures, see “Group Multiple Parameter Structures into an Array” (Simulink).

**Structure Padding**

By default, the code generator does not explicitly add padding fields to structure types. Structure types can appear in the generated code through, for example, the standard data
structures (see “Standard Data Structures in the Generated Code” (Simulink Coder)), Simulink.Bus objects, and parameter structures that you use in a model.

However, when you use a code replacement library with Embedded Coder, you can specify data alignment (including structure padding) as part of the replacement library. For more information, see “Provide Data Alignment Specifications for Compilers” on page 54-138.

**Limitations**

- With built-in Simulink Coder and Embedded Coder features, you cannot generate or use a custom structure that contains a field whose value is a pointer. You can do so manually by creating an advanced custom storage class and writing accompanying TLC code (see “Finely Control Data Representation by Writing TLC Code for a Custom Storage Class” on page 26-39).

- You cannot use the built-in storage class Struct, or any structured storage class that you create with the Custom Storage Class Designer (you set the storage class property Type to FlatStructure), to set data defaults in the Code Mapping Editor.

Switch Between Sets of Parameter Values During Simulation and Code Execution

To store multiple independent sets of values for the same block parameters, you can use an array of structures. To switch between the parameter sets, create a variable that acts as an index into the array, and change the value of the variable. You can change the value of the variable during simulation and, if the variable is tunable, during execution of the generated code.

Explore Example Model

Open this example model:

```
open_system('sldemo_fuelsys_dd_controller')
```

This model represents the fueling system of a gasoline engine. The output of the model is the rate of fuel flow to the engine.

Navigate to the `switchable_compensation` nested subsystem.

```
open_system(['sldemo_fuelsys_dd_controller/fuel_calc/',...  ...
 'switchable_compensation'])
```
This subsystem corrects and filters noise out of the fuel rate signal. The subsystem uses different filter coefficients based on the fueling mode, which the control logic changes based on sensor failures in the engine. For example, the control algorithm activates the low_mode subsystem during normal operation. It activates the rich_mode subsystem in response to sensor failure.

Open the low_mode subsystem.

```matlab
open_system(['sldemo_fuelsys_dd_controller/fuel_calc/',...
    'switchable_compensation/low_mode'])
```
The Discrete Filter block filters the fuel rate signal. In the block dialog box, the **Numerator** parameter sets the numerator coefficients of the filter.

The sibling subsystem **rich_mode** also contains a Discrete Filter block, which uses different coefficients.

Update the model diagram to display the signal data types. The input and output signals of the block use the single-precision, floating-point data type **single**.

In the lower-left corner of the model, click the data dictionary badge. The data dictionary for this model, sldemo_fuelsys_dd_controller.sldd, opens in the Model Explorer.

In the Model Explorer **Model Hierarchy** pane, select the **Design Data** node.

In the **Contents** pane, view the properties of the Simulink.NumericType objects, such as **s16En15**. All of these objects currently represent the single-precision, floating-point data type **single**. The model uses these objects to set signal data types, including the input and output signals of the Discrete Filter blocks.

Suppose that during simulation and execution of the generated code, you want each of these subsystems to switch between different numerator coefficients based on a variable whose value you control.

**Store Parameter Values in Array of Structures**

Store the existing set of numerator coefficients in a Simulink.Parameter object whose value is a structure. Each field of the structure stores the coefficients for one of the Discrete Filter blocks.
lowBlock = ['sldemo_fuelsys_dd_controller/fuel_calc/switchable_compensation/low_mode/Discrete Filter'];
richBlock = ['sldemo_fuelsys_dd_controller/fuel_calc/switchable_compensation/rich_mode/Discrete Filter'];
params.lowNumerator = eval(get_param(lowBlock,'Numerator'));
params.richNumerator = eval(get_param(richBlock,'Numerator'));
params = Simulink.Parameter(params);

Copy the value of params into a temporary variable. Modify the field values in this temporary structure, and assign the modified structure as the second element of params.

temp = params.Value;
temp.lowNumerator = params.Value.lowNumerator * 2;
temp.richNumerator = params.Value.richNumerator * 2;
params.Value(2) = temp;
clear temp

The value of params is an array of two structures. Each structure stores one set of filter coefficients.

Create Variable to Switch Between Parameter Sets

Create a Simulink.Parameter object named Ctrl.

Ctrl = Simulink.Parameter(2);
Ctrl.DataType = 'uint8';

In the low_mode subsystem, in the Discrete Filter block dialog box, set the Numerator parameter to the expression params(Ctrl).lowNumerator.

set_param(lowBlock,'Numerator','params(Ctrl).lowNumerator');

In the Discrete Filter block in the rich_mode subsystem, set the value of the Numerator parameter to params(Ctrl).richNumerator.

set_param(richBlock,'Numerator','params(Ctrl).richNumerator');

The expressions select one of the structures in params by using the variable Ctrl. The expressions then dereference one of the fields in the structure. The field value sets the values of the numerator coefficients.

To switch between the sets of coefficients, you change the value of Ctrl to the corresponding index in the array of structures.
Use Bus Object as Data Type of Array of Structures

Optionally, create a Simulink.Bus object to use as the data type of the array of structures. You can:

- Control the shape of the structures.
- For each field, control characteristics such as data type and physical units.
- Control the name of the struct type in the generated code.

Use the function Simulink.Bus.createObject to create the object and rename the object as paramsType.

```matlab
Simulink.Bus.createObject(params.Value)
paramsType = slBus1;
clear slBus1
```

You can use the Simulink.NumericType objects from the data dictionary to control the data types of the structure fields. In the bus object, use the name of a data type object to set the DataType property of each element.

```matlab
paramsType.Elements(1).DataType = 's16En15';
paramsType.Elements(2).DataType = 's16En7';
```

Use the bus object as the data type of the array of structures.

```matlab
params.DataType = 'Bus: paramsType';
```

Use Enumerated Type for Switching Variable

Optionally, use an enumerated type as the data type of the switching variable. You can associate each of the parameter sets with a meaningful name and restrict the allowed values of the switching variable.

Create an enumerated type named FilterCoeffs. Create an enumeration member for each of the structures in params. Set the underlying integer value of each enumeration member to the corresponding index in params.

```matlab
Simulink.defineIntEnumType('FilterCoeffs',{'Weak','Aggressive'},[1 2])
```

Use the enumerated type as the data type of the switching variable. Set the value of the variable to Aggressive, which corresponds to the index 2.

```matlab
Ctrl.Value = FilterCoeffs.Aggressive;
```
Add New Objects to Data Dictionary

Add the objects that you created to the data dictionary `sldemo_fuelsys_dd_controller.sldd`.

```matlab
dictObj = Simulink.data.dictionary.open('sldemo_fuelsys_dd_controller.sldd');
sectObj = getSection(dictObj,'Design Data');
addEntry(sectObj,'Ctrl',Ctrl)
addEntry(sectObj,'params',params)
addEntry(sectObj,'paramsType',paramsType)
```

You can also store enumerated types in data dictionaries. However, you cannot import the enumerated type in this case because you cannot save changes to `sldemo_fuelsys_dd_controller.sldd`. For more information about storing enumerated types in data dictionaries, see “Enumerations in Data Dictionary” (Simulink).

Switch Between Parameter Sets During Simulation

Open the example model `sldemo_fuelsys_dd`, which references the controller model `sldemo_fuelsys_dd_controller`.

```matlab
open_system('sldemo_fuelsys_dd')
```

Fault-Tolerant Fuel Control System

The sensor switches simulate any combination of sensor failures. The Engine Speed Selector switch simulates different engine speeds (rad/s).
Set the simulation stop time to Inf so that you can interact with the model during simulation.

Begin a simulation run and open the Scope block dialog box. The scope shows that the fuel flow rate (the fuel signal) oscillates with significant amplitude during normal operation of the engine.

In the Model Explorer, view the contents of the data dictionary `sldemo_fuelsys_dd_controller.sldd`. Set the value of `Ctrl` to `FilterCoeffs.Weak`.

Update the `sldemo_fuelsys_dd` model diagram. The scope shows that the amplitude of the fuel rate oscillations decreases due to the less aggressive filter coefficients.

Stop the simulation.

**Generate and Inspect Code**

If you have Simulink Coder software, you can generate code that enables you to switch between the parameter sets during code execution.

In the Model Explorer, view the contents of the data dictionary `sldemo_fuelsys_dd_controller.sldd`. In the Contents pane, set Column View to Storage Class.

Use the StorageClass column to apply the storage class ExportedGlobal to `params` so that the array of structures appears as a tunable global variable in the generated code. Apply the same storage class to `Ctrl` so that you can change the value of the switching variable during code execution.

Alternatively, to configure the objects, use these commands:

```plaintext
tempEntryObj = getEntry(sectObj,'params');
params = getValue(tempEntryObj);
params.StorageClass = 'ExportedGlobal';
setValue(tempEntryObj,params);

tempEntryObj = getEntry(sectObj,'Ctrl');
Ctrl = getValue(tempEntryObj);
Ctrl.StorageClass = 'ExportedGlobal';
setValue(tempEntryObj,Ctrl);
```

Generate code from the controller model.
rtwbuild('sldemo_fuelsys_dd_controller')

### Starting build procedure for model: sldemo_fuelsys_dd_controller
### Successful completion of code generation for model: sldemo_fuelsys_dd_controller

In the code generation report, view the header file
`sldemo_fuelsys_dd_controller_types.h`. The code defines the enumerated data type `FilterCoeffs`.

```c
file = fullfile('sldemo_fuelsys_dd_controller_ert_rtw',...
    'sldemo_fuelsys_dd_controller_types.h');
rtwdemodbtype(file,'#ifndef DEFINED_TYPEDEF_FOR_FilterCoeffs_,'
    '/* Forward declaration for rtModel */',1,0)

#ifndef DEFINED_TYPEDEF_FOR_FilterCoeffs_
#define DEFINED_TYPEDEF_FOR_FilterCoeffs_

typedef enum {
    Weak = 1,                                        /* Default value */
    Aggressive
} FilterCoeffs;

#endif
```

The code also defines the structure type `paramsType`, which corresponds to the Simulink.Bus object. The fields use the single-precision, floating-point data type from the model.

```c
rtwdemodbtype(file,'#ifndef DEFINED_TYPEDEF_FOR_paramsType_,'
    '#ifndef DEFINED_TYPEDEF_FOR_FilterCoeffs_',1,0)

#ifndef DEFINED_TYPEDEF_FOR_paramsType_
#define DEFINED_TYPEDEF_FOR_paramsType_

typedef struct {
    real32_T lowNumerator[2];
    real32_T richNumerator[2];
} paramsType;

#endif
```

View the source file `sldemo_fuelsys_dd_controller.c`. The code uses the enumerated type to define the switching variable `Ctrl`. 

22-203
The code algorithm in the model step function uses the switching variable to index into the array of structures.

To switch between the parameter sets stored in the array of structures, change the value of \texttt{Ctrl} during code execution.

Design Data Interface by Configuring Inport and Outport Blocks

The data interface of a model is the means by which the model exchanges data (for example, signal values) with other, external models or systems. Customize the data interface of a model to:

- Enable integration of the generated code with your own code.
- Improve traceability and readability of the code.

At the top level of a model, Inport and Outport blocks represent the input and output signals of the model. To customize the data interface in the generated code, configure these blocks. Early in the design process, when a model can contain unconnected Inport and Outport blocks, use this technique to specify the interface before developing the internal algorithm.

When you apply storage classes to Inport and Outport blocks, each block appears in the generated code as a field of a global structure or as a separate global variable that the generated algorithm references directly. If you have Embedded Coder, you can use function prototype control instead of storage classes to pass data into and out of the model `step` function as formal parameters. See “Customize Generated C Function Interfaces” on page 29-2.

**Design Data Interface**

Open the example model `rtwdemo_basicsc`.

```
open_system('rtwdemo_basicsc')
```
Configure the model to show the generated names of blocks.
set_param('rtwdemo_basicsc','HideAutomaticNames','off')

In the model, select View > Model Data Editor.

In the Model Data Editor, select the Inports/Outports tab. Each row in the table represents an Outport block or a signal that exits an Inport block.

Name the signal data that the Outport block Out1 represents. Set Signal Name to output_sig.

For each of the signals that exit the Inport blocks, set Data Type to single or to a different data type. Due to the data type inheritance settings that the other blocks in the model use by default, downstream signals in the rest of the model use the same or a similar data type.

Optionally, configure other design attributes such as Min and Max (minimum and maximum values).
Set the **Change View** drop-down list to **Code**.

For the Outport block and all of the Inport blocks, set **Storage Class** to **ExportedGlobal**. To configure all of the blocks at once, select all of the rows in the table.

To configure the blocks and signals, you can use these commands at the command prompt.

```matlab
portHandles = get_param('rtwdemo_basicsc/In1','portHandles');
outPortHandle = portHandles.Outport;
set_param(outPortHandle,'StorageClass','ExportedGlobal');

portHandles = get_param('rtwdemo_basicsc/In2','portHandles');
outPortHandle = portHandles.Outport;
set_param(outPortHandle,'StorageClass','ExportedGlobal');

portHandles = get_param('rtwdemo_basicsc/In3','portHandles');
outPortHandle = portHandles.Outport;
set_param(outPortHandle,'StorageClass','ExportedGlobal');

portHandles = get_param('rtwdemo_basicsc/In4','portHandles');
outPortHandle = portHandles.Outport;
set_param(outPortHandle,'StorageClass','ExportedGlobal');

set_param('rtwdemo_basicsc/Out1','SignalName','output_sig',... 'StorageClass','ExportedGlobal')
```

Generate code from the model.

```matlab
rtwbuild('rtwdemo_basicsc');
```
The generated algorithm in the model step function directly references these global variables to calculate and store the output signal value, output_sig.

While you use the Model Data Editor to configure the interface of a system, consider using the interface display to view the system inputs and outputs (Inport and Outport blocks) at a high level. See “Configure Data Interface for Component” (Simulink).

**Reduce Manual Data Entry by Configuring Default Storage Class (Embedded Coder)**

If you have Embedded Coder, you can configure a default storage class for Inport blocks and Outport blocks. As you add such blocks to the model, they acquire the storage class that you specify.

In the model, set Configuration Parameters > Code Generation > System target file to ert.tlc.

In the model, select Code > C/C++ Code > Configure Model in Code Perspective.

Underneath the block diagram, under Code Mappings > Data Defaults, for the Inports and Outports rows, set Storage Class to ExportedGlobal.

Underneath the block diagram, open the Model Data Editor by clicking the Model Data Editor tab.

Use the Model Data Editor to set the storage class of the Inport and Outport blocks to Auto. With this setting, the blocks acquire the default storage classes that you specified in Code Mappings > Data Defaults.

With Auto, the global variables that correspond to the Inport and Outport blocks are subject to a naming rule that you specify in the model configuration parameters. By default, the naming rule adds the name of the model to the name of each variable. To remove the model name, change the value of Configuration Parameters > Code Generation > Symbols > Global variables from $R$N$M to $N$M. The token $R$ represents the model name.

Alternatively, to configure the data defaults and the configuration parameter, at the command prompt, use these commands:
set_param('rtwdemo_basicsc','SystemTargetFile','ert.tlc')
coder.mapping.create('rtwdemo_basicsc')
coder.mapping.defaults.set('rtwdemo_basicsc','Inports',...  
    'StorageClass','ExportedGlobal')
coder.mapping.defaults.set('rtwdemo_basicsc','Outports',...  
    'StorageClass','ExportedGlobal')

portHandles = get_param('rtwdemo_basicsc/In1','portHandles');
outPortHandle = portHandles.Outport;
set_param(outPortHandle,'StorageClass','Auto');

portHandles = get_param('rtwdemo_basicsc/In2','portHandles');
outPortHandle = portHandles.Outport;
set_param(outPortHandle,'StorageClass','Auto');

portHandles = get_param('rtwdemo_basicsc/In3','portHandles');
outPortHandle = portHandles.Outport;
set_param(outPortHandle,'StorageClass','Auto');

portHandles = get_param('rtwdemo_basicsc/In4','portHandles');
outPortHandle = portHandles.Outport;
set_param(outPortHandle,'StorageClass','Auto');

set_param('rtwdemo_basicsc/Out1','SignalName','output_sig',...
    'StorageClass','Auto')

set_param('rtwdemo_basicsc','CustomSymbolStrGlobalVar','$N$M')

**Route Signal Data to Multiple Outputs**

You can route a single signal to multiple Outport blocks and apply a different storage class to each Outport. For example, use this technique to send signal data to a custom function (such as a device driver) and to a global variable that your custom algorithmic code can use:

1. Branch the target signal line to each Outport block.
2. For more efficient code, set the storage class of the target signal line to Auto (the default). Optimizations can then eliminate the signal line from the generated code.
3. Use the Model Data Editor to apply the custom storage class GetSet to one Outport block and ExportToFile to the other Outport block. Apply a signal name to each block.
open_system('ex_route_sig')

**Limitations**

You cannot apply a storage class to an Outport block if the input to the block has a variable size. Instead, apply the storage class to the signal line.

Generate Efficient Code for Bus Signals

In a model, you use bus signals to package multiple signals together into a single signal line. You can create virtual or nonvirtual bus signals. The representation in the generated code depends on:

- For a virtual bus, the generated code appears as if the bus did not exist.
- Generated code for a nonvirtual bus represents the bus data with a structure. When you want to trace the correspondence between the model and the code, the use of a structure in the generated code can be helpful. To generate structures using nonvirtual bus signals, see “Organize Data into Structures in Generated Code” on page 22-177.

For general information about buses, see and “Virtual and Nonvirtual Buses” (Simulink).

To generate efficient code from models that contain bus signals, eliminate unnecessary data copies by following best practices as you construct the model.

**Code Efficiency for Bus Signals**

When you use buses in a model for which you intend to generate code:

- Setting bus diagnostic configuration parameters can make model development easier.
- The bus implementation techniques, and the choice of a nonvirtual or virtual bus, can influence the speed, size, and clarity of the generated code.
- Some useful bus implementation techniques are not immediately obvious.

When you work with buses, these guidelines help you to improve the results. The guidelines describe techniques to:

- Simplify the layout of the model.
- Increase the efficiency of generated code.
• Define data structures for function (subsystem) interfaces.
• Define data structures that match existing data structures in external C code.

There are some trade-offs among speed, size, and clarity. For example, the code for nonvirtual buses is easier to read because the buses appear in the code as structures, but the code for virtual buses is faster because virtual buses do not require copying signal data. Apply some of the guidelines based on where you are in the application development process.

**Set Bus Diagnostics**

Simulink provides diagnostics that you can use to optimize bus usage. Set the following values on the *Configuration Parameters > Diagnostics > Connectivity* pane.

<table>
<thead>
<tr>
<th>Buses</th>
<th>Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unspecified bus object at root Outport block:</td>
<td>warning</td>
</tr>
<tr>
<td>Element name mismatch:</td>
<td>warning</td>
</tr>
<tr>
<td>Mux blocks used to create bus signals:</td>
<td>error</td>
</tr>
<tr>
<td>Bus signal treated as vector:</td>
<td>warning</td>
</tr>
<tr>
<td>Non-bus signals treated as bus signals:</td>
<td>none</td>
</tr>
<tr>
<td>Repair bus selections:</td>
<td>Warn and repair</td>
</tr>
</tbody>
</table>

**Optimize Virtual and Nonvirtual Buses**

Virtual buses are graphical conveniences that do not affect generated code. As a result, the code generation engine is able to fully optimize the signals in the bus. Use virtual buses rather than nonvirtual buses wherever possible. You can convert between virtual and nonvirtual buses by using Signal Conversion blocks. In some cases, Simulink automatically converts a virtual bus to a nonvirtual bus when required. For example, a Stateflow chart converts an input virtual bus to a nonvirtual bus.

To bundle function-call signals, you must use a virtual bus.

You must use nonvirtual buses for:

• Nonauto storage classes
• Generating a specific structure from the bus
• Root-level Inport or Outport blocks when the bus has mixed data types

**Avoid Nonlocal Nested Buses in Nonvirtual Buses**

Buses can contain subordinate buses. To generate efficient code, set the storage classes of subordinate buses to `Auto`. Setting the storage class to `Auto` eliminates:

• Allocation of redundant memory for the subordinate bus signal and for the parent bus signal
• Additional copy operations (copying data to the subordinate bus, and then copying from the subordinate bus to the final bus)

This model contains nonvirtual bus signals. The subordinate bus signals `Sub_Bus_1` and `Sub_Bus_2` use the storage class `Auto`.

The generated code algorithm efficiently assigns the input signal data to the bus signals.

```c
void ex_nonvirtual_buses_step(void)
{
    Nonvirtual_In_One.SimpleBus_1.A1 = A1;
    Nonvirtual_In_One.SimpleBus_1.A2 = A2;
    Nonvirtual_In_One.SimpleBus_2.A3 = A3;
    Nonvirtual_In_One.SimpleBus_2.A4 = A4;
    Nonvirtual_In_One.A5 = A5;
}
```

Control Signal and State Initialization in the Generated Code

To initialize signals and discrete states with custom values for simulation and code generation, you can use signal objects and block parameters. Data initialization increases application reliability and is a requirement of safety critical applications. Initializing signals for both simulation and code generation can expedite transitions between phases of Model-Based Design.

For basic information about specifying initial values for signals and discrete states in a model, see “Initialize Signals and Discrete States” (Simulink).

Signal and State Initialization in the Generated Code

The initialization behavior for code generation is the same as that for model simulation with the following exceptions:

- RSim executables can use the Data Import/Export pane of the Configuration Parameters dialog box to load input values from MAT-files. GRT and ERT executables cannot load input values from MAT-files.
- The initial value for a block output signal or root level input or output signal can be overwritten by an external (calling) program.
- Setting the initial value for persistent signals is relevant if the value is used or viewed by an external application.

When you generate code, initialization statements are placed in model.c or model.cpp in the model's initialize code.

For example, consider the model rtwdemo_sigobj_iv.
If you create and initialize signal objects in the base workspace, the code generator places initialization code for the signals in the file `rtwdemo_sigobj_iv.c` under the `rtwdemo_sigobj_iv_initialize` function, as shown below.

```c
/* Model initialize function */
void rtwdemo_sigobj_iv_initialize(void)
{
    .
    .
    /* exported global signals */
    S3 = -3.0;
    S2 = -2.0;
    .
    .
    /* exported global states */
    X1 = 0.0;
    X2 = 0.0;
    .
    .
    /* external inputs */
    S1 = -4.5;
    .
    .

    The following code shows the initialization code for the enabled subsystem’s Unit Delay block state X1 and output signal S2.

    void MdlStart(void) {
        .
        .
        /* InitializeConditions for UnitDelay: '<S2>/Unit Delay' */
        X1 = aal1;
    }
```
For an enabled subsystem, the initial value is also used as a reset value if the subsystem's Outport block parameter **Output when disabled** is set to **reset**. The following code from `rtwdemo_sigobj_iv.c` shows the assignment statement for S3 as it appears in the model output function `rtwdemo_sigobj_iv_output`.

```c
static void rtwdemo_sigobj_iv_output(void)
{
    ...

    /* Disable for enable system: '<Root>/Enabled Subsystem (state X1 inside)' */
    /* (Virtual) Outport Block: '<S2>/Out1' */
    S2 = aa2;
}
```

### Generate Tunable Initial Conditions

You can represent initial conditions for signals and states by creating tunable global variables in the generated code. These variables allow you to restart an application by using initial conditions that are stored in memory.

If you set **Configuration Parameters > Optimization > Default parameter behavior** to **Tunable**, initial conditions appear as tunable fields of the global parameters structure.

Whether you set **Default parameter behavior** to **Tunable** or **Inlined**, you can use a tunable parameter to specify the **InitialValue** property of a signal object or the **Initial condition** parameter of a block. For basic information about tunable parameters, see “Create Tunable Calibration Parameter in the Generated Code” (Simulink Coder).

This example shows how to use tunable parameters to specify initial conditions for signals and states.

### Explore Example Model

Open the example model `rtwdemo_sigobj_iv` and configure it to show the generated names of blocks. The signal S2 uses a Simulink `Signal` object in the base workspace.
Double-click the `Simulink.Signal` object S2 to view its properties. The **Initial value** property is set to `aa2`. The object uses the variable `aa2` to specify an initial condition for the signal S2. The **Storage class** property is set to `ExportedGlobal`. To use a `Simulink.Signal` object to initialize a signal, the signal object must use a storage class other than `Auto` or, if the corresponding data category in the Code Mapping Editor uses a storage class setting other than `Default`, `Model default`.

On the **Optimization** pane, in the Configuration Parameters dialog box, click **Configure**. The variable `aa2` is a tunable parameter that uses the storage class `ExportedGlobal`.

In the model, open the Enabled Subsystem. In the Outport block dialog box, the parameter **Output when disabled** is set to `reset`. When the subsystem becomes disabled, the output signal S2 resets to the initial value `aa2`.

Open the Unit Delay block dialog box. On the **State Attributes** tab, the **State name** box is set to `X1`.

Open the Enable block dialog box. The parameter **States when enabling** is set to `reset`. When the subsystem transitions from a disabled state to an enabled state, it resets internal block states, such as `X1`, to their initial values.
In the base workspace, double-click the `Simulink.Signal` object `X1` to view its properties. The **Initial value** property is set to `aa1`.

Double-click the `Simulink.Parameter` object `aa1` to view its properties. The **Storage class** property is set to `ExportedGlobal`. You can generate tunable initial conditions for block states by using tunable parameters such as `aa1` and `Simulink.Signal` objects such as `X1`.

**Generate and Inspect Code**

Generate code with the example model.

```
### Starting build procedure for model: rtwdemo_sigobj_iv
### Successful completion of build procedure for model: rtwdemo_sigobj_iv
```

In the code generation report, view the file `rtwdemo_sigobj_iv.c`. The code uses global variables to represent the block state `X1` and the signal `S2`.

```c
/* Exported block states */
real_T X1;                             /* '<S2>/Unit Delay' */

/* Exported block signals */
real_T S1;                             /* '<Root>/In1' */
real_T S3;                             /* '<Root>/Signal Conversion' */
real_T S2;                             /* '<S2>/Unit Delay' */
```

The code uses global variables to represent the tunable parameters `aa1` and `aa2`.

```c
/* Exported block parameters */
real_T aa1 = -2.5;                     /* Variable: aa1 */
real_T aa2 = -2.0;                     /* Variable: aa2 */
```

The model initialization function uses the tunable parameter `aa1` to initialize the state `X1`. The function also uses the tunable parameter `aa2` to initialize the signal `S2`.

```c
/* SystemInitialize for Enabled SubSystem: '<Root>/Enabled Subsystem (state X1 inside)' */
/* InitializeConditions for UnitDelay: '<S2>/Unit Delay' */
X1 = aa1;

/* SystemInitialize for Outport: '<S2>/Out1' */
```
S2 = aa2;

In the model step function, when the Enabled Subsystem transitions from a disabled state to an enabled state, the Unit Delay block state \( X1 \) resets to its initial value.

```matlab
if (rtb_PulseGenerator > 0) {
    if (!rtwdemo_sigobj_iv_DW.EnabledSubsystemstateX1inside_M) {
        /* InitializeConditions for UnitDelay: '<S2>/Unit Delay' */
        X1 = aa1;
        rtwdemo_sigobj_iv_DW.EnabledSubsystemstateX1inside_M = true;
    }
}
```

If the Enabled Subsystem becomes disabled during code execution, the algorithm uses the tunable initial condition \( \text{aa2} \) to set the value of the signal \( S2 \).

```matlab
} else {
    if (rtwdemo_sigobj_iv_DW.EnabledSubsystemstateX1inside_M) {
        /* Disable for Outport: '<S2>/Out1' */
        S2 = aa2;
        rtwdemo_sigobj_iv_DW.EnabledSubsystemstateX1inside_M = false;
    }
}
```

**Generate Tunable Initial Condition Structure for Bus Signal**

When you use a MATLAB® structure to specify initialization values for the signal elements in a bus, you can create a tunable global structure in the generated code.

If you set **Configuration Parameters > Optimization > Default parameter behavior** to Tunable, the initial condition appears as a tunable substructure of the global parameters structure.

Whether you set **Default parameter behavior** to Tunable or Inlined, you can specify the initial condition by using a tunable `Simulink.Parameter` object whose value is a structure. If you apply a storage class other than Auto to the parameter object, the structure is tunable in the generated code.

To generate efficient code by avoiding data type mismatches between the structure and the bus signal, use either:
Typed expressions to specify the values of the structure fields. Match the data type of each field with the data type of the corresponding signal element.

A Simulink.Bus object to control the data types of the structure fields and the signal elements.

For basic information about using structures to initialize bus signals, and to decide how to control field data types, see “Specify Initial Conditions for Bus Signals” (Simulink).

**Generate Tunable Initial Condition Structure**

This example shows how to use a tunable structure parameter to initialize a virtual bus signal.

Open the example model `rtwdemo_tunable_init_struct` and configure it to show the generated names of blocks.

In the model, select **View > Model Data Editor**.

On the **Inports/Outports** tab, the **Data Types** column shows that each Inport block in the model uses a different output data type.

Open the Bus Creator block dialog box. The block output is a virtual bus.

In the Configuration Parameters dialog box, open the **Optimization** pane. The configuration parameter **Default parameter behavior** is set to **Tunable**. By default, block parameters, including initial conditions, appear in the generated code as tunable fields of the global parameters structure.
In the Model Data Editor, inspect the **States** tab.

For the Unit Delay block, set **Initial Value** to a structure that specifies an initial condition for each of the three signal elements. To generate efficient code, match the data types of the structure fields with the data types of the corresponding signal elements. For example, set **Initial Value** to the expression `struct('thermocpl', 15.23, 'magFlow', uint32(79), 'posSwitch', false).

`set_param('rtwdemo_tunable_init_struct/Unit Delay','InitialCondition','struct(''thermocpl'',15.23,''magFlow'',uint32(79),''posSwitch'',false)')`

Generate code from the example model.

```
### Starting build procedure for model: rtwdemo_tunable_init_struct
### Successful completion of build procedure for model: rtwdemo_tunable_init_struct
```

In the code generation report, view the file `rtwdemo_tunable_init_struct_types.h`. The code defines a structure type whose fields use the data types that you specified in the `struct` expression.

```
#ifndef DEFINED_TYPEDEF_FOR_struct_mqGiljsItE0G7cf1bNqMu_
#define DEFINED_TYPEDEF_FOR_struct_mqGiljsItE0G7cf1bNqMu_

typedef struct {
    real_T thermocpl;
    uint32_T magFlow;
    boolean_T posSwitch;
} struct_mqGiljsItE0G7cf1bNqMu;
```

View the file `rtwdemo_tunable_init_struct.h`. The struct type definition of the global parameters structure contains a substructure, `UnitDelay_InitialCondition`, which represents the **Initial condition** parameter of the Unit Delay block.

```
struct P_rtwdemo_tunable_init_struct_T_ {
    struct_mqGiljsItE0G7cf1bNqMu UnitDelay_InitialCondition;/* Mask Parameter: UnitDelay_InitialCondition
```

View the file `rtwdemo_tunable_init_struct_data.c`. This source file allocates memory for the global parameters structure. The substructure `UnitDelay_InitialCondition` appears.

```
/* Block parameters (default storage) */
```

---

22-223
P rtwdemo_tunable_init_struct_T rtwdemo_tunable_init_struct_P = {
    /* Mask Parameter: UnitDelay_InitialCondition
     * Referenced by:
     *   '<Root>/Unit Delay'
     *   '<Root>/Unit Delay'
     *   '<Root>/Unit Delay'
     */
    {
        15.23,
        79U,
        0
    },
};

View the file rtwdemo_tunable_init_struct.c. The model initialization function uses
the fields of the substructure to initialize the block states.

/* InitializeConditions for UnitDelay: '<Root>/Unit Delay' */
rtwdemo_tunable_init_struct_DW.UnitDelay_1_DSTATE =
    rtwdemo_tunable_init_struct_P.UnitDelay_InitialCondition.thermocpl;
rtwdemo_tunable_init_struct_DW.UnitDelay_2_DSTATE =
    rtwdemo_tunable_init_struct_P.UnitDelay_InitialCondition.magFlow;
rtwdemo_tunable_init_struct_DW.UnitDelay_3_DSTATE =
    rtwdemo_tunable_init_struct_P.UnitDelay_InitialCondition.posSwitch;

Use Bus Object to Specify Data Types

If you create a bus object, you can use it to specify the data type of the bus signal and the
tunable initial condition structure. Before code generation, the Simulink.Parameter
object casts the values of the structure fields to the data types of the signal elements. For
basic information about creating bus objects and using them in models, see “When to Use
Bus Objects” (Simulink).

Open the example model rtwdemo_init_struct_busobj and configure it to show the
generated names of blocks.
In the base workspace, double-click the Simulink.Bus object ComponentData. The object defines three signal elements: thermocpl, magFlow, and posSwitch. The elements each use a different data type.

In the model, open the Model Data Editor (View > Model Data Editor). The Inports/Outports tab shows that for the Inport block DataIn, the output data type (Data Type column) is set to Bus: ComponentData.

At the command prompt, create the structure parameter initStruct. You can specify the field values by using untyped expressions. To improve readability, specify the field posSwitch with a Boolean value.

```matlab
initStruct = struct(...
    'thermocpl',15.23,...
    'magFlow',79,...
    'posSwitch',false ...
);

initStruct = Simulink.Parameter(initStruct);
```

In the Model Data Editor, inspect the Parameters tab.

In the model, click the Unit Delay block. The Model Data Editor highlights the row that corresponds to the Initial condition parameter of the block.

In the Model Data Editor, set the parameter value (Value column) to initStruct.
Click the **Show/refresh additional information** button. The parameter object, `initStruct`, appears in the data table as a row.

Use the **Data Type** column to set the data type of `initStruct` to **Bus: ComponentData**.

```plaintext
initStruct.DataType = 'Bus: ComponentData';
```

Set the **Change View** drop-down list to **Code**.

Use the **Storage Class** column to apply the storage class **ExportedGlobal** to `initStruct`.

```plaintext
initStruct.StorageClass = 'ExportedGlobal';
```

Generate code from the example model.

```plaintext
### Starting build procedure for model: rtwdemo_init_struct_busobj
### Successful completion of build procedure for model: rtwdemo_init_struct_busobj
```

In the code generation report, view the file `rtwdemo_init_struct_busobj_types.h`. The code creates a structure type `ComponentData` whose fields use the data types in the bus object.

```plaintext
#ifndef DEFINED_TYPEDEF_FOR_ComponentData_
#define DEFINED_TYPEDEF_FOR_ComponentData_

typedef struct {
    real_T thermocpl;
    uint32_T magFlow;
    boolean_T posSwitch;
} ComponentData;

View the file `rtwdemo_init_struct_busobj.c`. The code creates a global variable to represent the tunable parameter object `initStruct`.

```plaintext
/* Exported block parameters */
ComponentData initStruct = {
    15.23,
    79U,
    0
} ;                                    /* Variable: initStruct */
```
The model initialization function uses the structure fields to initialize the block states.

```plaintext
/* InitializeConditions for UnitDelay: '<Root>/Unit Delay' */
rtwdemo_init_struct_busobj_DW.UnitDelay_1_DSTATE = initStruct.thermocpl;
rtwdemo_init_struct_busobj_DW.UnitDelay_2_DSTATE = initStruct.magFlow;
rtwdemo_init_struct_busobj_DW.UnitDelay_3_DSTATE = initStruct.posSwitch;
```

To change the data type of any of the three signal elements, specify the new type in the bus object. The signal element in the model uses the new type. Before simulation and code generation, the parameter object `initStruct` casts the corresponding structure field to the new type.

Initialization of Signal, State, and Parameter Data in the Generated Code

Signal lines, block parameters, and block states in a model can appear in the generated code as data, for example, as global variables. By default, the code initializes this data before execution of the primary algorithm. To match the numerics of simulation in Simulink, the code generator chooses the initial values based on specifications that you make in the model.

By understanding how the generated code initializes data, you can:

• Model a system that reinitializes states during execution, which means that the application can restart the entire system.
• Store initial values in memory as variables, which can persist between execution runs. You can then overwrite these values before starting or restarting a system.
• Generate efficient code by eliminating storage for invariant initial values and by preventing the generation of code that unnecessarily or redundantly initializes data.

For basic information about initializing signals and states in a model, see “Initialize Signals and Discrete States” (Simulink) and “Load State Information” (Simulink).

Static Initialization and Dynamic Initialization

To initialize a data item such as a global variable, an application can use either static or dynamic initialization.

• Static initialization occurs in the same statement that defines (allocates memory for) the variable. The initialization does not occur inside a function definition.

  The code can be more efficient because none of the generated model functions execute initialization statements.

• Dynamic initialization occurs inside a function. For each model or nonvirtual subsystem, the code generator typically creates one or more functions that are dedicated to initialization.

  The generated code or your code can restart a system by calling the initialization function or functions at any time during execution.
Real-World Ground Initialization Requiring Nonzero Bit Pattern

Each data item has a real-world ground value. This value can depend on the data type of the item. For example, for a signal whose data type is `double` or `int8`, the real-world ground value is zero. For an enumeration, the ground value is the default enumeration member.

For some kinds of data, to represent a real-world ground value, a computer stores zero in memory (all bits zero). However, for some other data, a computer stores a nonzero value in memory. This data includes, for example:

- Fixed-point data with bias. The code initializes such a data item to the stored integer value that, given the scaling and bias, represents real-world zero.
- An enumeration whose default member maps to an integer value other than zero. For example, if the default member is `High` with an underlying integer value of 3, the code initializes such a data item to `High`.

Initialization of Signal and State Data

In a model, you can control signal and state initial values through block parameters. For example, to set the initial value of a Unit Delay block, you use the `Initial condition` parameter. In some cases, you can also use the `InitialValue` property of a `Simulink.Signal` object. For most of these block parameters, the default value is 0.

You can also initialize states by using State Writer blocks in Initialize Function subsystems and the `Initial states` model configuration parameter.

By default, the generated code dynamically initializes signal and state data (and other data, such as the model error status) in the generated initialization function. The function, named `model_initialize` by default, performs signal and state initialization operations in this order:

1. Initializes all of the signal and state data in the default generated structures, such as the DWork structure, to a stored value of zero.
2. Initializes additional signal and state data that are not in the default generated structures to the relevant real-world ground value.

This initialization applies only to data that meet both of these criteria:
• The generated code defines (allocates memory for) the data.
• The data use a storage class other than Auto (the default storage class) or Model default (when the Code Mapping Editor specifies the Default storage class, the default setting).

For example, the code applies this operation to data items that use the storage class ExportedGlobal.

3 Initializes each signal and state to the real-world value that the model specifies, for example, through the Initial condition parameter of a Unit Delay block.

4 Initializes each state to the real-world value that you assign by using a State Writer block. The function performs this initialization only if you use an Initialize Function subsystem in the model.

5 Initializes each state to the real-world value that you specify with the configuration parameter Initial states.

After this initialization function executes, each data item has the last real-world value that the function assigned. For example, if you use a State Writer block to initialize a block state to 5 while also using the Initial states configuration parameter to initialize the same state to 10, the state ultimately uses 10 as an initial value.

**memset for Bulk Initialization**

To initialize signal or state data items that have contiguous storage to a stored value of zero, the generated code can call memset in an initialization function. Data items that have contiguous storage include the DWork structure, arrays, or data items that use a multiword data type.

If your application requires it, you can prevent the generated code from using memset for initializing floating-point data to stored zero. See “Use memset to initialize floats and doubles to 0.0” (Simulink Coder).

**Tunable Initial Values**

You can configure the way that tunable block parameters, such as the Gain parameter of a Gain block, appear in the generated code. Most block parameters that set initial values (for example, Initial condition) are tunable. For example, the configuration parameter Default parameter behavior can determine whether the initial values appear in the generated code as inlined constants or as tunable global data. You can also use parameter objects and storage classes to control the representation of these initial values.
Initialization of Signal, State, and Parameter Data in the Generated Code

For tunable initial values, in the model initialization function, the right-hand side of the assignment statement is a global variable, structure field, or other data whose value you can change in memory.

To make initial values tunable in the generated code, see “Control Signal and State Initialization in the Generated Code” on page 22-216.

Initialization of Parameter Data

The generated code statically initializes parameter data to the values that you specify in Simulink.

To express the initial value of a tunable parameter (a global variable) as a mathematical expression involving system constants or other macros, which requires Embedded Coder, see “Initialization by Mathematical Expression (Embedded Coder)” (Simulink Coder).

Kinds of Parameter Data

These model elements appear in the generated code as parameter data:

• Tunable block parameters, such as the Gain parameter of a Gain block, when you set Default parameter behavior to Tunable. Each parameter appears as a field of a dedicated global structure.

• Some tunable block parameters when you set Default parameter behavior to Inlined. When the code generator cannot inline the value of a parameter as a literal number, the parameter appears as a field of a dedicated global const structure.

• Simulink.Parameter objects to which you apply a storage class or custom storage class that has an exported data scope. For example, the built-in storage class ExportedGlobal has an exported data scope, but the storage class ImportedExtern does not.

Initialization by Mathematical Expression (Embedded Coder)

You can set the value of a parameter object (such as Simulink.Parameter) to a mathematical expression involving numbers, MATLAB variables, and other parameter objects. See “Set Variable Value by Using a Mathematical Expression” (Simulink).

If you use this technique with Embedded Coder, you can generate code that initializes the corresponding parameter data (global variable) by using the specified expression. For an example, see “Initialize Parameter Value From System Constant or Other Macro
Data Initialization in the Generated Code

This example shows how the generated code initializes signal, state, and parameter data.

Explore Example Model

Open the example model, rtwdemo_rtwintro.

```matlab
open_system('rtwdemo_rtwintro')
```

In the model, select View > Model Data Editor.
In the Model Data Editor, inspect the **States** tab. For the Unit Delay block state, the **Initial Value** is set to 0, the default, which means the initial value of the state is zero. The state is named \( X \).

Set **Initial Value** to a nonzero number, for example, 5.

```matlab
set_param('rtwdemo_rtwintro/X','InitialCondition','5')
```

Set the **Change view** drop-down list to **Code**.

In the data table, set **Storage Class** to **ExportedGlobal**. With this setting, the block state appears in the generated code as a separate global variable.

```matlab
set_param('rtwdemo_rtwintro/X','StateStorageClass','ExportedGlobal')
```

In the model, open the **Amplifier** subsystem, which is a triggered subsystem.

In the Model Data Editor, inspect the **Parameters** tab and set the **Change view** drop-down list to **Design**. To set and inspect initial values of signals and states, you can use the **Parameters** tab instead of the **States** tab.

The Model Data Editor shows that for the Outport block, the **Initial output** (InitialOutput) parameter is set to 0, the default. This subsystem output requires an initial value because the subsystem executes conditionally. Leave the initial value at the default.

In the model, clear **Configuration Parameters > Signal storage reuse**. When you clear this setting, signal lines appear in the generated code as fields of a generated structure whose purpose is to store signal data. This representation of the signals makes it easier to see how the code generator initializes data.

```matlab
set_param('rtwdemo_rtwintro','OptimizeBlockI0Storage','off')
```

In the model, inspect the configuration parameter **Configuration Parameters > Optimization > Default parameter behavior**. The configuration parameter is set to **Inlined**, which means block parameters, including initial values, appear in the generated code as inlined literals or as **const** data.

Navigate to the root level of the model.

In the Model Data Editor, click the **Show/refresh additional information** button.

Near the **Filter contents** box, click the **Filter using selection** button.
In the model, click the Constant block labeled INC. The Model Data Editor shows that the Constant value (Value) parameter of the block is set to INC. INC is a MATLAB variable in the base workspace.

For INC, set the value in the Value column to Simulink.Parameter(uint8(1)). MATLAB converts INC to a Simulink.Parameter object.

Use the Storage Class column to apply the storage class ExportedGlobal to INC. With this setting, the generated code defines INC as a global variable. Concerning initialization, INC is an item of parameter data.

INC = Simulink.Parameter(INC);
INC.StorageClass = 'ExportedGlobal';

**Generate and Inspect Code**

Generate code from the model.

rtwbuild('rtwdemo_rtwintro');

### Starting build procedure for model: rtwdemo_rtwintro
### Successful completion of build procedure for model: rtwdemo_rtwintro

In the generated file rtwdemo_rtwintro.c, outside the definition of any function, the code statically initializes the parameter data INC. The value of INC is 1.

file = fullfile('rtwdemo_rtwintro_grt_rtw','rtwdemo_rtwintro.c');
rtwdemodbtype(file,'/* Exported block parameters */','uint8_T INC = 1U;',1,1)

/* Exported block parameters */
uint8_T INC = 1U; /* Variable: INC */

In the same file, inspect the definition of the rtwdemo_rtwintro_initialize function. First, the function uses memset to initialize all of the internal signals in the model to a stored value of 0.

rtwdemodbtype(file,'/* block I/O */','sizeof(B_rtwdemo_rtwintro_T);',1,1)

/* block I/O */
(void) memset(((void *) &rtwdemo_rtwintro_B), 0,
sizeof(B_rtwdemo_rtwintro_T));
The function then initializes the Unit Delay state, \( X \), to the appropriate ground value. In this case, the ground value is zero.

\[
\text{rtwdemodbtype(file,'/* exported global states */','X = 0U;',1,1)}
\]

\[
/* exported global states */
X = 0U;
\]

The function also initializes other data, including the root-level inputs and outputs (Inport and Outport blocks), to the appropriate ground values.

\[
\text{rtwdemodbtype(file,'/* external inputs */','Amplifier_Trig_ZCE = POS_ZCSIG;',1,1)}
\]

\[
/* external inputs */
rtwdemo_rtwintro_U.Input = 0;
/* external outputs */
rtwdemo_rtwintro_Y.Output = 0;
rtwdemo_rtwintro_PrevZCX.Amplifier_Trig_ZCE = POS_ZCSIG;
\]

The function then initializes \( X \) to the value that you specified in the Initial condition block parameter.

\[
\text{rtwdemodbtype(file,'/* InitializeConditions for UnitDelay: '<Root>/X' */,...'X = 5U;',1,1)}
\]

\[
/* InitializeConditions for UnitDelay: '<Root>/X' */
X = 5U;
\]

Finally, the function initializes the output of the Amplifier subsystem.

\[
\text{rtwdemodbtype(file,'SystemInitialize for Triggered SubSystem',...'
End of SystemInitialize for SubSystem',1,1)}
\]

\[
/* SystemInitialize for Triggered SubSystem: '<Root>/Amplifier' */
/* SystemInitialize for Outport: '<Root>/Output' incorporates:
 * Outport: '<S1>/Out'
 */
rtwdemo_rtwintro_Y.Output = 0;
**Inspect Difference Between Stored Value and Real-World Value**

For some data, even if the real-world initial value is zero, a computer stores a nonzero value in memory. To observe this difference, apply a slope-bias fixed-point data type to the block state, X. To run this example, you must have Fixed-Point Designer™.

In the Model Data Editor, inspect the **Signals** tab.

In the model, click the output signal of the Switch block, `switch_out`.

Use the **Data Type** column of the Model Data Editor to set the signal data type to `fixdt(1,16,1,3)`. This expression represents a fixed-point data type with a slope of 1 and a bias of 3.

```
set_param('rtwdemo_rtwintro/Switch','OutDataTypeStr','fixdt(1,16,1,3)')
```

In the model, select **View > Property Inspector** and click the Sum block.

In the Property Inspector, under **Signal Attributes**, clear **Require all inputs to have the same data type**.

```
set_param('rtwdemo_rtwintro/Sum','InputSameDT','off')
```

To prevent compilation errors on different platforms, select the model configuration parameter **Generate code only**. This setting causes the model to generate only code.

```
set_param('rtwdemo_rtwintro','GenCodeOnly','on')
```

Generate code from the model.

```
rtwbuild('rtwdemo_rtwintro')
```

The model initialization function first initializes X to the appropriate real-world ground value, 0. Due to the slope-bias data type, which has bias 3, this real-world value corresponds to a stored value of -3.

```
rtwdemodbtype(file,'/* exported global states */','X = -3;',1,1)
```

```
/* exported global states */
X = -3;
```
The function then initializes $X$ to the real-world initial value that you specified in the **Initial condition** block parameter, 5. This real-world value corresponds to a stored value of 2.

```matlab
rtwdemodtype(file,'/* InitializeConditions for UnitDelay: '<Root>/X' */','X = 2;',1,1)

/* InitializeConditions for UnitDelay: '<Root>/X' */
X = 2;
```

### Modeling Goals

<table>
<thead>
<tr>
<th>Goal</th>
<th>More Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>Explicitly model initialization behavior by using blocks</td>
<td>You can explicitly model initialization and reset behavior by using Initialize Function and Reset Function subsystems. In the subsystems, use State Writer blocks to calculate and assign an initial value for a state dynamically. The corresponding code appears in the model initialization function. For more information, see “Generate Code That Responds to Initialize, Reset, and Terminate Events” on page 9-2.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Goal</th>
<th>More Information</th>
</tr>
</thead>
</table>
| Prevent generation of code that explicitly initializes data to zero | If your application environment already initializes global variables to zero, for more efficient code, you can prevent the generation of statements that explicitly initialize global variables to zero. This optimization applies only to signals and states whose initial values are stored in memory as zero. For example, the code generator does not apply the optimization to:  
  - Data for which you specify a nonzero initial value by using a block parameter.  
  - Data whose real-world initial value is zero but whose corresponding stored value is not zero.  
  - Enumerated data whose default member maps to a nonzero integer.  
  
The optimization requires Embedded Coder. For more information, see “Remove Initialization Code” on page 59-4. |
<table>
<thead>
<tr>
<th><strong>Goal</strong></th>
<th><strong>More Information</strong></th>
</tr>
</thead>
</table>
| Generate code that imports data from your external code | You can generate code that reuses (imports) data that your external code defines. For example, you can apply the storage class `ImportedExtern` to a signal line, block state, or parameter object. For imported data:  
  • The generated code does not initialize parameter data. Your code must initialize imported parameter data.  
  • The generated initialization functions dynamically initialize some signal and state data. Unlike data that the generated code allocates, the code does not initialize imported signal or state data to a stored value of zero. Instead, the code immediately initializes the data to the real-world value that you specify in Simulink.  
For more information, including how to prevent the generated code from initializing imported data, see “Exchange Data Between External Calling Code and Generated Code” (Simulink Coder). |

Declare Workspace Variables as Tunable Parameters Using the Model Parameter Configuration Dialog Box

You can use the Model Parameter Configuration dialog box to declare numeric MATLAB variables in the base workspace as tunable parameters. You can select code generation options, such as storage class, for each tunable parameter.

However, it is a best practice to instead use parameter objects to declare tunable parameters. Do not use the Model Parameter Configuration dialog box to select parameter objects in the base workspace. To use parameter objects, instead of the Model Parameter Configuration dialog box, to declare tunable parameters, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 22-81.

**Note** You cannot use the Model Parameter Configuration dialog box to declare tunable parameters for a referenced model. Use `Simulink.Parameter` objects instead.

Declare Existing Workspace Variables as Tunable Parameters

Use the Model Parameter Configuration dialog box to declare existing workspace variables as tunable parameters for a model.

1. In the Configuration Parameters dialog box, on the **Optimization** pane, click **Configure**.
2. In the Model Parameter Configuration dialog box, under **Source list**, select a method to populate the list of available workspace variables.
   - Select **MATLAB workspace** to view all of the numeric variables that are defined in the base workspace.
   - Select **Referenced workspace variables** to view only the numeric variables in the base workspace that the model uses. Selecting this option begins a diagram update and a search for used variables, which can take time for a large model.
3. In the Model Parameter Configuration dialog box, under **Source list**, select one or more workspace variables.
4. Click **Add to table**. The variables appear as tunable parameters under **Global (tunable) parameters**, and appear in italic font under **Source list**.
5. Optionally, select a parameter under **Global (tunable) parameters**, and adjust the code generation settings for the parameter. For more information about adjusting the
code generation options for tunable parameters, see “Set Tunable Parameter Code Generation Options” on page 22-244

6 Click OK to apply your selection of tunable parameters and close the dialog box.

**Declare New Tunable Parameters**

Use the Model Parameter Configuration dialog box to declare new tunable parameters. You can use this technique to declare the names of tunable parameters, and to adjust their code generation settings, before you create the corresponding workspace variables.

1 In the Configuration Parameters dialog box, on the **Optimization > Signals and Parameters** pane, click **Configure**.

2 In the Model Parameter Configuration dialog box, under **Global (tunable) parameters**, click **New**.

3 Under the **Name** column, specify a name for the new tunable parameter.

4 Optionally, adjust the code generation settings for the new parameter. For more information about adjusting the code generation options for tunable parameters, see “Set Tunable Parameter Code Generation Options” on page 22-244

5 Click OK to apply your changes and close the dialog box.

**Set Tunable Parameter Code Generation Options**

To set the properties of tunable parameters listed under **Global (tunable) parameters** in the Model Parameter Configuration dialog box, select a parameter and specify a storage class and, optionally, a storage type qualifier.
Programmatically Declare Workspace Variables as Tunable Parameters

Tune Parameters from the Command Line

When parameters are MATLAB workspace variables, the Model Parameter Configuration dialog box is the recommended way to see or set the properties of tunable parameters. In addition to that dialog box, you can also use MATLAB `get_param` and `set_param` commands.

**Note** You can also use Simulink.Parameter objects for tunable parameters. See “Create Tunable Calibration Parameter in the Generated Code” on page 22-121 for details.

The following commands return the tunable parameters and corresponding properties:
• `get_param(gcs,'TunableVars')`
• `get_param(gcs,'TunableVarsStorageClass')`
• `get_param(gcs,'TunableVarsTypeQualifier')`

The following commands declare tunable parameters or set corresponding properties:

• `set_param(gcs,'TunableVars',str)`
  The argument `str` (character vector) is a comma-separated list of variable names.

• `set_param(gcs,'TunableVarsStorageClass',str)`
  The argument `str` (character vector) is a comma-separated list of storage class settings.

  The valid storage class settings are
  • Auto
  • ExportedGlobal
  • ImportedExtern
  • ImportedExternPointer

• `set_param(gcs,'TunableVarsTypeQualifier',str)`
  The argument `str` (character vector) is a comma-separated list of storage type qualifiers.

The following example declares the variable `k1` to be tunable, with storage class `ExportedGlobal` and type qualifier `const`. The number of variables and number of specified storage class settings must match. If you specify multiple variables and storage class settings, separate them with a comma.

```matlab
set_param(gcs,'TunableVars','k1')
set_param(gcs,'TunableVarsStorageClass','ExportedGlobal')
set_param(gcs,'TunableVarsTypeQualifier','const')
```
Share Data Between Code Generated from Simulink, Stateflow, and MATLAB

Stateflow and MATLAB Coder can fully define their data definitions, or they can inherit them from Simulink. Data definition capabilities include:

- Inheriting input/output data types and sizes from Simulink.
- Parameterized data types and sizes. That is, data type and size may be specified as a function of another data's type and size, e.g., \( \text{type}(y) = \text{type}(u) \) and \( \text{size}(y) = \text{size}(u) \).
- Inferred output size and type from Simulink via signal attribute back propagation.
- Parameter scoped data, which allows referencing Simulink parameters in Stateflow and MATLAB.

Open Example Model

Open the example model `rtwdemo_dynamicio`.

```matlab
open_system('rtwdemo_dynamicio')
```
Instructions

1. Compile the model (Simulation > Update Diagram) and note the displayed signal types and sizes.

2. Change the data type and/or size of the Constant block and recompile the model. Note that the attributes of the signals automatically adapt to the Constant block specification.

3. Generate and inspect code using the blue buttons in the model. Note that K is shared by the Gain and sfVerticalSum block.

Notes

- The data type and size of all Stateflow and MATLAB data is inherited from Simulink.
- The Gain block and the Stateflow chart sfVerticalSum share the Simulink parameter K, which is defined in the MATLAB workspace as a Simulink.Parameter with Model default storage class (i.e., rtP.K in the generated code).
Data Definition and Declaration Management in Embedded Coder

Control Placement of Global Data Definitions and Declarations in Generated Files

The generated code can create standard, global structure variables whose fields represent the signal, state, and parameter data in a model. With storage classes, you can configure data to appear in the code as separate global variables or custom global structures. For information about the standard data structures, see “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 22-50 and “How Generated Code Exchanges Data with an Environment” on page 22-33. For information about storage classes, see “Choose a Storage Class for Controlling Data Representation in the Generated Code” on page 22-69.

You can control the file placement of the variable definitions and declarations. Use the information in the table.
<table>

| • Reduce the size of a generated file by creating multiple smaller files  
• Organize data into different files to make generated code easier to understand | Depending on the setting of Configuration Parameters > File packaging format, generated files such as `model.c` and `model_data.c` can contain many definitions of global variables. Corresponding header files can contain many declarations.  
• To make `model.c` smaller, consider setting **File packaging format** to Modular or Compact (with separate data file). Then, the generated code defines the standard structures that represent tunable and constant parameter data in `model_data.c` instead of `model.c`.  
• To place different categories of data (for example, global parameters, block states, and internal signals) in specific files by default, use the Code Mapping Editor. For each category of data, use a storage class such as ExportToFile and specify the custom attribute **Header file**. See “Configure Default Code Generation for Data” on page 21-8.  
• For precise control over the file placement of data, apply storage classes such as ExportToFile to individual data items. Use the custom attributes of the storage class, such as **Definition file** and **Header file**, to specify file placement for each data item. To configure multiple data elements at once, you can use the Model Data Editor. For an example, see “Definition and Declaration of Signal Data” on page 14-9. |
<table>
<thead>
<tr>
<th><strong>Goal</strong></th>
<th><strong>Details and Techniques</strong></th>
</tr>
</thead>
</table>
| Combine multiple files into a single file | - Consider setting the model configuration parameter **File packaging format** to **Compact**. Then, the code generator does not create the `model_data.c` file. Instead, the definitions of the standard structures that store tunable and constant parameter data appear in `model.c`.  
  - When you apply a custom storage class such as `ExportToFile` to data elements, leave the custom attributes **Definition file** and **Header file** blank, the default value. Also, set the model configuration parameter **Data definition** to **Data defined in source file**. Then, the data definitions appear in `model.c` with the definitions of other global data. |
### Goal
Separate data definitions from function definitions

### Details and Techniques
By default, the generated file that defines the entry-point functions for a model or subsystem also defines the data for that model or subsystem. When you frequently make changes to data, especially initial values for tunable parameters, the changing source code files can impede verification and make change management more difficult. To separate the data from the functions:

- Consider setting the model configuration parameter **File packaging format** to a value that results in the generation of the separate data file *

model_data.c*. Then, the definitions of the standard structures that store tunable and constant parameter data appear in this file instead of in *

model.c*.

- Apply storage classes such as **ExportToFile** to data elements by using the Code Mapping Editor and the Model Data Editor. Use the custom attributes of the custom storage class, such as **Definition file** and **Header file**, to specify file placement. For more information, see “Configure Default Code Generation for Data” on page 21-8 and “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 26-19.

### Goal
Isolate data definitions in separate files for component-based, team-oriented model development

### Details and Techniques
See “Organize Data to Support Component-Based, Team-Oriented Model Development” on page 23-9.
<table>

<tbody>
<tr>
<td>Aggregate definitions of variant control parameters (#define macros) into a single header file</td>
<td>As described in “Generate Preprocessor Conditionals for Variant Systems” on page 15-35, a variant control parameter is a parameter object such as Simulink.Parameter. You apply a storage class that makes the object appear in the generated code as a macro. To control the file placement, choose one of these techniques:</td>
</tr>
</tbody>
</table>

- For each variant control parameter that uses the storage class Define, set the Header file property to the same value. To configure these objects in a list that you can search, sort, and filter, you can use the Model Data Editor Parameters tab. For an example, see “Generate Variant Control Macros in Same Header File” on page 15-38. |

- Create one or more storage classes that represent variant control parameters. In the Custom Storage Class Designer, you can set Header file to a value that applies to all of the variant control parameters that use the storage class. With this technique, you do not need to manually specify a header file for each variant control parameter. For more information, see “Create Custom Storage Classes by Using the Custom Storage Class Designer” on page 26-26. |
Organize Data to Support Component-Based, Team-Oriented Model Development

Depending on your model configuration, data definitions can appear aggregated in large generated files. In a system of components (subsystems or referenced models), you can separate and organize the data definitions into manageable, meaningful files based on the component hierarchy.
<table>

</tr>
</tbody>
</table>

**Specify Default Placement**

When you create data in a model by adding blocks and signal lines, by default, the data definitions appear in `model.c`. To specify a different default placement, use these tools and parameters:

- The model configuration parameter **File packaging format**. The setting that you choose determines whether the code generator places the standard structures that store tunable and constant parameter data in `model_data.c` instead of `model.c`. See “File packaging format”.
- The Code Mapping Editor. For each category of model data, you can specify a default storage class, which controls file placement. For example, apply the storage class
ExportToFile to a data category and, in the Property Inspector, use the DefinitionFile, HeaderFile, and Owner custom attributes to control file placement.

- The model configuration parameters Data definition and Data declaration. These configuration parameters specify the default file placement for data items to which you apply storage classes.

- These configuration parameters do not affect data items to which you apply the storage classes ExportedGlobal, ImportedExtern, and ImportedExternPointer.

- If you apply a storage class that explicitly specifies definition and declaration files for a data element, those specifications override the Data definition and Data declaration configuration parameters.

For more information, see “Data definition” and “Data declaration”.

- The subsystem block parameter Function with separate data. When you select this parameter, the standard structures that store the subsystem data, such as the DWork structure, appear as separate structure variables. By default, the variable definitions appear in the source file that defines the subsystem execution function. See “Generate Modular Function Code” on page 29-65.

**Override Default Placement for Individual Data Items**

For an individual data item, to override the default file placement, use the Model Data Editor to apply a storage class directly. For example, to make a data item appear in the generated code as a global variable, apply the custom storage class ExportToFile. Then, use the Definition file, Header file custom attributes to control file placement. To apply storage classes directly, see “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 26-19.

**Prevent Name Clashes by Configuring Data Item as static**

To apply the C keyword static to a global variable, which can help you avoid name clashes by limiting the scope of the variable name to the file that defines the variable, choose one of these techniques:

- Apply the built-in storage class FileScope. For more information, see “Choose a Storage Class for Controlling Data Representation in the Generated Code” on page 22-69.
• If FileScope does not satisfy your requirements, create your own custom storage class by using the Custom Storage Class Designer. In the Designer, set **Data scope** to File or Auto.

  • With File, the data element appears in the code as a **static** global variable.
  
  • With Auto, the code generator first attempts to represent the data element with a local variable in a function. If this attempt fails, the code generator uses a **static** global variable.

  For an example that shows how to create your own custom storage class by using the Designer, see “Create and Apply a Custom Storage Class” on page 26-26.

You cannot apply **static** to the standard data structures such as the DWork structure.

To access **static** data, you can configure the generated code to include an interface such as an a2l (ASAP2) file. For more information, see “Export ASAP2 File for Data Measurement and Calibration” on page 47-2. To place the data in a specific memory location by including pragmas or other decorations in the generated code, create your own memory section and custom storage class. See “Control Data and Function Placement in Memory by Inserting Pragmas” on page 30-2.

**Code Generation Impact of Storage Location for Parameter Objects**

You can create a parameter object (such as Simulink.Parameter) in the base workspace, a model workspace, or a data dictionary. However, when you apply a storage class or custom storage class to the object, the location of the object can impact the file placement of the corresponding data definition in the generated code. See “Code Generation Impact of Storage Location for Parameter Objects” on page 22-130.

**Specify Default #include Syntax for Data Header Files**

To control the file placement of a data item, such as a signal line or block state, in the generated code, you can apply a storage class to the data item (see “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 26-19). You then use the **Header file** custom attribute to specify the generated or external header file that contains the declaration of the data.

To reduce maintenance effort and data entry, when you specify **Header file**, you can omit delimiters (" or <> and use only the file name. You can then control the default delimiters...
that the generated code uses for the corresponding `#include` directives. To use angle brackets by default, set **Configuration Parameters > Code Generation > Code Placement > `#include file delimiters`** to `#include <header.h>`.

Establish Data Ownership in a System of Components

This example shows how to establish ownership of global data in the code generated from a system of components (referenced models).

When you create a global variable in the generated code by applying a storage class to a data element in a referenced model (see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 22-81), under certain conditions, the code generator places the variable definition with the code generated from the top model in the hierarchy. This default placement can make it more difficult to determine which component is responsible for the data and to manage code changes in a team-based development environment.

To establish ownership of a global variable by placing the definition with the code generated from the relevant component, apply a storage class such as ExportToFile and specify the Owner custom attribute. Alternatively, for parameter objects such as Simulink.Parameter that you use in only one component, you can establish ownership by storing the object in a model workspace instead of the base workspace or a data dictionary.

Explore Example Model

Copy the script file prepare_sldemo_fuelsys_dd_ctrl.m to your current folder.

```matlab
[~, ~] = copyfile(fullfile(matlabroot,'examples','ecoder','main','prepare_sldemo_fuelsys_dd_ctrl.m'),...
    'prepare_sldemo_fuelsys_dd_ctrl.m','f');
```

Run the copy of the script in your current folder. The script opens the model sldemo_fuelsys_dd_controller and prepares it for this example.

```matlab
prepare_sldemo_fuelsys_dd_ctrl
open_system('sldemo_fuelsys_dd_controller')
```
This controller model contains two component models, airflow_calc and fuel_calc. The two outputs of airflow_calc, est_airflow and fb_correction, are inputs of fuel_calc.

Open the airflow_calc model.

open_system('airflow_calc')
In this model, select View > Model Data Editor.

In the Model Data Editor, set the Change view drop-down list to Code.

In the model, select the upper Outport block.

In the Model Data Editor, inspect the value in the Storage Class column. The signal that this block represents, est_airflow, uses the storage class ExportToFile. With this setting, the signal appears in the generated code as a global variable. The Outport block labeled fb_correction also uses this setting.

In the Model Data Editor, select the Parameters tab and click the Show/refresh additional information button. The Model Data Editor now shows information about workspace variables and objects, such as Simulink.Parameter objects, that the model uses to set block parameter values.

In the Filter contents box, enter numerator. The Simulink.Parameter object numerator_param, which is in the base workspace, sets the value of the Numerator parameter in the Discrete Filter block labeled Throttle Transient. The object uses the storage class ExportToFile.
Select the **Signals** tab.

In the **Filter contents** box, enter e0. The signal e0, which is internal to the airflow_calc component, also uses ExportToFile. The signal is internal because it is not a root-level input or output of the model.

Open the fuel_calc model.

```matlab
open_system('fuel_calc')
```

In the Model Data Editor for this model, on the **Inports/Outports** tab, set **Change view** to Code. The Inport blocks est_airflow and fb_correction use the same storage class, ExportToFile, as the corresponding Outport blocks in airflow_calc. The Outport block labeled fuel_rate also uses ExportToFile.

**Generate and Inspect Code**

Generate code from the controller model, sldemo_fuelsys_dd_controller.

```matlab
rtwbuild('sldemo_fuelsys_dd_controller')
```
### Starting build procedure for model: airflow_calc
### Successful completion of build procedure for model: airflow_calc
### Starting build procedure for model: fuel_calc
### Successful completion of build procedure for model: fuel_calc
### Starting build procedure for model: sldemo_fuelsys_dd_controller
### Successful completion of build procedure for model: sldemo_fuelsys_dd_controller

In the code generation report, under **Referenced Models**, click the hyperlink to inspect the code generated for **airflow_calc**.

The file `airflow_calc.c` defines the global variable that represents the signal \( e_0 \). Because the blocks that write to and read from \( e_0 \) exist only in `airflow_calc`, the code generator assumes that this component owns the signal.

```matlab
file = fullfile('slprj','ert','airflow_calc','airflow_calc.c');
rtwdemodbtype(file,'/* Definition for custom storage class: ExportToFile */',...
'    real32_T e0;',1,1)

/* Definition for custom storage class: ExportToFile */
real32_T e0;
```

In the code generation report, return to the code generated for **sldemo_fuelsys_dd_controller**.

The file `sldemo_fuelsys_dd_controller.c` defines the other global variables.

```matlab
file = fullfile('sldemo_fuelsys_dd_controller_ert_rtw',...
    'sldemo_fuelsys_dd_controller.c');
rtwdemodbtype(file,....
    '    /* Definition for custom storage class: ExportToFile */',...
    '    real32_T numerator_param[2] = { 0.01F, -0.01F } ;',1,1);

/* Definition for custom storage class: ExportToFile */
real32_T est_airflow;
real32_T fb_correction;
real32_T fuel_rate;
real32_T numerator_param[2] = { 0.01F, -0.01F } ;
```

Because the signals `est_airflow` and `fb_correction` pass between the two components and through the top-level controller model, the code generator assumes that **sldemo_fuelsys_dd_controller** owns the signals. The code generator makes a similar assumption about `fuel_rate`. Because the parameter object `numerator_param`
exists in the base workspace, any model in the hierarchy can use the object. Therefore, the code generator assumes that sldemo_fuelsys_dd_controller owns the parameter.

You can configure each shared signal and the parameter object so that the corresponding variable definition appears in the code generated for the relevant component.

**Configure Data Ownership**

In this example, you configure code generation settings so that:

- The code generated for the airflow_calc model defines the signals that pass between the two components, est_airflow and fb_correction.
- The code generated for airflow_calc defines the parameter data, numerator_param.
- The code generated for fuel_calc defines the output signal that it calculates, fuel_rate.

In the airflow_calc model, select View > Property Inspector.

In the Model Data Editor, select the Inports/Outports tab.

Find the row that corresponds to the Outport block est_airflow.

In the row, click the icon in the left column. The Property Inspector shows the properties of the Outport block.

In the Property Inspector, under Code, set CoderInfo.CustomAttributes.Owner to airflow_calc. The code generator places the definition of the global variable with the code generated for airflow_calc.

For fb_correction, use the Model Data Editor and the Property Inspector to set Owner to airflow_calc.

Select the Parameters tab.

Find the row that corresponds to the parameter object, numerator_param.

In the row, double-click the icon in the left column. The Model Explorer opens and displays the properties of numerator_param.

In the Model Hierarchy pane, expand the airflow_calc node so that you can see the subordinate Model Workspace node.
Use the Model Explorer to move `numerator_param` from the base workspace to the `airflow_calc` model workspace. For example, in the Model Hierarchy pane, select **Base Workspace**. Then, drag `numerator_param` from the Contents pane to the Model Workspace node in the Model Hierarchy pane. With this change, the code generator assumes that `airflow_calc` owns `numerator_param`, and places the variable definition in the code generated for `airflow_calc`.

In the `fuel_calc` model, select **View > Property Inspector**.

For the Inport blocks `est_airflow` and `fb_correction`, use the Model Data Editor and the Property Inspector to set **Owner** to `airflow_calc`. With this configuration, the `fuel_calc` code does not define the variables.

For the Outport block, use the Model Data Editor and the Property Inspector to set **Owner** to `fuel_calc`.

Alternatively, to configure the data in the models, use these commands at the command prompt:

```matlab
temp = Simulink.Signal;
temp.CoderInfo.StorageClass = 'Custom';
temp.CoderInfo.CustomStorageClass = 'ExportToFile';
temp.CoderInfo.CustomAttributes.Owner = 'airflow_calc';

set_param('airflow_calc/est_airflow','SignalName','est_airflow')
set_param('airflow_calc/est_airflow','SignalObject',copy(temp))
set_param('airflow_calc/fb_correction','SignalName','fb_correction')
set_param('airflow_calc/fb_correction','SignalObject',copy(temp))

mdlwks = get_param('airflow_calc','ModelWorkspace');
assignin(mdlwks,'numerator_param',copy(numerator_param));

portHandles = get_param('fuel_calc/est_airflow','portHandles');
outportHandle = portHandles.Outport;
set_param(outportHandle,'Name','est_airflow')
set_param(outportHandle,'SignalObject',copy(temp))

portHandles = get_param('fuel_calc/fb_correction','portHandles');
outportHandle = portHandles.Outport;
set_param(outportHandle,'Name','fb_correction')
set_param(outportHandle,'SignalObject',copy(temp))

temp.CoderInfo.CustomAttributes.Owner = 'fuel_calc';
```
set_param('fuel_calc/fuel_rate','SignalName','fuel_rate')
set_param('fuel_calc/fuel_rate','SignalObject',copy(temp))

clear temp portHandles outportHandle numerator_param

In each of the three models, select **Configuration Parameters > Use owner from data object for data definition placement**. With this setting cleared (the default), the code generator ignores the values that you specify for **Owner**.

set_param('fuel_calc','EnableDataOwnership','on')
set_param('airflow_calc','EnableDataOwnership','on')
set_param('sldemo_fuelsys_dd_controller','EnableDataOwnership','on')

Save the component models.

save_system('fuel_calc')
save_system('airflow_calc')

**Generate Improved Code**

Generate code from the controller model, sldemo_fuelsys_dd_controller.

rtwbuild('sldemo_fuelsys_dd_controller')

### Starting build procedure for model: airflow_calc
### Successful completion of build procedure for model: airflow_calc
### Starting build procedure for model: fuel_calc
### Successful completion of build procedure for model: fuel_calc
### Starting build procedure for model: sldemo_fuelsys_dd_controller
### Successful completion of build procedure for model: sldemo_fuelsys_dd_controller

Now, the file sldemo_fuelsys_dd_controller.c does not define any of the global variables.

In the code generation report, inspect the code generated for airflow_calc.

The file airflow_calc.c now defines the global variables that belong to airflow_calc.

file = fullfile('slprj','ert','airflow_calc','airflow_calc.c');
rtwdemodbtype(file,'/* Definition for custom storage class: ExportToFile */',...
'    * real32_T numerator_param[2] = { 0.01F, -0.01F } ;',1,1)

/* Definition for custom storage class: ExportToFile */
real32_T e0;
real32_T est_airflow;
real32_T fb_correction;
real32_T numerator_param[2] = { 0.01F, -0.01F };

Inspect the code generated for fuel_calc. The file fuel_calc.c defines the global variable fuel_rate.

file = fullfile('slprj','ert','fuel_calc','fuel_calc.c);
rtwdemodbtype(file,'/* Definition for custom storage class: ExportToFile */',
  'real32_T fuel_rate;',1,1)

/* Definition for custom storage class: ExportToFile */
real32_T fuel_rate;

**Create Single Point of Specification for Signals That Pass Between Components**

The signal data elements est_airflow and fb_correction are represented by Outport blocks in airflow_calc and by Inport blocks in fuel_calc. If you want to change the configuration of one of these signals, you must make the change in both models. For example, if you want to change the storage class of est_airflow from ExportToFile to Volatile, you must change the storage class twice: once for the Outport block in airflow_calc and again for the Inport block in fuel_calc.

To make maintenance of each signal easier, store the code generation settings in a Simulink.Signal object, which can exist in the base workspace or a data dictionary.

In the Model Data Editor for airflow_calc, on the Inports/Outports tab, find the row that corresponds to est_airflow.

For that row, in the **Signal Name** column, click the cell.

In the cell, next to the est_airflow text, click the action button (with three vertical dots). Select **Create and Resolve**.

In the **Create New Data** dialog box, set **Value** to Simulink.Signal and click **Create**. A Simulink.Signal object named est_airflow appears in the base workspace. In the Model Data Editor, for est_airflow, the check box in the **Resolve** check box is selected, which means the Outport block acquires code generation settings from the signal object in the base workspace.

In the est_airflow property dialog box, set **Storage class** to ExportToFile.
Set **Owner** to `airflow_calc`.

Use the Model Data Editor to create a similar signal object for `fb_correction`.

In the Model Data Editor for `fuel_calc`, on the **Inports/Outports** tab, in the **Resolve** column, select the check boxes for `est_airflow` and `fb_correction`. Now, each Inport block acquires code generation settings from the corresponding signal object.

Alternatively, to create the signal object and configure the blocks and lines in the model, at the command prompt, use these commands:

```matlab
est_airflow = Simulink.Signal;
est_airflow.CoderInfo.StorageClass = 'Custom';
est_airflow.CoderInfo.CustomStorageClass = 'ExportToFile';
est_airflow.CoderInfo.CustomAttributes.Owner = 'airflow_calc';

fb_correction = Simulink.Signal;
fb_correction.CoderInfo.StorageClass = 'Custom';
fb_correction.CoderInfo.CustomStorageClass = 'ExportToFile';
fb_correction.CoderInfo.CustomAttributes.Owner = 'airflow_calc';

set_param('airflow_calc/est_airflow','MustResolveToSignalObject','on')
set_param('airflow_calc/fb_correction','MustResolveToSignalObject','on')

portHandles = get_param('fuel_calc/est_airflow','portHandles');
outportHandle = portHandles.Outport;
set_param(outportHandle,'MustResolveToSignalObject','on')

portHandles = get_param('fuel_calc/fb_correction','portHandles');
outportHandle = portHandles.Outport;
set_param(outportHandle,'MustResolveToSignalObject','on')

clear portHandles outportHandle
```

Save the component models and generate code from `sldemo_fuelsys_dd_controller`. The code is the same as it was before you created the `Simulink.Signal` objects. Now, you can make changes to the signal objects instead of the corresponding blocks and lines in the models.

```bash
save_system('airflow_calc')
save_system('fuel_calc')
rtwbuild('sldemo_fuelsys_dd_controller')
```
### Starting build procedure for model: airflow_calc

Control Data Type Names in Generated Code

By default, the generated code uses Simulink Coder data type aliases to define scalar and array variables. For example, the Simulink Coder type `real32_T` corresponds to the Simulink type `single`. The code defines these types through `typedef` statements that build on C primitive types such as `float` and `short`. You can configure the code to use custom type names instead.

The code also aggregates signal, block parameter, and state data into structures (see “How Generated Code Exchanges Data with an Environment” on page 22-33 and “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 22-50) by default. You can specify a naming rule for these structure types. You can also place data items into separate custom structures whose type names you can control.

Control these type names to help you to:

- Conform to coding standards. For an example, see “Replace and Rename Data Types to Conform to Coding Standards” on page 24-27.
- Integrate the generated code with your external code. For an example, see “Exchange Structured and Enumerated Data Between Generated and External Code” on page 24-34.
- Make the generated code more readable and meaningful.

For custom types, you can also specify that the generated code reuse type definitions, for example, `typedef` statements, from your external code.

For information about data type names that you cannot control and about custom data types that the generated code does not support, see “Limitations” on page 24-21.

To inform the code generator about the bit length of generic C types such as `int` and `short` for your target hardware, use `Hardware Implementation` configuration parameters. See “Configure Run-Time Environment Options” on page 7-2.

Control Names of Primitive Data Types

To rename a Simulink Coder primitive data type such as `int8_T`, first create a `Simulink.AliasType` object whose name matches the type name that you want the generated code to use. For example, to create a type named `myType`, at the command prompt, enter:
myType = Simulink.AliasType;

Set the BaseType property to the name of the Simulink data type that corresponds to the target Simulink Coder data type. For example, if the target type is `int8_T`, specify `int8`. To identify the Simulink data type, use the information in the table.

<table>
<thead>
<tr>
<th>Simulink Coder Type Name</th>
<th>Corresponding Simulink Type Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>real_T</td>
<td>double</td>
</tr>
<tr>
<td>real32_T</td>
<td>single</td>
</tr>
<tr>
<td>int32_T</td>
<td>int32</td>
</tr>
<tr>
<td>int16_T</td>
<td>int16</td>
</tr>
<tr>
<td>int8_T</td>
<td>int8</td>
</tr>
<tr>
<td>uint32_T</td>
<td>uint32</td>
</tr>
<tr>
<td>uint16_T</td>
<td>uint16</td>
</tr>
<tr>
<td>uint8_T</td>
<td>uint8</td>
</tr>
<tr>
<td>boolean_T</td>
<td>boolean</td>
</tr>
</tbody>
</table>

For configuring data type replacement throughout an entire model (`Configuration Parameters > Code Generation > Data Type Replacement`), you can alternatively use one of these types:

- `uint8`
- `int8`
- `intn*`

<table>
<thead>
<tr>
<th>int_T</th>
<th>intn*</th>
</tr>
</thead>
<tbody>
<tr>
<td>uint_T</td>
<td>uintn*</td>
</tr>
<tr>
<td>char_T</td>
<td>intn*</td>
</tr>
</tbody>
</table>

* Replace `n` with the number of bits displayed in `Configuration Parameters > Hardware Implementation` for either `Number of bits: int` or `Number of bits: char`. Use the appropriate number of bits for the data type that you want to rename.

**Note** The `boolean_T` BaseType must promote to a signed `int`. 
For example, to replace the type name `uint8_T` with `myType`, set the `BaseType` property of the `Simulink.AliasType` object to 'int8'.

```
myType.BaseType = 'int8';
```

Then, use one or both of these techniques to apply the type to data items in a model:

- Configure data type replacements. Throughout the code that you generate from a model, you can replace a Simulink Coder data type name with the name of the `Simulink.AliasType` object. You configure data type replacements through model configuration parameters (Configuration Parameters > Code Generation > Data Type Replacement).

For an example that shows how to use data type replacement, see “Replace and Rename Data Types to Conform to Coding Standards” on page 24-27.

- Use the name of the `Simulink.AliasType` object to specify the data type of an individual signal, that is, a block output, or block parameter. By default, due to data type propagation and inheritance (see “Data Type Inheritance Rules” (Simulink)), the signals, states, and parameters of other downstream blocks typically inherit the same data type. Optionally, you can configure data items in upstream blocks to inherit the type (Inherit: Inherit via back propagation) or stop the propagation at an arbitrary block by specifying a noninherited data type setting.

To specify a data type for an individual data item, use the Model Data Editor (View > Model Data Editor). You can use the name of the same `Simulink.AliasType` object to specify the data types of multiple data items.

For an example that shows how to use a `Simulink.AliasType` object directly in a model, see “Create Data Type Alias in the Generated Code” on page 24-12.
<table>

<th><strong>Technique</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Change the name of a primitive type that the generated code uses to define variables by default (for example, <code>int8_T</code>).</td>
<td>Configure a data type replacement for an entire model. To replace a default Simulink Coder data type name with the corresponding Simulink type name, for example, to replace <code>int8_T</code> with <code>int8</code>, you do not need to create a <code>Simulink.AliasType</code> object. See “Use Simulink Data Type Names Instead of Simulink Coder Data Type Names” on page 24-6. To share data type replacements throughout a model reference hierarchy, use referenced configuration sets (see “Share a Configuration Across Referenced Models” (Simulink)).</td>
</tr>
<tr>
<td>Configure the generated code to define a particular data item, such as a variable, by using a specific, meaningful type name.</td>
<td>In the model, locate the data item that corresponds to the variable. For example, trace from the code generation report to the model. Use the name of the <code>Simulink.AliasType</code> object to set the data type of the item. If necessary, to prevent other data items in upstream and downstream blocks from using the same type name, configure those items to use a data type setting that is not inherited. By default, most signals use the inherited type <code>Inherit: Inherit via internal rule</code>.</td>
</tr>
</tbody>
</table>
## Control Names of Primitive Types

<table>
<thead>
<tr>
<th>Technique</th>
<th>Use the same type name for multiple signals and other data items in a data path, which is a series of connected blocks.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Technique</td>
<td>In the model, use the name of a Simulink.AliasType object to set the data type of one of the signals in the path, for example, a root-level Inport block or a Constant block. For example, if the path begins with an Inport block at the root level of the model, you can specify the type in that block. By default, due to data type propagation, the data items in the other blocks typically inherit the same type.</td>
</tr>
<tr>
<td>Technique</td>
<td>In most cases, no matter where on the data path you specify the type, downstream data items inherit the type. You can configure upstream data items to inherit the type, too. Consider specifying the type in a block that you do not expect to remove or change frequently.</td>
</tr>
<tr>
<td>Technique</td>
<td>Configure the generated code to replace an implementation-dependent type, such as char_T or boolean_T, and another type of equivalent bit length with a single type name that you specify.</td>
</tr>
<tr>
<td>Technique</td>
<td>Use the name of the Simulink.AliasType object to configure multiple data type replacements simultaneously. See “Replace Implementation-Dependent Types with the Same Type Name” on page 24-8.</td>
</tr>
</tbody>
</table>

## Use Simulink Data Type Names Instead of Simulink Coder Data Type Names

For consistency between the data type names that you see in a model and in the generated code, you can configure data type replacements so the code uses Simulink type names instead of Simulink Coder names. For each Simulink Coder type that you want to rename, use the Simulink data type name to specify the replacement name. You do not need to create Simulink.AliasType objects.
To replace boolean_T, int_T, or uint_T, use the information in the table.

<table>
<thead>
<tr>
<th>Simulink Coder Type Name</th>
<th>Replacement Names to Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>boolean_T</td>
<td>One of these names:</td>
</tr>
<tr>
<td></td>
<td>• boolean</td>
</tr>
<tr>
<td></td>
<td>• uint8</td>
</tr>
<tr>
<td></td>
<td>• int8</td>
</tr>
<tr>
<td></td>
<td>• intn*</td>
</tr>
<tr>
<td>int_T</td>
<td>intn*</td>
</tr>
<tr>
<td>uint_T</td>
<td>uintn*</td>
</tr>
<tr>
<td>char_T</td>
<td>intn*</td>
</tr>
</tbody>
</table>

* Replace n with the number of bits displayed in **Configuration Parameters > Hardware Implementation** for either **Number of bits: int** or **Number of bits: char**. Use the appropriate number of bits for the data type that you want to replace.
You cannot use this technique to replace `real_T` with `double` or `real32_T` with `single`.

**Replace Implementation-Dependent Types with the Same Type Name**

Some Simulink Coder type names map to C primitives that are implementation-dependent. For example, the Simulink Coder type `int_T` maps to the C type `int`, whose bit length depends on the native integer size of your target hardware. Other implementation-dependent types include `boolean_T`, `char_T`, and `uint_T`.

For more readable, simpler code, you can use the same type name to replace multiple Simulink Coder types of the same size. For example, if the native integer size of your hardware is 32 bits, you can replace `int_T` and `int32_T` with the same type name, say, `myInt`.

1. Configure your target hardware settings in **Configuration Parameters** > **Hardware Implementation**.

2. Create a Simulink.AliasType object named `myInt`. In this case, because `int_T` and `int32_T` represent a 32-bit signed integer, set `BaseType` to `int32`.

   ```
   myInt = Simulink.AliasType('int32')
   ```

3. Configure the same data type replacement for `int32_T` and `int_T`. 
Many-to-one data type replacement does not support the `char` (char_T) built-in data type. Use `char` only in one-to-one data type replacements.

**Define Abstract Numeric Types and Rename Types**

This model shows user-defined types, consisting of numeric and alias types. Numeric types allow you to define abstract numeric types, which is particularly useful for fixed-point types. Alias types allow you to rename types, which allows you to create a relationship for types.

**Explore Example Model**

Open the example model and configure it to show the generated names of blocks.

```matlab
load_system('rtwdemo_udt')
set_param('rtwdemo_udt','HideAutomaticNames','off')
only
```
Key Features of User-Defined Types

- Displayed and propagated on signal lines
- Used to parameterize a model by type (e.g., In1 specifies its **Output data type** as ENG_SPEED)
- Types with a common ancestor can be mixed, whereby the common ancestor is propagated (e.g., output of Sum1)
- Intrinsically supported by the Simulink Model Explorer
- Include an optional header file attribute that is ideal for importing legacy types (ignored for GRT targets)
- Types used in the generated code (ignored for GRT targets)

Instructions

1. Inspect the user-defined types in the Model Explorer by double-clicking the first yellow button below.
2. Inspect the replacement data type mapping by double-clicking the second yellow button below.
3. Compile the diagram to display the types in this model (Simulation > Update Diagram or **Ctrl+D**).
4. Generate code with the blue button below and inspect model files to see how user-defined types appear in the generated code.
5. Modify the attributes of ENG_SPEED and ENG_SPEED_OFFSET and repeat steps 1-4.
Notes

• User-defined types are a feature of Simulink that facilitate parameterization of the data types in a model. Embedded Coder preserves alias data type names (e.g., ENG_SPEED) in the generated code, whereas Simulink Coder implements user-defined types as their base type (e.g., real32_T).

• Embedded Coder also enables you to replace the built-in data types with user-defined data types in the generated code.

Control Names of Structure Types

To control the names of the standard structures that Simulink Coder creates by default to store data (model_P for parameter data, for example), use Configuration Parameters > Code Generation > Symbols > Global types to specify a naming rule. For more information, see “Customize Generated Identifiers” on page 78-21.

When you use nonvirtual buses and parameter structures to aggregate signals and block parameters into a custom structure in the generated code, control the name of the structure type by creating a Simulink.Bus object. For more information, see “Organize Data into Structures in Generated Code” on page 22-177.

Generate Code That Reuses Data Types From External Code

To generate code that reuses a data type definition from your external C code, specify the data scope of the corresponding data type object or enumeration in Simulink as Imported. With this setting, the generated code includes (#include) the definition from your code. For more information about controlling the file placement of a custom data type, see “Control File Placement of Custom Data Types” on page 24-23.

Instead of creating individual data type objects and enumerated types, and then configuring them, consider creating the objects and types by using the Simulink.importExternalCTypes function. By default, the function configures the new objects and types so that the generated code imports (reuses) the type definitions from your code. You can then use the objects and types to set data types in a model and to configure data type replacements. For more information, see Simulink.importExternalCTypes and “Exchange Structured and Enumerated Data Between Generated and External Code” on page 24-34.
Create Data Type Alias in the Generated Code

This example shows how to configure the generated code to use a data type name (typedef) that you specify.

Export Type Definition

When you integrate code generated from a model with code from other sources, your model code can create an exported typedef statement. Therefore, all of the integrated code can use the type. This example shows how to export the definition of a data type to a generated header file.

Create a `Simulink.AliasType` object named `mySingleAlias` that acts as an alias for the built-in data type `single`.

```matlab
mySingleAlias = Simulink.AliasType('single')
```

```matlab
generated code

mySingleAlias =

AliasType with properties:

    Description: '
    DataScope: 'Auto'
    HeaderFile: '
    BaseType: 'single'

Configure the object to export its definition to a header file called `myHdrFile.h`.

```matlab
mySingleAlias.DataScope = 'Exported';
mySingleAlias.HeaderFile = 'myHdrFile.h';
```

Open the model `rtwdemo_basicsc`.

```matlab
open_system('rtwdemo_basicsc')
```
Configure the model to show the generated names of blocks.

```matlab
set_param('rtwdemo_basicsc','HideAutomaticNames','off')
```

In the model, select **View > Model Data Editor**.

In the model, select the Inport block labeled `In1`.

Use the **Data Type** column to set the data type to `mySingleAlias`.

```matlab
set_param('rtwdemo_basicsc/In1','OutDataTypeStr','mySingleAlias')
```

In the model, set **Configuration Parameters > Code Generation > System target file** to `ert.tlc`. The code generator honors data type aliases such as `mySingleAlias` only if you select an ERT-based system target file.

```matlab
set_param('rtwdemo_basicsc','SystemTargetFile','ert.tlc')
```

Generate code from the model.

```matlab
rtwbuild('rtwdemo_basicsc')
```
### Starting build procedure for model: rtwdemo_basicsc
### Successful completion of build procedure for model: rtwdemo_basicsc

In the code generation report, view the file `rtwdemo_basicsc_types.h`. The code creates a `#include` directive for the generated file `myHdrFile.h`.

```matlab
file = fullfile('rtwdemo_basicsc_ert_rtw','rtwdemo_basicsc_types.h');
rtwdemodbtype(file,'#include "myHdrFile.h"',
              '#include "myHdrFile.h"',1,1)

#include "myHdrFile.h"
```

View the file `myHdrFile.h`. The code uses the identifier `mySingleAlias` as an alias for the data type `real32_T`. By default, generated code represents the Simulink data type `single` by using the identifier `real32_T`.

The code also provides a macro guard of the form `RTW_HEADER_filename_h_`. When you export a data type definition to integrate generated code with code from other sources, you can use macro guards of this form to prevent unintentional identifier clashes.

```matlab
file = fullfile('rtwdemo_basicsc_ert_rtw','myHdrFile.h');
rtwdemodbtype(file,'#ifndef RTW_HEADER_myHdrFile_h_,'
              ' * File trailer for generated code.',1,0)

#ifndef RTW_HEADER_myHdrFile_h_
#define RTW_HEADER_myHdrFile_h_
#include "rtwtypes.h"
typedef real32_T mySingleAlias;
typedef creal32_T cmySingleAlias;
#endif                                 /* RTW_HEADER_myHdrFile_h_ */
```

View the file `rtwdemo_basicsc.h`. The code uses the data type alias `mySingleAlias` to define the structure field `input1`, which corresponds to the Inport block labeled `In1`.

```matlab
file = fullfile('rtwdemo_basicsc_ert_rtw','rtwdemo_basicsc.h');
rtwdemodbtype(file,...
              '/* External inputs (root import signals with default storage) */',...
              '} ExtU_rtwdemo_basicsc_T;',1,1)
```
typedef struct {
    mySingleAlias input1;                /* '<Root>/In1' */
    real32_T input2;                     /* '<Root>/In2' */
    real32_T input3;                     /* '<Root>/In3' */
    real32_T input4;                     /* '<Root>/In4' */
} ExtU_rtwdemo_basicsc_T;

Import Type Definition

When you integrate code generated from a model with code from other sources, to avoid redundant typedef statements, you can import a data type definition from the external code. This example shows how to import your own definition of a data type from a header file that you create.

Use a text editor to create a header file to import. Name the file ex_myImportedHdrFile.h. Place it in your working folder. Copy the following code into the file.

```c
#ifndef HEADER_myImportedHdrFile_h_
#define HEADER_myImportedHdrFile_h_

typedef float myTypeAlias;

#endif
```

The code uses the identifier myTypeAlias to create an alias for the data type float. The code also uses a macro guard of the form HEADER_filename_h. When you import a data type definition to integrate generated code with code from other sources, you can use macro guards of this form to prevent unintentional identifier clashes.

At the command prompt, create a Simulink.AliasType object named myTypeAlias that creates an alias for the built-in type single. The Simulink data type single corresponds to the C data type float.

```c
myTypeAlias = Simulink.AliasType('single')
```

myTypeAlias =

AliasType with properties:
Configure the object so that generated code imports the type definition from the header file `ex_myImportedHdrFile.h`.

```plaintext
myTypeAlias.DataScope = 'Imported';
myTypeAlias.HeaderFile = 'ex_myImportedHdrFile.h';
```

Open the model `rtwdemo_basicsc`.

```plaintext
open_system('rtwdemo_basicsc')
```

In the model, select **View > Model Data Editor**.

In the model, select the Inport block labeled `In1`.

Use the **Data Type** column to set the data type to `myTypeAlias`.

```plaintext
set_param('rtwdemo_basicsc/In1','OutDataTypeStr','myTypeAlias')
```

In the model, set **Configuration Parameters > Code Generation > System target file** to `ert.tlc`. The code generator honors data type aliases such as `mySingleAlias` only if you select an ERT-based system target file.

```plaintext
set_param('rtwdemo_basicsc','SystemTargetFile','ert.tlc')
```

Generate code from the model.

```plaintext
rtwbuild('rtwdemo_basicsc')
```

```plaintext
### Starting build procedure for model: rtwdemo_basicsc
### Successful completion of build procedure for model: rtwdemo_basicsc
```

In the code generation report, view the file `rtwdemo_basicsc_types.h`. The code creates a `#include` directive for your header file `ex_myImportedHdrFile.h`.

```plaintext
file = fullfile('rtwdemo_basicsc_ert_rtw','rtwdemo_basicsc_types.h');
rtwmoddbtype(file,#include "ex_myImportedHdrFile.h",...
    /* Forward declaration for rtModel */',1,0)

#include "ex_myImportedHdrFile.h"
```
View the file `rtwdemo_basicsc.h`. The code uses the data type alias `myTypeAlias` to define the structure field `input1`, which corresponds to the Inport block labeled `In1`.

```c
file = fullfile('rtwdemo_basicsc_ert_rtw','rtwdemo_basicsc.h');
rtwdemoddbtype(file,...
    '/* External inputs (root inport signals with default storage) */',...
    '} ExtU_rtwdemo_basicsc_T;',1,1)

/* External inputs (root inport signals with default storage) */
typedef struct {
    myTypeAlias input1;                  /* '<Root>/In1' */
    real32_T input2;                     /* '<Root>/In2' */
    real32_T input3;                     /* '<Root>/In3' */
    real32_T input4;                     /* '<Root>/In4' */
} ExtU_rtwdemo_basicsc_T;

Display Base Data Types and Aliases on Model Diagram

When you display signal data types on the model diagram by selecting Display > Signals and Ports > Port Data Types, by default, the diagram displays aliases (such as `myTypeAlias`) instead of base data types (such as `int16`). To display the base types, choose an option for Display > Signals and Ports > Port Data Type Display Format. For more information, see “Port Data Types” (Simulink).

Create a Named Fixed-Point Data Type in the Generated Code

This example shows how to create and name a fixed-point data type in generated code. You can use the name of the type to specify parameter and signal data types throughout a model and in generated code.

The example model `rtwdemo_fixpt1` uses fixed-point data types. So that you can more easily see the fixed-point data type in the generated code, in this example, you create a Simulink.Parameter object that appears in the code as a global variable.

Create a Simulink.AliasType object that defines a fixed-point data type. Name the object `myFixType`. The generated code uses the name of the object as a data type.

```c
myFixType = Simulink.AliasType('fixdt(1,16,4)');
```

Open the model `rtwdemo_fixpt1`.

```c
open_system('rtwdemo_fixpt1')
```
Configure the model to show the generated names of the blocks.

```matlab
set_param('rtwdemo_fixpt1','HideAutomaticNames','off')
```

In the model, select **View > Model Data Editor**.

In the Model Data Editor, select the **Parameters** tab.

In the model, select the Gain block.

In the Model Data Editor, for the row that represents the Gain parameter of the Gain block, in the **Value** column, specify myParam.
Click the action button (with three vertical dots) next to the parameter value. Select Create.

In the Create New Data dialog box, set Value to Simulink.Parameter(8). In this example, for more easily readable code, you set the parameter value to 8 instead of -3.2. Click Create. A Simulink.Parameter object named myParam appears in the base workspace. The object stores the real-world value 8, which the Gain block uses for the value of the Gain parameter.

In the Simulink.Parameter property dialog box, set Storage class to ExportedGlobal. Click OK. With this setting, myParam appears in the generated code as a separate global variable.

In the Model Data Editor, use the Data Type column to set the data type of the Gain parameter of the Gain block to myFixType.

On the Signals tab, use the Data Type column to set the data type of the Gain block output to myFixType.

Use the Data Type column to set the data type of the Conversion block output to myFixType.

Alternatively, you can use these commands at the command prompt to configure the blocks and create the object:

```matlab
set_param('rtwdemo_fixpt1/Gain','Gain','myParam','OutDataTypeStr','myFixType',
          'ParamDataTypeStr','myFixType')
myParam = Simulink.Parameter(8);
myParam.StorageClass = 'ExportedGlobal';
set_param('rtwdemo_fixpt1/Conversion','OutDataTypeStr','myFixType')
```

In the model, set Configuration Parameters > Code Generation > System target file to ert.tlc. With this setting, the code generator honors data type aliases such as myFixType.

```matlab
set_param('rtwdemo_fixpt1','SystemTargetFile','ert.tlc')
```

Select the configuration parameter Generate code only.

```matlab
set_param('rtwdemo_fixpt1','GenCodeOnly','on')
```

Generate code from the model.

```matlab
rtwbuild('rtwdemo_fixpt1')
```
Starting build procedure for model: rtwdemo_fixpt1

Successful completion of code generation for model: rtwdemo_fixpt1

In the code generation report, view the file rtwdemo_fixpt1_types.h. The code defines the type myFixType based on an integer type of the specified word length (16).

```c
file = fullfile('rtwdemo_fixpt1_ert_rtw','rtwdemo_fixpt1_types.h');
rtwdemodbtype(file,'#ifndef DEFINED_TYPEDEF_FOR_myFixType_,'
    '/* Forward declaration for rtModel */',1,0)

#ifndef DEFINED_TYPEDEF_FOR_myFixType_
#define DEFINED_TYPEDEF_FOR_myFixType_

typedef int16_T myFixType;
typedef cint16_T cmyFixType;
#endif
```

View the file rtwdemo_fixpt1.c. The code uses the type myFixType, which is an alias of the integer type int16, to define the variable myParam.

```c
file = fullfile('rtwdemo_fixpt1_ert_rtw','rtwdemo_fixpt1.c');
rtwdemodbtype(file,'myFixType myParam = 128;','myFixType myParam = 128;',1,1)

myFixType myParam = 128;               /* Variable: myParam

The stored integer value 128 of myParam is not the same as the real-world value 8 because of the scaling that the fixed-point data type myFixType specifies. For more information, see “Scaling” (Fixed-Point Designer) in the Fixed-Point Designer documentation.

The line of code that represents the Gain block applies a right bit shift corresponding to the fraction length specified by myFixType.

```c
rtwdemodbtype(file,...
    'rtwdemo_fixpt1_Y.Out1 = (myFixType)((myParam * rtb_Conversion) >> 4);','...
    'rtwdemo_fixpt1_Y.Out1 = (myFixType)((myParam * rtb_Conversion) >> 4);',1,1)
```
rtwdemo_fixpt1_Y.Out1 = (myFixType)((myParam * rtb_Conversion) >> 4);

**Rename Data Type Object**

To rename a data type object such as `Simulink.AliasType` or `Simulink.Bus` after you create it (for example, when coding standards change or when you encounter a naming conflict), you can allow Simulink to rename the object and correct all of the references to the object that appear in a model or models. In the Model Explorer, right-click the variable and select **Rename All**. For more information, see “Rename Variables” (Simulink).

**Display Signal Data Types on Block Diagram**

For readability, you can display signal data types directly on a block diagram. When you use custom names for primitive data types, you can choose to display the custom name (the alias), the underlying primitive, or both. See “Port Data Types” (Simulink).

**Limitations**

- You cannot configure the generated code to use these custom C data types:
  - Array types
  - Pointer types
  - `const` or `volatile` types
- You cannot configure the generated code to use generic C primitive types such as `int` and `short`.

**Data Type Replacement Limitations**

When you select the model configuration parameter **Replace data type names in the generated code** on the **Code Generation > Data Type Replacement** pane of the Configuration Parameters dialog box, these limitations apply:

- Data type replacement does not support multiple levels of mapping. Each replacement data type name maps directly to one or more built-in data types.
- Data type replacement is not supported for simulation target code generation for referenced models.
If you select the **Classic call interface** configuration parameter for your model, data type replacement is not supported.

Code generation performs data type replacements while generating `.c`, `.cpp`, and `.h` files. Code generation places these files in build folders (including top and referenced model build folders) and in the `_sharedutils` folder. Exceptions are as follows:

- `rtwtypes.h`
- `multiword_types.h`
- `model_reference_types.h`
- `builtin_typeid_types.h`
- `model_sf.c` or `.cpp` (ERT S-function wrapper)
- `model_dt.h` (C header file supporting external mode)
- `model_capi.c` or `.cpp`
- `model_capi.h`

Data type replacement is not supported for complex data types.

Many-to-one data type replacement is not supported for the `char` data type. Attempting to use `char` as part of a many-to-one mapping to a custom data type represents a violation of the MISRA C specification. For example, if you map `char` (`char_T`) and either `int8` (`int8_T`) or `uint8` (`uint8_T`) to the same replacement type, the result is a MISRA C violation. If you try to generate C++ code, the code generator makes invalid implicit type casts, resulting in compile-time errors. Use `char` only in one-to-one data type replacements.

For ERT S-functions, replace the `boolean` data type with only an 8-bit integer, `int8`, or `uint8`.

Set the `DataScope` property of a `Simulink.AliasType` object to `Auto` (default) or `Imported`.

Control File Placement of Custom Data Types

By default, when you use data type objects, such as Simulink.AliasType and Simulink.Bus, and custom enumerations to specify data types for signals and block parameters, the code generated from the model defines the types (for example, with typedef statements). To ease integration of the generated code with other existing code and to modularize the generated code, you can control the file placement of the type definitions by adjusting the properties of the objects and the enumerations.

Data Scope and Header File

To control the file placement of a custom type definition in generated code, set the DataScope and HeaderFile properties of the data type object according to the table. Similarly, for an enumeration that you define in a MATLAB file, set the return arguments of the getDataScope and getHeaderFile methods.

- `typename` is the name of the custom data type.
- `filename` is the name of a header file.
- `model` is the name of the model.

<table>
<thead>
<tr>
<th>Goal</th>
<th>Specify DataScope as</th>
<th>Specify HeaderFile as</th>
</tr>
</thead>
<tbody>
<tr>
<td>Export type definition to <code>model_types.h</code></td>
<td>Auto</td>
<td>Empty</td>
</tr>
<tr>
<td>Import type definition from a header file that you create, <code>filename</code></td>
<td>Auto or Imported</td>
<td><code>filename</code> (if necessary, include a .h extension)</td>
</tr>
<tr>
<td>Export type definition to a generated header file, <code>filename.h</code></td>
<td>Exported</td>
<td><code>filename</code> or <code>filename.h</code></td>
</tr>
<tr>
<td>Export type definition to a generated header file, <code>typename.h</code></td>
<td>Exported</td>
<td>Empty</td>
</tr>
</tbody>
</table>

When you import a data type definition (for example, by setting DataScope to Imported), the generated model code creates an #include directive for your header file in place of a type definition. You supply the header file that contains the definition.
Considerations for Data Type Replacement

- If you use data type replacement to replace a built-in Simulink data type with your own data type in generated code (see “Model Configuration Parameters: Code Generation Data Type Replacement”), typedef statements and #include directives appear in rtwtypes.h instead of model_types.h.

- When a Simulink.AliasType or Simulink.NumericType object participates in data type replacements, you cannot set the DataScope property of the object to Exported. Therefore, if you want the code generator to generate the corresponding typedef statement, you cannot control the file placement of the statement. However, you can set DataScope to Imported, which means that you can configure the code to reuse the typedef statement that your external code provides.

As a workaround, instead of using the data type object as a data type replacement, use the object to set the data types of individual data items in a model. To configure many data items, you can use the Model Data Editor and take advantage of data type propagation and inheritance. For more information, see “Control Names of Primitive Data Types” on page 24-2.

Import Definition of Numerically Complex Data Type

You can use a Simulink.AliasType object with numerically complex data (i). In this case, if you configure the generated code to import the type definition from your external code (for example, by setting the DataScope property to Imported), your code must provide two complementary typedef statements.

Suppose your external header file myAliasTypes.h defines the data type IAT_int32 as an alias of a 32-bit integer. The file must define two types: IAT_int32 and cIAT_int32:

```c
#ifndef myAliasTypes_H_
#define myAliasTypes_H_

#include "rtwtypes.h"

typedef int32_T IAT_int32;
typedef cint32_T cIAT_int32;

#endif
```

You do not need to create two Simulink.AliasType objects. In this example, you create one object, IAT_int32. The generated code then creates complex data (variables) by using both IAT_int32 and cIAT_int32.
**Macro Guards**

When you export one or more data type definitions to a generated header file, the file contains a file-level macro guard of the form `RTW_HEADER_filename_h`.

Suppose you use several Simulink.AliasType objects: `mySingleAlias`, `myDoubleAlias`, and `myIntAlias` with these properties:

- DataScope set to Exported
- HeaderFile set to `myTypes.h`

When you generate code, the guarded file `myTypes.h` contains the typedef statements:

```c
#ifndef RTW_HEADER_myTypes_h_
#define RTW_HEADER_myTypes_h_
#include "rtwtypes.h"

typedef real_T myDoubleAlias;
typedef real32_T mySingleAlias;
typedef int16_T myIntAlias;
#endif
```

When you export data type definitions to `model_types.h`, the file contains a macro guard of the form `_DEFINED_TYPEDEF_FOR_typename_` for each typedef statement. Suppose you use a Simulink.AliasType object `mySingleAlias` with these properties:

- DataScope set to Auto
- HeaderFile not specified

When you generate code, the file `model_types.h` contains the guarded typedef statement:

```c
#ifndef _DEFINED_TYPEDEF_FOR_mySingleAlias_
#define _DEFINED_TYPEDEF_FOR_mySingleAlias_

typedef real32_T mySingleAlias;
#endif
```

Related Examples
- “Control Data Type Names in Generated Code” on page 24-2
Replace and Rename Data Types to Conform to Coding Standards

By default, the generated code uses data type aliases such as real_T and int32_T. The code uses these aliases to define global and local variables. If your coding standards require that you use other data type aliases, including aliases that your existing code defines, you can:

- Configure data type replacement for the entire model.
- Configure individual data items (such as signals, parameters, and states) to use specific data type aliases.

For information about controlling data types in a model, see “Control Signal Data Types” (Simulink).

Inspect External C Code

Save this C code into a file named my_types.h in your current folder. This file represents a header file in your existing code that defines custom data type aliases by using typedef statements.

```c
#include <stdbool.h>

typedef double my_dblPrecision;
typedef short my_int16;
typedef bool my_bool;
```

Explore Example Model and Default Generated Code

1. Open the example model ex_data_type Replacement.
   ```c
   open_system(fullfile(docroot,'toolbox','ecoder','examples',...
   'ex_data_type_replacement'))
   ```
2. In the model, select View > Model Data Editor.
3. In the Model Data Editor, inspect the Signals tab.
4. Set the Change view drop-down list to Code. In the data table, the Storage Class column shows that named signal lines such as temp use the storage class ExportedGlobal. With this setting, the signal lines appear in the generated code as separate global variables.
5. Set the **Change view** drop-down list to **Design**.
6. Update the block diagram.

Simulink assigns a specific data type to each signal that uses an inherited data type setting such as **Inherit: Inherit via internal rule**.

7. In the data table, expand the width of the **Data Type** column. The column shows that the signals in the model use a mix of the data types `int16`, `double`, and `boolean`. You can also see these data types in the model.

8. Generate code from the model.

9. In the code generation report, inspect the shared utility file `rtwtypes.h`. The code uses **typedef** statements to rename the primitive C data types by using standard Simulink Coder aliases. For example, the code renames the primitive type `double` by using the alias `real_T`.

   ```
   typedef double real_T;
   ```

10. Inspect the file `ex_data_type_replacement.c`. The code uses the default data type aliases to declare and define variables. For example, the code uses the data types `real_T`, `int16_T`, and `boolean_T` to define the global variables `flowIn`, `temp`, and `intlk`.

    ```
    real_T flowIn; /* '<Root>/In3' */
    int16_T temp;  /* '<Root>/Add2' */
    boolean_T intlk; /* '<S1>/Compare' */
    ```

    The model step function defines local variables by using the same data type aliases.

    ```
    real_T rtb_Add;
    real_T rtb_FilterCoefficient;
    ```

### Reuse External Data Type Definitions

Configure the generated code to define variables by using the custom data types defined in `my_types.h` instead of the default type names.

1. At the command prompt, create a `Simulink.AliasType` object for each data type alias that your external code defines.

   ```
   Simulink.importExternalCTypes('my_types.h');
   ```

   In the base workspace, the `Simulink.importExternalCTypes` function creates the objects `my_dblPrecision`, `my_int16`, and `my_bool`. 

---
For each object, the function sets the DataScope property to 'Imported' and the HeaderFile property to 'my_types.h'. With these settings, the code generator does not create a typedef statement for each object, but instead the generated code reuses the statements from my_types.h by including (#include) the file.

2 In the model, in the Configuration Parameters dialog box, on the Code Generation > Data Type Replacement pane, select Replace data type names in the generated code.

3 Specify the options in the Replacement Name column according to the table.

<table>
<thead>
<tr>
<th>Simulink Name</th>
<th>Replacement Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>double</td>
<td>my_dblPrecision</td>
</tr>
<tr>
<td>int16</td>
<td>my_int16</td>
</tr>
<tr>
<td>boolean</td>
<td>my_bool</td>
</tr>
</tbody>
</table>

4 Generate code from the model.

5 In the code generation report, inspect the file rtwtypes.h. Now, the code uses an #include directive to import the contents of the external header file my_types.h, which contains the custom data type aliases.

```
#include "my_types.h"  /* User defined replacement datatype for int16_T real_T boolean_T */
```

6 Inspect the file ex_data_type_replacement.c. The code uses the custom data type aliases my_dblPrecision, my_int16, and my_bool to define the global variables such as flowIn, temp, and intlk.

```
my_dblPrecision flowIn;       /* '<Root>/In3' */
my_int16 temp;                /* '<Root>/Add2' */
my_bool intlk;                /* '<S1>/Compare' */
```

The model step function defines local variables by using the custom data type aliases.

```
my_dblPrecision rtb_Add;
my_dblPrecision rtb_FilterCoefficient;
```

**Create Meaningful Data Type Aliases for Individual Data Items**

Suppose your coding standards require that important data items use a data type whose name indicates the real-world significance. You can create more Simulink.AliasType objects to represent these custom data type aliases. Use the objects to set the data types of data items in the model.
In the Model Data Editor **Data Type** column, use the Simulink.AliasType objects to set the data types of these block outputs. You can select a signal line in the model, which highlights the corresponding row in the Model Data Editor, or search for the signals in the Model Data Editor by using the **Filter contents** box.

<table>
<thead>
<tr>
<th>Block</th>
<th>Output Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Flow Setpoint</td>
<td>flow_T</td>
</tr>
<tr>
<td>Add2 (which feeds the Compare block)</td>
<td>diffTemp_T</td>
</tr>
</tbody>
</table>

2 Use the Model Data Editor **Imports/Outports** tab to set the data type of the third Inport block to flow_T.

3 In the model, select **View > Property Inspector**.

4 Select the block labeled Flow Controller. In the Property Inspector, click **Open** to open the block dialog box.

5 On the **Data Types** tab, set **Sum output** to ctrl_T. Click **OK**.

   With these data type settings, some of the named signals, such as temp and flowIn, use data types that evoke real-world quantities, such as liquid flow rate and temperature.

6 At the command prompt, create Simulink.AliasType objects to represent these new custom data type aliases.

```matlab
flow_T = Simulink.AliasType('double');
diffTemp_T = Simulink.AliasType('int16');
ctrl_T = Simulink.AliasType('double');
```

   In the model, the signals flowIn and flowSetPt use the primitive data type double, so the data type alias flow_T maps to double.

7 Update the block diagram.

   Due to data type inheritance, other signals also use the custom data type aliases. For example, the output data type of the Add block fed by the third Inport block is set to **Inherit: Inherit via internal rule**. The internal rule chooses the same data type that the block inputs use, flow_T.

8 Generate code from the model.

9 The file `ex_data_typeReplacementTypes.h` defines the new data types flow_T, diffTemp_T, and ctrl_T as aliases of my_dblPrecision and my_int16.
typedef my_dblPrecision flow_T;
typedef my_int16 diffTemp_T;
typedef my_dblPrecision ctrl_T;

In the file ex_data_type_replacement.c, the code defines global variables by using the new type names.

flow_T flowIn;                         /* '<Root>/In3' */
flow_T flowSetPt;                      /* '<Root>/Flow Setpoint' */
ctrl_T flowCtrl;                       /* '<Root>/Interlock' */
diffTemp_T temp;                           /* '<Root>/Add2' */

For blocks that do not use the new data types, the corresponding generated code continues to use the replacement types that you specified earlier. For example, in the file ex_data_type_replacement.h, the outputs of the blocks In1 and In2 appear as structure fields that use the replacement type my_int16.

/* External inputs (root inport signals with auto storage) */
typedef struct {
    my_int16 In1;                        /* '<Root>/In1' */
    my_int16 In2;                        /* '<Root>/In2' */
} ExtU_ex_data_type_replacement_T;

Create Single Point of Definition for Primitive Types

The custom data type aliases flow_T and ctrl_T map to the primitive data type double. If you want to change this underlying data type from double to single (float), you must remember to modify the BaseType property of both Simulink.AliasType objects.

To more easily make this change, you can create a Simulink.NumericType object and configure both Simulink.AliasType objects to refer to it. Then, you need to modify only the Simulink.NumericType object. A Simulink.NumericType object enables you to share a data type without creating a data type alias.

1 At the command prompt, create a Simulink.NumericType object to represent the primitive data type single.

sharedType = Simulink.NumericType;
sharedType.DataTypeMode = 'Single';

2 Configure the Simulink.AliasType objects flow_T and ctrl_T to acquire an underlying data type from this new object.
3 In the model, select **Display > Signals and Ports > Port Data Type Display Format > Base and Alias Types** (see “Port Data Types” (Simulink)). Update the block diagram.

The data type indicators in the model show that the aliases `flow_T` and `ctrl_T` map to the primitive type `single`. To change this underlying primitive type, you can modify the `DataTypeMode` property of the `Simulink.NumericType` object, `sharedType`.

By default, the `Simulink.NumericType` object does not cause another `typedef` statement to appear in the generated code.

If you generate code from the model while the `Simulink.NumericType` object represents the data type `single`, the generated code maps `flow_T` and `ctrl_T` to the default Simulink Coder data type alias `real32_T`, which maps to the C data type `float`. You can replace `real32_T` in the same way that you replaced `real_T`, `int16_T`, and `boolean_T` (*Configuration Parameters > Code Generation > Data Type Replacement*).

### Permanently Store Data Type Objects

The `Simulink.NumericType` and `Simulink.AliasType` objects in the base workspace do not persist if you end your current MATLAB session. To permanently store these objects, consider migrating your model to a data dictionary. See “Migrate Models to Use Simulink Data Dictionary” (Simulink).

### Create and Maintain Objects Corresponding to Multiple C typedef Statements

To create `Simulink.AliasType` objects for a large number of typedef statements in your external C code, consider using the `Simulink.importExternalCTypes` function.

Exchange Structured and Enumerated Data Between Generated and External Code

This example shows how to generate code that exchanges data with external, existing code. Construct and configure a model to match data types with the external code and to avoid duplicating type definitions and memory allocation (definition of global variables). Then, compile the generated code together with the external code into a single application.

Inspect External Code

Create the file ex_cc_algorithm.c in your current folder.

```c
#include "ex_cc_algorithm.h"

inSigs_T inSigs;

float_32 my_alg(void)
{
    if (inSigs.err == TMP_HI) {
        return 27.5;
    }
    else if (inSigs.err == TMP_LO) {
        return inSigs.sig1 * calPrms.cal3;
    }
    else {
        return inSigs.sig2 * calPrms.cal3;
    }
}
```

The C code defines a global structure variable named inSigs. The code also defines a function, my_alg, that uses inSigs and another structure variable named calPrms.

Create the file ex_cc_algorithm.h in your current folder.

```c
#ifndef ex_cc_algorithm_h
#define ex_cc_algorithm_h

typedef float float_32;

typedef enum {
```
The file defines float_32 as an alias of the C data type float. The file also defines an enumerated data type, err_T, and two structure types, inSigs_T and calPrms_T.

The function my_alg is designed to calculate a return value by using the fields of inSigs and calPrms, which are global structure variables of the types inSigs_T and calPrms_T. The function requires another algorithm to supply the signal data that inSigs stores.

This code allocates memory for inSigs, but not for calPrms. Create a model whose generated code:

- Defines and initializes calPrms.
- Calculates values for the fields of inSigs.
- Reuses the type definitions (such as err_T and float_32) that the external code defines.
Create Simulink Model

1. So that you can create enumerated and structured data in the Simulink model, first create Simulink representations of the data types that the external code defines. Store the Simulink types in a new data dictionary named `ex_cc_integ.sldd`.

   ```matlab
   Simulink.importExternalCTypes('ex_cc_algorithm.h',
    'DataDictionary','ex_cc_integ.sldd');
   ```

   The data dictionary appears in your current folder.

2. To inspect the dictionary contents in the Model Explorer, in your current folder, double-click the file, `ex_cc_integ.sldd`.

   The `Simulink.importExternalCTypes` function creates `Simulink.Bus`, `Simulink.AliasType`, and `Simulink.data.dictionary.EnumTypeDefinition` objects that correspond to the custom C data types from `ex_cc_algorithm.h`.

3. Create a new model and save it in your current folder as `ex_struct_enum_integ`.

4. Link the model to the data dictionary. In the model, select **File > Model Properties > Link to Data Dictionary**.

5. Add algorithmic blocks that calculate the fields of `inSigs`.
Now that you have the algorithm model, you must:

- Organize the output signals into a structure variable named `inSigs`.
- Create the structure variable `calPrms`.
- Include `ex_cc_algorithm.c` in the build process that compiles the code after code generation.
Configure Generated Code to Write Output Data to Existing Structure Variable

1. Add a Bus Creator block near the existing Outport blocks. The output of a Bus Creator block is a bus signal, which you can configure to appear in the generated code as a structure.

2. In the Bus Creator block, set these parameters:
   - **Number of inputs** to 3
   - **Output data type** to Bus: inSigs_T
   - **Output as nonvirtual bus** to selected

3. Delete the three existing Outport blocks (but not the signals that enter the blocks).

4. Connect the three remaining signal lines to the inputs of the Bus Creator block.

5. Add an Outport block after the Bus Creator block. Connect the output of the Bus Creator to the Outport.

6. In the Outport block, set the **Data type** parameter to Bus: inSigs_T.

7. In the model, select **View > Model Data Editor**.

8. On the **Imports/Outports** tab, for the Inport blocks labeled In2 and In3, change **Data Type** from Inherit: auto to float_32.

9. Change the **Change View** drop-down list from Design to Code.

10. For the Outport block, set **Signal Name** to inSigs.

11. Set **Storage Class** to ImportFromFile.

12. Set **Header File** to ex_cc_algorithm.h.

13. Inspect the **Signals** tab.

14. In the model, select the output signal of the Multiport Switch block.

15. In the Model Data Editor, for the selected signal, set **Name** to err.

16. Set the name of the output signal of the Gain block to sig1.

17. Set the name of the output signal of the Gain1 block to sig2.

When you finish, the model stores output signal data (such as the signals err and sig1) in the fields of a structure variable named inSigs.
Because you set **Storage Class** to **ImportFromFile**, the generated code does not allocate memory for **inSigs**.

**Configure Generated Code to Define Parameter Data**

Configure the generated code to define the global structure variable, **calPrms**, that the external code needs.

1. In the Model Explorer **Model Hierarchy** pane, under the dictionary node **ex_cc_integ**, select the **Design Data** node.
2. In the **Contents** pane, select the Simulink.Bus object **calPrms_T**.
3. In the Dialog pane (the right pane), click **Launch Bus Editor**.
4. In the Bus Editor, in the left pane, select **calPrms_T**.
5 On the Bus Editor toolbar, click the Create/Edit a Simulink.Parameter Object from a Bus Object button.

6 In the MATLAB Editor, copy the generated MATLAB code and run the code at the command prompt. The code creates a Simulink.Parameter object in the base workspace.

7 In the Model Explorer Model Hierarchy pane, select Base Workspace.

8 Use the Model Explorer to move the parameter object, calPrms_T_Param, from the base workspace to the Design Data section of the data dictionary.

9 With the data dictionary selected, in the Contents pane, rename the parameter object as calPrms.

10 In the Model Data Editor, select the Parameters tab.

11 Set the Change view drop-down list to Design.

12 For the Gain block, replace the value 13.8900013 with calPrms.cal1.

13 In the other Gain block, use calPrms.cal2.

14 While editing the value of the other Gain block, next to calPrms.cal2, click the action button : and select calPrms > Open.

15 In the calPrms property dialog box, next to the Value box, click the action button : and select Open Variable Editor.

16 Use the Variable Editor to set the field values in the parameter object.

   - For the fields cal1 and cal2, use the numeric values that the Gain blocks in the model previously used.
   - For cal3, use a nonzero number such as 15.229995.

When you finish, close the Variable Editor.

17 In the property dialog box, set Storage class to ExportedGlobal. Click OK.

18 Use the Model Explorer to save the changes that you made to the dictionary.

**Generate, Compile, and Inspect Code**

1 Configure the model to include ex_cc_algorithm.c in the build process. Set Configuration Parameters > Code Generation > Custom Code > Additional build information > Source files to ex_cc_algorithm.c.

2 Generate code from the model.
Inspect the generated file `ex_struct_enum_integ.c`. The file defines and initializes `calPrms`.

```c
/* Exported block parameters */
calPrms_T calPrms = {
    13.8900013F,
    0.998300076F,
    15.23F
} ;                                    /* Variable: calPrms
```

The generated algorithm in the model `step` function defines a local variable for buffering the value of the signal `err`.

```c
err_T rtb_err;
```

The algorithm then calculates and stores data in the fields of `inSigs`.

```c
inSigs.err = rtb_err;
inSigs.sig1 = (rtU.In2 + rtDW.DiscreteTimeIntegrator_DSTATE) * calPrms.cal1;
inSigs.sig2 = (real32_T)(calPrms.cal2 * rtDW.DiscreteTimeIntegrator_DSTATE);
```

**Replace Data Type Names Throughout Model**

To generate code that uses `float_32` instead of the default, `real32_T`, instead of manually specifying the data types of block output signals and bus elements, you can use data type replacement (`Configuration Parameters > Code Generation > Data Type Replacement`). For more information, see “Replace and Rename Data Types to Conform to Coding Standards” on page 24-27.

Specify Boolean and Data Type Limit Identifiers

You can use command-line parameters to replace the default Boolean and data type limit identifiers. If you want to associate the data type limit identifiers with the data type names, consider replacing the default identifiers. You can also use command-line parameters to import a header file with the Boolean and data type limit identifier definitions.

### Data Type Limit Identifiers

You can control the data type limit identifiers in the generated code by using the command-line parameters in this table.

<table>
<thead>
<tr>
<th>Data Type Limit</th>
<th>Default Identifier</th>
<th>Command-Line Parameter</th>
</tr>
</thead>
<tbody>
<tr>
<td>8-bit integer maximum</td>
<td>MAX_int8_T</td>
<td>MaxIdInt8</td>
</tr>
<tr>
<td>16-bit integer maximum</td>
<td>MAX_int16_T</td>
<td>MaxIdInt16</td>
</tr>
<tr>
<td>32-bit integer maximum</td>
<td>MAX_int32_T</td>
<td>MaxIdInt32</td>
</tr>
<tr>
<td>8-bit unsigned integer maximum</td>
<td>MAX_uint8_T</td>
<td>MaxIdUint8</td>
</tr>
<tr>
<td>16-bit unsigned integer maximum</td>
<td>MAX_uint16_T</td>
<td>MaxIdUint16</td>
</tr>
<tr>
<td>32-bit unsigned integer maximum</td>
<td>MAX_uint32_T</td>
<td>MaxIdUint32</td>
</tr>
<tr>
<td>8-bit integer minimum</td>
<td>MIN_int8_T</td>
<td>MinIdInt8</td>
</tr>
<tr>
<td>16-bit integer minimum</td>
<td>MIN_int16_T</td>
<td>MinIdInt16</td>
</tr>
<tr>
<td>32-bit integer minimum</td>
<td>MIN_int32_T</td>
<td>MinIdInt32</td>
</tr>
</tbody>
</table>

For example, to change the default identifiers for the 8-bit integer data limit minimum and maximum to `s4g_S4MIN` and `s4g_S4MAX`, respectively:

```matlab
def param(gcs,'MinIdInt8','s4g_S4MIN');
def param(gcs,'MaxIdInt8','s4g_S4MAX');
```

If you do not import a header file, the generated file `rtwtypes.h` defines the 8-bit integer data minimum and maximum identifiers:
If you do import a header file defining the data type limit identifiers, the header file is included in `rtwtypes.h`.

### Boolean Identifiers

You can control the Boolean identifiers in the generated code by using the command-line parameters in this table. When changing boolean identifiers, you must define `false` to be numerically equivalent to 0, and `true` to be numerically equivalent to 1.

<table>
<thead>
<tr>
<th>Boolean</th>
<th>Default Identifier</th>
<th>Command-Line Parameter</th>
</tr>
</thead>
<tbody>
<tr>
<td>True</td>
<td><code>true</code></td>
<td><code>BooleanTrueId</code></td>
</tr>
<tr>
<td>False</td>
<td><code>false</code></td>
<td><code>BooleanFalseId</code></td>
</tr>
</tbody>
</table>

For example, to change the default Boolean true and false identifiers:

```matlab
set_param(gcs,'BooleanTrueId','bTrue');
set_param(gcs,'BooleanFalseId','bFalse')
```

If you do not import a header file, the generated file `rtwtypes.h` defines the Boolean identifiers:

```c
#define bFalse                (0U)
#define bTrue                  (1U)
```

If you do import a header file defining the Boolean identifiers, the header file is included in `rtwtypes.h`.

**Note** When changing boolean identifiers, you must define `false` to be numerically equivalent to 0, and `true` to be numerically equivalent to 1.

### Boolean and Data Type Limit Identifier Header Files

You can import a header file that defines Boolean and data type limit identifiers using the command-line parameter `TypeLimitIdReplacementHeaderFile`. The header file is included in `rtwtypes.h`. You must use the command-line parameters to specify the Boolean and data type limit identifiers that are included in the imported header file.
For example, if you have a header file `myfile.h` with data type limit definitions, use `TypeLimitIdReplacementHeaderFile` to include the definitions in the generated code:

```matlab
set_param(gcs,'TypeLimitIdReplacementHeaderFile','myfile.h');
```

The generated file `rtwtypes.h` includes `myfile.h`.

```c
/* Import type limit identifier replacement definitions. */
#include "myfile.h"
```

</table>

The following table describes the properties and property values for `mpt.Parameter` and `mpt.Signal` data objects that appear in the Model Explorer.

**Note** You can create `mpt.Signal` and `mpt.Parameter` objects in the base MATLAB or model workspace. However, if you create a signal object in a model workspace, the object's storage class must be set to `Auto`.

The figure below shows an example of the Model Explorer. When you select an `mpt.Parameter` or `mpt.Signal` data object in the middle pane, its properties and property values display in the rightmost pane.

In the Properties column, the table lists the properties in the order in which they appear on the Model Explorer.
## Parameter and Signal Property Values

<table>
<thead>
<tr>
<th>Class: Parameter, Signal, or Both</th>

## Examples of Property Value Changes on Generated Code

<table>
<thead>
<tr>
<th>What I noticed when inspecting the .c/.cpp file</th>
<th>Change I made to property value settings</th>
<th>What I noticed after regenerating and reinspecting the file</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example 1: Parameter data objects can be declared or defined as constants. I know that the data object GAIN is a parameter. I want this to be declared or defined in the .c file as a variable. But I notice that GAIN is declared as a constant by the statement <code>const real_T GAIN = 5.0;</code>. Also, this statement is in the constant section of the file.</td>
<td>In the Model Explorer, I clicked the data object GAIN. I noticed that the property value for its <strong>Memory section</strong> property is set at MemConst. I changed this to Default.</td>
<td>I notice two differences. One is that now GAIN is declared as a variable with the statement <code>real_T GAIN = 5.0;</code>. The second difference is that the declaration now is located in the MemConst memory section in the .c or .cpp file.</td>
</tr>
<tr>
<td>Example 2: I notice again the declaration of GAIN in the .c file mentioned in Example 1. It appears as <code>real_T GAIN = 5.0;</code>. But I have changed my mind. I want data object GAIN to be #define.</td>
<td>I changed the <strong>Storage class</strong> selection to Define (Custom).</td>
<td>GAIN is not declared in the .c file as a MemConst parameter. Rather, it is defined as a #define macro by the code <code>#define GAIN 5.0</code>, and this is located near the top of the .c file with the other preprocessor directives.</td>
</tr>
<tr>
<td>Example 3: I changed my mind again after doing Example 2. I do want GAIN defined using the #define preprocessor directive. But I do not want to include the #define in this file. I know it exists in another file and I want to reference that file.</td>
<td>On the Model Explorer, I notice that the property value for the <strong>Header file</strong> property is blank. I changed this to filename.h. (I chose the ANSI C/C++ double quote mechanism for the #include, but could have chosen the angle bracket mechanism.) Also, I must make the user-defined filename.h available to the compiler, placing it either in the system path or local directory.</td>
<td>#define GAIN 5.0 is not present in this .c file. Instead, the #include filename.h code appears as a preprocessor directive at the top of the file.</td>
</tr>
<tr>
<td>What I noticed when inspecting the <code>.c/.cpp</code> file</td>
<td>Change I made to property value settings</td>
<td>What I noticed after regenerating and reinspecting the file</td>
</tr>
<tr>
<td>-------------------------------------------------</td>
<td>------------------------------------------</td>
<td>---------------------------------------------------------------</td>
</tr>
<tr>
<td>Example 4: I have one more change I want to make. Let us say that we have declared the data object <code>data_in</code>, and that its declaration statement in the <code>.c</code> file reads <code>real_T data_in = 0.0;</code>. I want to replace this statement with an alias in the <code>.c</code> file.</td>
<td>In the Model Explorer, I selected the data object <code>data_in</code>. I noticed that the <strong>Alias</strong> field is blank. I changed this to <code>data_in_alias</code>, which I know is a valid ANSI C/C++ variable name.</td>
<td>The identifier <code>data_in_alias</code> now appears in the <code>.c</code> file everywhere <code>data_in</code> appeared.</td>
</tr>
</tbody>
</table>

### Specify Persistence Level for Signals and Parameters

With this procedure, you can control the persistence level of signal and parameter objects associated with a model. Persistence level allows you to make intermediate variables or parameters global during initial development. At the later stages of development, you can use this procedure to remove these signals and parameters for efficiency. Use the **Persistence Level** property of `mpt.Signal` and `mpt.Parameter` data objects. For descriptions of the properties on the Model Explorer, see “MPT Data Object Properties” on page 25-2.

Notice also the **Signal display level** and **Parameter tune level** fields on the **Code Placement** pane of the Configuration Parameters dialog box, as illustrated in the next figure.
The **Signal display level** field allows you to specify whether or not the code generator defines a signal data object as global data in the generated code. The number you specify in this field is relative to the number you specify in the **Persistence level** field. The **Signal display level** number is for `mpt` (module packaging tool) signal data objects in the model. The **Persistence level** number is for a particular `mpt` signal data object. If the data object's **Persistence level** is equal to or less than the **Signal display level**, the signal appears in the generated code as global data with the custom attributes that you specified. For example, this would occur if **Persistence level** is 2 and **Signal display level** is 5.

Otherwise, the code generator automatically determines how the particular signal data object appears in the generated code. Depending on the settings on the **Optimization**
pane of the Configuration Parameters dialog box, the signal data object could appear in the code as local data without the custom attributes you specified for that data object. Or, based on expression folding, the code generator could remove the data object so that it does not appear in the code.

The **Parameter tune level** field allows you to specify whether or not the code generator declares a parameter data object as tunable global data in the generated code.

The number you specify in this field is relative to the number you specify in the **Persistence level** field. The **Parameter tune level** number is for mpt parameter data objects in the model. The **Persistence level** number is for a particular mpt parameter data object. If the data object’s **Persistence level** is equal to or less than the **Parameter tune level**, the parameter appears tunable in the generated code with the custom attributes that you specified. For example, this would occur if **Persistence level** is 2 and **Parameter tune level** is 5.

Otherwise, the parameter is inlined in the generated code, and the code generation settings determine its exact form.

Note that, in the initial stages of development, you might be more concerned about debugging than code size. Or, you might want one or more particular data objects to appear in the code so that you can analyze intermediate calculations of an equation. In this case, you might want to specify the **Parameter tune level** (**Signal display level** for signals) to be higher than **Persistence level** for some mpt parameter (or signal) data objects. This results in larger code size, because the code generator defines the parameter (or signal) data objects as global data, which have the custom properties you specified. As you approach production code generation, however, you might have more concern about reducing the size of the code and less need for debugging or intermediate analyses. In this stage of the tradeoff, you could make the **Parameter tune level** (**Signal display level** for signals) greater than **Persistence level** for one or more data objects, generate code and observe the results. Repeat until satisfied.

1. With the model open, in the Configuration Parameters dialog box, select **Code Generation > Code Placement**.
2. Type the desired number in the **Signal display level** or **Parameter tune level** field, and click **Apply**.
3. In the Model Explorer, type the desired number in the **Persistence** field for the selected signal or parameter, and click **Apply**.
4. Save the model and generate code.
Register mpt User Object Types

- “Introduction” on page 25-19
- “Register mpt User Object Types Using sl_customization.m” on page 25-19
- “mpt User Object Type Customization Using sl_customization.m” on page 25-20

Introduction

Embedded Coder allows you to create custom mpt object types and specify properties and property values to be associated with them. Once created, a user object type can be applied to data objects displayed in Model Explorer. When you apply a user object type to a data object, by selecting a type name in the User object type pull-down list in Model Explorer, the data object is automatically populated with the properties and property values that you specified for the user object type.

To register mpt user object type customizations, use the Simulink customization file sl_customization.m. This file is a mechanism that allows you to use MATLAB code to perform customizations of the standard Simulink user interface. The Simulink software reads the sl_customization.m file, if present on the MATLAB path, when it starts and the customizations specified in the file are applied to the Simulink session. For more information on the sl_customization.m customization file, see “Registering Customizations” (Simulink).

Register mpt User Object Types Using sl_customization.m

To register mpt user object type customizations, you create an instance of sl_customization.m and include it on the MATLAB path of the Simulink installation that you want to customize. The sl_customization function accepts one argument: a handle to a customization manager object. For example,

```matlab
function sl_customization(cm)
```

As a starting point for your customizations, the sl_customization function must first get the default (factory) customizations, using the following assignment statement:

```matlab
hObj = cm.slDataObjectCustomizer;
```

You then invoke methods to register your customizations. The customization manager object includes the following methods for registering mpt user object type customizations:

- addMPTObjectType(hObj, objectTypeName, classtype, propName1, propValue1, propName2, propValue2, ...)
addMPTObjectType(hObj, objectTypeName, classtype, {propName1, propName2, ...}, {propValue1, propValue2, ...})

Registers the specified user object type, along with specified values for object properties, and adds the object type to the top of the user object type list, as displayed in the User object type pull-down list in the Model Explorer.

• **objectTypeName** — Name of the user object type
• **classType** — Class to which the user object type applies: 'Signal', 'Parameter', or 'Both'
• **propName** — Name of a property of an mpt or mpt-derived data object to be populated with a corresponding propValue when the registered user object type is selected
• **propValue** — Specifies the value for a corresponding propName

moveMPTObjectTypeToTop(hObj, objectTypeName)

Moves the specified user object type to the top of the user object type list, as displayed in the User object type pull-down list in the Model Explorer.

moveMPTObjectTypeToEnd(hObj, objectTypeName)

Moves the specified user object type to the end of the user object type list, as displayed in the User object type pull-down list in the Model Explorer.

removeMPTObjectType(hObj, objectTypeName)

Removes the specified user object type from the user object type list.

Your instance of the sl_customization function should use these methods to register mpt object type customizations for your Simulink installation.

The Simulink software reads the sl_customization.m file when it starts. If you subsequently change the file, to use the changes, you must restart your MATLAB session.

**mpt User Object Type Customization Using sl_customization.m**

The sl_customization.m file shown in “mpt User Object Type Customization Using sl_customization.m” on page 25-20 uses the addMPTObjectType method to register the user signal types EngineType and FuelType for mpt objects.

**Example 25.1. sl_customization.m for mpt Object Type Customizations**

```matlab
function sl_customization(cm)
% Register user customizations
```
% Get default (factory) customizations
hObj = cm.slDataObjectCustomizer;

% Add commonly used signal types
hObj.addMPTObjectType(...
    'EngineType','Signal',...
    'DataType', 'uint8',...
    'Min', 0,...
    'Max', 255,...
    'Unit','m/s');

hObj.addMPTObjectType(...
    'FuelType','Signal',...
    'DataType', 'int16',...
    'Min', -12,...
    'Max', 3000,...
    'Unit','mg/hr');

end

If you include the above file on the MATLAB path of the Simulink installation that you want to customize, the specified customizations will appear in Model Explorer. For example, you could view the customizations as follows:

1. Start a MATLAB session.
2. Open Model Explorer, for example, by entering the MATLAB command `daexplr`.
3. Select Base Workspace.
4. Add an mpt signal, for example, by selecting Add > Add Custom.
5. In the right-hand pane display for the added mpt signal, examine the User object type drop-down list, noting the impact of the changes specified in “mpt User Object Type Customization Using sl_customization.m” on page 25-20.
6. From the User object type drop-down list, select one of the registered user signal types, for example, FuelType, and verify that the displayed settings are consistent with the arguments specified to the `addMPTObjectType` method in sl_customization.m.
Custom Storage Classes in Embedded Coder

Reuse Parameter Data from External Code in the Generated Code

This example shows how to generate code that imports a parameter value from your external code.

Create External Code Files

Suppose your external code defines a vector parameter `myGains` with three elements. Save the definition in your current folder in a file called `ex_vector_import_src.c`.

```c
#include "ex_vector_import_decs.h"

my_int8 myGains[3] = {
    2,
    4,
    6
};
```

Save the declaration in your current folder in a file called `ex_vector_import_decs.h`.

```c
#include "ex_vector_import_cust_types.h"

extern my_int8 myGains[3];
```

Save the data type definition `my_int8` in your current folder in a file called `ex_vector_import_cust_types.h`.

```c
typedef signed char my_int8;
```

Import Parameter Value for Simulation

In your current folder, right-click the file `ex_vector_import_src.c` and select **Import Data**.

In the Import dialog box, set **Output Type** to **Numeric Matrix**.

Set the name of the generated MATLAB variable to `tempVar`.

Select only the parameter values (2, 4, and 6) to import.
Import the data by clicking the green check mark. The MATLAB variable `tempVar` appears in the base workspace.

Alternatively, use the command prompt to manually create `tempVar`.

```matlab
tempVar = [2;4;6];
```

At the command prompt, create a `Simulink.Parameter` object that represents `myGains`.

```matlab
myGains = Simulink.Parameter(tempVar);
```

**Create and Configure Model**

Create the model `ex_vector_import`.

```matlab
open_system('ex_vector_import')
```

In the model, select **View > Model Data Editor**.

In the Model Data Editor, inspect the **Parameters** tab.

Use the **Value** column to set the value of the **Gain** parameter in the Gain block to `myGains`.

Click the **Show/refresh additional information** button. The data table now contains a row that represents the parameter object, `myGains`.

Use the **Data Type** column to set the data type of `myGains` to `my_int8`.

For the other row (which represents the `Gain` parameter of the Gain block), set **Data Type** to `Inherit: Inherit from 'Gain'`. With this setting, the `Gain` parameter inherits the data type `my_int8` from `myGains`.

Set the **Change view** drop-down list to **Code**.

Set these properties for `myGains`:

- **Storage Class** to `ImportFromFile`
- **Header File** to `ex_vector_import_decs.h`

Alternatively, use these commands at the command prompt to configure the object and the block:

```matlab
set_param('ex_vector_import/Gain','Gain','myGains',... 'ParamDataTypeStr','Inherit: Inherit from ''Gain''')
myGains.DataType = 'my_int8';
myGains.CoderInfo.StorageClass = 'Custom';
myGains.CoderInfo.CustomStorageClass = 'ImportFromFile';
myGains.CoderInfo.CustomAttributes.HeaderFile = 'ex_vector_import_decs.h';
```

At the command prompt, create a `Simulink.AliasType` object to represent your custom data type `my_int8`. Set the **DataScope** and **HeaderFile** properties to import the type definition from your external code.

```matlab
my_int8 = Simulink.AliasType('int8');
my_int8.DataScope = 'Imported';
my_int8.HeaderFile = 'ex_vector_import_cust_types.h';
```

Set **Configuration Parameters > Code Generation > Custom Code > Additional build information > Source files** to `ex_vector_import_src.c`.

```matlab
set_param('ex_vector_import','CustomSource','ex_vector_import_src.c')
```

**Generate and Inspect Code**

Generate code from the model.

```matlab
rtwbuild('ex_vector_import')
```
## Starting build procedure for model: ex_vector_import
### Successful completion of build procedure for model: ex_vector_import

The generated file `ex_vector_import.h` includes the external header files `ex_vector_import_decs.h` and `ex_vector_import_cust_types.h`, which contain the parameter variable declaration (`myGains`) and custom type definition (`my_int8`).

```matlab
file = fullfile('ex_vector_import_ert_rtw','ex_vector_import.h');
rtwdemodbtype(file,'#include "ex_vector_import_cust_types.h"',...'
    '#include "ex_vector_import_cust_types.h"',1,1)
rtwdemodbtype(file,'/* Includes for objects with custom storage classes. */',...'
    '#include "ex_vector_import_decs.h"',1,1)

#include "ex_vector_import_cust_types.h"

/* Includes for objects with custom storage classes. */
#include "ex_vector_import_decs.h"
```

The generated code algorithm in the model step function in the generated file `ex_vector_import.c` uses `myGains` for calculations.

```matlab
file = fullfile('ex_vector_import_ert_rtw','ex_vector_import.c');
rtwdemodbtype(file,'/* Model step function */','/* Model initialize function */',1,0)

/* Model step function */
void ex_vector_import_step(void)
{
    /* Outport: '<Root>/Out1' incorporates:
    *  Gain: '<Root>/Gain'
    *  Inport: '<Root>/In1'
    */
    rtY.Out1[0] = (real_T)myGains[0] * rtU.In1;
    rtY.Out1[1] = (real_T)myGains[1] * rtU.In1;
}
```

The generated code does not define (allocate memory for) or initialize the global variable `myGains` because the data scope of the corresponding parameter object is imported.

When you simulate the model in Simulink, the model uses the value stored in the Value property of the parameter object. However, if you use external mode simulation, the
external executable begins the simulation by using the value from your code. See “Considerations for Other Modeling Goals” on page 42-100.

Related Examples

- “Exchange Data Between External C/C++ Code and Simulink Model or Generated Code” on page 42-90
- “Import Parameter Data with Conditionally Compiled Dimension Length” on page 26-7
Import Parameter Data with Conditionally Compiled Dimension Length

Suppose your external code conditionally allocates memory for and initializes lookup table and breakpoint set data based on a dimension length that you specify as a \texttt{#define} macro. This example shows how to generate code that imports this external global data.

\textbf{Create External Code Files}

Save the definition of the breakpoint set data $T1\text{Break}$ and lookup table data $T1\text{Data}$ in your current folder in a file called \texttt{ex_vec_symdim_src.c}. These global variables have either 9 or 11 elements depending on the value of the macro $bp\text{Len}$.

\begin{verbatim}
#include "ex_vec_symdim_decs.h"

#if bpLen == 11
  double T1Break[bpLen] = {
    -5.0, -4.0, -3.0, -2.0, -1.0, 0.0, 1.0, 2.0, 3.0, 4.0, 5.0
  };

  double T1Data[bpLen] = {
    -1.0, -0.99, -0.98, -0.96, -0.76, 0.0, 0.76, 0.96, 0.98, 0.99, 1.0
  }
#endif
\end{verbatim}
} ;
#endif

#if bpLen == 9
double T1Break[bpLen] = {
    -4.0,
    -3.0,
    -2.0,
    -1.0,
    0.0,
    1.0,
    2.0,
    3.0,
    4.0
} ;

double T1Data[bpLen] = {
    -0.99,
    -0.98,
    -0.96,
    -0.76,
    0.0,
    0.76,
    0.96,
    0.98,
    0.99
} ;
#endif

Save the declarations of the variables and the definition of the macro in your current folder in a file called ex_vec_symdim_decs.h.

#define bpLen 11
extern double T1Break[bpLen];
extern double T1Data[bpLen];

**Explore and Configure Example Model**

Open the example model rtwdemo_basicsc.

open_system('rtwdemo_basicsc')
Open the Table1 block dialog box. The block refers to variables, T1Data and T1Break, in the base workspace. These variables store the lookup table and breakpoint set data with 11 elements.

At the command prompt, convert the variables to Simulink.Parameter objects.

```
T1Data = Simulink.Parameter(T1Data);
T1Break = Simulink.Parameter(T1Break);
```

Configure the objects to import the data definitions from your external code.

```
T1Data.CoderInfo.StorageClass = 'Custom';
T1Data.CoderInfo.CustomStorageClass = 'ImportFromfile';
T1Data.CoderInfo.CustomAttributes.HeaderFile = 'ex_vec_symdim_decs.h';

T1Break.CoderInfo.StorageClass = 'Custom';
T1Break.CoderInfo.CustomStorageClass = 'ImportFromfile';
T1Break.CoderInfo.CustomAttributes.HeaderFile = 'ex_vec_symdim_decs.h';
```

At the command prompt, create a Simulink.Parameter object to represent the custom macro bpLen.
bpLen = Simulink.Parameter(11);
bpLen.Min = 9;
bpLen.Max = 11;
bpLen.DataType = 'int32';
bpLen.CoderInfo.StorageClass = 'Custom';
bpLen.CoderInfo.CustomStorageClass = 'ImportedDefine';

Use bpLen to set the dimensions of the lookup table and breakpoint set data. Configure the model to enable symbolic dimensions by selecting the configuration parameter **Allow symbolic dimension specification**.

T1Data.Dimensions = '[1 bpLen]';
T1Break.Dimensions = '[1 bpLen]';
set_param('rtwdemo_basicsc','AllowSymbolicDim','on')

Set **Configuration Parameters > Code Generation > Custom Code > Additional build information > Source files** to `ex_vec_symdim_src.c`.

set_param('rtwdemo_basicsc','CustomSource','ex_vec_symdim_src.c')

To generate code with custom storage classes such as `ImportFromFile`, you must use an ERT-based system target file. Set **Configuration Parameters > Code Generation > System target file** to `ert.tlc`.

set_param('rtwdemo_basicsc','SystemTargetFile','ert.tlc')

**Generate and Inspect Code**

Generate code from the model.

rtwbuild('rtwdemo_basicsc')

### Starting build procedure for model: rtwdemo_basicsc
### Successful completion of build procedure for model: rtwdemo_basicsc

The generated code algorithm is in the model **step function** in the generated file `rtwdemo_basicsc.c`. The algorithm passes T1Break, T1Data, and bpLen as argument values to the function that performs the table lookup. In this case, bpLen controls the upper bound of the binary search that the function uses.

file = fullfile('rtwdemo_basicsc_ert_rtw','rtwdemo_basicsc.c');
rtwdemodbtype(file,'.X = look1_iflf_binlx','bpLen - 1U',1,1)
rtwdemo_basicsc DW.X = look1_iflf_binlx(rtwdemo_basicsc_U.input2,
  (&(T1Break[0])), (&(T1Data[0])), bpLen - 1U) * 2.0F;

For more information about symbolic dimensions, see “Implement Dimension Variants for
Array Sizes in Generated Code” on page 15-2.

**Related Examples**

- “Exchange Data Between External C/C++ Code and Simulink Model or Generated
  Code” on page 42-90
- “Reuse Parameter Data from External Code in the Generated Code” on page 26-2
Access Structured Data Through a Pointer That External Code Defines

This example shows how to generate code that uses global data that some handwritten code defines. In the handwritten code, a pointer variable points to one of two structure variables that contain parameter data. A handwritten function switches the pointer between the two structures. The generated code accesses the parameter data by dereferencing the pointer variable.

Explore External Code

Open the example source file rtwdemo_importstruct_user.c. The code defines a structure variable ReferenceStruct as constant (const) data and statically initializes each field.

```c
/* Constant default data struct: ReferenceStruct */
const DataStruct_type ReferenceStruct =
{
    11,  /* OFFSET */
    2   /* GAIN */
};
```

The code defines another structure variable, WorkingStruct, as volatile (volatile) data.

```c
/* Volatile data struct: WorkingStruct */
volatile DataStruct_type WorkingStruct;
```

The code defines a function that copies the field values from ReferenceStruct to WorkingStruct.

```c
/* Function to initialize WorkingStruct with data from ReferenceStruct */
void Init_WorkingStruct(void)
{
    memcpy((void*)&WorkingStruct, &ReferenceStruct, sizeof(ReferenceStruct));
}
```

The code defines StructPointer, which is a const volatile pointer to a structure. The code initializes the pointer to the address of ReferenceStruct.
/* Create pointer to the default data struct, e.g. ReferenceStruct */
const volatile DataStruct_type *StructPointer = &ReferenceStruct;

Finally, the code defines a function that can dynamically set StructPointer to point to either ReferenceStruct or WorkingStruct.

/* Function to switch between structures */
void SwitchStructPointer(Dataset_T Dataset)
{
    switch (Dataset)
    {
    case Working:
        StructPointer = &WorkingStruct;
        break;
    default:
        StructPointer = &ReferenceStruct;
    }
}

The example header file rtwdemo_importstruct_user.h defines the enumeration Dataset_T and the structure type Datastruct_type. The file includes (#include) the built-in Simulink® Coder™ header file rtwtypes.h, which defines (typedef) Simulink Coder data types such as int16_T.

#include "rtwtypes.h"

typedef enum {
    Reference=0,
    Working
} Dataset_T;

typedef struct DataStruct_tag {
    int16_T   OFFSET; /* OFFSET */
    int16_T   GAIN;   /* GAIN */
} DataStruct_type;

The file also declares the global variables and the functions.

**Purpose of External Code**

The code is designed so that the source code of a control algorithm (whether generated or handwritten) can read data from either ReferenceStruct or WorkingStruct by
dereferencing (->) StructPointer. A software engineer can write code that
dynamically switches StructPointer between the address of WorkingStruct and
ReferenceStruct by passing the corresponding enumeration member as the input
argument in calls to the SwitchStructPointer function.

Later, in preparation for calibration while the algorithm executes, a calibration tool can
make StructPointer point to WorkingStruct. The tool can then modify the fields of
WorkingStruct.

If necessary for safety or in preparation for shutting down the application, the calibration
tool can point StructPointer to ReferenceStruct instead. ReferenceStruct stores
default parameter values that do not change during execution.

**Explore Example Model**

Open the example model, rtwdemo_importstruct.
The model creates variables and objects in the base workspace. The Constant block and the Gain block use the ECoderDemos.Parameter objects GAIN and OFFSET to set the Constant value and Gain block parameters. ECoderDemos is an example custom package that defines two classes, Parameter and Signal, and some custom storage classes.

In the model, select View > Model Data Editor.
In the Model Data Editor, inspect the **Parameters** tab.

Set the **Change view** drop-down list to **Code**.

Click the **Show/refresh additional information** button.

The Model Data Editor shows rows that correspond to the **Constant value** and **Gain** parameters of the blocks and rows that corresponds to **OFFSET** and **GAIN**, which set the parameter values. In the **Storage Class** column, **OFFSET** and **GAIN** use the custom storage class **StructPointer**, which the **ECoderDemos** package defines.

Open the Custom Storage Class Designer and inspect the custom storage classes in the **ECoderDemos** package. At the command prompt, use this command:

```
cscdesigner('ECoderDemos')
```

This example package defines multiple custom storage classes, including **StructPointer**. You cannot edit the definitions. However, you can create your own packages and custom storage classes later. For an example that shows how to create a package and a custom storage class, see “Create and Apply a Custom Storage Class” on page 26-26.

Under **Custom storage class definitions**, click **StructPointer**. The settings for this custom storage class enable the generated code to interact with the pointer variable, **StructPointer**, from the external code. For example, the custom storage class uses these settings:

- **Data scope** is set to **Imported** because the example external code defines (allocates memory for) **StructPointer**. With this setting, the code generator avoids generating unnecessary, duplicate definitions for the data items, such as the **ECoderDemos.Parameter** objects, that use the custom storage class.
- **Data access** is set to **Pointer** because in the example external code, **StructPointer** is a pointer.
- **Memory section** is set to **ConstVolatile** because the example external code defines **StructPointer** as constant, volatile data (**const volatile**).
- **Type** is set to **FlatStructure** because in the example external code, **StructPointer** points to a structure. With this setting, the generated code treats each data item (**ECoderDemos.Parameter** object) as a field of a flat structure whose variable name and type name you can specify.
- On the **Structure Attributes** tab, **Struct name** is set to **StructPointer**. For a **FlatStructure** custom storage class, **Struct name** specifies the name of the
structure variable in the generated code. In this example, StructPointer is the name of the variable that the external code defines.

- **Type name** is set to DataStruct_type, which is the name of the structure type that the example external code defines.

In the model, in the **Configuration Parameters** dialog box, inspect the **Code Generation > Custom Code** pane.

Under **Insert custom C code in generated**, select **Initialize function**. In this model, this configuration parameter is set so that the generated code calls the Init_WorkingStruct function before execution of the primary algorithm. Init_WorkingStruct initializes the fields of WorkingStruct with the values from ReferenceStruct.

Under **Additional build information**, select **Source files**. This configuration parameter identifies the example external code file `rtwdemo_importstruct_user.c` for inclusion in the build process after code generation.

**Generate and Inspect Code**

Generate code from the model.

In the generated file `rtwdemo_importstruct.c`, the model initialization function calls Init_WorkingStruct.

```c
/* Model initialize function */
void rtwdemo_importstruct_initialize(void)
{
    /* user code (Initialize function Body) */

    /* Initialize the volatile memory data set before switching to it */
    Init_WorkingStruct();
}

/*

The algorithm in the model execution (step) function dereferences the pointer variable StructPointer.

```c
/* Model step function */
void rtwdemo_importstruct_step(void)
```
{  /* Gain: '<Root>/Gain' incorporates:
   *  Constant: '<Root>/Offset'
   *  Inport: '<Root>/In'
   *  Sum: '<Root>/Sum'
   */
   Sensor_Out = (int16_T)((int16_T)(Sensor_In - StructPointer->OFFSET) *
                          StructPointer->GAIN);
}

- "Create Tunable Calibration Parameter in the Generated Code" on page 22-121
- "Switch Between Sets of Parameter Values During Simulation and Code Execution" on page 22-196
- "Create Custom Storage Classes by Using the Custom Storage Class Designer" on page 26-26
Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements

In “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 22-81, you control the declaration and definition of global variables in the generated code by applying storage classes directly to individual data elements. With Embedded Coder and an ERT-based system target file, you can use custom storage classes for more precise control over the way that data appear in the generated code.

To achieve C code patterns such as grouping variables into flat structures and to control declaration and definition file placement, you can use the custom storage classes from the built-in package Simulink.

For information about applying storage classes to categories of data by default, by using the Code Mapping Editor, see “Configure Default Code Generation for Data” on page 21-8.

Built-In Custom Storage Classes

For a list of built-in custom storage classes that you can choose, see “Choose a Storage Class for Controlling Data Representation in the Generated Code” on page 22-69.

Create Your Own Custom Storage Class

If the custom storage classes from the Simulink package do not satisfy your requirements, you can define your own custom storage classes. For information about defining your own custom storage class, see “Create Code Definitions to Override Default Settings” on page 20-3.

Techniques to Apply Custom Storage Classes Interactively

To directly apply a custom storage class from the built-in package Simulink interactively, use the same techniques that you use to directly apply standard storage classes, described in “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 22-81.

To apply a custom storage class from a package other than Simulink (such as a package that you create):
• To apply the custom storage class to a signal, state, or Data Store Memory block (without creating a data object), configure the data item to use custom storage classes from the target package instead of the Simulink package. For example, if the name of the target package is `myPackage`, in a Signal Properties dialog box or the Property Inspector, set **Signal object class** to `myPackage.Signal`. If the target class does not appear in the list, see “Target Class Does Not Appear in List of Signal Object Classes” on page 26-20.

If you use the Model Data Editor, to identify the target package, you must use a different technique. See “Apply Custom Storage Class from Specific Package to Signal, State, or Data Store Memory Block Using the Model Data Editor” on page 26-20.

• To apply the custom storage class by using a data object (required for block parameters), instead of creating a `Simulink.Signal` or `Simulink.Parameter` object, create a `myPackage.Signal` or `myPackage.Parameter` object. To create data objects from your package, see “Create Data Objects from Another Data Class Package” (Simulink). For an example that shows how to create and apply your own custom storage class, see “Create and Apply a Custom Storage Class” on page 26-26.

**Target Class Does Not Appear in List of Signal Object Classes**

When you use the **Signal object class** drop-down list in a dialog box or in the Property Inspector, if the class that you want does not appear in the list:

1. From the list, select **Customize class lists**.
2. In the dialog box, under **Signal classes**, select the check box next to the class that you want. For example, to use custom storage classes from the built-in package `mpt`, select the check box next to `mpt.Signal`. Click **OK**.

   If you created your own package, the classes that the package defines appear in the dialog box only if you put the package folder in your current folder or put the parent folder of the package folder on the MATLAB path.

3. From the drop-down list, select the option that corresponds to what you selected. For example, select `mpt.Signal`.

**Apply Custom Storage Class from Specific Package to Signal, State, or Data Store Memory Block Using the Model Data Editor**

When you use the Model Data Editor, to apply custom storage classes from a specific package, use the Model Explorer to create a signal object from the target package. Then, when you open the Model Data Editor, the **Storage class** column displays custom storage classes from the target package.
1. In the Model Explorer **Model Hierarchy** pane, select **Base Workspace**.
2. In the toolbar, click the arrow next to the **Add Signal** button.
3. In the drop-down list, select **Customize class lists**.
4. In the **Customize class lists** dialog box, select a signal class from the target package. Click **OK**.
5. In the Model Explorer toolbar, click the arrow next to the **Add Signal** button.
6. In the drop-down list, select the target signal class.

   An object of the target signal class appears in the base workspace. Optionally, delete this unnecessary object.

7. Use the Model Data Editor to apply custom storage classes from the target package to other data items. In the Model Data Editor, in the **Storage class** column, the drop-down list allows you to select custom storage classes from the target package.

To learn how to use the Model Data Editor to configure a data interface, see “Design Data Interface by Configuring Inport and Outport Blocks” (Simulink Coder).

**Techniques to Apply Custom Storage Classes Programmatically**

To apply a custom storage class to an individual data item programmatically:

1. Create a signal or parameter data object from the target package. For example, create a Simulink.Signal object or a myPackage.Parameter object.

   ```matlab
   myParam = Simulink.Parameter(5.2);
   ```

2. In the nested Simulink.CoderInfo object, set the **StorageClass** property to 'Custom'. Then, use the **CustomStorageClass** property to specify the custom storage class.

   ```matlab
   myParam.CoderInfo.StorageClass = 'Custom';
   myParam.CoderInfo.CustomStorageClass = 'ExportToFile';
   ```

3. If the custom storage class allows you to specify additional settings such as **Header file** (see “Specify File Names and Other Data Attributes With Storage Class (Embedded Coder)” on page 22-76), in the nested Simulink.CoderInfo object, use the **CustomAttributes** property to specify values for the additional settings.

   ```matlab
   myParam.CoderInfoCustomAttributes.HeaderText = 'myHeader.h';
   ```
Choose one of these techniques to apply the custom storage class to a data item in a model:

- To apply the custom storage class directly to a signal, state, or Data Store Memory block, name the signal or state. Then, use the data object you created to set the SignalObject signal property, the SignalObject block parameter (for an Outport block), or the StateSignalObject block parameter. Clear the data object you created. For an example, see “Apply Custom Storage Class Directly to Signal Line Programmatically” on page 26-22.

- To apply the custom storage class by keeping the data object you created (required for parameters), associate the data object with the data item in the model. To make this association, see “Use Data Objects in Simulink Models” (Simulink).

### Apply Custom Storage Class Directly to Signal Line Programmatically

This example shows how to apply a custom storage class directly to a signal line in a model, without an external data object.

1. Open the example model `rtwdemo_secondOrderSystem`.

   ```matlab
   rtwdemo_secondOrderSystem
   ```

2. Create a handle to the output of the block named Force: f(t).

   ```matlab
   portHandles = get_param('rtwdemo_secondOrderSystem/Force: f(t)', 'PortHandles');
   outportHandle = portHandles.Outport;
   ```

3. Set the name of the corresponding signal to `ForceSignal`.

   ```matlab
   set_param(outportHandle, 'Name', 'ForceSignal')
   ```

4. In the base workspace, create a signal object and specify a custom storage class and relevant additional settings such as `HeaderFile`.

   ```matlab
   tempObj = Simulink.Signal;
   tempObj.CoderInfo.StorageClass = 'Custom';
   tempObj.CoderInfo.CustomStorageClass = 'ExportToFile';
   tempObj.CoderInfoCustomAttributes.HeaderFile = 'myHdrFile.h';
   ```

   You can create the object from the data class package Simulink, or from any other package, such as a package that you create.

5. Embed the signal object in the target signal line by attaching a copy of the temporary workspace object.
set_param(outportHandle,'SignalObject',tempObj);

6 Clear the object from the base workspace. The signal now uses an embedded copy of the object.

    clear tempObj

**Modify Custom Storage Class Applied Directly to Signal Line**

To modify an existing embedded signal object, copy the object into the base workspace, modify the copy, and reattach the copy to the signal or state. For example, to change the custom storage class of the embedded signal object that you attached to the signal *ForceSignal* in “Apply Custom Storage Class Directly to Signal Line Programmatically” on page 26-22:

1 Copy the existing embedded signal object into the base workspace.

    tempObj = get_param(outportHandle,'SignalObject');

2 Modify the properties of the object in the workspace.

    tempObj.CoderInfo.CustomStorageClass='ImportFromFile';
    tempObj.CoderInfo.CustomAttributes.HeaderFile = 'myOtherHdrFile.h';

3 Reattach a copy of the signal object.

    set_param(outportHandle,'SignalObject',tempObj);
    clear tempObj

**Organize Parameter Data into a Structure by Using the Struct Custom Storage Class**

This example shows how to use the **Struct** custom storage class to organize block parameter values into a structure in the generated code. You apply the storage class directly to individual data items in a model.

To create a custom structure of parameter data in the generated code, consider creating a corresponding structure in Simulink. See “Organize Data into Structures in Generated Code” on page 22-177.

1 Create the `ex_struct_param` model with three Constant blocks and three Outport blocks.
In the model, select **View > Model Data Editor**.

In the Model Data Editor, select the **Parameters** tab.

In the model, select the upper Constant block.

In the Model Data Editor, use the **Value** column to set the constant value to \( p_1 \).

Next to \( p_1 \), click the action button \( \ddagger \) and select **Create**.

In the Create New Data dialog box, set **Value** to `Simulink.Parameter(1.0)` and click **Create**.

A `Simulink.Parameter` object named \( p_1 \) appears in the base workspace.

In the property dialog box for \( p_1 \), click **OK**.

Use the Model Data Editor to set the other constant values by using parameter objects named \( p_2 \) (value 2.0) and \( p_3 \) (value 3.0).

In the Model Data Editor, set the **Change view** drop-down list to **Code**.

Click the **Show/refresh additional information** button.

The data table now contains rows that correspond to the new parameter objects.

Use the **Storage Class** column to apply the custom storage class **Struct** to all three parameter objects.

Use the **Struct Name** column to set the structure name to **my_struct**.

Press **Ctrl+B** to generate code.

The file `ex_struct_param.h` defines a structure type, `my_struct_type`.

```c
/* Type definition for custom storage class: Struct */
typedef struct my_struct_tag {
  real_T p1;
  real_T p2;
```
The file `ex_struct_param.c` defines the global variable `my_struct`.

```c
/* Definition for custom storage class: Struct */
my_struct_type my_struct = {
    /* p1 */
    1.0,
    /* p2 */
    2.0,
    /* p3 */
    3.0
};
```

**Custom Storage Class Limitations**

For information about limitations, see “Storage Class Limitations” on page 22-77.

Create Custom Storage Classes by Using the Custom Storage Class Designer

You can use built-in custom storage classes such as ExportToFile to control the appearance of data in the generated code (see “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 26-19). If the built-in custom storage classes do not satisfy your requirements, you can create your own custom storage classes. As described in “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 20-2, to create a custom storage class that you can apply to individual data elements (for example, in the Model Data Editor), you must create the storage class in a package by using the Custom Storage Class Designer.

A package also defines Signal and Parameter data classes (see “Data Objects” (Simulink)). A data object from a package such as Simulink can use custom storage classes defined in that package but not custom storage classes that are defined in packages.

For information about using the Custom Storage Class Designer to create memory sections, see “Control Data and Function Placement in Memory by Inserting Pragmas” on page 30-2.

Create and Apply a Custom Storage Class

This example shows how to control code generated from a model by creating and applying your own custom storage class.

Explore Example Model

Open the model rtwdemo_cscpredef. You can control code generated from this model by defining your own data classes and creating your own custom storage classes.

In this example, you export the declarations and definitions of multiple signals and parameters in the model to one declaration header file and one definition file.

Create Data Class Package

To create custom storage classes, you first create a data class package to contain the custom storage class definitions. Data objects that you create from your package can use all of the custom storage classes that the package defines.
1. Create your own data class package by copying the example package folder +SimulinkDemos. Navigate to the example package folder.

   ```
   % Remember the current folder path
   currentPath = pwd;

   % Navigate to the example package folder
   demoPath = '\toolbox\simulink\simdemos\dataclasses';
   cd([matlabroot,demoPath])
   ```

2. Copy the +SimulinkDemos folder to your clipboard.

3. Return to your working folder.

   ```
   cd(currentPath)
   ```

4. Paste the +SimulinkDemos folder from your clipboard into your working folder. Rename the copied folder to +myPackage.

5. Navigate inside the +myPackage folder to the file Signal.m to edit the definition of the Signal class.

6. Uncomment the methods section that defines the method setupCoderInfo. In the call to the function useLocalCustomStorageClasses, replace 'packageName' with 'myPackage'. When you finish, the section appears as follows:

   ```
   methods
   function setupCoderInfo(h)
       % Use custom storage classes from this package
       useLocalCustomStorageClasses(h, 'myPackage');
   end
   end % methods
   ```

   The function useLocalCustomStorageClasses allows you to apply the custom storage classes that myPackage defines to data objects that you create from myPackage.

7. Save and close the file.

8. Navigate inside the +myPackage folder to the file Parameter.m to edit the definition of the Parameter class. Uncomment the methods section that defines the method setupCoderInfo and replace 'packageName' with 'myPackage'.

9. Save and close the file.
Create Custom Storage Class

You can use the Custom Storage Class Designer to create or to edit the custom storage classes that a data class package defines.

1. Set your current folder to the folder that contains the package myPackage.
2. Open the Custom Storage Class Designer.
   ```matlab
cscdesigner('myPackage')
```
3. Select the custom storage class ExportToFile.
4. In the Name field, rename the custom storage class to ExportToGlobal.
5. In the Header file drop-down list, change the selection from Instance specific to Specify. In the new field, provide the header file name global.h.
6. In the Definition file drop-down list, change the selection from Instance specific to Specify. In the new field, provide the definition file name global.c.
7. Click OK. Click Yes to save changes to the data class package myPackage.

Apply Custom Storage Class

To apply your own custom storage class, you create data objects from your package and configure the objects to use your custom storage class.

1. Create data objects to represent some of the parameters and signals in the example model. Create the objects using the data class package myPackage.
   ```matlab
   % Parameters
   templimit = myPackage.Parameter(202);
   pressurelimit = myPackage.Parameter(45.2);
   O2limit = myPackage.Parameter(0.96);
   rpmlimit = myPackage.Parameter(7400);
   % Signals
   tempalarm = myPackage.Signal;
   pressurealarm = myPackage.Signal;
   O2alarm = myPackage.Signal;
   rpmlalarm = myPackage.Signal;
   
   2. Set the custom storage class of each object to ExportToGlobal.
   ```matlab
   % Parameters
   templimit.CoderInfo.StorageClass = 'Custom';
   templimit.CoderInfo.CustomStorageClass = 'ExportToGlobal';
   ```
pressurelimit.CoderInfo.StorageClass = 'Custom';
pressurelimit.CoderInfo.CustomStorageClass = 'ExportToGlobal';
O2limit.CoderInfo.StorageClass = 'Custom';
O2limit.CoderInfo.CustomStorageClass = 'ExportToGlobal';
rpmlimit.CoderInfo.StorageClass = 'Custom';
rpmlimit.CoderInfo.CustomStorageClass = 'ExportToGlobal';

% Signals
tempalarm.CoderInfo.StorageClass = 'Custom';
tempalarm.CoderInfo.CustomStorageClass = 'ExportToGlobal';
pressurealarm.CoderInfo.StorageClass = 'Custom';
pressurealarm.CoderInfo.CustomStorageClass = 'ExportToGlobal';
O2alarm.CoderInfo.StorageClass = 'Custom';
O2alarm.CoderInfo.CustomStorageClass = 'ExportToGlobal';
rpmalarm.CoderInfo.StorageClass = 'Custom';
rpmalarm.CoderInfo.CustomStorageClass = 'ExportToGlobal';

3 Select the **Signal name must resolve to Simulink signal object** option for each of the target signals in the model. You can select the option by using the Signal Properties dialog box, the **Resolve** column in the Model Data Editor, or by using the command prompt.

% Signal tempalarm
portHandles = get_param('rtwdemo_cscpredef/RelOp1','PortHandles');
outputPortHandle = portHandles.Outport;
set_param(outputPortHandle,'MustResolveToSignalObject','on')

% Signal pressurealarm
portHandles = get_param('rtwdemo_cscpredef/RelOp2','PortHandles');
outputPortHandle = portHandles.Outport;
set_param(outputPortHandle,'MustResolveToSignalObject','on')

% Signal O2alarm
portHandles = get_param('rtwdemo_cscpredef/RelOp3','PortHandles');
outputPortHandle = portHandles.Outport;
set_param(outputPortHandle,'MustResolveToSignalObject','on')

% Signal rpmalarm
portHandles = get_param('rtwdemo_cscpredef/RelOp4','PortHandles');
outputPortHandle = portHandles.Outport;
set_param(outputPortHandle,'MustResolveToSignalObject','on')

Generate Code

1 Generate code for the example model.
In the code generation report, view the generated header file `global.h`. The file contains the `extern` declarations of all of the model signals and parameters that use the custom storage class `ExportToGlobal`.

```c
/* Declaration for custom storage class: ExportToGlobal */
extern boolean_T O2alarm;
extern real_T O2limit;
extern boolean_T pressurealarm;
extern real_T pressurelimit;
extern boolean_T rpmalarm;
extern real_T rpmlimit;
extern boolean_T tempalarm;
extern real_T templimit;
```

View the generated file `global.c`. The file contains the definitions of the model signals and parameters that use the custom storage class `ExportToGlobal`.

```c
/* Definition for custom storage class: ExportToGlobal */
boolean_T O2alarm;
real_T O2limit = 0.96;
boolean_T pressurealarm;
real_T pressurelimit = 45.2;
boolean_T rpmalarm;
real_T rpmlimit = 7400.0;
boolean_T tempalarm;
real_T templimit = 202.0;
```

### Modify a Built-In Custom Storage Class

You cannot directly modify a built-in custom storage class, such as `ExportToFile` from the Simulink package, but you can create a copy, and then modify the copy. When you create a new package with no `csc_registration.m` file, and then open the Custom Storage Class Designer for the first time in that package, Simulink copies the definitions of the built-in custom storage classes into the package. Then, in the Custom Storage Class Designer, you can modify the copied definitions. Alternatively, to keep the built-in custom storage classes available in your package, copy one of them by clicking **Copy**, then modify the resulting copy.
Control Data Representation by Configuring Custom Storage Class Properties

The Custom Storage Class Designer is a tool for creating and managing custom storage classes and memory sections. To open the Custom Storage Class Designer for a specific package, for example, `+mypkg`, at the command prompt, use the `cscdesigner` function:

```
cscdesigner('mypkg')
```

The name of the folder that represents a package begins with a`. When you use `cscdesigner`, omit the `+` from the name of the target package.

To control the effect that a custom storage class has on data in a model, you specify properties of the storage class in the Custom Storage Class Designer. To determine how to generate a particular kind of code, use the information in the table.

<table>
<thead>
<tr>
<th>Kind of Data in Generated Code</th>
<th>Technique</th>
</tr>
</thead>
<tbody>
<tr>
<td>Structure</td>
<td>Set <strong>Type</strong> to <em>FlatStructure</em>. See “Generate Structured Data” on page 26-33.</td>
</tr>
<tr>
<td>Macro</td>
<td>Set <strong>Data initialization</strong> to <strong>Macro</strong> and clear <strong>For signals</strong>. See “Generate a Macro” on page 26-32.</td>
</tr>
<tr>
<td>Pointer</td>
<td>Set <strong>Data access</strong> to <strong>Pointer</strong> and <strong>Data scope</strong> to <em>Auto</em>, <em>Imported</em>, or <em>Instance specific</em>. Your external code must define the pointer variable.</td>
</tr>
<tr>
<td>static data (file-scoped data)</td>
<td>Set <strong>Data scope</strong> to <em>File</em>.</td>
</tr>
<tr>
<td>const or volatile data</td>
<td>Set <strong>Memory section</strong> to a memory section that specifies <em>const</em>, <em>volatile</em>, or both. For example, use one of the built-in memory sections MemConst, MemVolatile, and MemConstVolatile. To create your own memory section, see “Control Data and Function Placement in Memory by Inserting Pragmas” on page 30-2.</td>
</tr>
</tbody>
</table>
### Kind of Data in Generated Code

<table>
<thead>
<tr>
<th>Technique</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Calls to external functions to read and write to data</td>
<td>See “Call Custom Accessor Functions or Macros Instead of Reading and Writing to Variables” on page 26-34.</td>
</tr>
</tbody>
</table>

### Allow Users of Custom Storage Class to Specify Property Value

For some properties of a custom storage class, such as **Data scope**, instead of specifying a value in the Custom Storage Class Designer, you can allow users of the storage class to specify the value. You can create a single, flexible custom storage class instead of multiple custom storage classes that vary only by a few property values.

For example, suppose you create a custom storage class that yields a global variable in the generated code. You can configure the storage class so that a user can set the **Data scope** property to **Exported** for a signal in a model and set the property to **Imported** for a different signal.

In the Custom Storage Class Designer, for each property that you want to configure in this way, set the property value to **Instance specific**. Then, when a user applies the custom storage class to a data item, the property appears to the user as a custom attribute for that data item. For information about instance-specific custom attributes, see “Specify File Names and Other Data Attributes With Storage Class (Embedded Coder)” on page 22-76.

### Generate a Macro

To create a custom storage class that yields a macro in the generate code, set **Data initialization** to **Macro** and clear **For signals**.

When you set **Data initialization** to **Macro**, **Definition file** has no meaning. To prevent users of the custom storage class from specifying a meaningless definition file, in the Custom Storage Class Designer, set **Definition file** to **Specify** and leave the text box empty.

- To define the macro in a header file (**#define**), specify the name of the header file with the **Header file** property.
- To provide the macro definition as a compiler option or compiler flag, set **Data access** to **Imported** and **Header file** to **Specify**. Leave the **Header file** text box empty. Then, the generated code does not define the macro and does not include (**#include**) a header file.
To specify the compiler option or flag, use the model configuration parameter **Configuration Parameters > Code Generation > Custom Code > Additional build information > Defines**. See Code Generation Pane: Custom Code: Additional Build Information: Defines (Simulink Coder).

**Generate Structured Data**

To create a custom storage class that aggregates data items into a flat structure (similar to the built-in custom storage class *Struct*), set **Type** to *FlatStructure*. The **Structure Attributes** tab appears.

- To control the name of the global structure variable that appears in the generated code, use the **Struct name** property and text box.
- If you set **Struct name** to *Instance specific*, users of the custom storage class specify the name of the structure variable. In this case, the code generator derives the name of the structure type from the name of the variable.

To more precisely control the name and other characteristics of the structure type, set **Struct name** to *Specify*. Control the type characteristics by using the additional properties that appear.

- To generate a structure with bit fields (similar to the built-in custom storage class *BitField*), select **Bit-pack booleans**. Data items that use the data type *boolean* appear in the generated code as bit fields of the structure.

**Control Assignment of Initial Value in Generated Code**

- To use the default Simulink Coder initialization strategy, set **Data initialization** to the default value, *Auto*.

  - The generated code statically initializes parameter data with an assignment statement at the top of a *.c* or *.cpp* source file, outside of any function.
  - The generated code dynamically initializes signal and state data as part of the initialization function of the model (named *model_initialize* by default).

- To statically initialize the data, set **Data initialization** to *Static*.
- To dynamically initialize the data, set **Data initialization** to *Dynamic*.
- To prevent the generated code from initializing the data, set **Data initialization** to *None*. When your external code initializes the data, use this setting to prevent the generated code from overwriting your initialization.
Call Custom Accessor Functions or Macros Instead of Reading and Writing to Variables

Using the built-in custom storage class GetSet, you can generate code that calls your external, custom functions instead of directly interacting with variables. For general information about GetSet, see “Access Data Through Functions with Custom Storage Class GetSet” on page 26-42.

To create a similar custom storage class, set Type to AccessFunction.

- Specify the names of the external functions.
  - To apply the same get or set function naming scheme to all data items that use the custom storage class, set Get function and Set function to Specify. Then, in the text boxes, specify the function naming scheme, for example, get_myData_$N. Use the token $N in a naming scheme to represent the name of each data item. If you do not use the token, each data item uses the same specified get or set function name, so the model generates an error when you generate code.
  - To specify a different get or set function name for each data item, set Get function or Set function to Instance specific. Later, when you create a data item and apply the custom storage class, specify the function name by configuring the custom attributes of the data item.
  - Specify the name of the header file that declares the get and set functions with the Header file property. In this case, Definition file has no meaning. To prevent users of the custom storage class from specifying a meaningless definition file, set Definition file to Specify and leave the text box empty.
  - If you implement the get mechanism for scalar or array data as a macro instead of a function, you can generate code that omits parentheses when reading that data. On the Access Function Attributes tab, select Get data through macro (omit parentheses).

Generate Code That Uses Data From External Code

When your external code defines data, to avoid generating a duplicate definition, you must configure the generated code to read and write to the existing data. In the Custom Storage Class Designer, set Data scope to Imported. The code generator does not generate a definition for the global variable or macro.

- If your code defines a pointer variable, to generate code that interacts with the pointer, set Data access to Pointer.
If you generate structured data by setting **Type** to **FlatStructure**, your code must define the structure type and the global structure variable.

If your code initializes state or signal data, you can prevent the generated code from overwriting your initialization by setting **Data initialization** to None. See “Prevent Duplicate Initialization Code for Global Variables” on page 42-103.

**Generate Code Comments with Data Definitions and Declarations**

To customize the comments that appear in the generated code, on the **Comments** tab, set **Comment rules** to **Specify**. To specify a comment that appears with the declaration of each data item, use the **Declaration comment** box. To specify a comment that appears with the definition, use the **Definition comment** box.

For structured data (you set **Type** to **FlatStructure**), to specify a comment that appears with the structure type definition, use the **Type comment** box.

**Avoid Errors During Code Generation by Validating Custom Storage Class Configuration**

As you configure a custom storage class in the Custom Storage Class Designer, to check for possible errors in the configuration, click **Validate**.

For example, validating the custom storage class warns you if you accidentally set **Data initialization** to **Macro** with **For signals** selected. A signal cannot appear in the generated code as a macro.

**Make Custom Storage Classes Available Outside the Current Folder**

To use a custom storage class that you create, you must make the defining package available. Either set your current folder to the folder that contains the package or add the folder containing the package folder to the MATLAB path (see “What Is the MATLAB Search Path?” (MATLAB)). Adding the package to the MATLAB path enables you to use the custom storage classes no matter where you set your current folder.

**Share Custom Storage Class Between Packages**

When you create a package, you can refer to a custom storage class defined in another package such as the built-in package **Simulink** or a different package that you created.
Then, the defining package and any referencing packages can use the custom storage class. When you want to make a change to the custom storage class, you make the change only once, in the defining package.

To configure a package to refer to a custom storage class that another package defines:

1. In the Custom Storage Class Designer, select the **Custom Storage Class** tab.
2. Use **Select Package** to select the referencing package. The package must be writable.
3. In the **Custom storage class definitions** pane, select the existing definition below which you want to insert the reference.
4. Click **New Reference**.

   A new reference with a default name and properties appears below the previously selected definition. The new reference is selected and a **Reference** tab appears that shows the initial properties.
5. Use **Name** to specify a name for the new reference. The name must be unique in the importing package, but can duplicate the name in the source package. The name cannot be a TLC keyword.
6. Set **Refer to custom storage class in package** to specify the package that contains the custom storage class that you want to reference.
7. Set **Custom storage class to reference** to specify the custom storage class to be referenced.
8. Click **OK** or **Apply**. To save the changes permanently, click **Save**.

### Control Appearance of Storage Class Drop-Down List

When you apply a custom storage class to a data item, you select the custom storage class from a drop-down list.

- To control the order of the custom storage classes in the list, in the Custom Storage Class Designer, use the **Up** and **Down** buttons. The order of the custom storage classes in drop-down lists matches the order that you specify in the Custom Storage Class Designer.
- To prevent a user of a custom storage class from applying the storage class to parameter data or to signal and state data, use the **For parameters** and **For signals** check boxes. When you clear one of these properties, for the corresponding kind of data, the custom storage class does not appear in the drop-down list.
For example, if your custom storage class yields a macro in the generated code because you set `Data initialization` to `Macro`, to prevent users from applying the custom storage class to signal data, clear `For signals`.

**Protect Custom Storage Class Definitions**

When you click `Save` in the Custom Storage Class Designer, the Designer saves memory section and custom storage class definitions into the `csc_registration.m` file in the package folder. To determine the location of this file, in the Custom Storage Class Designer, inspect the value of `Filename`.

You can prevent changes to the custom storage class definitions of an entire package by converting the `csc_registration.m` file from a MATLAB file to a P-file. Use the `pcode` function.

A best practice is to keep both `csc_registration.m` and `csc_registration.p` in your package folder. That way, if you need to modify the custom storage classes by using the Designer, you can delete `csc_registration.p` and later regenerate it after you finish the modifications. Because the P-coded version of the file takes precedence, when both files exist in the package, the custom storage classes are protected and cannot be modified in the Custom Storage Class Designer.

**Further Customize Generated Code by Writing TLC Code**

If creating your own custom storage class by manipulating the properties in the Custom Storage Class Designer does not satisfy your requirements, you can finely control the generated code by writing TLC code for your custom storage class. Use an advanced mode of the Custom Storage Class Designer and, for the custom storage class, set `Type` to `Other`. See “Finely Control Data Representation by Writing TLC Code for a Custom Storage Class” on page 26-39.

Finely Control Data Representation by Writing TLC Code for a Custom Storage Class

If creating your own custom storage class by using the properties in an Embedded Coder Dictionary or the Custom Storage Class Designer does not meet your requirements for controlling data representation in the generated code, you can write TLC code that explicitly controls the effect that a custom storage class has on the code. For example, to create a custom storage class that yields arbitrarily nested structures, you must write TLC code. In the Custom Storage Class Designer, these advanced custom storage classes have Type set to Other. You cannot create such a storage class in an Embedded Coder Dictionary, so you cannot use the storage class as a default code generation setting in the Code Mapping Editor.

For an example, see “Generate Code That Dereferences Data from a Literal Memory Address” on page 52-21. For general information about TLC code, see “Why Use the Target Language Compiler?” (Simulink Coder).

Create Custom Attributes Class for Custom Storage Class

As described in “Allow Users of Custom Storage Class to Specify Property Value” on page 26-32, instance-specific properties enable users of a custom storage class to control the effect that the storage class has on each data item. For example, the built-in custom storage class ExportToFile has several instance-specific properties such as Header file and Definition file.

When you create a custom storage class with Type set to Other, to add your own instance-specific properties that are not built into the Custom Storage Class Designer, create a custom attributes class for your package. A custom attributes class is a MATLAB class that you create as a subclass of Simulink.CustomStorageClassAttributes. Each property that you add to your custom attributes class appears to the user of the custom storage class as an instance-specific property.

To create your custom attributes class, see “Define Data Classes” (Simulink).

Write TLC Code for Custom Storage Class

To control the effect of your custom storage class, write TLC code that specifies the code to generate for each data item.
In your package folder (for example, +myPackage), create a tlc folder.

Copy a TLC template such as TEMPLATE_v1.tlc from the folder matlabroot/toolbox/rtw/targets/ecoder/csc_templates (open) into your tlc folder.

Write your TLC code, following the comments in the template file. The comments describe how to specify, for example, how the generated code declares, defines, and accesses (by value or by reference) each data item.

Create Custom Storage Class by Using Custom Storage Class Designer

To create your custom storage class in your package, you open the Custom Storage Class Designer in an advanced mode.

1. At the command prompt, enter:
   
   cscdesigner -advanced

2. Select your package and create a custom storage class.

3. For the custom storage class, set **Type** to **Other**. In the **Other Attributes** pane, specify the name of your TLC file and the name of your custom attributes class.

4. Set the properties on the **Other Attributes** pane.

   - **Is grouped**: Select this option if you intend to combine multiple data items into a single entity in the generated code. For example, the built-in custom storage classes BitField and Struct are grouped because they can aggregate multiple data items into a single structure variable.
   - **TLC file name**: Enter the name of your TLC file. The Custom Storage Class Designer assumes that the file exists in the package tlc folder, so specify only the name of the file, not the file path.
   - **CSC attributes class name**: (optional) If you created a custom attributes class, enter the full name of the class, including the package name. For example, specify myPackage.myCustomAttsClass. For more information, see “Create Custom Attributes Class for Custom Storage Class” on page 26-39.

5. On the **General** and **Comments** panes, specify values for the remaining properties.

Access Data Through Functions with Custom Storage Class GetSet

To integrate the generated code with legacy code that uses specialized functions to read from and write to data, you can use the custom storage class GetSet. Signals, block parameters, and states that use GetSet appear in the generated code as calls to accessor functions. You provide the function definitions.

To generate code that conforms to the AUTOSAR standard by accessing data through Rte function calls, use the Configure AUTOSAR Interface dialog box. See “AUTOSAR Component Configuration”.

Access Legacy Data Using Get and Set Functions

This example shows how to generate code that interfaces with legacy code by using specialized get and set functions to access data.

View the example legacy header file ComponentDataHdr.h. The file defines a large structure type ComponentData.

```c
typedef struct {
    ScalarData scalars;
    VectorData vectors;
    StructData structs;
    MatricesData matrices;
} ComponentData;
```

The field scalars is a substructure that uses the structure type ScalarData. The structure type ScalarData defines three scalar fields: inSig, scalarParam, and outSig.

```c
typedef struct {
    ScalarData scalars;
    VectorData vectors;
    StructData structs;
    MatricesData matrices;
} ComponentData;
```
double inSig;
double scalarParam;
double outSig;
} ScalarData;

View the example legacy source file getsetSrc.c. The file defines and initializes a global variable ex_getset_data that uses the structure type ComponentData. The initialization includes values for the substructure scalars.

rtwdemodbtype('getsetSrc.c','/* Field "scalars" */','/* End of "scalars" */',1,1)

    /* Field "scalars" */
    {
        3.9,
        12.3,
        0.0
    },
    /* End of "scalars" */

The file also defines functions that read from and write to the fields of the substructure scalars. The functions simplify data access by dereferencing the leaf fields of the global structure variable ex_getset_data.

rtwdemodbtype('getsetSrc.c',...,
    '/* Scalar get() and set() functions */','/* End of scalar functions */',1,1)

    /* Scalar get() and set() functions */

double get_inSig(void)
{
    return ex_getset_data.scalars.inSig;
}

void set_inSig(double value)
{
    ex_getset_data.scalars.inSig = value;
}

double get_scalarParam(void)
{
    return ex_getset_data.scalars.scalarParam;
View the example legacy header file getsetHdrScalar.h. The file contains the extern prototypes for the get and set functions defined in getsetSrc.c.

Open the example model rtwdemo_getset_scalar. The model creates the data objects inSig, outSig, and scalarParam in the base workspace. The objects correspond to the signals and parameter in the model.

open_system('rtwdemo_getset_scalar')

In the base workspace, double-click the object inSig to view its properties. The object uses the custom storage class GetSet. The GetFunction and SetFunction properties are set to the defaults, get_$N and set_$N. The generated code uses the function names that you specify in GetFunction and SetFunction to read from and write to the data. The code replaces the token $N with the name of the data object. For example, for the data object inSig, the generated code uses calls to the legacy functions get_inSig and set_inSig.
For the data object inSig, the `HeaderFile` property is set to `getsetHdrScalar.h`. This legacy header file contains the `get` and `set` function prototypes. The data objects outSig and scalarParam also use the custom storage class GetSet and the header file `getsetHdrScalar.h`.

In the model Configuration Parameters dialog box, on the Code Generation > Custom Code pane, under Include list of additional, select Source files. The Source files box identifies the source file `getsetSrc.c` for inclusion during the build process. This legacy source file contains the `get` and `set` function definitions and the definition of the global structure variable ex_getset_data.

Generate code with the example model.

```
rtwbuild('rtwdemo_getset_scalar');
```

### Starting build procedure for model: rtwdemo_getset_scalar
### Successful completion of build procedure for model: rtwdemo_getset_scalar

In the code generation report, view the file `rtwdemo_getset_scalar.c`. The model step function uses the legacy `get` and `set` functions to execute the algorithm. The generated code accesses the legacy signal and parameter data by calling the custom, handwritten `get` and `set` functions.

```
rtwdemodbtype(fullfile('rtwdemo_getset_scalar_ert_rtw','rtwdemo_getset_scalar.c'),...
    '/* Model step function */','}',1,1)

/* Model step function */
void rtwdemo_getset_scalar_step(void)
{
    /* Gain: '<Root>/Gain' incorporates:
     * Inport: '<Root>/In1'
     */
    set_outSig(get_scalarParam() * get_inSig());
}
```

You can generate code that calls your custom `get` and `set` functions as long as the functions that you write accept and return the expected values. For scalar data, the functions must have these characteristics:

- The `get` function must return a single scalar numeric value of the appropriate data type, and must not accept any arguments (void).
• The set function must not return anything (void), and must accept a single scalar numeric value of the appropriate data type.

**Use GetSet with Vector Data**

This example shows how to apply the custom storage class GetSet to signals and parameters that are vectors.

View the example legacy header file ComponentDataHdr.h. The file defines a large structure type ComponentData.

```c
rtwdemodbtype('ComponentDataHdr.h','/* ComponentData */','} ComponentData;',1,1)

/* ComponentData */
typedef struct {
    ScalarData scalars;
    VectorData vectors;
    StructData structs;
    MatricesData matrices;
} ComponentData;
```

The field vectors is a substructure that uses the structure type VectorData. The structure type VectorData defines three vector fields: inVector, vectorParam, and outVector. The vectors each have five elements.

```c
rtwdemodbtype('ComponentDataHdr.h','/* VectorData */','} VectorData;',1,1)

/* VectorData */
typedef struct {
    double inVector[5];
    double vectorParam[5];
    double outVector[5];
} VectorData;
```

View the example legacy source file getsetSrc.c. The file defines and initializes a global variable ex_getset_data that uses the structure type ComponentData. The initialization includes values for the substructure vectors.

```c
rtwdemodbtype('getsetSrc.c','/* Field "vectors" */','/* End of "vectors" */',1,1)
```
/* Field "vectors" */
{
    {5.7, 6.8, 1.2, 3.5, 10.1},
    {12.3, 18.7, 21.2, 28, 32.9},
    {0.0, 0.0, 0.0, 0.0, 0.0}
},
/* End of "vectors" */

The file also defines functions that read from and write to the fields of the substructure vectors. The functions simplify data access by dereferencing the leaf fields of the global structure variable ex_getset_data. To access the vector data, all of the functions accept an integer index argument. The get function returns the vector value at the input index. The set function assigns the input value to the input index.

```
srtwmoddbtype('getsetSrc.c',...  
    '/* Vector get() and set() functions */','/* End of vector functions */',1,1)

    /* Vector get() and set() functions */

double get_inVector(int index)
{
    return ex_getset_data.vectors.inVector[index];
}

void set_inVector(int index, double value)
{
    ex_getset_data.vectors.inVector[index] = value;
}

double get_vectorParam(int index)
{
    return ex_getset_data.vectors.vectorParam[index];
}

void set_vectorParam(int index, double value)
{
    ex_getset_data.vectors.vectorParam[index] = value;
}

double get_outVector(int index)
{

```

Access Data Through Functions with Custom Storage Class GetSet
View the example legacy header file getsetHdrVector.h. The file contains the extern prototypes for the get and set functions defined in getsetSrc.c.

Open the example model rtwdemo_getset_vector. The model creates the data objects inVector, outVector, and vectorParam in the base workspace. The objects correspond to the signals and parameter in the model.

open_system('rtwdemo_getset_vector')

In the base workspace, double-click the object inVector to view its properties. The object uses the custom storage class GetSet. The property HeaderFile is specified as getsetHdrVector.h. This legacy header file contains the get and set function prototypes.

In the model Configuration Parameters dialog box, on the Code Generation > Custom Code pane, the example legacy source file getsetSrc.c is identified for inclusion during the build process. This legacy source file contains the get and set function definitions and the definition of the global structure variable ex_getset_data.

Generate code with the example model.

rtwbuild('rtwdemo_getset_vector');

### Starting build procedure for model: rtwdemo_getset_vector
### Successful completion of build procedure for model: rtwdemo_getset_vector
In the code generation report, view the file `rtwdemo_getset_vector.c`. The model step function uses the legacy get and set functions to execute the algorithm.

```c
rtwdemodbtype(fullfile('rtwdemo_getset_vector_ert_rtw','rtwdemo_getset_vector.c'),...
   /* Model step function */','}',1,1)

/* Model step function */
void rtwdemo_getset_vector_step(void)
{
    int32_T i;

    /* Gain: '<Root>/Gain' incorporates:
     *  Inport: '<Root>/In1'
     */
    for (i = 0; i < 5; i++) {
        set_outVector(i, get_vectorParam(i) * get_inVector(i));
    }
}
```

When you use the custom storage class `GetSet` with vector data, the get and set functions that you provide must accept an index input. The get function must return a single element of the vector. The set function must write to a single element of the vector.

### Use GetSet with Structured Data

This example shows how to apply the custom storage class `GetSet` to nonvirtual bus signals and structure parameters in a model.

View the example legacy header file `ComponentDataHdr.h`. The file defines a large structure type `ComponentData`.

```c
rtwdemodbtype('ComponentDataHdr.h',...
   /* ComponentData */','} ComponentData;',1,1)

/* ComponentData */

typedef struct {
    ScalarData scalars;
    VectorData vectors;
    StructData structs;
    MatricesData matrices;
} ComponentData;
```

26-49
The field structs is a substructure that uses the structure type StructData. The
structure type StructData defines three fields: inStruct, structParam, and
outStruct.

rtwdemodbtype('ComponentDataHdr.h','/* StructData */','} StructData;',1,1)

/* StructData */
typedef struct {
    SigBus inStruct;
    ParamBus structParam;
    SigBus outStruct;
} StructData;

The fields inStruct, structParam, and outStruct are also substructures that use the
structure types SigBus and ParamBus. Each of these two structure types define three
scalar fields.

rtwdemodbtype('ComponentDataHdr.h','/* SigBus */','} ParamBus',1,1)

/* SigBus */
typedef struct {
    double cmd;
    double sensor1;
    double sensor2;
} SigBus;

/* ParamBus */
typedef struct {
    double offset;
    double gain1;
    double gain2;
} ParamBus;

View the example legacy source file getsetSrc.c. The file defines and initializes a global
variable ex_getset_data that uses the structure type ComponentData. The
initialization includes values for the substructure structs.

rtwdemodbtype('getsetSrc.c',...
    '/* Field "structs" */','/* End of "structs" */',1,1)
The file also defines functions that read from and write to the fields of the substructure `structs`. The functions simplify data access by dereferencing the fields of the global structure variable `ex_getset_data`. The functions access the data in the fields `inStruct`, `structParam`, and `outStruct` by accepting and returning complete structures of the types `SigBus` and `ParamBus`.

```c
rtwdemodbtpe('getsetSrc.c', ...
  '/* Structure get() and set() functions */',...
  '/* End of structure functions */',1,1)

/* Structure get() and set() functions */

SigBus get_inStruct(void)
{
  return ex_getset_data.structs.inStruct;
}

void set_inStruct(SigBus value)
{
  ex_getset_data.structs.inStruct = value;
}

ParamBus get_structParam(void)
{
  return ex_getset_data.structs.structParam;
}

void set_structParam(ParamBus value)
{
  ex_getset_data.structs.structParam = value;
}

SigBus get_outStruct(void)
```
{    return ex_getset_data.structs.outStruct;}

void set_outStruct(SigBus value)
{    ex_getset_data.structs.outStruct = value;
}

View the example legacy header file getsetHdrStruct.h. The file contains the extern prototypes for the get and set functions defined in getsetSrc.c.

Open the example model rtwdemo_getset_struct. The model creates the data objects inStruct, structParam, and outStruct in the base workspace. The objects correspond to the signals and parameter in the model.

open_system('rtwdemo_getset_struct')

In the base workspace, double-click the object inStruct to view its properties. The object uses the custom storage class GetSet. The property HeaderFile is specified as getsetHdrStruct.h. This legacy header file contains the get and set function prototypes.
The model also creates the bus objects ParamBus and SigBus in the base workspace. The signals and parameter in the model use the bus types that these objects define. The property DataScope of each bus object is set to Imported. The property HeaderFile is set to ComponentDataHdr.h. The generated code imports these structure types from the legacy header file ComponentDataHdr.h.

In the model Configuration Parameters dialog box, on the Code Generation > Custom Code pane, the example legacy source file getsetSrc.c is identified for inclusion during the build process. This legacy source file contains the get and set function definitions and the definition of the global structure variable ex_getset_data.

Generate code with the example model.

```matlab
twbuild('rtwdemo_getset_struct');
```

```bash
## Starting build procedure for model: rtwdemo_getset_struct
## Successful completion of build procedure for model: rtwdemo_getset_struct
```

In the code generation report, view the file rtwdemo_getset_struct.c. The model step function uses the legacy get and set functions to execute the algorithm.

```matlab
rtwedobdtypedef(fullfile('rtwdemo_getset_struct_ert_rtw', ...
    'rtwdemo_getset_struct.c'),...
    '/* Model step function */','}',1,1)

/* Model step function */
void rtwdemo_getset_struct_step(void)
{
    /* Bias: '<Root>/Bias' incorporates:
        * Inport: '<Root>/In1'
        */
    rtDW.BusCreator.cmd = (get_inStruct()).cmd + (get_structParam()).offset;

    /* Gain: '<Root>/Gain' incorporates:
        * Inport: '<Root>/In1'
        */
    rtDW.BusCreator.sensor1 = (get_structParam()).gain1 * (get_inStruct()).sensor1;

    /* Gain: '<Root>/Gain1' incorporates:
        * Inport: '<Root>/In1'
        */
    rtDW.BusCreator.sensor2 = (get_structParam()).gain2 * (get_inStruct()).sensor2;
```
When you use the custom storage class `GetSet` with structured data, the get and set functions that you provide must return and accept complete structures. The generated code dereferences individual fields of the structure that the get function returns.

The output signal of the Bus Creator block is a test point. This signal is the input for a Signal Conversion block. The test point and the Signal Conversion block exist so that the generated code defines a variable for the output of the Bus Creator block. To provide a complete structure argument for the function `set_outStruct`, you must configure the model to create this variable.

### Use GetSet with Matrix Data

This example shows how to apply the custom storage class `GetSet` to signals and parameters that are matrices.

View the example legacy header file `ComponentDataHdr.h`. The file defines a large structure type `ComponentData`.

```c
typedef struct {
    ScalarData scalars;
    VectorData vectors;
    StructData structs;
    MatricesData matrices;
} ComponentData;
```

The field `matrices` is a substructure that uses the structure type `MatricesData`. The structure type `MatricesData` defines three fields: `matrixInput`, `matrixParam`, and `matrixOutput`. The fields store matrix data as serial arrays. In this case, the input and parameter fields each have 15 elements. The output field has nine elements.
/* MatricesData */

typedef struct {
  double matrixInput[15];
  double matrixParam[15];
  double matrixOutput[9];
} MatricesData;

View the example legacy source file getsetSrc.c. The file defines and initializes a global variable ex_getset_data that uses the structure type ComponentData. The initialization includes values for the substructure matrices.

rtwdemodbtype('getsetSrc.c',...
  /* Field "matrices" */','/* End of "matrices" */',1,1)

  /* Field "matrices" */
  {
   {12.0, 13.9, 7.4,
    0.5, 11.8, 6.4,
    4.7, 5.3, 13.0,
    0.7, 16.1, 13.5,
    1.6, 0.5, 3.1},

   {8.3, 12.0, 11.5, 2.0, 5.7,
    7.5, 12.8, 11.1, 8.4, 9.9,
    10.9, 4.6, 2.7, 16.3, 3.8},

   {0.0, 0.0, 0.0,
    0.0, 0.0, 0.0,
    0.0, 0.0, 0.0}
  }
  /* End of "matrices" */

The input matrix has five rows and three columns. The matrix parameter has three rows and five columns. The matrix output has three rows and three columns. The file defines macros that indicate these dimensions.

rtwdemodbtype('getsetSrc.c',...
  /* Matrix dimensions */','/* End of matrix dimensions */',1,1)

  /* Matrix dimensions */
The file also defines functions that read from and write to the fields of the substructure matrices.

```c
#define MATRIXINPUT_NROWS 5
#define MATRIXINPUT_NCOLS 3

#define MATRIXPARAM_NROWS 3
#define MATRIXPARAM_NCOLS 5

#define MATRIXOUTPUT_NROWS MATRIXPARAM_NROWS
#define MATRIXOUTPUT_NCOLS MATRIXINPUT_NCOLS
```

```c
/* Matrix get() and set() functions */

double get_matrixInput(int colIndex)
{
    int rowIndexGetInput = MATRIXINPUT_NCOLS * (colIndex % MATRIXINPUT_NROWS) + colIndex / MATRIXINPUT_NROWS;
    return ex_getset_data.matrices.matrixInput[rowIndexGetInput];
}

void set_matrixInput(int colIndex, double value)
{
    int rowIndexSetInput = MATRIXINPUT_NCOLS * (colIndex % MATRIXINPUT_NROWS) + colIndex / MATRIXINPUT_NROWS;
    ex_getset_data.matrices.matrixInput[rowIndexSetInput] = value;
}

double get_matrixParam(int colIndex)
{
    int rowIndexGetParam = MATRIXPARAM_NCOLS * (colIndex % MATRIXPARAM_NROWS) + colIndex / MATRIXPARAM_NROWS;
    return ex_getset_data.matrices.matrixParam[rowIndexGetParam];
}

void set_matrixParam(int colIndex, double value)
{
    int rowIndexSetParam = MATRIXPARAM_NCOLS * (colIndex % MATRIXPARAM_NROWS) + colIndex / MATRIXPARAM_NROWS;
    ex_getset_data.matrices.matrixParam[rowIndexSetParam] = value;
}

double get_matrixOutput(int colIndex)
{
    // Implementation...
}
```

```c
rtwdemodbtpe('getsetSrc.c',...,
    /* Matrix get() and set() functions */','/* End of matrix functions */',1,1)

/* Matrix get() and set() functions */

double get_matrixInput(int colIndex)
{
    int rowIndexGetInput = MATRIXINPUT_NCOLS * (colIndex % MATRIXINPUT_NROWS) + colIndex / MATRIXINPUT_NROWS;
    return ex_getset_data.matrices.matrixInput[rowIndexGetInput];
}

void set_matrixInput(int colIndex, double value)
{
    int rowIndexSetInput = MATRIXINPUT_NCOLS * (colIndex % MATRIXINPUT_NROWS) + colIndex / MATRIXINPUT_NROWS;
    ex_getset_data.matrices.matrixInput[rowIndexSetInput] = value;
}

double get_matrixParam(int colIndex)
{
    int rowIndexGetParam = MATRIXPARAM_NCOLS * (colIndex % MATRIXPARAM_NROWS) + colIndex / MATRIXPARAM_NROWS;
    return ex_getset_data.matrices.matrixParam[rowIndexGetParam];
}

void set_matrixParam(int colIndex, double value)
{
    int rowIndexSetParam = MATRIXPARAM_NCOLS * (colIndex % MATRIXPARAM_NROWS) + colIndex / MATRIXPARAM_NROWS;
    ex_getset_data.matrices.matrixParam[rowIndexSetParam] = value;
}

double get_matrixOutput(int colIndex)
{
    // Implementation...
}
```
The code that you generate from a model represents matrices as serial arrays. Therefore, each of the `get` and `set` functions accept a single scalar index argument.

The generated code uses column-major format to store and to access matrix data. However, many C applications use row-major indexing. To integrate the generated code with the example legacy code, which stores the matrices `matrixInput` and `matrixParam` using row-major format, the custom `get` functions use the column-major index input to calculate an equivalent row-major index. The generated code algorithm, which interprets matrix data using column-major format by default, performs the correct matrix math because the `get` functions effectively convert the legacy matrices to column-major format. The `set` function for the output, `matrixOutput`, also calculates a row-major index so the code writes the algorithm output to `matrixOutput` using row-major format. Alternatively, to integrate the column-major generated code with your row-major legacy code, you can manually convert the legacy code to column-major format by transposing your matrix data and algorithms.

View the example legacy header file `getsetHdrMatrix.h`. The file contains the `extern` prototypes for the `get` and `set` functions defined in `getsetSrc.c`.

Open the example model `rtwdemo_getset_matrix`. The model creates the data objects `matrixInput`, `matrixParam`, and `matrixOutput` in the base workspace. The objects correspond to the signals and parameter in the model.

```c
load_system('rtwdemo_getset_matrix')
set_param('rtwdemo_getset_matrix','SimulationCommand','Update')
open_system('rtwdemo_getset_matrix')
```
In the base workspace, double-click the object matrixInput to view its properties. The object uses the custom storage class GetSet. The property HeaderFile is specified as getsetHdrMatrix.h. This legacy header file contains the get and set function prototypes.

In the model Configuration Parameters dialog box, on the **Code Generation > Custom Code** pane, the example legacy source file getsetSrc.c is identified for inclusion during the build process. This legacy source file contains the get and set function definitions and the definition of the global structure variable ex_getset_data.

Generate code with the example model.

```matlab
rtwbuild('rtwdemo_getset_matrix');
```

### Starting build procedure for model: rtwdemo_getset_matrix
### Successful completion of build procedure for model: rtwdemo_getset_matrix

In the code generation report, view the file rtwdemo_getset_matrix.c. The model step function uses the legacy get and set functions to execute the algorithm.

```matlab
rtwdemodbtype(fullfile('rtwdemo_getset_matrix_ert_rtw',...
'de_getset_matrix.c'),'/* Model step function */',1,1)
```

```c
/* Model step function */
void rtwdemo_getset_matrix_step(void)
{
    int32_t i;
    int32_t i_0;
    int32_t i_1;
}
```
int32_T matrixOutput_tmp;

/* Product: '<Root>/Product' incorporates:
 *  Constant: '<Root>/Constant'
 *  Inport: '<Root>/In1'
 */
for (i_0 = 0; i_0 < 3; i_0++) {
  for (i = 0; i < 3; i++) {
    matrixOutput_tmp = i + 3 * i_0;
    set_matrixOutput(matrixOutput_tmp, 0.0);
    for (i_1 = 0; i_1 < 5; i_1++) {
      set_matrixOutput(matrixOutput_tmp, get_matrixParam(3 * i_1 + i) * get_matrixInput(5 * i_0 + i_1) + get_matrixOutput(3 * i_0 + i));
    }
  }
}

Specify Header File or Function Naming Scheme for All Data Items

By default, you specify a header file name, get function name, and set function name for each data item, such as a signal or parameter, that uses the custom storage class GetSet.

To configure a single header file, get function naming scheme, or set function naming scheme to use for every data item, you can use the Custom Storage Class Designer to create your own copy of GetSet. You can specify the header file or function names in a single location.

Follow these steps to create your own custom storage class by creating your own data class package, creating a copy of GetSet, and applying the new custom storage class to data items in your model.

1. Create your own data class package, myPackage, by copying the example package folder +SimulinkDemos and renaming the copied folder as +myPackage. Modify the Parameter and Signal class definitions so that they use the custom storage class definitions from myPackage. For an example, see “Create Data Class Package” on page 26-26.

2. Set your current folder to the folder that contains the package folder. Alternatively, add the folder containing the package folder to your MATLAB path.

3. Open the Custom Storage Class Designer:

cscdesigner('myPackage')

26-59
4 Select the custom storage class GetSet. Click Copy to create a copy called GetSet_1.

5 Select the new custom storage class GetSet_1. In the General tab, set Name to myGetSet.

6 Set the drop-down list Header file to Specify. In the new text box, set Header file to myFcnHdr.h. Click Apply.

7 On the Access Function Attributes tab, set the drop-down lists Get function and Set function to Specify.

8 In the new boxes, set Get function to myGetFcn_$N and Set function to mySetFcn_$N. Click OK. Click Yes in response to the message about saving changes.

9 When you generate code, the token $N expands into the name of the data item that uses this custom storage class.

10 Apply the custom storage class myGetSet from your package to a data item. For example, create a myPackage.Parameter object in the base workspace.

```matlab
myParam = myPackage.Parameter(15.23);
myParam.CoderInfo.StorageClass = 'Custom';
myParam.CoderInfo.CustomStorageClass = 'myGetSet';
```

11 Use the object to set a parameter value in your model. When you generate code, the code algorithm accesses the parameter through the functions that you specified. The code uses an #include directive to include the header file that you specified.

## Access Scalar and Array Data Through Macro Instead of Function Call

If you implement the get mechanism for scalar or array data as a macro instead of a function, you can generate code that omits parentheses when reading that data.

- For scalar data, your macro must yield the scalar value.
- For array data, your macro must yield the starting memory address.

Create your own AccessFunction storage class by using the Custom Storage Class Designer, as described in “Specify Header File or Function Naming Scheme for All Data Items” on page 26-59. In the Designer, on the Access Function Attributes tab, select Get data through macro (omit parentheses).
GetSet Custom Storage Class Restrictions

- GetSet does not support complex signals.
- Multiple data in the same model cannot use the same GetFunction or SetFunction.
- Some blocks do not directly support GetSet.
- Custom S-functions do not directly support GetSet.

To use GetSet with an unsupported block or a custom S-function:

1. Insert a Signal Conversion block at the output of the block or function.
2. In the Signal Conversion block dialog box, select Exclude this block from 'Block reduction' optimization.
3. Assign the custom storage class GetSet to the output of the Signal Conversion block.

Integrate External Application Code with Code Generated from PID Controller

This example shows how to generate C code from a control algorithm model and integrate that code with existing, external application code. In the complete application, which consists of three modules, the algorithm module must exchange data with other modules through global variables. In the example, you configure the generated code to interact with existing external variables, resemble the external code in appearance and organization, and conform to specific coding requirements.

Inspect External Code

Set your current folder to a writable location.

Copy the script prepare_ext_code to your current folder and run the script. The script copies external code files into several folders.

```matlab
try
    copyfile(fullfile(matlabroot,'examples','ecoder','main','prepare_ext_code.m'),...
        'prepare_ext_code.m','f');
    catch
end
run('prepare_ext_code.m');
```

In your current folder, open `ext_code_main.c`. This application code represents an embedded system with a trivial scheduling algorithm (a `while` loop) and three modules whose algorithms run in every execution cycle: `ex_ext_inputs_proc`, `ex_ext_ctrl_alg`, and `ex_ext_outputs_proc`.

```matlab
type('ext_code_main.c')
```

In the `shared` folder, inspect `ex_ext_projTypes.h`. The file defines two custom data types (typedef) that the data in the modules use.

```matlab
type(fullfile('shared','ex_ext_projTypes.h'))
```

In the `io_drivers` folder, inspect `ex_sensor_accessors.c`. This file defines functions, `get_fromSensor_flow` and `get_fromSensor_temp`, that return raw data recorded by a flow sensor and a temperature sensor. For this example, the functions return trivial sinusoidal stimuli for the control algorithm.

```matlab
type(fullfile('io_drivers','ex_sensor_accessors.c'))
```
In the `ex_ext_inputs_proc` folder, inspect `ex_ext_inputs_proc.c`. The `ex_ext_inputs_proc` module reads the sensor data (by calling the accessor functions), filters the data, and stores it in two global variables, `PROC_INPUT_FLOW` and `PROC_INPUT_TEMP`. These global variables are defined in the file `ex_ext_proc_inputs.c` and declared in `ex_ext_proc_inputs.h`.

```matlab
type(fullfile('ex_ext_inputs_proc','ex_ext_inputs_proc.c'))
```

The filter algorithm in this module and the algorithms in the other two modules require state data, which must persist between execution cycles of the application. Each module stores relevant state data as global variables. For example, in the `ex_ext_inputs_proc` module, `ex_ext_inputs_proc.c` defines these variables:

- `flowFilterIn_state_data`
- `tempFilterIn_state_data`
- `flowFilterIn_tmp_data`
- `tempFilterIn_tmp_data`

The empty `ex_ext_ctrl_alg` folder is a placeholder for the generated code. The `ex_ext_ctrl_alg` module must perform PID control on the filtered flow and temperature measurements. Later, you examine the requirements for this code, which are based on the code in the other modules.

In the `ex_ext_outputs_proc` folder, inspect `ex_ext_outputs_proc.c`. This module reads the PID output signals from global variables named `CONTR_SIG_FLOW` and `CONTR_SIG_TEMP`. The `ex_ext_ctrl_alg` module (the generated code) must define these variables. The `ex_ext_outputs_proc` module then filters these signals and passes the filtered values to functions that represent device drivers for actuators (for example, a valve and a heater filament).

```matlab
type(fullfile('ex_ext_outputs_proc','ex_ext_outputs_proc.c'))
```

The actuator functions are defined in the `io_drivers` folder in the file `ex_actuator_accessors.c`.

The figure shows the intended flow of data through the system. The figure also shows the code files that define and declare the data (global variables) that cross the module boundaries.

Inspect Simulink Model and Determine Requirements for Generated Code

Open the example model `ex_ext_ctrl_alg`.

```matlab
open_system('ex_ext_ctrl_alg')
```

The blocks in the model implement the required PID control algorithm. The model uses default code generation settings for an ERT-based system target file (`ert.tlc`).

To complete the application by performing the function of the `ex_ext_ctrl_alg` module, the code generated from this model must:

- Use the custom data types `dataPath_flow_T` and `dataPath_temp_T` from the external file `ex_ext_projTypes.h`.
- Read filtered sensor data from the global variables `PROC_INPUT_FLOW` and `PROC_INPUT_TEMP`. The generated code must not define these variables because the module `ex_ext_inputs_proc` defines them, declaring them in `ex_ext_proc_inputs.h`.
- Write PID control signals to global variables named `CONTR_SIG_FLOW` and `CONTR_SIG_TEMP`. The generated code must define these variables and declare them in a file named `ex_ext_ctrl_sigs.h`. Then, the `ex_ext_outputs_proc` module can read the raw control signals from them.
- Conform to variable naming standards that govern the external application. For example, the generated code must store state data in global variables whose names end in `_data`. In addition, for this example, the names of local function variables must end in `_local`.
- Conform to standards that govern the organization of the code in each of the external files. For example, each file contains sections, delimited by comments, that aggregate similar code constructs such as type definitions, variable declarations, and function definitions.

So that you and others can interact with the control algorithm during execution, for this example, you also configure the generated code to define and declare `const` global variables named `PARAM_setpoint_flow` and `PARAM_setpoint_temp`, which represent the PID controller setpoints. The definitions must appear in a file named `ex_ext_ctrl_params.c` and the declarations must appear in a file named `ex_ext_ctrl_params.h`.

**Configure Model to Use Custom Data Types**

Set your current folder to the shared folder.
Use the function `Simulink.importExternalCTypes` to generate `Simulink.AliasType` objects that represent the custom data types `dataPath_flow_T` and `dataPath_temp_T`.

```matlab
cd('shared')
Simulink.importExternalCTypes('ex_ext_projTypes.h);
```

The objects appear in the base workspace.

In the `ex_ext_ctrl_alg` model, select **View > Model Data Editor**.

In the Model Data Editor, for the Inport block that represents **PROC_INPUT_FLOW**, set **Data Type** to `dataPath_flow_T`.

For the Inport block that represents **PROC_INPUT_TEMP**, set **Data Type** to `dataPath_temp_T`.

Select the **Signals** tab.

In the model, select the output signal of each Constant block. In the Model Data Editor, set **Data Type** to **Inherit: Inherit via back propagation**. With this setting, each Constant block inherits its output data type from the block immediately downstream, in this case, a Sum block.

Alternatively, to configure the data types, at the command prompt, use these commands.

```matlab
set_param('ex_ext_ctrl_alg/In1','OutDataTypeStr','dataPath_flow_T')
set_param('ex_ext_ctrl_alg/In2','OutDataTypeStr','dataPath_temp_T')
set_param('ex_ext_ctrl_alg/Flow Setpt','OutDataTypeStr','Inherit: Inherit via back propagation')
set_param('ex_ext_ctrl_alg/Temp Setpt','OutDataTypeStr','Inherit: Inherit via back propagation')
```

Update the block diagram. The diagram shows that, due to data type inheritance and propagation, all of the signals in the model use a custom data type.

**Configure Interface Data**

Configure the model to generate code that accesses and defines the correct global variables such as `PROC_INPUT_FLOW` and `CONTR_SIG_TEMP`.

In the Model Data Editor, select the **Imports/Outports** tab and set the **Change view** drop-down list to **Code**.
Select the rows that correspond to the two Inport blocks.

For either row, set **Storage Class** to `ImportFromFile` and **Header File** to `ex_ext_proc_inputs.h`. With the storage class `ImportFromFile`, each Inport block appears in the generated code as a global variable. However, the generated code does not define the variable, instead including (#include) the variable declaration from `ex_ext_proc_inputs.h`.

For the rows that correspond to the Outport blocks, set:

- **Storage Class** to `ExportToFile`
- **Header file** to `ex_ext_ctrl_sigs.h`
- **Definition File** to `ex_ext_ctrl_sigs.c`

With `ExportToFile`, the generated code defines the global variable.

Alternatively, to configure the signals, at the command prompt, use these commands.

```matlab
temp = Simulink.Signal;
temp.CoderInfo.StorageClass = 'Custom';
temp.CoderInfo.CustomStorageClass = 'ImportFromFile';
temp.CoderInfo.CustomAttributes.HeaderFile = 'ex_ext_proc_inputs.h';

portHandles = get_param('ex_ext_ctrl_alg/In1','portHandles');
outportHandle = portHandles.Outport;
set_param(outportHandle,'SignalObject',copy(temp))

portHandles = get_param('ex_ext_ctrl_alg/In2','portHandles');
outportHandle = portHandles.Outport;
set_param(outportHandle,'SignalObject',copy(temp))

temp.CoderInfo.CustomStorageClass = 'ExportToFile';
temp.CoderInfo.CustomAttributes.HeaderFile = 'ex_ext_ctrl_sigs.h';
temp.CoderInfo.CustomAttributes.DefinitionFile = 'ex_ext_ctrl_sigs.c';

set_param('ex_ext_ctrl_alg/Out1','SignalObject',copy(temp))
set_param('ex_ext_ctrl_alg/Out2','SignalObject',copy(temp))
```

To apply a storage class to a block parameter, such as the **Constant value** parameter of a Constant block, you must create a parameter object such as `Simulink.Parameter`. You can use the Model Data Editor to create parameter objects.

Select the **Parameters** tab and set **Change view** to Design.
In the model, select the Constant block labeled Flow Setpt.

In the Model Data Editor, set Value to PARAM_setpoint_flow.

Next to PARAM_setpoint_flow, click the action button (with three vertical dots) and select Create.

In the Create New Data dialog box, set Value to Simulink.Parameter(3).

Set Location to Model Workspace and click Create.

In the PARAM_setpoint_flow property dialog box, set Storage class to Const.

Set HeaderFile to ex_ext_ctrl_params.h and DefinitionFile to ex_ext_ctrl_params.c.

For the other Constant block, use the Model Data Editor to create a Simulink.Parameter object named PARAM_setpoint_temp with value 2.

Alternatively, to configure the blocks, at the command prompt, use these commands.

```matlab
PARAM_setpoint_flow = Simulink.Parameter(3);
PARAM_setpoint_flow.CoderInfo.StorageClass = 'Custom';
PARAM_setpoint_flow.CoderInfo.CustomStorageClass = 'Const';
PARAM_setpoint_flow.CoderInfoCustomAttributes.HeaderFile = 'ex_ext_ctrl_params.h';
PARAM_setpoint_flow.CoderInfoCustomAttributes.DefinitionFile = 'ex_ext_ctrl_params.c';

PARAM_setpoint_temp = copy(PARAM_setpoint_flow);
PARAM_setpoint_temp.Value = 2;

mdlwks = get_param('ex_ext_ctrl_alg','ModelWorkspace');
assignin(mdlwks,'PARAM_setpoint_flow',copy(PARAM_setpoint_flow))
assignin(mdlwks,'PARAM_setpoint_temp',copy(PARAM_setpoint_temp))

set_param('ex_ext_ctrl_alg/Flow Setpt','Value','PARAM_setpoint_flow')
set_param('ex_ext_ctrl_alg/Temp Setpt','Value','PARAM_setpoint_temp')

clear temp PARAM_setpoint_flow PARAM_setpoint_temp mdlwks portHandles outportHandle
```

**Configure Internal Data**

In the external code, internal data that does not participate in the module interfaces, such as state data and local variables in functions, conform to naming schemes. In the model,
configure internal data that appears in the generated code to mimic these naming schemes.

In the model Configuration Parameters dialog box, inspect the Code Generation > Symbols pane. When you specify values for the naming schemes under Identifier format control:

- $R$ represents the name of the model, ex_ext_ctrl_alg.
- $N$ represents the name of each model element to which the scheme applies, such as a signal, block state, or standard data structure.
- $M$ represents name-mangling text that the code generator inserts, if necessary, to avoid name clashes. For most naming rules, this token is required.

Set Global variables to $R$N_data$M$. This setting controls the names of global variables, such as those that represent state data. The naming scheme $R$N_data $M$ most closely approximates the scheme that the state variables in the external code use.

Set Local temporary variables and Local block output variables to $N_local$M.

Alternatively, to set the configuration parameters, at the command prompt, use these commands.

```
set_param('ex_ext_ctrl_alg','CustomSymbolStrGlobalVar','$R$N_data$M')
set_param('ex_ext_ctrl_alg','CustomSymbolStrTmpVar','$N_local$M')
set_param('ex_ext_ctrl_alg','CustomSymbolStrBlkIO','$N_local$M')
```

Configure the state data in the model to appear in the generated code as separate global variables instead of fields of the standard DWork structure. In the model, select Code > C/C++ Code > Configure Model in Code Perspective.

Underneath the block diagram, under Code Mappings > Data Defaults, for the Internal data row, in the Storage Class column select ExportedGlobal.

Alternatively, to configure this default storage class, use these commands at the command prompt:

```
coder.mapping.create('ex_ext_ctrl_alg');
coder.mappingdefaults.set('ex_ext_ctrl_alg','InternalData',
    'StorageClass','ExportedGlobal');
```

**Configure Organization of Code in Each Generated File**

Set your current folder to the ex_ext_ctrl_alg folder.
At the command prompt, navigate to the folder that contains the built-in code generation template `ert_code_template.cgt`. By default, when you generate code with the system target file `ert.tlc`, this template governs the organization and, in part, the appearance of the code in each generated file.

```matlab
currentFolder = pwd;
cd(fullfile(matlabroot,'toolbox','rtw','targets','ecoder'))
```
Copy the `ert_code_template.cgt` file to your clipboard.

Return to the `ex_ext_ctrl_alg` folder. To avoid overwriting your clipboard, instead of using the command prompt to navigate to the folder, you can use the **Back** button in MATLAB.

```matlab
cd(currentFolder)
clear currentFolder
```
Paste the file into the `ex_ext_ctrl_alg` folder. Rename the file as `ex_my_code_template.cgt`.

Open the file and replace all of the contents with this code.

```matlab
type(fullfile(matlabroot,'examples','ecoder','ex_my_code_template.cgt'))
```
This new template conforms more closely to the organization of the external files. For example, the template organizes similar code constructs into named sections (delimited by comments) and, at the top of the template, specifies only minimal information about each generated file.

In the model, select **Configuration Parameters > Code Generation > Templates**.

Under **Code templates** and **Data templates**, set the four configuration parameters to `ex_my_code_template.cgt`.

Alternatively, to copy the file and set the parameters, at the command prompt, use these commands.

```matlab
copyfile(fullfile(matlabroot,'examples','ecoder','ex_my_code_template.cgt'),...
    'ex_my_code_template.cgt','f')
set_param('ex_ext_ctrl_alg','ERTSrcFileBannerTemplate','ex_my_code_template.cgt')
set_param('ex_ext_ctrl_alg','ERTHdrFileBannerTemplate','ex_my_code_template.cgt')
```
set_param('ex_ext_ctrl_alg','ERTDataSrcFileTemplate','ex_my_code_template.cgt')
set_param('ex_ext_ctrl_alg','ERTDataHdrFileTemplate','ex_my_code_template.cgt')

**Generate and Inspect Code**

Because the external code already defines a main function, select **Configuration Parameters > Generate code only** and clear **Configuration Parameters > Generate an example main program**.

set_param('ex_ext_ctrl_alg','GenCodeOnly','on')
set_param('ex_ext_ctrl_alg','GenerateSampleERTMain','off')

Generate code from the model.

rtwbuild('ex_ext_ctrl_alg')

In the code generation report, inspect the generated files. The code meets the requirements. For example, `ex_ext_ctrl_sigs.c` defines the control output signals, CONTR_SIG_FLOW and CONTR_SIG_TEMP.

file = fullfile('ex_ext_ctrl_alg_ert_rtw','ex_ext_ctrl_sigs.c');
rtwdemodbtype(file,'dataPath_flow_T CONTR_SIG_FLOW;','dataPath_temp_T CONTR_SIG_TEMP;',1,1)

The setpoint parameters appear in `ex_ext_ctrl_params.c`.

file = fullfile('ex_ext_ctrl_alg_ert_rtw','ex_ext_ctrl_params.c');
rtwdemodbtype(file,'const dataPath_flow_T PARAM_setpoint_flow = 3.0;','const dataPath_temp_T PARAM_setpoint_temp = 2.0;',1,1)

The file `ex_ext_ctrl_alg.c` defines global variables to store state data. The variables follow the naming scheme that you specified.

file = fullfile('ex_ext_ctrl_alg_ert_rtw','ex_ext_ctrl_alg.c');
rtwdemodbtype(file,'dataPath_temp_T ex_ext_Integrator_DSTATE_b_data','dataPath_flow_T ex_ext_ctrl__Filter_DSTATE_data;',1,1)

In the same file, the model execution function, `ex_ext_ctrl_alg_step`, creates local function variables to store temporary calculations. The variables follow the naming scheme that you specified.

rtwdemodbtype(file,'dataPath_flow_T Diff_local;','dataPath_temp_T FilterCoefficient_localn;',1,1)
Some of the global and local variable names contain extra mangling characters that prevent name clashes. These extra characters correspond to the $M$ token that you specified in the naming schemes.

The generated code files are in the generated folders `ex_ext_ctrl_alg_ert_rtw` and `slprj`. You must configure file management systems and build tools to use these folders and files.

Configure Generated Code According to Interface Control Document Interactively

This example shows how to configure code generation settings for a model according to specifications in an interface control document (ICD). Store necessary Simulink variables and objects, such as Simulink.Parameter objects, in a data dictionary.

An ICD describes the data interface between two software components. To exchange and share data, the components declare and define global variables that store signal and parameter values. The ICD names the variables and lists characteristics such as data type, physical units, and parameter values. When you create models of the components in Simulink, you can configure the generated code to conform to the interface specification.

In this example, the ICD is a Microsoft® Excel® workbook.

Explore Interface Control Document

Navigate to the folder `matlabroot/examples/ecoder` (open). Copy this file to a writable, working folder:

- `ex_ICD_PCG_inter.xls`

In Microsoft® Excel® or another compatible program, open the `ex_ICD_PCG_inter.xls` workbook and view the first worksheet, Signals. Each row of the worksheet describes a signal that crosses the interface boundary.

Inspect the cell values in the worksheet. The Owner column indicates the name of the component that allocates memory for each signal. The DataType column indicates the signal data type in memory. For example, the worksheet uses the expression `Bus: EngSensors` to indicate a structure type named EngSensors.

In the Parameters worksheet, the Value column indicates the value of each parameter. If the value of the parameter is nonscalar, the value is stored in its own separate worksheet, which has the same name as the parameter.

In the Numeric Types worksheet, each row represents a named numeric data type. In this ICD, the data use fixed-point data types (Fixed-Point Designer). The IsAlias column indicates whether the C code uses the name of the data type (for example, s16En3) or uses the name of the primitive integer data type that corresponds to the word length (such as short). The DataScope column indicates whether the generated code exports or imports the definition of the type.
In the **Structure Types** worksheet, each row represents either a structure type or a field of a structure type. For structure types, the value in the **DataType** column is **struct**. Subsequent rows that do not use **struct** represent fields of the preceding structure type. This ICD defines a structure type, **EngSensors**, with four fields: throttle, speed, ego, and map.

In the **Enumerated Types** worksheet, similar to the **Structure Types** worksheet, each row represents either an enumerated type or an enumeration member. This ICD defines an enumerated type **sldemo_FuelModes**.

**Write External Code**

Some data items in the ICD belong to **other_component**, which is a component that exists outside of MATLAB. Create the code files that define and declare this external data.

Create the header file **ex_inter_types.h** in your current folder. This file defines the structure type **EngSensors** and numeric data types such as **u8En7**.

```c
#ifndef INTER_TYPES_H__
#define INTER_TYPES_H__

typedef short s16En3;
typedef short s16En7;
typedef unsigned char u8En7;
typedef short s16En15;

/* Structure type for instrument measurements. */
typedef struct {
    /* Throttle angle. */
    s16En3 throttle;

    /* Engine speed. */
    s16En3 speed;

    /* EGO sensors. */
    s16En7 ego;

    /* Manifold pressure. */
    u8En7 map;
} EngSensors;
```

26-74
Create the source file `ex_inter_sigs.c` in your current folder. This file defines the imported signal sensors.

```c
#include "ex_inter_sigs.h"

EngSensors sensors;                    /* Instrument measurements. */
```

Create the header file `ex_inter_sigs.h` in your current folder.

```c
#include "ex_inter_types.h"

extern EngSensors sensors;   /* Instrument measurements. */
```

**Explore Example Model**

Run the script `prepare_sldemo_fuelsys_dd_inter`. For this example, the script prepares a system model, `sldemo_fuelsys_dd`.

```matlab
run(fullfile(matlabroot,'examples','ecoder','main','prepare_sldemo_fuelsys_dd_inter'))
```

Open the system model `sldemo_fuelsys_dd`.

`sldemo_fuelsys_dd`
This system model references a controller model. In this example, you generate code from the controller model.

Open the controller model `sldemo_fuelsys_dd_controller`.

`sldemo_fuelsys_dd_controller`
Some of the signals in the controller model have names, for example, the input signal `sensors`. Some block parameters in the model refer to `Simulink.Parameter` objects in a data dictionary. For example, in the `airflow_calc` subsystem, the `Pumping Constant` block uses the parameter objects `PumpCon`, `SpeedVect`, and `PressVect`. These parameter objects set the values of the corresponding block parameters. You can apply code generation settings to the signals and parameter objects.

The controller model is linked to a data dictionary, `sldemo_fuelsys_dd_controller.sldd`. In the lower-left corner of the model, click the dictionary badge to open the dictionary in the Model Explorer. Then, in the Model Explorer Model Hierarchy pane, select the Design Data node.

The dictionary already stores:
- The parameter objects
- `Simulink.NumericType` objects such as `u8En7`
- A `Simulink.Bus` object, `EngSensors`
- The definition of an enumerated data type, `sldemo_FuelModes`

**Configure Model According to ICD**

Navigate to the root level of the controller model and select View > Model Data Editor.
In the Model Data Editor, activate the Change scope button. The Model Data Editor now shows information about data items in the subsystems.

Click the Show/refresh additional information button. The Model Data Editor now shows information about data objects (the Simulink.Parameter objects in the data dictionary) that the model uses.

Select the Inports/Outports tab (which is selected by default).

In the model, select the Inport block labeled sensors. The Model Data Editor highlights the corresponding row.

In the ICD, select the Signals tab.

Use the Model Data Editor to configure the signal according to the information in the ICD:

- Set the value in the Data Type column to Bus: EngSensors. In this case, the value is already set.
- Set the Change view drop-down list to Code and, for sensors, set Storage Class to ImportFromFile. Use this storage class because the Owner column in the ICD implies that a different component, not sldemo_fuelsys_dd_controller, provides the C-code definition of the sensors variable. With this storage class, the generated code does not define the variable.
- Set Header File to ex_inter_sigs.h. When you use a storage class that represents imported data, such as ImportFromFile, you cannot specify Definition File in the Model Data Editor. Instead, include the definition file (in this case, ex_inter_sigs.c) in the code generation and build process by using Configuration Parameters > Code Generation > Custom Code > Additional build information > Source files.

In the model, select the Outport block labeled fuel_rate.

Use the Model Data Editor to configure fuel_rate according to the ICD. To access design properties such as minimum value (Min) and physical unit (Unit), set Change view to Design. For code generation settings, because the ICD specifies sldemo_fuelsys_dd_controller as the owner of the other signals, set Storage Class to ExportToFile.

Inspect the Signals tab.
Set **Change view** to Code and configure code generation settings for the signal `fuel_mode`.

You cannot use the Model Data Editor to configure design properties for `fuel_mode` (such as data type) because `fuel_mode` is an output of a Stateflow chart. In the model, navigate into the chart.

Select **View > Model Explorer > Model Explorer**.

In the Model Explorer **Contents** pane (the middle pane), select the `fuel_mode` data item.

In the Dialog pane (the right pane), configure `fuel_mode` according to the ICD. In this case, the signal data type is already set, so you can specify only the description.

Navigate to the root level of the model.

In the ICD and the Model Data Editor, select the **Parameters** tab. In the Model Data Editor, set **Change view** to **Design**.

In the Model Data Editor, use the **Filter contents** box to search for the first parameter, `PressEst`. The Model Data Editor shows two rows: One row that corresponds to the parameter object `PressEst` and one row that corresponds to the block parameter that uses `PressEst`.

Use the Model Data Editor to configure `PressEst` according to the ICD. The parameter value (the **Value** column) is already set. Because the ICD specifies `sldemo_fuelsys_dd_controller` as the owner of `PressEst`, set **Storage Class** to `ExportToFile`.

Use the Model Data Editor to configure the other parameters. Optionally, to apply a change to multiple parameters at once, select multiple rows in the data table.

In the lower-left corner of the model, click the dictionary badge to open the data dictionary in the Model Explorer.

In the **Model Hierarchy** pane, select the **Design Data** node.

In the **Contents** pane (the middle pane), select the `Simulink.NumericType` object `u8En7`. This object represents one of the primitive typedef statements in `ex_inter_types.h`.

In the ICD, select the **Numeric Types** tab.
Use the Model Explorer Dialog pane (the right pane) to configure the object according to the ICD.

Use the Model Explorer to configure the other Simulink.NumericType objects. You can use the Contents pane to perform batch operations.

In the Contents pane, click the Simulink.Bus object EngSensors. This object represents the structure type that ex_inter_types.h defines.

In the Dialog pane (the right pane), click Launch Bus Editor.

In the ICD, select the Structure Types tab.

Use the Bus Editor to configure the bus object and the signal elements in the bus (such as throttle) according to the ICD.

In the ICD, select the Enumerated Types tab.

In the Model Explorer Contents pane, click the enumerated type definition sldemo_FuelModes.

Use the Dialog pane to configure the type according to the ICD. Set Storage Type to Native Integer and Data Scope to Exported.

**Generate and Inspect Code**

Configure the controller model to compile the generated code into an executable by clearing the model configuration parameter Generate code only.

Generate code from the controller model.

```cpp
### Starting build procedure for model: sldemo_fuelsys_dd_controller
### Successful completion of build procedure for model: sldemo_fuelsys_dd_controller

The generated header file sldemo_FuelModes.h defines the enumeration sldemo_FuelModes.

typedef enum {
    LOW = 1, /* Default value */
    RICH,
    DISABLED
} sldemo_FuelModes;
```
The file `sldemo_fuelsys_dd_controller_types.h` includes (#include) the external header file `ex_inter_types.h`, which defines data types such as `u8En7` and the structure type `EngSensors`.

```cpp
#include "ex_inter_types.h"
```

The file `sldemo_fuelsys_dd_controller_private.h` includes the header file `ex_inter_sigs.h`. This external header file contains the extern declaration of the signal `sensors`, which a different software component owns.

The data header file `global_data.h` declares the exported parameters and signals that the ICD specifies. To share this data, other components can include this header file.

```cpp
/* Exported data declaration */

/* Declaration for custom storage class: ExportToFile */
extern u8En7 PressEst[855];
extern s16En15 PumpCon[551];
extern s16En15 RampRateKiZ[25];
extern s16En3 SpeedEst[1305];
extern s16En7 ThrotEst[551];
extern sldemo_FuelModes fuel_mode;
extern s16En7 fuel_rate;
```

The data definitions (memory allocation) appear in the source files that the ICD specifies: `params.c` and `signals.c`. For example, `params.c` defines and initializes the parameter `RampRateKiZ`.

```cpp
s16En15 RampRateKiZ[25] = { 393, 786, 1180, 1573, 1966, 786, 1573, 2359, 3146, 3932, 1180, 2359, 3539, 4719, 5898, 1573, 3146, 4719, 6291, 7864, 1966, 3932, 5898, 7864, 9830 };
```

The algorithm is in the model step function in the file `sldemo_fuelsys_dd_controller.c`. The algorithm uses the global data that the ICD identifies. For example, the algorithm uses the value of the signal `fuel_mode` in a switch block to control the flow of execution.

```cpp
/* SwitchCase: '<S10>/Switch Case' */
switch (fuel_mode) {
    case LOW:
```
/* Outputs for IfAction SubSystem: '<S10>/low_mode' incorporates: */
 *  ActionPort: '<S12>/Action Port' */

/* DiscreteFilter: '<S12>/Discrete Filter' incorporates: */
 *  DiscreteIntegrator: '<S1>/Discrete Integrator' */

DiscreteFilter_tmp = (int16_T)(int32_T)((int32_T)((int32_T)
 rtDWork.DiscreteIntegrator_DSTATE << 14) - (int32_T)(-12137 * (int32_T)
 rtDWork.DiscreteFilter_states_g)) >> 14);

Configure Generated Code According to Interface Control Document

Import specifications from an interface control document (ICD), configure code generation settings for a model according to the specifications, and store the settings in data dictionaries.

An ICD describes the data interface between two software components. To exchange and share data, the components declare and define global variables that store signal and parameter values. The ICD names the variables and lists characteristics such as data type, physical units, and parameter values. When you create models of the components in Simulink, you can configure the generated code to conform to the interface specification.

In this example, the ICD is a Microsoft® Excel® workbook.

Explore Interface Control Document

Navigate to the folder `matlabroot/examples/ecoder` (open). Copy this file to a writable, working folder:

- `ex_ICD_PCG.xls`

Navigate to the folder `matlabroot/examples/ecoder/main` (open). Copy this file to the same writable, working folder:

- `ex_importICD_PCG.m`

In Microsoft® Excel® or another compatible program, open the `ex_ICD_PCG.xls` workbook and view the first worksheet, Signals. Each row of the worksheet describes a signal that crosses the interface boundary.

Inspect the cell values in the worksheet. The Owner column indicates the name of the component that allocates memory for each signal. The DataType column indicates the signal data type in memory. For example, the worksheet uses the expression `Bus: EngSensors` to represent a structure type named `EngSensors`.

In the Parameters worksheet, the Value column indicates the value of each parameter. If the value of the parameter is nonscalar, the value is stored in its own separate worksheet, which has the same name as the parameter.

In the Numeric Types worksheet, each row represents a named numeric data type. In this ICD, the data use fixed-point data types (Fixed-Point Designer). The IsAlias column
indicates whether the C code uses the name of the data type (for example, u8En7) or uses the name of the primitive integer data type that corresponds to the word length. The DataScope column indicates whether the generated code exports or imports the definition of the type.

In the Structure Types worksheet, each row represents either a structure type or a field of a structure type. For structure types, the value in the DataType column is struct. Subsequent rows that do not use struct represent fields of the preceding structure type. This ICD defines a structure type, EngSensors, with four fields: throttle, speed, ego, and map.

In the Enumerated Types worksheet, similar to the Structure Types worksheet, each row represents either an enumerated type or an enumeration member. This ICD defines an enumerated type sldemo_FuelModes.

**Write External Code**

Some data items in the ICD belong to other component, which is a component that exists outside of MATLAB. Create the code files that define and declare this external data.

Create the source file ex_inter_sigs.c in your current folder. This file defines the imported signal sensors.

```c
#include "ex_inter_sigs.h"

EngSensors sensors; /* Instrument measurements. */
```

Create the header file ex_inter_sigs.h in your current folder.

```c
#include "ex_inter_types.h"

extern EngSensors sensors; /* Instrument measurements. */
```

Create the header file ex_inter_types.h in your current folder. This file defines the structure type EngSensors and numeric data types such as u8En7.

```c
#ifndef INTER_TYPES_H_
#define INTER_TYPES_H_

typedef short s16En3;
```

```c
#endif
```
typedef short s16En7;

typedef unsigned char u8En7;

typedef short s16En15;

/* Structure type for instrument measurements. */
typedef struct {
    /* Throttle angle. */
    s16En3 throttle;

    /* Engine speed. */
    s16En3 speed;

    /* EGO sensors. */
    s16En7 ego;

    /* Manifold pressure. */
    u8En7 map;
} EngSensors;

#endif

Explore Example Model

Run the script `prepare_sldemo_fuelsys_dd`. The script prepares a system model, `sldemo_fuelsys_dd`, for this example.

`run(fullfile(matlabroot,'examples','ecoder','main','prepare_sldemo_fuelsys_dd'))`

Open the system model, `sldemo_fuelsys_dd`.

`sldemo_fuelsys_dd`
This system model references a controller model. In this example, you generate code from the controller model.

Open the controller model, sldemo_fuelsys_dd_controller.

sldemo_fuelsys_dd_controller
Data items in the controller model refer to `Simulink.Signal` and `Simulink.Parameter` objects in the base workspace. For example, the input signal `sensors` refers to a `Simulink.Signal` object that has the same name. These objects store settings such as data types, block parameter values, and physical units. The names of these data items and objects match the names of the signals and parameters in the ICD.

**Import ICD Specifications into Simulink**

To configure code generation settings for the data items, import the settings from the ICD.

Open the example script `ex_importICD_PCG`. The script imports the data from each worksheet of the ICD into variables in the base workspace. It then configures the properties of the `Simulink.Signal` and `Simulink.Parameter` objects in the base workspace by using the imported data.

```
edit('ex_importICD_PCG')
```

If the base workspace already contains a data object that corresponds to a target data item in the ICD, the script configures the properties of the existing object. If the object does not exist, the script creates the object.

Run the `ex_importICD_PCG` script.
run('ex_importICD_PCG')

The script configures the data objects in the base workspace for code generation according to the specifications in the ICD. The Simulink.Bus object EngSensors represents the structure type from the ICD. The Simulink.NumericType objects, such as u8En7, represent the fixed-point data types.

ans =

'Cannot redefine enumerated type sldemo_FuelModes because open models and existing

**Generate and Inspect Code**

Configure the controller model to compile the generated code into an executable by clearing the model configuration parameter **Generate code only**.

Generate code from the controller model.

```
### Starting build procedure for model: sldemo_fuelsys_dd_controller
### Successful completion of build procedure for model: sldemo_fuelsys_dd_controller
```

The generated header file sldemo_FuelModes.h defines the enumeration sldemo_FuelModes.

```c
typedef enum {
    LOW = 1,                             /* Default value */
    RICH,
    DISABLED
} sldemo_FuelModes;
```

The file sldemo_fuelsys_dd_controller_types.h includes (#include) the external header file ex_inter_types.h, which defines data types such as u8En7 and the structure type EngSensors.

```c
#include "ex_inter_types.h"
```

The file sldemo_fuelsys_dd_controller_private.h includes the header file ex_inter_sigs.h. This external header file contains the extern declaration of the signal sensors, which a different software component owns.
The data header file `global_data.h` declares the exported parameters and signals that the ICD specifies. To share this data, other components can include this header file.

/* Exported data declaration */

/* Declaration for custom storage class: ExportToFile */
extern u8En7 PressEst[855];            /* Lookup table to estimate pressure on sensor failure. */
extern s16En15 PumpCon[551];           /* Lookup table to determine pumping constant based on measured engine speed and manifold pressure. */
extern s16En15 RampRateKiZ[25];        /* Lookup table to determine throttle rate. */
extern s16En3 SpeedEst[1305];          /* Lookup table to estimate engine speed on sensor failure. */
extern s16En7 ThrotEst[551];           /* Lookup table to estimate throttle angle on sensor failure. */
extern sldemo_FuelModes fuel_mode;     /* Fueling mode of engine. Enrich air/fuel mixture on sensor failure. */
extern int16_T fuel_rate;              /* Fuel rate setpoint. */

The data definitions (memory allocation) appear in the source files that the ICD specifies, `params.c` and `signals.c`. For example, `params.c` defines and initializes the parameter `RampRateKiZ`.

s16En15 RampRateKiZ[25] = { 393, 786, 1180, 1573, 1966, 786, 1573, 2359, 3146, 3932, 1180, 2359, 3539, 4719, 5898, 1573, 3146, 4719, 6291, 7864, 1966, 3932, 5898, 7864, 9830 } ;                 /* Lookup table to determine throttle rate. */

The algorithm is in the model step function in the file `sldemo_fuelsys_dd_controller.c`. The algorithm uses the global data that the ICD identifies. For example, the algorithm uses the value of the signal `fuel_mode` in a switch block to control the flow of execution.

/* SwitchCase: '<S10>/Switch Case' incorporates:
 *  Constant: '<S11>/shutoff'
 */
switch (fuel_mode) {
    case LOW:
        /* Outputs for IfAction SubSystem: '<S10>/low_mode' incorporates:
         *  ActionPort: '<S12>/Action Port'
        */
        /* DiscreteFilter: '<S12>/Discrete Filter' incorporates:
         *  DiscreteIntegrator: '<S1>/Discrete Integrator'
        */
        DiscreteFilter_tmp = (int16_T)(int32_T)((int32_T)((int32_T)(rtDWork.DiscreteIntegrator_DSTATE << 14) - (int32_T)(-12137 * (int32_T)rtDWork.DiscreteFilter_states_g)) >> 14);
        
        Configure Generated Code According to Interface Control Document
26-89
Change Ownership of Data in ICD

When you make changes to the ICD, you can reuse the `ex_importICD_PCG` script to reconfigure the model. Change the ownership of the signal sensors, the structure type, and the fixed-point data types from `other_component` to `sldemo_fuelsys_dd_controller`.

In the ICD, on the `signals` worksheet, for the signal `sensors`, set these cell values:

- **Owner** to `sldemo_fuelsys_dd_controller`
- **HeaderFile** to `global_data.h`
- **DefinitionFile** to `signals.c`

On the `Numeric Types` worksheet, for all of the fixed-point data types, set:

- **DataScope** to `Exported`
- **HeaderFile** to `exported_types.h`.

On the `Structure Types` worksheet, for the structure type `EngSensors`, set:

- **DataScope** to `Exported`
- **HeaderFile** to `exported_types.h`.

Rerun the `ex_importICD_PCG` script.

```ans = 'Cannot redefine enumerated type sldemo_FuelModes because open models and existing'```

Generate code from the model.

```#
### Starting build procedure for model: sldemo_fuelsys_dd_controller
### Successful completion of build procedure for model: sldemo_fuelsys_dd_controller
```

The generated file `exported_types.h` defines the structure type `EngSensors` and the fixed-point data types.

```
typedef int16_T s16En3;
typedef int16_T s16En7;
typedef uint8_T u8En7;
```
/* Structure type for instrument measurements. */
typedef struct {
    s16En3 throttle;
    s16En3 speed;
    s16En7 ego;
    u8En7 map;
} EngSensors;

typedef int16_T s16En15;

The file signals.c now includes the definition of the signal sensors.

/* Exported data definition */

/* Definition for custom storage class: ExportToFile */
sldemo_FuelModes fuel_mode;            /* Fueling mode of engine. Enrich air/fuel mixture on sensor failure. */
int16_T fuel_rate;                     /* Fuel rate setpoint. */
EngSensors sensors;                    /* Instrument measurements. */

Migrate Base Workspace Data to Data Dictionary

Objects and variables that you create in the base workspace (for example, Simulink.Parameter objects) are not saved with the model. When you end your MATLAB session, the objects and variables do not persist. To permanently store the objects and variables, link one or more models to one or more data dictionaries.

Data dictionaries also enable you to track changes made to the objects and variables, which helps you to:

• Reconcile the data stored in MATLAB with the data stored in the ICD.
• Export data from MATLAB to the ICD.

1 In the top model, sldemo_fuelsys_dd, select File > Model Properties > Link to Data Dictionary.
2 In the Model Properties dialog box, select Data Dictionary. Click New.
3 In the Create a new Data Dictionary dialog box, set File name to sysDict and click Save.
4 In the Model Properties dialog box, click OK.
5 Click OK in response to the message about migrating referenced variables.
6 Click Yes in response to the message about removing the imported items from the base workspace.

7 Click OK in response to the message about enumerated type migration.

The variables and objects that the models use all exist in the new data dictionary `sysDict.sldd`, which is in your current folder. All three models in the model reference hierarchy are linked to this dictionary.

**Create Reference Dictionary**

To establish clear ownership of the data that you store in a dictionary, create reference dictionaries.

1. Open the controller model, `sldemo_fuelsys_dd_controller`. Select **File > Model Properties > Link to Data Dictionary**. Click **New**.

2. Set the name of the new dictionary to `ctrlDict.sldd` and click **Save**. In the Model Properties dialog box, click **OK**.

3. In response to the message about changing the dictionary or moving the data, click **Move Data**. Click Yes in response to the message about migrating data.

The variables and objects that the controller model uses now exist in the referenced dictionary `ctrlDict.sldd`. Because `sysDict.sldd` references `ctrlDict.sldd`, you can view all of the data by opening `sysDict.sldd` in the Model Explorer.

Now that the model data acquire code generation settings from objects and variables that are stored in data dictionaries, you can modify the `ex_importICD_PCG` script so it accesses the dictionaries instead of the base workspace. For more information about the programmatic interface for data dictionaries, see “Store Data in Dictionary Programmatically” (Simulink).

**Store Enumerated Type Definition in Data Dictionary**

You can import the definition of the enumerated type `sldemo_FuelModes` into the controller dictionary. See “Enumerations in Data Dictionary” (Simulink).

**Store Signal and State Design Attributes Inside or Outside of Model File**

In this example, you use `Simulink.Signal` objects to specify design attributes such as data types, minimum and maximum values, and physical units. The signal objects store these specifications outside of the model file.
Alternatively, you can store these specifications in the model file by using block and port parameters, which you can access through the Model Data Editor, the Property Inspector, and other dialog boxes.

To decide where to store the specifications, see “Store Design Attributes of Signals and States” (Simulink).

Generate Local Variables with Localizable Custom Storage Class

For signals, if possible, generate variables that are local to functions rather than in global storage. Generating local variables prevents the code generator from implementing optimizations that remove these variables from the generated code. Local variables improve observability, readability, and are helpful in debugging the generated code.

Minimizing the use of global variables by using local variables interacts with stack usage control. For example, stack size can determine the number of local and global variables that the code generator can allocate in the generated code. For more information, see “Customize Stack Space Allocation” (Simulink Coder).

Example Model

The model `rtwdemo_localizable_csc` contains two signals that have a Localizable custom storage class. In the Latching subsystem, the signal with the label Latch has a Localizable custom storage class. In the Debug subsystem, the signal with the label Debug has a Localizable custom storage class.
Generate Code with Localizable Storage Class

1. Open the model.

   ```matlab
   model='rtwdemo_localizable_csc';
   open_system(model);
   ```

2. To observe the specification, for each signal, open the Signal Properties dialog box and select the **Code Generation** tab. The **Signal object class** parameter is set to
Simulink.Signal. The **Storage class** parameter is set to **Localizable (Custom)**.

3 Build the model. The **Debug_b** function contains this code:

```c
static void Debug_b(const real_T rtu_In1[6], const real_T rtu_In2[6], real_T rtd_A[6])
{
    real_T Debug;
    int32_T i;
    for (i = 0; i < 6; i++) {
        Debug = rtu_In1[i] * rtu_In2[i];
        rtd_A[i] += Debug;
    }
}
```

The **Latching** function contains this code:

```c
static void Latching(const real_T rtu_In1[36], real_T rty_Out1[6], real_T rty_Out2[6], real_T rtd_A[6])
{
    real_T Latch[6];
    int32_T i;
    int32_T i_0;
    for (i = 0; i < 6; i++) {
        rty_Out2[i] = -rtd_A[i];
        Latch[i] = rtd_A[i];
    }

    for (i = 0; i < 6; i++) {
        rty_Out1[i] = 0.0;
        for (i_0 = 0; i_0 < 6; i_0++) {
            rty_Out1[i] += rtu_In1[6 * i_0 + i] * Latch[i_0];
        }
    }
}
```

Both functions contain variables for holding intermediate values. The **Debug_b** function contains the variable **Debug**. The **Latching** function contains the variable **Latch**.

### Generate Code Without Localizable Storage Class

1 Change the signal storage class from **Localizable** to **ExportToFile**. For each signal, open the **Signal Properties** dialog box. On the **Code Generation** tab, for the **Storage class** parameter, select **ExportToFile**. The **rtw.demo_localizable_csc.c** file contains these two global variable declarations:

```c
real_T Debug[6];
real_T Latch[6];
```

The **Debug_b** function contains this code:
static void Debug_b(const real_T rtu_In1[6], const real_T rtu_In2[6], real_T rtd_A[6])
{
    int32_T i;
    for (i = 0; i < 6; i++) {
        Debug[i] = rtu_In1[i] * rtu_In2[i];
        rtd_A[i] += Debug[i];
    }
}

The Latching function contains this code:

static void Latching(const real_T rtu_In1[36], real_T rty_Out1[6], real_T rty_Out2[6], real_T rtd_A[6])
{
    int32_T i;
    int32_T i_0;
    for (i = 0; i < 6; i++) {
        Latch[i] = rtd_A[i];
        rty_Out2[i] = -Latch[i];
    }
    for (i = 0; i < 6; i++) {
        rty_Out1[i] = 0.0;
        for (i_0 = 0; i_0 < 6; i_0++) {
            rty_Out1[i] += rtu_In1[6 * i_0 + i] * Latch[i_0];
        }
    }
}

The code readability and observability is the same as with the Localizable storage class specification except the labeled signals are global variables.

2 Remove the Debug and Latch labels. Build the model. The Debug_b function contains this code:

static void Debug(const real_T rtu_In1[6], const real_T rtu_In2[6], real_T rtd_A[6])
{
    int32_T i;
    for (i = 0; i < 6; i++) {
        rtd_A[i] += rtu_In1[i] * rtu_In2[i];
    }
}

The Latching function contains this code:

static void Latching(const real_T rtu_In1[36], real_T rty_Out1[6], real_T rty_Out2[6], real_T rtd_A[6])
{
    int32_T i;
    int32_T i_0;
    for (i = 0; i < 6; i++) {
        rty_Out2[i] = -rtd_A[i];
        rty_Out1[i] = 0.0;
        for (i_0 = 0; i_0 < 6; i_0++) {
            rty_Out1[i] += rtu_In1[6 * i_0 + i] * rtd_A[i_0];
        }
    }
}
Without the `Localizable` or `ExportToFile` custom storage classes, the code generator removes the `Debug` and `Latch` variables. Without these variables, the readability and observability of the generated code decreases.

**Additional Information**

- For the code generator to localize signals with the `Localizable` Custom storage class specification, in the Configuration Parameters dialog box, you must select the `Enable Local Block Outputs` parameter. This parameter is on by default.
- You can specify the same `Localizable` storage class on two signals that are in different reusable subsystems. Therefore, you can create a library block from a reusable subsystem with a `Localizable` custom storage class specification.
- The code generator does not create a local variable for a signal that must stay global. A few cases in which the code generator can not localize a signal are:
  - Input and output signals of a Nonreusable subsystem even when the `Function interface` parameter is set to `Allow arguments`.
  - Signal is holding a state because its receiver and drive blocks execute at different rates.
  - `Localizable` specification is on a signal that crosses the boundary of a conditionally executed subsystem.

Data Object Wizard in Embedded Coder
Create Data Objects for Code Generation with Data Object Wizard

To specify code generation options for signal lines, block parameters, and states in a model, you can use data objects that you store in a workspace or data dictionary. For basic information about data objects, see “Data Objects” (Simulink).

You can use the Data Object Wizard to create data objects for:

- New or existing models that do not use data objects.
- Existing models to which you have added signal lines or blocks.

This example shows how to use the Data Object Wizard to create and configure data objects for code generation from the built-in package Simulink.

**Create Data Objects**

Open the example model rtwdemo_basicsc.

```matlab
open_system('rtwdemo_basicsc')
```
The model creates numeric variables in the base workspace. Blocks in the model use these variables to set parameter values (such as the Gain parameter of a Gain block). Some of the signals and block states in the model have explicit names, such as input1.

In the model, select Code > Data Objects > Data Object Wizard.
Data Object Wizard

Find model data that are not associated with data objects and create objects for these data.

Object Name

Class

Model name: rtwdemo_basicsc

Find options
- Root inputs
- Root outputs
- States
- Data stores
- Block outputs
- Parameters
- Alias types

Select All Deselect All Change Class

Find Create Cancel Help
In the Data Object Wizard, click **Find**. The wizard proposes the creation of `Simulink.Parameter` objects to replace the variables and the creation of `Simulink.Signal` objects to represent the signals and states.
The wizard finds only signals, parameters, data stores, and states whose storage class is set to Auto. For example, if you use the Signal Properties dialog box to specify a storage class other than Auto for a signal line, the wizard does not propose a data object.

Click Select All.

Click Create. The data objects appear in the base workspace.

For detailed information about the options that you can choose in the Data Object Wizard, see “Create Data Objects for a Model Using Data Object Wizard” (Simulink).

**Set Storage Class for Data Objects**

Storage classes determine how the generated code uses variables to represent signals, parameters, and states. For data objects from the built-in package Simulink, the default storage class is Auto. To specify storage classes for the new data objects, you can use the Model Explorer.

Open the Model Explorer.

In the Model Hierarchy pane, select Base Workspace.
In the Contents pane, from the drop-down list Column View, select Storage Class.

Select all of the new data objects. For example, select the object input1, hold Shift, and select the object X.

Set the property StorageClass for all of the data objects to ExportToFile. To change the storage class for all of the selected objects, in the StorageClass column, click any of the objects. In the drop-down list, select ExportToFile. The change that you make propagates to all of the selected objects.

Specify the HeaderFile property for all of the objects as myExportedHdrFile.h.
In the model, set **Configuration Parameters > Code Generation > System target file** to `ert.tlc`. With this setting, the code generator honors custom storage classes such as `ExportToFile`.

**Generate and Inspect Code**

Generate code from the model.

```plaintext
### Starting build procedure for model: rtwdemo_basicsc
### Successful completion of build procedure for model: rtwdemo_basicsc
```

In the code generation report, view the generated file `myExportedHdrFile.h`. The file contains `extern` declarations for the global variables that correspond to the data objects.

```c
/* Exported data declaration */
/* Declaration for custom storage class: ExportToFile */
extern int8_T K1;
extern real_T K2;
extern real32_T LOWER;
extern real32_T T1Break[11];
extern real32_T T1Data[11];
extern real32_T T2Break[3];
extern real32_T T2Data[9];
extern real32_T UPPER;
extern real32_T X;
extern real32_T input1;
extern real32_T input2;
extern real32_T input3;
extern real32_T input4;
extern boolean_T mode;
extern real32_T output;
```

View the file `rtwdemo_basicsc.c`. The file contains the definitions for the global variables. The code assigns numeric values for the variables that correspond to parameter objects.

```c
/* Exported data definition */
/* Definition for custom storage class: ExportToFile */
int8_T K1 = 2;
real_T K2 = 3.0;
```
real32_T LOWER = -10.0F;
real32_T T1Break[11] = { -5.0F, -4.0F, -3.0F, -2.0F, -1.0F, 0.0F, 1.0F, 2.0F,
                       3.0F, 4.0F, 5.0F } ;

real32_T T1Data[11] = { -1.0F, -0.99F, -0.98F, -0.96F, -0.76F, 0.0F, 0.76F,
                       0.96F, 0.98F, 0.99F, 1.0F } ;

real32_T T2Break[3] = { 1.0F, 2.0F, 3.0F } ;

real32_T T2Data[9] = { 4.0F, 16.0F, 10.0F, 5.0F, 19.0F, 18.0F, 6.0F, 20.0F,
                      23.0F } ;

real32_T UPPER = 10.0F;
real32_T X;
real32_T input1;
real32_T input2;
real32_T input3;
real32_T input4;
boolean_T mode;
real32_T output;

Configure Code Generation for Model Entry-Point Functions

What Is an Entry-Point Function?

An entry point is a location in code where a transfer of program control (execution) occurs. The main function (main()) is the entry point to a C/C++ program and is called when the application starts executing. Calls to other functions, for example from the main function, provide entry points to function code. Program control is transferred to the called function. The function code executes, and when finished, returns control to the main or other calling function.

When producing code for a model, the code generator defines a set of entry-point functions that you can call to execute the generated code. You can call the generated functions from external code or from a version of the generated main function that you modify.

The Code Interface Report section of the code generation report lists the entry-point functions that the code generator produces for a model. For more information, see “Analyze the Generated Code Interface” on page 38-19.

Categories and Types of Generated Entry-Point Functions

The entry-point functions that the code generator produces for a model and the calling interface for the functions depends on whether the model is:

- Rate-based or is an export-function model
- Configured for reusable, multi-instance code generation

Depending on the style and configuration of a model, the code generator produces one or more of these entry-point functions.

**Configure Whether Entry-Point Functions Are Reusable**

By default, for top models, the code generator produces code that is not reusable or reentrant. Entry-point functions have a void-void interface. Code communicates with other code by directly accessing global data structures that reside in shared memory.
If your application requires reusable, multi-instance entry-point function code, you can configure the code generator to call each function (instance) with unique data. In this case, the code is reentrant.

You configure whether entry-point functions are reusable with the model configuration parameter “Code interface packaging” (Simulink Coder) and related parameters. The parameter settings that you choose depend on factors such as configuration selections for the system target file, programming language, and argument interface.

**Default Configurations for Single-Instance C Entry-Point Functions**

By default, for GRT- and ERT-based system target files, the code generator produces single-instance C entry-point functions. The generated code:

- Creates an execution function with no arguments (void).
- Allocates memory statically (at compile time) for model data structures.

The default model configuration parameter settings for configuring single-instance entry-point function code are:

- “Language” (Simulink Coder) set to C.
- “Code interface packaging” (Simulink Coder) set to Nonreusable function.

**Generate Reusable, Multi-Instance C Entry-Point Functions**

You can configure the code generator to produce reusable entry-point functions in C for either a GRT- or ERT-based system target file. However, the function interfaces that the code generator produces by default varies. Assuming that model configuration parameter “Language” (Simulink Coder) is set to C and “Code interface packaging” (Simulink Coder) is set to Reusable function, the code generator produces this entry-point function code for each system target file scenario.
If you are using an ERT-based system target file and want to generate reusable, multi-instance C entry-point functions that are reentrant, set “Language” (Simulink Coder) to C and set “Code interface packaging” (Simulink Coder) to Reusable function. Also consider:

- Using dynamic memory allocation to initialize model data structures. Select “Use dynamic memory allocation for model initialization” (Simulink Coder).
- Packing values of model root-level Inport blocks into a structure, packing values of root-level Outport blocks into a second structure, and passing the structures to the execution function as arguments by reference. Set “Pass root-level I/O as” (Simulink Coder) to Structure reference.
- Packing values of model root-level Inport blocks and Output blocks into the real-time model data structure and passing that structure to the execution function as an argument by reference. Set “Pass root-level I/O as” (Simulink Coder) to Part of model data structure.

**Generate Reusable, Multi-Instance C++ Entry-Point Functions**

The C++ class interface encapsulates model data as class properties and entry-point functions as class methods. That interface is available for use with ERT-based system
target files. To use the interface, set “Language” (Simulink Coder) to C++ and set “Code interface packaging” (Simulink Coder) to C++ class. You can:

- Preview and customize the C++ class interface by clicking “Configure C++ Class Interface” (Simulink Coder). Customization means that you can generate code for integration with external code and, if necessary, make sure that the code complies with coding standards.

- Configure the visibility of class inheritance by specifying whether to generate the block parameter structure as a public, private, or protected data member. Set “Parameter visibility” (Simulink Coder) to public, private, or protected.

- Generate C++ interface code for model block parameters that meet code performance or tunability requirements. The code can be noninlined or inlined access methods. Set “Parameter access” (Simulink Coder) to Method or Inlined method.

- Generate C++ interface code for model root-level Inport and Outport blockset that meets code performance, data tunability, or data packaging requirements. The code can be one of these types of access methods.

<table>
<thead>
<tr>
<th>For Access Method Type</th>

<td>Inlined structure-based method</td>
</tr>
</tbody>
</table>

**Configure Generated Entry-Point Function Declarations**

Depending on application requirements, such as integration or compliance with code standards, you might need to configure how the code generator produces declarations for entry-point functions. Embedded Coder provides multiple configuration options.

- Apply a default function naming rule to a category of functions across a model. For example, a default naming rule can produce a model_step function for each rate in the multi-rate model. In the Code Mapping Editor, map a function category to a function customization template that is defined to use the function naming rule (see Code Mapping Editor). If necessary, you can override the default naming of function by using function prototype control (see “Customize Generated C Function Interfaces” on page 29-2 or “Customize Generated C++ Class Interfaces” on page 29-36).
• Configure a specific entry-point function interface, including function and argument naming, use of C type qualifiers (for example, const), and argument order. See “Generate Reusable, Multi-Instance C Entry-Point Functions” on page 28-4 and “Generate Reusable, Multi-Instance C++ Entry-Point Functions” on page 28-5.

**Configure Placement of Entry-Point Functions in Memory**

If your application requires that you configure the placement of entry-point functions in memory, for example, to optimize the generated code for specific hardware, you can apply a default memory section to a category of functions across a model. In the Code Mapping Editor, map a function category to a function customization template that is defined to use a specific memory section. See Code Mapping Editor.

**How to Interface with Generated Entry-Point Functions**

1. After generating code for a model, open and review the Code Interface Report. The report lists the generated entry-point functions and, if applicable, variables representing external input and output ports.

2. Add `#include` statements to your external code that include the generated header files that declare the model entry-point functions.

3. Add an `#include` statement that includes the generated file `rtwtypes.h`. This file provides necessary type definitions, `#define` statements, and enumerations.

4. Initialize target-specific data structures and hardware, such as ADCs or DACs.

5. If applicable, initialize data for each instance of a reusable model.

6. If applicable, write input data to generated variables that represent model Inport blocks.

7. Call the generated entry-point functions or, if appropriate, set up use of the `rt_OneStep` function.

8. If applicable, read data from generated variables that represent model Outport blocks.

Generate C++ Class Interface to Model or Subsystem Code

On the Configuration Parameters dialog box, set the **Code Generation > Interface** “Code interface packaging” (Simulink Coder) parameter to C++ class for generating a C++ class interface to model code. The generated interface encapsulates required model data into C++ class attributes and model entry point functions into C++ class methods. The benefits of C++ class encapsulation include:

- Greater control over access to model data
- Ability to create multiple instances of model classes
- Easier integration of model code into C++ programming environments

C++ class encapsulation also works for right-click builds of nonvirtual subsystems. (For information on requirements that apply, see “Generate C++ Class Interface to Nonvirtual Subsystem Code” on page 28-10.)

**Generate C++ Class Interface to Model Code**

To generate encapsulated C++ class code from a GRT-based model:

1. Set the Configuration Parameters dialog box parameter **Code Generation > Language** to C++. This selection also enables C++ class code interface packaging for the model.

2. On the **Code Generation > Interface** pane, verify that the parameter **Code interface packaging** (Simulink Coder) is set to C++ class.

3. Examine the setting of **Multi-instance code error diagnostic** (Simulink Coder). Leave the parameter at its default value **Error** unless you need to alter the severity level for diagnostics displayed when a model violates requirements for generating multi-instance code.

4. Generate code for the model.

5. Examine the C++ model class code in the generated files `model.h` and `model.cpp`. For example, the following code excerpt from the H file generated for the example
model rtwdemo_secondOrderSystem shows the C++ class declaration for the model.

```cpp
/* Class declaration for model rtwdemo_secondOrderSystem */
class rtwdemo_secondOrderSystemModelClass {
    /* public data and function members */
    public:
        /* External outputs */
        ExtY_rtwdemo_secondOrderSyste_T rtwdemo_secondOrderSystem_Y;

        /* Model entry point functions */
        /* model initialize function */
        void initialize();

        /* model step function */
        void step();

        /* model terminate function */
        void terminate();

        /* Constructor */
        rtwdemo_secondOrderSystemModelClass();

        /* Destructor */
        ~rtwdemo_secondOrderSystemModelClass();

        /* Real-Time Model get method */
        RT_MODEL_rtwdemo_secondOrderS_T * getRTM();
};
```

For more information about generating and calling model entry-point functions, see “Configure Code Generation for Model Entry-Point Functions” (Simulink Coder).

**Note** If you have an Embedded Coder license and you have selected an ERT target for your model, use additional **Code Generation > Interface** pane parameters to customize the generated C++ class interface.

### Generate C++ Class Interface to Nonvirtual Subsystem Code

You can generate C++ class interfaces for right-click builds of nonvirtual subsystems in Simulink models, if the following requirements are met:

- The model is configured for the C++ language and C++ class code interface packaging.
• The subsystem is convertible to a Model block using the function
Simulink.SubSystem.convertToModelReference. For referenced model
conversion requirements, see the Simulink reference page
Simulink.SubSystem.convertToModelReference.

To configure C++ class interfaces for a subsystem that meets the requirements:

1. Open the containing model and select the subsystem block.
2. Right-click the subsystem and select **C/C++ Code > Build This Subsystem**.
3. When the subsystem build completes, examine the C++ class interfaces in the
generated files and the HTML code generation report. For more information about
generating and calling model entry-point methods, see “Configure Code Generation
for Model Entry-Point Functions” (Simulink Coder).

**Note** If you have an Embedded Coder license and you have selected an ERT target for
your model, you can use the MATLAB command RTW.configSubsystemBuild to
customize the generated C++ class interface to subsystem code.

### C++ Class Interface Limitations

• Among the data exchange interfaces available on the **Interface** pane of the
Configuration Parameters dialog box, only the C API interface is supported for C++
class code generation. If you select **External mode** or **ASAP2 interface**, code
generation fails with a validation error.

• If a model root inport value connects to a Simscape conversion block, you must insert
a Simulink Signal Conversion block between the root inport and the Simscape
conversion block. On the Simulink Signal Conversion block parameter dialog box,
select **Exclude this block from 'Block reduction' optimization**.

• You cannot use a C++ class interface in cases when a referenced model cannot have a
combined output/update function. Cases include a model that
  • Has a continuous sample time
  • Saves states

Execution of Code Generated from a Model

The code generator produces algorithmic code as defined by your model. You can include external (for example, custom or legacy) code in a model by using techniques explained in “Choose an External Code Integration Workflow” (Simulink Coder).

The code generator also provides an interface that executes the generated model code. The interface and model code are compiled together to create an executable program. The next figure shows a high-level object-oriented view of the executable.

The Object-Oriented View of a Real-Time Program

In general, the conceptual design of the model execution driver does not change between the rapid prototyping and embedded style of generated code. The following sections describe model execution for single-tasking and multitasking environments both for simulation (non-real-time) and for real time. For most model code, the multitasking environment provides the most efficient model execution (that is, fastest sample rate).

The following concepts are useful in describing how model code executes.

- **Initialization**: `model_init` initializes the interface code and the model code.
- **ModelOutputs**: Calls blocks in your model that have a sample hit at the current time and has them produce their output. `model_output` can be done in major or minor time steps. In major time steps, the output is a given simulation time step. In minor time steps, the interface integrates the derivatives to update the continuous states.
- **ModelUpdate**: `model_update` calls blocks that have a sample hit at the current point in time and has them update their discrete states or similar type objects.
• **ModelDerivatives**: Calls blocks in your model that have continuous states and has them update their derivatives. `model_derivatives` is only called in minor time steps.

• **ModelTerminate**: `model_terminate` terminates the program if it is designed to run for a finite time. It destroys the real-time model data structure, deallocates memory, and can write data to a file.

### Program Execution

A real-time program cannot require 100% of the CPU time. This requirement provides an opportunity to run background tasks during the free time.

Background tasks include operations such as writing data to a buffer or file, allowing access to program data by third-party data monitoring tools, or using Simulink external mode to update program parameters.

It is important, however, that the program be able to preempt the background task so the model code can execute in real time.

The way the program manages tasks depends on capabilities of the environment in which it operates.

### Program Timing

Real-time programs require careful timing of the task invocations (either by using an interrupt or a real-time operating system tasking primitive) so that the model code executes to completion before another task invocation occurs. The timing includes time to read and write data to and from external hardware.

The next figure illustrates interrupt timing.
**Task Timing**

The sample interval must be long enough to allow model code execution between task invocations.

In the figure above, the time between two adjacent vertical arrows is the sample interval. The empty boxes in the upper diagram show an example of a program that can complete one step within the interval and still allow time for the background task. The gray box in the lower diagram indicates what happens if the sample interval is too short. Another task invocation occurs before the task is complete. Such timing results in an execution error.

Note also that, if the real-time program is designed to run forever (that is, the final time is 0 or infinite so that the while loop never exits), then the shutdown code does not execute.

For more information on how the timing engine works, see “Absolute and Elapsed Time Computation” (Simulink Coder).

**External Mode Communication**

External mode allows communication between the Simulink block diagram and the standalone program that is built from the generated code. In this mode, the real-time program functions as an interprocess communication server, responding to requests from the Simulink engine.
Data Logging in Single-Tasking and Multitasking Model Execution

“Debug” on page 31-34 explains how you can save system states, outputs, and time to a MAT-file at the completion of the model execution. The LogTXY function, which performs data logging, operates differently in single-tasking and multitasking environments.

If you examine how LogTXY is called in the single-tasking and multitasking environments, you will notice that for single-tasking LogTXY is called after ModelOutputs. During this ModelOutputs call, blocks that have a hit at time $t$ execute, whereas in multitasking, LogTXY is called after ModelOutputs($tid=0$), which executes only the blocks that have a hit at time $t$ and that have a task identifier of 0. This results in differences in the logged values between single-tasking and multitasking logging. Specifically, consider a model with two sample times, the faster sample time having a period of 1.0 second and the slower sample time having a period of 10.0 seconds. At time $t = k*10$, $k=0,1,2...$ both the fast ($tid=0$) and slow ($tid=1$) blocks execute. When executing in multitasking mode, when LogTXY is called, the slow blocks execute, but the previous value is logged, whereas in single-tasking the current value is logged.

Another difference occurs when logging data in an enabled subsystem. Consider an enabled subsystem that has a slow signal driving the enable port and fast blocks within the enabled subsystem. In this case, the evaluation of the enable signal occurs in a slow task, and the fast blocks see a delay of one sample period; thus the logged values will show these differences.

To summarize differences in logged data between single-tasking and multitasking, differences will be seen when

- Any root outport block has a sample time that is slower than the fastest sample time
- Any block with states has a sample time that is slower than the fastest sample time
- Any block in an enabled subsystem where the signal driving the enable port is slower than the rate of the blocks in the enabled subsystem

For the first two cases, even though the logged values are different between single-tasking and multitasking, the model results are not different. The only real difference is where (at what point in time) the logging is done. The third (enabled subsystem) case results in a delay that can be seen in a real-time environment.
Non-Real-Time Single-Tasking Systems

The pseudocode below shows the execution of a model for a non-real-time single-tasking system.

\[
\text{main()}
\]
\[
\{
\quad \text{Initialization}
\quad \text{While (time < final time)}
\quad \quad \text{ModelOutputs} \quad \quad \text{-- Major time step.}
\quad \quad \text{LogTXY} \quad \quad \text{-- Log time, states and root outports.}
\quad \quad \text{ModelUpdate} \quad \quad \text{-- Major time step.}
\quad \quad \text{Integrate} \quad \quad \text{-- Integration in minor time step for}
\quad \quad \quad \quad \quad \quad \text{models with continuous states.}
\quad \text{ModelDerivatives}
\quad \text{Do 0 or more}
\quad \quad \text{ModelOutputs}
\quad \quad \text{ModelDerivatives}
\quad \text{EndDo -- Number of iterations depends upon the solver}
\quad \text{Integrate derivatives to update continuous states.}
\quad \text{EndIntegrate}
\quad \text{EndWhile}
\quad \text{Termination}
\}
\]

The initialization phase begins first. This consists of initializing model states and setting up the execution engine. The model then executes, one step at a time. First, \text{ModelOutputs} executes at time \( t \), then the workspace I/O data is logged, and then \text{ModelUpdate} updates the discrete states. Next, if your model has continuous states, \text{ModelDerivatives} integrates the continuous states' derivatives to generate the states for time \( t_{new} = t + h \), where \( h \) is the step size. Time then moves forward to \( t_{new} \) and the process repeats.

During the \text{ModelOutputs} and \text{ModelUpdate} phases of model execution, only blocks that reach the current point in time execute.

Non-Real-Time Multitasking Systems

The pseudocode below shows the execution of a model for a non-real-time multitasking system.

\[
\text{main()}
\]
\[
\{
\}
Initialization
While (time < final time)
  ModelOutputs(tid=0)   -- Major time step.
  LogTXY                -- Log time, states, and root
                      -- outports.
  ModelUpdate(tid=0)   -- Major time step.
  Integrate       -- Integration in minor time step for
                      -- models with continuous states.
  ModelDerivatives
  Do 0 or more
  ModelOutputs(tid=0)
  ModelDerivatives
  EndDo (Number of iterations depends upon the solver.)
  Integrate derivatives to update continuous states.
EndIntegrate
For i=1:NumTids
  ModelOutputs(tid=i) -- Major time step.
  ModelUpdate(tid=i)  -- Major time step.
EndFor
EndWhile
Termination
}

Multitasking operation is more complex than single-tasking execution because the output and update functions are subdivided by the *task identifier* (tid) that is passed into these functions. This allows for multiple invocations of these functions with different task identifiers using overlapped interrupts, or for multiple tasks when using a real-time operating system. In simulation, multiple tasks are emulated by executing the code in the order that would occur if no preemption existed in a real-time system.

Multitasking execution assumes that all task rates are multiples of the base rate. The Simulink product enforces this when you create a fixed-step multitasking model. The multitasking execution loop is very similar to that of single-tasking, except for the use of the task identifier (tid) argument to ModelOutputs and ModelUpdate.

**Note** You cannot use tid values from code generated by a target file and not by Simulink Coder. Simulink Coder tracks the use of tid when generating code for a specific subsystem or function type. When you generate code in a target file, this argument cannot be tracked because the scope does not have subsystem or function type. Therefore, tid becomes an undefined variable and your target file fails to compile.
Real-Time Single-Tasking Systems

The pseudocode below shows the execution of a model in a real-time single-tasking system where the model is run at interrupt level.

```plaintext
rtOneStep()
{
    Check for interrupt overflow
    Enable "rtOneStep" interrupt
    ModelOutputs    -- Major time step.
    LogTXY          -- Log time, states and root outports.
    ModelUpdate    -- Major time step.
    Integrate      -- Integration in minor time step for models
                      -- with continuous states.
                      ModelDerivatives
                      Do 0 or more
                      ModelOutputs
                      ModelDerivatives
                      EndDo (Number of iterations depends upon the solver.)
                      Integrate derivatives to update continuous states.
                      EndIntegrate
}
main()
{
    Initialization (including installation of rtOneStep as an
                    interrupt service routine, ISR, for a real-time clock).
    While(time < final time)
        Background task.
    EndWhile
    Mask interrupts (Disable rtOneStep from executing.)
    Complete any background tasks.
    Shutdown
}
```

Real-time single-tasking execution is very similar to non-real-time single-tasking execution, except that instead of free-running the code, the rt_OneStep function is driven by a periodic timer interrupt.

At the interval specified by the program's base sample rate, the interrupt service routine (ISR) preempts the background task to execute the model code. The base sample rate is the fastest in the model. If the model has continuous blocks, then the integration step size determines the base sample rate.
For example, if the model code is a controller operating at 100 Hz, then every 0.01 seconds the background task is interrupted. During this interrupt, the controller reads its inputs from the analog-to-digital converter (ADC), calculates its outputs, writes these outputs to the digital-to-analog converter (DAC), and updates its states. Program control then returns to the background task. All of these steps must occur before the next interrupt.

**Real-Time Multitasking Systems**

The following pseudocode shows how a model executes in a real-time multitasking system where the model is run at interrupt level.

```plaintext
rtOneStep()
{
    Check for interrupt overflow
    Enable "rtOneStep" interrupt
    ModelOutputs(tid=0)     -- Major time step.
    LogTXY                  -- Log time, states and root outports.
    ModelUpdate(tid=0)      -- Major time step.
    Integrate               -- Integration in minor time step for
    -- models with continuous states.
        ModelDerivatives
    Do 0 or more
        ModelOutputs(tid=0)
        ModelDerivatives
    EndDo (Number of iterations depends upon the solver.)
    Integrate derivatives and update continuous states.
    EndIntegrate
    For i=1:NumTasks
        If (hit in task i)
            ModelOutputs(tid=i)
            ModelUpdate(tid=i)
        EndIf
    EndFor
}
main()
{
    Initialization (including installation of rtOneStep as an
    interrupt service routine, ISR, for a real-time clock).
    While(time < final time)
        Background task.
    EndWhile
}
```
Mask interrupts (Disable rtOneStep from executing.)
Complete any background tasks.
Shutdown

Running models at interrupt level in a real-time multitasking environment is very similar to the previous single-tasking environment, except that overlapped interrupts are employed for concurrent execution of the tasks.

The execution of a model in a single-tasking or multitasking environment when using real-time operating system tasking primitives is very similar to the interrupt-level examples discussed above. The pseudocode below is for a single-tasking model using real-time tasking primitives.

tSingleRate()
{
    MainLoop:
        If clockSem already "given", then error out due to overflow.
        Wait on clockSem
        ModelOutputs            -- Major time step.
        LogTXY                  -- Log time, states and root
                                    -- outports
        ModelUpdate             -- Major time step
        Integrate               -- Integration in minor time step
                                    -- for models with continuous
                                    -- states.
        ModelDerivatives
        Do 0 or more
            ModelOutputs
            ModelDerivatives
        EndDo (Number of iterations depends upon the solver.)
        Integrate derivatives to update continuous states.
        EndIntegrate
    EndMainLoop

main()
{
    Initialization
    Start/spawn task "tSingleRate".
    Start clock that does a "semGive" on a clockSem semaphore.
    Wait on "model-running" semaphore.
    Shutdown
}
In this single-tasking environment, the model executes as real-time operating system tasking primitives. In this environment, create a single task (tSingleRate) to run the model code. This task is invoked when a clock tick occurs. The clock tick gives a clockSem (clock semaphore) to the model task (tSingleRate). The model task waits for the semaphore before executing. The clock ticks occur at the fundamental step size (base rate) for your model.

**Multitasking Systems Using Real-Time Tasking Primitives**

The pseudocode below is for a multitasking model using real-time tasking primitives.

```plaintext
tSubRate(subTaskSem,i)
{
  Loop:
    Wait on semaphore subTaskSem.
    ModelOutputs(tid=i)
    ModelUpdate(tid=i)
  EndLoop
}
tBaseRate()
{
  MainLoop:
    If clockSem already "given", then error out due to overflow.
    Wait on clockSem
    For i=1:NumTasks
      If (hit in task i)
        If task i is currently executing, then error out due to overflow.
        Do a "semGive" on subTaskSem for task i.
      EndIf
    EndFor
    ModelOutputs(tid=0) -- major time step.
    LogTXY -- Log time, states and root outports.
    ModelUpdate(tid=0) -- major time step.
    Loop:
      -- Integration in minor time step for models with continuous states.
      ModelDerivatives
      Do 0 or more
      ModelOutputs(tid=0)
      ModelDerivatives
      EndDo (number of iterations depends upon the solver).
      Integrate derivatives to update continuous states.
  EndLoop
```

28-22
EndMainLoop
}
main()
{
  Initialization
  Start/spawn task "tSubRate".
  Start/spawn task "tBaseRate".
  
  Start clock that does a "semGive" on a clockSem semaphore.
  Wait on "model-running" semaphore.
  Shutdown
}

In this multitasking environment, the model is executed using real-time operating system tasking primitives. Such environments require several model tasks (tBaseRate and several tSubRate tasks) to run the model code. The base rate task (tBaseRate) has a higher priority than the subrate tasks. The subrate task for tid=1 has a higher priority than the subrate task for tid=2, and so on. The base rate task is invoked when a clock tick occurs. The clock tick gives a clockSem to tBaseRate. The first thing tBaseRate does is give semaphores to the subtasks that have a hit at the current point in time. Because the base rate task has a higher priority, it continues to execute. Next it executes the fastest task (tid=0), consisting of blocks in your model that have the fastest sample time. After this execution, it resumes waiting for the clock semaphore. The clock ticks are configured to occur at the fundamental step size for your model.

Rapid Prototyping and Embedded Model Execution Differences

The rapid prototyping program framework provides a common application programming interface (API) that does not change between model definitions.

The Embedded Coder product provides a different framework called the embedded program framework. The embedded program framework provides an optimized API that is tailored to your model. When you use the embedded style of generated code, you are modeling how you would like your code to execute in your embedded system. Therefore, the definitions defined in your model should be specific to your embedded targets. Items such as the model name, parameter, and signal storage class are included as part of the API for the embedded style of code.

One major difference between the rapid prototyping and embedded style of generated code is that the latter contains fewer entry-point functions. The embedded style of code can be configured to have only one function, model_step.
Thus, model execution code eliminates `Loop...EndLoop` statements and groups `ModelOutputs`, `LogTXY`, and `ModelUpdate` into a single statement, `model_step`.

For more information about how generated embedded code executes, see “Configure Code Generation for Model Entry-Point Functions” on page 28-2.

Rapid Prototyping Model Functions

Rapid prototyping code defines the following functions that interface with the main program (main.c or main.cpp):

- **Model()**: The model registration function. This function initializes the work areas (for example, allocating and setting pointers to various data structures) used by the model. The model registration function calls the `MdlInitializeSizes` and `MdlInitializeSampleTimes` functions. These two functions are very similar to the S-function `mdlInitializeSizes` and `mdlInitializeSampleTimes` methods.

- **MdlStart(void)**: After the model registration functions `MdlInitializeSizes` and `MdlInitializeSampleTimes` execute, the main program starts execution by calling `MdlStart`. This routine is called once at startup.

The function `MdlStart` has four basic sections:

- Code to initialize the states for each block in the root model that has states. A subroutine call is made to the “initialize states” routines of conditionally executed subsystems.

- Code generated by the one-time initialization (start) function for each block in the model.

- Code to enable the blocks in the root model that have enable methods, and the blocks inside triggered or function-call subsystems residing in the root model. Simulink blocks can have enable and disable methods. An enable method is called just before a block starts executing, and the disable method is called just after the block stops executing.

- Code for each block in the model whose output value is constant. The block code appears in the `MdlStart` function only if the block parameters are not tunable in the generated code and if the code generator cannot eliminate the block code through constant folding.

- **MdlOutputs(int_T tid)**: `MdlOutputs` updates the output of blocks. The `tid` (task identifier) parameter identifies the task that in turn maps when to execute blocks based upon their sample time. This routine is invoked by the main program during major and minor time steps. The major time steps are when the main program is taking an actual time step (that is, it is time to execute a specific task). If your model contains continuous states, the minor time steps will be taken. The minor time steps are when the solver is generating integration stages, which are points between major outputs. These integration stages are used to compute the derivatives used in advancing the continuous states.
• **MdlUpdate(int_T tid):** MdlUpdate updates the states and work vector state information (that is, states that are neither continuous nor discrete) saved in work vectors. The tid (task identifier) parameter identifies the task that in turn indicates which sample times are active, allowing you to conditionally update only states of active blocks. This routine is invoked by the interface after the major MdlOutputs has been executed. The solver is also called, and model_Derivatives is called in minor steps by the solver during its integration stages. All blocks that have continuous states have an identical number of derivatives. These blocks are required to compute the derivatives so that the solvers can integrate the states.

• **MdlTerminate(void):** MdlTerminate contains any block shutdown code. MdlTerminate is called by the interface, as part of the termination of the real-time program.

The contents of the above functions are directly related to the blocks in your model. A Simulink block can be generalized to the following set of equations.

\[
y = f_0(t, x_c, x_d, u)
\]

Output \(y\) is a function of continuous state \(x_c\), discrete state \(x_d\), and input \(u\). Each block writes its specific equation in a section of MdlOutputs.

\[
x_{d+1} = f_u(t, x_d, u)
\]

The discrete states \(x_d\) are a function of the current state and input. Each block that has a discrete state updates its state in MdlUpdate.

\[
\dot{x} = f_d(t, x_c, u)
\]

The derivatives \(x\) are a function of the current input. Each block that has continuous states provides its derivatives to the solver (for example, ode5) in model_Derivatives. The derivatives are used by the solver to integrate the continuous state to produce the next value.

The output, \(y\), is generally written to the block I/O structure. Root-level Outport blocks write to the external outputs structure. The continuous and discrete states are stored in the states structure. The input, \(u\), can originate from another block's output, which is located in the block I/O structure, an external input (located in the external inputs structure), or a state. These structures are defined in the model.h file that the Simulink Coder software generates.
The next example shows the general contents of the rapid prototyping style of C code written to the *model*.c file.

```c
/*
 * Version, Model options, TLC options,
 * and code generation information are placed here.
 */
#include

void MdlStart(void)
{

  /*
   * State initialization code.
   * Model start-up code - one time initialization code.
   * Execute any block enable methods.
   * Initialize output of any blocks with constant sample times.
   */
}

void MdlOutputs(int_T tid)
{
  /* Compute: y = f0(t,xc,xd,u) for each block as needed. */
}

void MdlUpdate(int_T tid)
{
  /* Compute: xd+1 = fu(t,xd,u) for each block as needed. */

  /* Compute: dxc = fd(t,xc,u) for each block in model_derivatives
     as needed. */
}

void MdlTerminate(void)
{
  /* Perform shutdown code for any blocks that
     have a termination action */
}
```

The next figure shows a flow chart describing the execution of the rapid prototyping generated code.
Rapid Prototyping Execution Flow Chart

Each block places code in specific `Mdl` routines according to the algorithm that it is implementing. Blocks have input, output, parameters, and states, as well as other general items. For example, in general, block inputs and outputs are written to a block I/O structure (`model_B`). Block inputs can also come from the external input structure (`model_U`) or the state structure when connected to a state port of an integrator (`model_X`), or ground (`rtGround`) if unconnected or grounded. Block outputs can also go to the external output structure (`model_Y`). The next figure shows the general mapping between these items.
Data View of the Generated Code

The following list defines the structures shown in the preceding figure:

- **Block I/O structure** (*model_B*): This structure consists of persistent block output signals. The number of block output signals is the sum of the widths of the data output ports of all nonvirtual blocks in your model. If you activate block I/O optimizations, the Simulink and Simulink Coder products reduce the size of the *model_B* structure by
  - Reusing the entries in the *model_B* structure
  - Making other entries local variables

  See “How Generated Code Stores Internal Signal, State, and Parameter Data” (Simulink Coder) for more information on these optimizations.

  Structure field names are determined either by the block's output signal name (when present) or by the block name and port number when the output signal is left unlabeled.

- **Block states structures**: The continuous states structure (*model_X*) contains the continuous state information for blocks in your model that have continuous states. Discrete states are stored in a data structure called the *DWork vector* (*model_DWork*).
• Block parameters structure (model_P): The parameters structure contains block parameters that can be changed during execution (for example, the parameter of a Gain block).

• External inputs structure (model_U): The external inputs structure consists of all root-level Inport block signals. Field names are determined by either the block's output signal name, when present, or by the Inport block's name when the output signal is left unlabeled.

• External outputs structure (model_Y): The external outputs structure consists of all root-level Outport blocks. Field names are determined by the root-level Outport block names in your model.

• Real work, integer work, and pointer work structures (model_RWork, model_IWork, model_PWork): Blocks might have a need for real, integer, or pointer work areas. For example, the Memory block uses a real work element for each signal. These areas are used to save internal states or similar information.

Options for Configuring Generated C Function Interfaces

To facilitate integration of external and generated code and achieve compliance with code standards and guidelines, you can configure how the code generator produces function interfaces from a model or subsystem. For this level of customization, you must configure the model with an ERT-based system target file.

**Function Interface Customization Limitations for Rate-Based Models**

The following limitations apply to customizations for generated function interfaces:

- You can configure function arguments for single-instance models only. To generate code for a single-instance model, set the model configuration parameter **Code interface packaging** to **Nonreusable function**. For referenced models, select One for the **Total number of instances allowed per top model** parameter.
- For reference models, if you set **Code interface packaging** to **Reusable function**, the code generator ignores function argument settings.
- You must select the model configuration parameter **Single output/update function**.
- Multirate models are supported, but you must configure the models for single tasking.
- You must configure root-level inports and outports to use the **Default** storage class.
- Do not configure function interface with the static **ert_main.c** provided by MathWorks. Specifying a function interface configuration other than the default creates a mismatch between the generated code and the default static **ert_main.c**.
- The code generator removes the data structure for the root inports of the model unless a subsystem implemented by a nonreusable function uses the value of one or more of the inports.
- The code generator removes the data structure for the root outports of the model except when you enable MAT-file logging, or if the sample time of one or more of the outports is not the fundamental base rate (including a constant rate).
- If you copy a subsystem block to create a block in a new model or the same model, the function interface information from the original subsystem block does not get copied to the new subsystem block.
- If you have a Stateflow license, for a Stateflow chart that uses a model root inport value, or that calls a subsystem that uses a model root inport value, do one of the following to generate code:
• Clear the **Execute (enter) Chart At Initialization** check box in the Stateflow chart.

• Make the Stateflow function a nonreusable function.

• Insert a Simulink Signal Conversion block immediately after the root inport. In the Signal Conversion block parameters dialog box, and select **Exclude this block from 'Block reduction' optimization**.

• If a model root inport value connects to a Simscape conversion block, insert a Simulink Signal Conversion block between the root inport and the Simscape conversion block. In the Signal Conversion block parameters dialog box, select **Exclude this block from 'Block reduction' optimization**.

• When building a referenced model that is configured with a function interface, do not use virtual buses as inputs or outputs to the referenced model. When bus signals cross referenced model boundaries, use nonvirtual buses.

• If the C function interface is not the default, the value is ignored for the model configuration parameter **Pass fixed-size scalar root inputs by value for code generation**. For more information, see “Pass fixed-size scalar root inputs by value for code generation” (Simulink).

• “Customize Arguments In Generated Step Function Prototype”

• “Environment for Configuring Model Data and Functions for Code Generation” on page 21-2
Configure Names for Generated C Initialize and Step Functions

You can configure a rate-based model so that the code generator produces custom names for generated entry-point initialize (model_initialize) and step (model_step) functions. For example, when you want to:

- Align the interface of code generated for a model that you are integrating with external code.
- Comply with code standards or guidelines.

You can configure the arguments for a generated step function interactively by using the Configure C/C++ Function Interface dialog box. Or, you can configure the arguments programmatically.

An interface preview for the step function updates dynamically as you make changes.

1. Open an existing model or create a new model.
2. Open the Configure C/C++ Function Interface dialog box. On the Code Generation>Interface pane of the Configuration Parameters dialog box, click Configure Model Functions. Unless a function prototype was previously configured, the dialog box opens showing a preview of the step function interface with no arguments (void-void). The dialog box also shows current function names.

For more information about configuring step function names, see “Configure C Step Function Arguments” on page 29-9.
If arguments have previously been configured for the model, the dialog box displays the current settings.
3 If necessary, change the names of the initialize and step functions by entering new names for **C Initialize Function** and **C Step Function Name**. Click **Apply**.

The function preview changes to reflect the new step function name.

Function names that you specify in this dialog box override function names previously configured with default mappings.
When you build a model as a top model, the **C Initialize Function** parameter controls the name of the function that initializes states to nonzero values. The code generator produces this function only if it contains such states or requires the function for some other less common task. The code generator determines the names of other initialization functions.

A referenced model contains at least one initialization function. When you build a model as a referenced model, **C Initialize Function** does not control the name of the **Model Initialize fcn for ModelReference Block**. The code generator determines the name of this function for referenced model builds.

- “Configure C Initialize and Step Function Interfaces Programmatically” on page 29-19
- “Customize Generated C Function Interfaces” on page 29-2
Configure C Step Function Arguments

You can configure a rate-based model so that the code generator produces custom argument interfaces for a generated entry-point step (model_step) function. For example, when you want to:

- Align the interface of code generated for a model that you are integrating with external code.
- Comply with code standards or guidelines.

1. Open an existing model or create a model.
2. Open the Configure C/C++ Function Interface dialog box. On the Code Generation > Interface pane in the Configuration Parameters dialog box, click Configure Model Functions. Unless a function prototype was previously configured, the dialog box opens showing a preview of an execution function prototype with no arguments (void-void). The dialog box also shows the current initialize and step functions names.

![Configure C/C++ Function Interface](image)

For more information about configuring step function names, see “Configure Names for Generated C Initialize and Step Functions” on page 29-5.

If arguments have previously been configured for the model, the dialog box displays the current settings.
3 Decide whether to configure or reconfigure arguments. If your application requires a void-void interface, clear Configure arguments for function prototype. Otherwise, select Configure arguments for function prototype.

4 Display current default settings for the step function arguments by clicking Get default. An update diagram is displayed and a table lists external I/O ports with property settings.
Configure the step function return argument by setting **C return argument** to **void** or **Out1**.

The function preview changes to reflect the updated step function interface.

Configure step function input and output arguments. For each external inport or outport, you can specify a C type qualifier and an argument name.

The function preview changes to reflect the updated step function interface.

- **C type qualifier**

These values are the possible values for the C type qualifier.

<table>
<thead>
<tr>
<th>C type qualifier</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Auto</td>
<td>--</td>
</tr>
<tr>
<td>Const</td>
<td>const arg</td>
</tr>
<tr>
<td>Pointer to const</td>
<td>const *arg</td>
</tr>
<tr>
<td>Pointer</td>
<td>*arg</td>
</tr>
<tr>
<td>Const pointer to const</td>
<td>const *const arg</td>
</tr>
</tbody>
</table>

When a model includes a referenced model, the code generator does the following:

- For the referenced model, sets the type qualifier for a root input argument in the step function interface to **Auto**. The code generator honors the interface specification by generating a type cast that discards the **const** qualifier from the source signal.
- For the parent of the reference model, sets the type qualifier for the source signal to a value other than **Auto**.

To override this behavior, add a **const** type qualifier to the referenced model.

- **Argument order**
You can adjust the argument order by selecting and dragging a row in the argument table.

- Referenced model arguments and prototype preview

When you use a model as a reference model, the list of input and output arguments in the prototype preview might not include arguments that appear in the prototype in the generated code. For example, a model named mdlref_counter has an inport with argument name arg_input, an outport with argument name arg_output, and a saturation block whose limits have workspace parameter argument names lower_saturation_limit and upper_saturation_limit.

The step function preview for this model is:

mdlref_counter_custom(arg_input, *arg_output)

The function prototype in the generated code, with the additional model parameter arguments, is:

mdlref_counter_custom(  
    real_T arg_input,  
    real_T *arg_output,  
    real_T rtp_lower_saturation_limit,  
    real_T rtp_upper_saturation_limit)

7 Validate the step function interface by clicking Validate. If failures occur, correct them and revalidate.

Combine I/O Arguments in Model Step Interface

When using the Configure C/C++ Function Interface dialog box, you can combine an input argument with an output argument for a model step function. This merging of input and output arguments allows the code generator to reuse and eliminate buffers in the generated code.

The following requirements apply to combining model step function input and output arguments:

- Assign the input and output arguments the same argument name.
- The corresponding Inport and Outport blocks must have the same data type and sample rate.
- The sample rate of the Inport and Outport blocks must be the same as the base rate of the model.
- A conditionally executed subsystem cannot drive the Outport block.
- A single, nonvirtual block output must drive the Outport block. For example, a Mux block, which merges multiple buffers, cannot drive the Outport block.

This example shows how to configure a step function with combined input and output arguments for example model rtwdemo_fcnprotoctrl:

1. Open the model.
2. In the Configuration Parameters dialog box, select the Code Generation > Interface pane.
3. Open the Configure C/C++ Function Interface dialog box by clicking Configure Model Functions or Configure C++ Class Interface.
4. Navigate to the view that allows you to modify model step function arguments. Select Configure arguments for function prototype. Then, click Get default. An update diagram is displayed and a table that lists external I/O ports with property settings.
5. Select an inport and outport pair. Properties of the two arguments must be the same, including the type and dimension. If necessary, change settings for C Type Qualifier and C Identifier Name so that they match. Make sure that the C Type Qualifier is not set to Auto. For this example, set the C Type Qualifier for ports In3 and Out2 to Pointer. Set the C Identifier Name for the two arguments to sharedArg. Validate the changes.
The interface preview is updated to reflect your changes. When you generate code from the model, the arguments are combined in the function prototype.

6 Generate code and a report. Use the report to verify that the generated step function code appears as expected.

```c
boolean_T rtwdemo_fcnprotoctrl_step_custom(const real_T argIn1, const BusObject * argIn2, uint8_T *argIn4, BusObject *sharedArg)
{
    boolean_T Out1;
    Out1 = ((rtDWork.UnitDelay_DSTATE > 10.0) || (argIn1 < 2.0));
    if (*argIn4 != 0) {
        S1 = *argIn2;
    } else {
        S1 = *sharedArg;
    }
    *sharedArg = S1;
    rtDWork.UnitDelay_DSTATE = argIn1;
    return Out1;
}
```

For this example, the shared argument appears in read code for the inport and write code for the outport.

Configure C Initialize and Step Function Interfaces Interactively

This example shows how to use the Configure C/C++ Function Interface dialog box to configure interfaces for the initialize and step functions for the rate-based example model `rtwdemo_counter`.

1. Open the model and save a copy to a writable working folder. The model is configured with the ERT system target file.

2. Generate code and a report.

3. From the report, open the generated file `rtwdemo_counter.c`. Locate and review the generated code for entry-point functions `rtwdemo_counter_initialize` and `rtwdemo_counter_step`.

```c
/* Model step function */
void rtwdemo_counter_step(void)
{
    ...
}

/* Model initialize function */
void rtwdemo_counter_initialize(void)
{
    ...
}
```

After reviewing the code, close the report window. Optionally, save `rtwdemo_counter.c` and other generated files to a different location for later comparison.

4. Configure the function names. In the Configure C Step Function Interface dialog box, set **C Initialize Function Name** to `rtwdemo_counter_cust_init`. Set **C Step Function Name** to `rtwdemo_counter_cust_run`.

5. Configure the step function arguments. For this example, change the configuration of the input port. Select **Configure arguments for step function prototype**. Then, click **Get default**. In the argument table, for Input port, set **C Type Qualifier** to Pointer to const. Click **Apply**.

The function prototype preview reflects the change.
Click **Validate**. A message indicates success. Validation found no failures.

Validation errors in this context prevent the code generator from producing code. If failures occur, resolve the errors before proceeding.

7 Click **OK**. Then, save the model.

8 Generate code and a report.
Verify that the generated code for the initialize and step entry-point functions is consistent with the prototype configuration changes that you made. From the report, open the generated file `rtwdemo_counter.c`. Locate and review the generated code for entry-point functions `rtwdemo_counter_cust_run` and `rtwdemo_counter_cust_init`.

```c
/* Model step function */
void rtwdemo_counter_cust_run(const int32_T *arg_Input, int32_T *arg_Output)
{
...
}

/* Model initialize function */
void rtwdemo_counter_cust_init(void)
{
    ...
}
```

You can use software-in-the-loop (SIL) testing to verify code generated for customized initialize and step functions. Create a SIL block by using your generated code. Then, integrate the SIL block into a model to verify that the generated code provides the same result as the original model or nonvirtual subsystem. For more information, see “Choose a SIL or PIL Approach” on page 67-12.

Typical uses of these functions include:

- Create and validate a function interface.
- Modify and validate an existing function interface.
- Create and validate a function interface, starting with default configuration information from a model.
- Reset the model function interface to the default ERT function configuration.
Create and Validate Function Interface

1. Create a model-specific C function interface with \( \text{obj} = \text{RTW.ModelSpecificCPrototype} \), where \( \text{obj} \) returns a handle to a new, empty function interface.

2. Add argument configuration information for your model ports by using \( \text{RTW.ModelSpecificCPrototype.addArgConf} \).

3. Attach the function interface to your loaded ERT-based model by using \( \text{RTW.ModelSpecificCPrototype.attachToModel} \).

4. Validate the function interface by using \( \text{RTW.ModelSpecificCPrototype.runValidation} \).

5. If validation succeeds, save your model. Then, generate code by using the \text{rtwbuild} function.

Modify and Validate an Existing Function Interface

1. Get the handle to an existing model-specific C function interface that is attached to your loaded ERT-based model with \( \text{obj} = \text{RTW.getFunctionSpecification(\text{modelName})} \). \text{modelName} is a character vector specifying the name of a loaded ERT-based model. \( \text{obj} \) returns a handle to a function interface attached to the specified model.

   You can use other functions on the returned handle only if the test \( \text{isa(obj, 'RTW.ModelSpecificCPrototype')} \) returns 1. If the model does not have a function interface configuration, the function returns \( [\] \). If the function returns a handle to an object of type \text{RTW.FcnDefault}, you cannot modify the existing function interface.

2. Use the Get and Set functions to test and reset such items as the function names, argument names, argument positions, argument categories, and argument type qualifiers.

3. Validate the function interface by using \( \text{RTW.ModelSpecificCPrototype.runValidation} \).

4. If validation succeeds, save your model, and then generate code by using the \text{rtwbuild} function.
Create and Validate Function Interface Starting With Default Configuration From Model

1. Create a model-specific C function interface by using `obj = RTW.ModelSpecificCPrototype`, where `obj` returns a handle to a new, empty function interface.
2. Attach the function interface to your loaded ERT-based model by using `RTW.ModelSpecificCPrototype.attachToModel`.
3. Get default configuration information from your model by using `RTW.ModelSpecificCPrototype.getDefaultConf`.
4. Use the Get and Set functions to test and reset such items as the function names, argument names, argument positions, argument categories, and argument type qualifiers.
5. Validate the function prototype by using `RTW.ModelSpecificCPrototype.runValidation`.
6. If validation succeeds, save your model. Then, generate code by using the `rtwbuild` function.

Reset Model Function Interface to Default ERT Function Configuration

Create an object of the ERT default function interface. Reset the model function interface and undo custom settings by calling the `RTW.FcnDefault` method, `attachToModel`:

```matlab
obj = RTW.FcnDefault;
obj.attachToModel(model);
```

`model` must be a loaded ERT-based model.

**Note** Do not use the same model-specific C function interface object across multiple models. If you do, changes that you make to the step and initialize functions in one model are propagated to other models, which is usually not what you want.

Sample Script for Configuring Function Interfaces

This example MATLAB script configures the model function interfaces for example model `rtwdemo_counter`. 

29-22
%% Open the rtwdemo_counter model
rtwdemo_counter

%% Select ert.tlc as the System Target File for the model
set_param(gcs,'SystemTargetFile','ert.tlc')

%% Create a model-specific C function prototype
a=RTW.ModelSpecificCPrototype

%% Add argument configuration information for Input and Output ports
addArgConf(a,'Input','Pointer','inputArg','const *')
addArgConf(a,'Output','Pointer','outputArg','none')

%% Attach the model-specific C function prototype to the model
attachToModel(a,gcs)

%% Rename the initialization function
setFunctionName(a,'InitFunction','init')

%% Rename the step function and change some argument attributes
setFunctionName(a,'StepFunction','step')
setArgPosition(a,'Output',1)
setArgCategory(a,'Input','Value')
setArgName(a,'Input','InputArg')
setArgQualifier(a,'Input','none')

%% Validate the function prototype against the model
[status,message]=runValidation(a)

%% if validation succeeded, generate code and build
if status
    rtwbuild(gcs)
end

- “Customize Generated C Function Interfaces” on page 29-2
Customize Generated Function Interfaces for Simulink Function and Function Caller Blocks

With Embedded Coder, you can customize the generated C/C++ function interfaces for Simulink Function and Function Caller blocks. Function code interface configuration supports easier integration of generated code with functions or function calls in external code, and customizations for coding standards or design requirements.

You can customize the generated C/C++ function interfaces for:

- Global Simulink functions
- Exported scoped Simulink functions

You cannot customize the generated C/C++ function interface for a scoped Simulink Function block that is not located at the root level of a model. For more information, see “Scoped and Global Simulink Function Blocks” (Simulink).

By opening a dialog box from a selected Simulink Function or Function Caller block, you can customize the C/C++ function prototype generated for that block. Your changes for the selected block also update other corresponding Simulink Function and Function Caller blocks in the model. The function visibility, global or scoped, set in the function Trigger Port block, determines which function attributes you can modify:

- For a global function, you can change the generated C/C++ function name, and the names, type qualifiers, and order of function arguments.
- For an exported scoped function, you can change the generated C/C++ function type qualifiers and the order of function arguments. You cannot change the function and argument names.

Your changes do not graphically alter the model and do not affect the Simulink function prototype defined in the block.

Embedded Coder supports Simulink function code interface configuration for ERT and ERT-derived targets, except for the AUTOSAR target.

Configure Generated C/C++ Function Interface for Global Simulink Function Block

This example shows you how to modify the generated C/C++ function interface for a Simulink Function block, and generate C code with the specified changes.
1 Open the example model `rtwdemo_functions`. Save it to a writable work area.

2 Right-click the Simulink Function block `f3`. In the right-click context menu, select `C/C++ Code > Configure C/C++ Function Interface`. The Configure C/C++ Function Interface dialog box opens.

The dialog box displays the Simulink function prototype defined in the block, \( y = f3(u) \), and the initial default C/C++ function prototype, `void f3(rtu_u, * rty_y)`.

3 Examine the dialog box settings for the C/C++ function name and the C/C++ argument identifier names — `$N` and `rt$I$N$M`.

In the Configuration Parameters dialog box, Code Generation > Symbols pane, the Subsystem method arguments parameter defines the default identifier format for Simulink Function arguments.

```
Subsystem method arguments: rt$I$N$M
```

`rt` is a text prefix. `$I$, `$N$, and `$M` are identifier format macros. For more information, see “Subsystem method arguments” (Simulink Coder).
4 In the Configure C/C++ Function Interface dialog box, modify the function and argument identifier names. Changes that you make in the dialog box override model configuration parameter defaults.

In the C/C++ function name field, and in the C/C++ Identifier Name field for each function argument, enter a custom name or identifier format. Specify valid C-identifier characters, identifier format macros, or a combination. This example uses function name function3 and, for both arguments, identifier format $N$M.

To see tips about available macros, hover over the C/C++ function name and C/C++ Identifier Name fields. For more information about the identifier format macros, see “Identifier Format Control” on page 39-22.

5 For the u argument, change the C/C++ Type Qualifier field from Auto to Pointer to const.

6 To reorder the generated arguments, drag the y argument row above the u argument row, and drop.

7 Click Apply and examine the updated C/C++ function prototype: void function3(* y, const * u).

Your modifications, whether made to a Simulink Function block or a Function Caller block, affect code generation for the Simulink Function block and corresponding Function Caller blocks in the model.
Optionally, you could change **C/C++ return argument** from void to y. The resulting C/C++ function prototype is \( y = \text{function3}(\text{const } * \ u) \).

8. Save the model changes and generate code for `rtwdemo_functions`.

9. Open the generated file `rtwdemo_functions.c` and search for `function3`. The generated function code reflects the changes to the generated C/C++ function prototype.

```c
/* Output and update for Simulink Function: '<Root>/f3' */
void function3(real_T *y, const real_T *u)
{
    ... 
    adder_h(rtB.Subtract, rtU.U2, *u, &rtB.FunctionCaller);
    ... 
    *y = rtB.FunctionCaller;
    ...
}
```
Configure Generated C/C++ Function Interface for Exported Scoped Simulink Function Block

In this example, you modify the generated C/C++ function interface for an exported scoped Simulink Function block, and generate C code with the specified changes.

For an exported scoped function, you can modify the generated C/C++ return argument and the C/C++ type qualifiers and order of generated function arguments. You cannot change the generated C/C++ function name and C/C++ argument identifier names.

1  Open the example model rtwdemo_functions. Save it to a writable work area.
2  Change the visibility of the global function f3 from global to scoped. Open the Simulink Function block f3. Inside the function block, double-click the Trigger Port block f3. In the block parameters dialog box, change the Function visibility parameter from global to scoped. Click Apply and OK.
3  At the top level of the model, right-click the Simulink Function block f3. In the right-click context menu, select C/C++ Code > Configure C/C++ Function Interface. The Configure C/C++ Function Interface dialog box opens.

The dialog box displays the Simulink function prototype defined in the block, \( y = f3(u) \), and the initial default C/C++ function prototype, \( \text{void rtwdemo_functions_f3(rtu_u, * rty_y)}. \)
4 For the \( u \) argument, change the **C/C++ Type Qualifier** field from Auto to Pointer to const.

5 To reorder the generated arguments, drag the \( y \) argument row above the \( u \) argument row, and drop.

6 Click **Apply** and examine the updated C/C++ function prototype: `void rtwdemo_functions_f3(* rty_y, const * rtu_u)`.

Your modifications, whether made to a Simulink Function block or a Function Caller block, affect code generation for the Simulink Function block and corresponding Function Caller blocks in the model.
Optionally, you could change **C/C++ return argument** from `void` to `y`. The resulting C/C++ function prototype is `y = rtwdemo_functions_f3(const * rtu_u)`.

7. Save the model changes and generate code for `rtwdemo_functions`.

8. Open the generated file `rtwdemo_functions.c` and search for `_f3`. The generated function code reflects the changes to the generated C/C++ function prototype.

```c
/* Output and update for Simulink Function: '<Root>/f3' */
void rtwdemo_functions_f3(real_T *rty_y, const real_T *rtu_u) {
    ...
    adder_h(rtB.Subtract, rtU.U2, *rtu_u, &rtB.FunctionCaller);
    ...
    *rty_y = rtB.FunctionCaller;
    ...
}
```

### Simulink Function Code Interface Limitations

- For C++ code generation, global Simulink functions are incompatible with C++ class interfaces for model entry-point functions.
• Simulink function code interface configuration does not support Simulink functions and function callers in Stateflow.

Customize Function Interfaces for Nonvirtual Subsystems

If you use the right-click build method to generate code for a nonvirtual subsystem that is in a rate-based model configured with an ERT-based system target file, you can configure the initialize and step function interfaces for the subsystem. You can configure the function interfaces for these types of nonvirtual subsystem blocks:

- Triggered subsystems
- Enabled subsystems
- Enabled trigger subsystems
- While subsystems
- For subsystems
- Stateflow blocks
- MATLAB function block

This example shows how to configure the function interfaces for the Amplifier subsystem in the example model `rtwdemo_counter`. In the Model Interface for Subsystem dialog box, open the model containing the subsystem and invoke the function.

1. Open the model that contains the nonvirtual subsystem block.
2. Open the Model Interface for Subsystem dialog box by using the function `RTW.configSubsystemBuild`.

```matlab
RTW.configSubsystemBuild('rtwdemo_counter/Amplifier');
```
Choose a **Function specification**: default function prototypes or model-specific prototypes. For this example, select **Model specific C prototypes**.
4  Expand the interface for configuring the prototypes by clicking **Get Default Configuration**.

As you make changes, the step function preview (under the table) is updated.

5  Configure the function names. Specify values for **Initialize function name** and **Step function name**.
Configure the step function arguments. For each argument, you can specify whether the argument is passed by value or by reference with a pointer (Category column), a name, and whether to apply a C type qualifier. Click Apply.

Validate the prototypes. Check the step function preview and click Validate. The interface validation reports success or whether failures occur.

Generate code for the subsystem. From the subsystem context menu, select C/C++ Code > Build This Subsystem. The code generator produces the initialize and step functions for the subsystem based on your customizations.
Customize Generated C++ Class Interfaces

Using the Code interface packaging (Simulink Coder) option C++ class, on the Code Generation > Interface pane of the Configuration Parameters dialog box, you can generate a C++ class interface to model code. The generated interface encapsulates required model data into C++ class attributes and model entry point functions into C++ class methods. The benefits of C++ class encapsulation include:

- Greater control over access to model data
- Ability to multiply instantiate model classes
- Easier integration of model code into C++ programming environments

C++ class encapsulation also works for right-click builds of nonvirtual subsystems. (For information on requirements that apply, see “Configure C++ Class Interfaces for Nonvirtual Subsystems” on page 29-55.)

The general procedure for generating C++ class interfaces to model code is as follows:

1. Configure your model to use an ert.tlc system target file provided by MathWorks.
2. Select the C++ language for your model.
3. Select C++ class code interface packaging for your model.
4. Optionally, configure related C++ class interface settings for your model code, using either a graphical user interface (GUI) or application programming interface (API).
5. Generate model code and examine the results.

To get started with an example, see “Simple Use of C++ Class Control” on page 29-37. For more details about configuring C++ class interfaces for your model code, see “Customize C++ Class Interfaces Using Graphical Interfaces” on page 29-44 and “Customize C++ Class Interfaces Programmatically” on page 29-55. For limitations that apply, see “C++ Class Interface Control Limitations” on page 29-62.

Note For an example of C++ class code generation, see the example model rtwdemo_cppclass.

In this section...

“Simple Use of C++ Class Control” on page 29-37
Simple Use of C++ Class Control

This example illustrates a simple use of C++ class code interface packaging. It generates C++ class code interfaces from an example model, without extensive modifications to default settings.

**Note** For details about setting C++ class parameters, see the sections that follow this example, beginning with “Customize C++ Class Interfaces Using Graphical Interfaces” on page 29-44.

To generate C++ class interfaces for a Simulink model:

1. Open a model for which you would like to generate C++ class code interfaces. This example uses the model `rtwdemo_counter`.
2. Configure the model to use an `ert.tlc` system target file provided by MathWorks. For example, open the Configuration Parameters dialog box, go to the **Code Generation** pane, select a target value from the **System target file** menu, and click **Apply**.
3. On the **Code Generation** pane of the Configuration Parameters dialog box, set the **Language** parameter to C++.

On the **Code Generation > Interface** pane, check that the **Code interface packaging** parameter is set to C++ class.

Click **Apply**.
**Note** To immediately generate the default style of C++ class code, without exploring the related model configuration options, skip steps 4–8 and go directly to step 9.

4 Go to the **Interface** pane of the Configuration Parameters dialog box and examine the **Code interface** subpane.

When you select **C++ class** code interface packaging for your model, additional C++ class interface controls become available in the **Code interface** subpane. See “Configure Code Interface Options” on page 29-44 for descriptions of these controls. You might want to modify the default settings according to your application.

5 Click the **Configure C++ Class Interface** button. This action opens the Configure C++ class interface dialog box, which allows you to configure the step method for your generated model class. The dialog box initially displays a view for configuring a **Default step method** for the model class. In this view, you can specify the model class name, step method name, and namespace for your model.
See “Configure Step Method for Your Model Class” on page 29-47 for descriptions of these controls.

**Note** If the default interface style meets your needs, you can skip steps 6–8 and go directly to step 9.

6 If you want root-level model input and output to be arguments on the step method, select the value **I/O arguments step method** from the **Function specification** menu. The dialog box displays a view for configuring an I/O arguments style step method for the model class.
See “Configure Step Method for Your Model Class” on page 29-47 for descriptions of these controls.

7 Click the **Get Default Configuration** button. This action causes a **Configure C++ class interface** subpane to appear in the dialog box. The subpane displays the initial interface configuration for your model, which provides a starting point for further customization.
See “Passing I/O Arguments” on page 29-50 for descriptions of these controls.

Perform this optional step only if you want to customize the configuration of the I/O arguments generated for your model step method.

**Note** If you choose to skip this step, you should click **Cancel** to exit the dialog box.

If you choose to perform this step, first you must check that the required option **Remove root level I/O zero initialization** is selected on the **Optimization** pane, and then navigate back to the I/O arguments step method view of the Configure C++ class interface dialog box.

Now you can use the dialog box controls to configure I/O argument attributes. For example, in the **Configure C++ class interface** subpane, in the row for the **Input** argument, you can change the value of **Category** from Value to Pointer and change the value of **Qualifier** from none to const *. The preview updates to reflect your changes. Click the **Validate** button to validate the modified interface configuration.

Continue modifying and validating until you are satisfied with the step method configuration.
Click **Apply** and **OK**.

Generate code for the model. When the build completes, the code generation report for `rtwdemo_counter` appears. Examine the report and observe that required model data is encapsulated into C++ class attributes and model entry point functions are encapsulated into C++ class methods. For example, click the link for `rtwdemo_counter.h` to see the class declaration for the model.
Note: If you configured custom I/O arguments for the model step method (optional step 8), examine the generated code for the step method in `rtwdemo_counter.h` and `rtwdemo_counter.cpp`. The arguments should reflect your changes. For example, if you performed the Input argument modifications in step 8, the input argument should appear as `const int32_T *arg_Input`. 
Customize C++ Class Interfaces Using Graphical Interfaces

- “Select C++ Class Code Interface Packaging” on page 29-44
- “Configure Code Interface Options” on page 29-44
- “Configure Step Method for Your Model Class” on page 29-47
- “Use Namespaces to Scope C++ Model Classes” on page 29-53
- “Configure C++ Class Interfaces for Nonvirtual Subsystems” on page 29-55

Select C++ Class Code Interface Packaging

To select C++ class code interface packaging, in the Configuration Parameters dialog box, on the Code Generation pane, set the Language parameter to C++. Then, in the Code Generation > Interface pane, check that the Code interface packaging parameter is set to C++ class:

Selecting this value:

- Disables model configuration options that C++ class does not support. For details, see “C++ Class Interface Control Limitations” on page 29-62.
- Adds additional C++ class interface parameters, which are described in the next section.

Configure Code Interface Options

When you select C++ class code interface packaging for your model, the Code interface parameters shown below are displayed on the Interface pane.
• **Multi-instance code error diagnostic**

  Specifies the severity level for diagnostics displayed when a model violates requirements for generating multi-instance code.

  - *None* — Proceed with build without displaying a diagnostic message.
  - *Warning* — Proceed with build after displaying a warning message.
  - *Error* (default) — Abort build after displaying an error message.

• **Remove error status field in real-time model data structure**

  Specifies whether to omit the error status field from the generated real-time model data structure `rtModel` (off by default). Selecting this option reduces memory usage.

  Be aware that selecting this option can cause the code generator to omit the `rtModel` data structure from generated code.

• **Parameter visibility**

  Specifies whether to generate the block parameter structure as a `public`, `private`, or `protected` data member of the C++ model class (`private` by default).

• **Parameter access**

  Specifies whether to generate access methods for block parameters for the C++ model class (`None` by default). You can select noninlined access methods (`Method`) or inlined access methods (`Inlined method`).

• **External I/O access**

  Specifies whether to generate access methods for root-level I/O signals for the C++ model class (`None` by default). If you want to generate access methods, you have the following options:

  - Generate either noninlined or inlined access methods.
  - Generate either per-signal or structure-based access methods. That is, you can generate a series of set and get methods on a per-signal basis, or generate just one set method that takes the address of an external input structure as an argument and, for external outputs (if applicable), just one get method that returns a reference to an external output structure. The generated code for structure-based access methods has the following general form:

```cpp
class ModelClass {
...
```
// Root imports set method
void setExternalInputs(const ExternalInputs* pExternalInputs);

// Root outports get method
const ExternalOutputs & getExternalOutputs() const;

**Note** This parameter affects generated code only if you are using the default style step method for your model class; not if you are explicitly passing arguments for root-level I/O signals using an I/O arguments style step method. For more information, see “Passing Default Arguments” on page 29-48 and “Passing I/O Arguments” on page 29-50.

- **Configure C++ Class Interface**

  Opens the Configure C++ class interface dialog box, which allows you to configure the step method for your model class. For more information, see “Configure Step Method for Your Model Class” on page 29-47.

Interface parameters that are related, but are less commonly used, appear under **Advanced parameters**:

- **Terminate function required**

  Specifies whether to generate the `model_terminate` method (on by default). This function contains model termination code and should be called as part of system shutdown.

- **Combine signal/state structures**

  Specifies whether to combine global block signals and global state data into one data structure in the generated code (off by default). Selecting this option reduces RAM and improves readability of the generated code.

- **Internal data visibility**

  Specifies whether to generate internal data structures, such as Block I/O, DWork vectors, Runtime model, Zero-crossings, and continuous states, as public, private, or protected data members of the C++ model class (private by default).

- **Internal data access**

  Specifies whether to generate access methods for internal data structures, such as Block I/O, DWork vectors, Runtime model, Zero-crossings, and continuous states, for the C++ model class (None by default). You can select noninlined access methods (Method) or inlined access methods (Inlined method).
- **Generate destructor**
  Specifies whether to generate a destructor for the C++ model class (on by default).

- **Use dynamic memory allocation for model block instantiation** (Simulink Coder)
  For a model containing Model blocks, specifies whether generated code should use dynamic memory allocation, during model object registration, to instantiate objects for referenced models configured with a C++ class interface (off by default). If you select this option, during instantiation of an object for the top model in a model reference hierarchy, the generated code uses the operator `new` to instantiate objects for referenced models.

  Selecting this option frees a parent model from having to maintain information about referenced models beyond its direct children. Clearing this option means that a parent model maintains information about its referenced models, including its direct and indirect children.

**Note**
- If you select this option, be aware that a `bad_alloc` exception might be thrown, per the C++ standard, if an out-of-memory error occurs during the use of `new`. You must provide code to catch and process the `bad_alloc` exception in case an out-of-memory error occurs for a `new` call during construction of a top model object.
- If **Use dynamic memory allocation for model block instantiation** is selected and the base model contains a Model block, the build process might generate copy constructor and assignment operator functions in the private section of the model class. The purpose of the functions is to prevent pointer members within the model class from being copied by other code. For more information, see “Model Class Copy Constructor and Assignment Operator” on page 29-61.

**Configure Step Method for Your Model Class**
To configure the step method for your model class, on the **Code Generation > Interface** pane, click the **Configure C++ Class Interface** button, which is available when you select C++ class code interface packaging for your model. This action opens the Configure C++ class interface dialog box, where you can configure the step method for your model class in either of two styles:

- “Passing Default Arguments” on page 29-48
Note The Default step method supports single-rate models and multirate models. The model can be configured for single-tasking operation or multi-tasking operation. This method also supports virtual bus crossing boundaries.

The I/O arguments step method supports single-rate models and multirate models. The model can be configured for single-tasking operation.

Passing Default Arguments

The Configure C++ class interface dialog box initially displays a view for configuring a Default step method for the model class.
• **Step method name**

  Allows you to specify a step method name other than the default, `step`.

• **Class name**

  Allows you to specify a model class name other than the default, `modelModelClass`.

• **Namespace**

  Allows you to specify a namespace for the model class. If specified, the namespace is emitted in the generated code for the model class. The **Namespace** parameter provides a means of scoping C++ model classes. In a model reference hierarchy, you can specify a different namespace for each referenced model.
- **Step function preview**

  Displays a preview of the model step function prototype as currently configured. The preview display is dynamically updated after you validate your current configuration.

  **Note** The list of step function arguments has an entry for each of the model’s root-level I/O ports. This list does not include model parameter arguments that can appear in the generated code when the model is used as a referenced model. For example, a model `sldemo_mdlref_counter_paramargs` has an inport with argument name `arg_input`, an outport with argument name `arg_output`, and a saturation block whose limits have workspace parameter argument names `lower_saturation_limit` and `upper_saturation_limit`.

  The step function preview for this model is:

  ```
  sldemo_mdlref_counter_paramargsModelClass :: step ( arg_input, * arg_output )
  ```

  The function prototype in the generated code differs from the preview. The prototype in the generated code (with the additional model parameter arguments) is:

  ```
  sldemo_mdlref_counter_paramargsModelClass::step ( 
    real_T arg_input, 
    real_T *arg_output, 
    real_T rtp_lower_saturation_limit, 
    real_T rtp_upper_saturation_limit)
  ```

- **Validate**

  Validates your current model step function configuration. The **Validation** pane displays the status and an explanation of any failure.

  **Passing I/O Arguments**

  If you select I/O arguments step method from the **Function specification** menu, the dialog box displays a view for configuring an I/O arguments style step method for the model class.

  **Note** To use the I/O arguments style step method, you must select the option **Remove root level I/O zero initialization** on the **Optimization** pane of the Configuration Parameters dialog box.
• Get Default Configuration

Click this button to get the initial interface configuration that provides a starting point for further customization.

• Step function preview

Displays a preview of the model step function prototype as currently configured. The preview dynamically updates as you make configuration changes.

• Validate

Validates your current model step function configuration. The Validation pane displays the status and an explanation of any failure.
When you click **Get Default Configuration**, the **Configure C++ class interface** subpane appears in the dialog box, displaying the initial interface configuration. For example:

- **Step method name**
  
  Allows you to specify a step method name other than the default, *step*.

- **Class name**
  
  Allows you to specify a model class name other than the default, *modelModelClass*.

- **Namespace**
  
  Allows you to specify a namespace for the model class. If specified, the namespace is emitted in the generated code for the model class. The **Namespace** parameter provides a means of scoping C++ model classes. In a model reference hierarchy, you can specify a different namespace for each referenced model.

- **Order**
  
  Displays the numerical position of each argument. Use the **Up** and **Down** buttons to change argument order.

- **Port Name**
  
  Displays the port name of each argument (not configurable using this dialog box).

- **Port Type**
  
  Displays the port type, *Inport* or *Outport*, of each argument (not configurable using this dialog box).

- **Category**
Displays the passing mechanism for each argument. To change the passing mechanism for an argument, select Value, Pointer, or Reference from the argument's Category menu.

- **Argument Name**

Displays the name of each argument. To change an argument name, click in the argument's **Argument name** field, position the cursor for text entry, and enter the new name.

- **Qualifier**

Displays the const type qualifier for each argument. To change the qualifier for an argument, select an available value from the argument's **Qualifier** menu. The possible values are:

  - none
  - const (value)
  - const* (value referenced by the pointer)
  - const*const (value referenced by the pointer and the pointer itself)
  - const & (value referenced by the reference)

**Tip** When a model includes a referenced model, the const type qualifier for the root input argument of the referenced model's specified step function interface is set to none and the qualifier for the source signal in the referenced model's parent is set to a value other than none, code generation honors the referenced model's interface specification by generating a type cast that discards the const type qualifier from the source signal. To override this behavior, add a const type qualifier to the referenced model.

**Use Namespaces to Scope C++ Model Classes**

Embedded Coder provides namespace control for scoping model classes generated using C++ class code interface packaging. In the Configure C++ class interface dialog box, use the **Namespace** parameter to specify a namespace for a model class. If specified, the namespace is emitted in the generated code for the model class. To scope the C++ model classes in a model reference hierarchy, you can specify a different namespace for each referenced model.

For an example of namespace control, see the example model rtwdemo_cppclass. This model assigns namespaces as follows:
• TopNS for top-level model rtwdemo_cppclass
• MiddleNS for referenced model rtwdemo_cppclass_refmid
• BottomNS for referenced model rtwdemo_cppclass_refbot

If you build the model with its default settings, you can examine the generated header and source files for each model to see where the namespace is emitted. For example, the **Namespace** setting for the model rtwdemo_cppclass_refmid is shown below, followed by excerpts of the emitted namespace code in the model header and source files.

```cpp
42   // Class declaration for model rtwdemo_cppclass_refmid
43   namespace MiddleNS {
44     class MiddleClass {
45       // public data and function members
46       public:
47         // Model entry point functions
... 52         // model step function
53         void StepMethod(const real_T *arg_In1, const real_T &arg_In2, real_T
54              *arg_Out1, real_T *arg_Out2);
... 87     }
88   }

15   #include "rtwdemo_cppclass_refmid.h"
16   #include "rtwdemo_cppclass_refmid_private.h"
17
18   namespace MiddleNS
19   {
20       // Model step function
21       void MiddleClass::StepMethod(const real_T *arg_In1, const real_T &arg_In2,
22           real_T *arg_Out1, real_T *arg_Out2)
23           {
... 43           }
83       }
```
Configure C++ Class Interfaces for Nonvirtual Subsystems

You can configure C++ class interfaces for right-click builds of nonvirtual subsystems in Simulink models, if the following requirements are met:

- The model is configured for the C++ language and C++ class code interface packaging.
- The subsystem is convertible to a Model block using the function `Simulink.SubSystem.convertToModelReference`. For referenced model conversion requirements, see the Simulink reference page `Simulink.SubSystem.convertToModelReference`.

To configure C++ class interfaces for a subsystem that meets the requirements:

1. Open the containing model and select the subsystem block.
2. Enter the following MATLAB command:

   ```matlab
   RTW.configSubsystemBuild(gcb)
   ```

   where `gcb` is the Simulink function `gcb`, returning the full block path name of the current block.

   This command opens a subsystem equivalent of the Configure C++ class interface dialog sequence that is described in detail in the preceding section, “Configure Step Method for Your Model Class” on page 29-47. (For more information about using the MATLAB command, see `RTW.configSubsystemBuild`.)

3. Use the Configure C++ class interface dialog boxes to configure C++ class settings for the subsystem.
4. Right-click the subsystem and select **C/C++ Code > Build This Subsystem**.
5. When the subsystem build completes, you can examine the C++ class interfaces in the generated files and the HTML code generation report.

Customize C++ Class Interfaces Programmatically

If you select the **Code interface packaging** option C++ class for your model, you can use the C++ class interface control functions (listed in C++ Class Interface Control Functions) to programmatically configure the step method for your model class.

Typical uses of these functions include:
• **Create and validate a new step method interface, starting with default configuration information from your Simulink model**

1. Create a model-specific C++ class interface with `obj = RTW.ModelCPPDefaultClass` or `obj = RTW.ModelCPPArgsClass`, where `obj` returns a handle to an newly created, empty C++ class interface.

2. Attach the C++ class interface to your loaded ERT-based Simulink model using `attachToModel`.

3. Get default C++ class interface configuration information from your model using `getDefaultConf`.

4. Use the Get and Set functions listed in C++ Class Interface Control Functions to test or reset the model class name and model step method name. Additionally, if you are using the I/O arguments style step method, you can test and reset argument names, argument positions, argument categories, and argument type qualifiers.

5. Validate the C++ class interface using `runValidation`. (If validation fails, use the error message information that `runValidation` returns to address the issues.)

6. Save your model and then generate code using the `rtwbuild` function.

• **Modify and validate an existing step method interface for a Simulink model**

1. Get the handle to an existing model-specific C++ class interface that is attached to your loaded ERT-based Simulink model using `obj = RTW.getClassInterfaceSpecification(modelName)`, where `modelName` is a character vector specifying the name of a loaded ERT-based Simulink model, and `obj` returns a handle to a C++ class interface attached to the specified model. If the model does not have an attached C++ class interface configuration, the function returns `[]`.

2. Use the Get and Set functions listed in C++ Class Interface Control Functions to test or reset the model class name and model step method name. Additionally, if the returned interface uses the I/O arguments style step method, you can test and reset argument names, argument positions, argument categories, and argument type qualifiers.

3. Validate the C++ class interface using `runValidation`. (If validation fails, use the error message information that `runValidation` returns to address the issues.)

4. Save your model and then generate code using the `rtwbuild` function.
**Note** You should not use the same model-specific C++ class interface control object across multiple models. If you do, changes that you make to the step method configuration in one model propagate to other models, which is usually not desirable.
## C++ Class Interface Control Functions

<table>
<thead>
<tr>
<th>Function</th>

Configure Step Method for Model Class

The following sample MATLAB script configures the step method for the `rtwdemo_counter` model class, using the C++ Class Interface Control Functions.

```matlab
%% Open the rtwdemo_counter model
rtwdemo_counter

%% Select ert.tlc as the System Target File for the model
set_param(gcs,'SystemTargetFile','ert.tlc')

%% Select C++ as the target language for the model
set_param(gcs,'TargetLang','C++')

%% Select C++ class as the code interface packaging for the model
set_param(gcs,'CodeInterfacePackaging','C++ class')

%% Set required option for I/O arguments style step method (cmd off = GUI on)
set_param(gcs,'ZeroExternalMemoryAtStartup','off')

%% Create a C++ class interface using an I/O arguments style step method
a=RTW.ModelCPPArgsClass

%% Attach the C++ class interface to the model
attachToModel(a,gcs)

%% Get the default C++ class interface configuration from the model
getDefaultConf(a)

%% Move the Output port argument from position 2 to position 1
setPosition(a,'Output',1)

%% Reset the model step method name from step to StepMethod
setStepMethodName(a,'StepMethod')

%% Change the Input port argument name, category, and qualifier
setArgName(a,'Input','inputArg')
setArgCategory(a,'Input','Pointer')
setArgQualifier(a,'Input','const *')

%% Validate the function prototype against the model
[status,message]=runValidation(a)
```
Specify Custom Storage Class for C++ Class Code Generation

To configure a Simulink parameter, signal, or state to use a custom storage class (CSC) with C++ class code generation:

1. Open an ERT-based model for which Language is set to C++ and Code interface packaging is set to C++ class.
2. Open the Configuration Parameters dialog box.
3. On the Code Generation > Interface pane, set the Multi-instance code error diagnostic (Simulink Coder) parameter to a value other than Error.

   ![Code interface](image)

4. If the option Configuration Parameters > Ignore custom storage classes is selected, clear it.

   Apply the changes.

5. In the model, select a custom storage class for a parameter, signal, or state. For example, select a signal, open its Properties dialog box, and view its code generation options. In the Storage class drop-down list, select a custom storage class, and then configure its attributes. Apply the changes.

   **Note** C++ class code generation does not support the following CSCs:
   
   • CSCs with Volatile specifications.
   • CSCs of type Other, except GetSet.

6. Build the model.
7. In the code generation report, examine the files model.h and model.cpp to observe the use of CSCs in the generated C++ code.
Model Class Copy Constructor and Assignment Operator

Code generation automatically adds a copy constructor and an assignment operator to C++ class declarations when required to securely handle pointer members. The constructor and operator are added as private member functions when both of the following conditions exist:

- The model option Use dynamic memory allocation for model block instantiation (Simulink Coder) is set to on.
- The base model contains a Model block. The Model block is not directly or indirectly within a subsystem for which Function packaging is set to Reusable function.

Under these conditions, the software generates a private copy constructor and assignment operator to prevent pointer members within the model class from being copied by other code.

**Note** To prevent generation of these functions, consider clearing the option Use dynamic memory allocation for model block instantiation.

The code excerpt below shows generated model.h code for a model class that has a pointer member. (Look for instances of MiddleClass_ptr). The copy constructor and assignment operator declarations are shown in bold.

class MiddleClass;  // class forward declaration for <S1>/Bottom model instance
typedef MiddleClass* MiddleClass_ptr;
...

// Class declaration for model cppclass_top
class Top {

  // private data and function members
  private:
    // Block signals
    BlockIO_cppclass_top cppclass_top_B;

    // Block states
    D_Work_cppclass_top cppclass_top_DWork;

    // Real-Time Model
    RT_MODEL_cppclass_top cppclass_top_M;

    // private member function(s) for subsystem '<Root>/Subsystem'
    void cppclass_top_Subsystem_Init();
    void cppclass_top_Subsystem_Start();
    void cppclass_top_Subsystem();
//Copy Constructor
Top(const Top &rhs);

//Assignment Operator
Top& operator= (const Top &rhs);

// model instance variable for '<S1>/Bottom model instance'
MiddleClass_ptr Bottom_model_instanceMDLOBJ1;
};

**C++ Class Interface Control Limitations**

- If a model has a custom model step function for which a scalar output is passed by value and is updated in a conditionally executed context, configure the output to be passed by pointer. In the model C++ class interface configuration dialog box, set **Category** to **Pointer**. Examples of a conditionally executed context include:
  - Output has a slower sample time than the fundamental rate of the model when the model is used as a referenced model.
  - Output is written to in a conditionally executed subsystem.
  - Output is written to by an S-function that might conditionally update the output.
  - Output is written to by a Hit Crossing block.
  - Output is written to by a Rate Transition block.
- The C++ class code interface packaging option does not support some Simulink model configuration options. Selecting C++ class disables the following items in the Configuration Parameters dialog box:
  - **Identifier format control** subpane on the **Symbols** pane
  - **File customization template** parameter on the **Templates** pane

**Note** The code and data templates on the **Templates** pane are supported for C++ class code generation. However, the following template file features that are supported for other language selections are not supported for C++ class generated code:
  - Free-form text outside template sections
  - Custom tokens
  - TLC commands (<! > tokens)
Global data placement (custom storage classes only) subpane on the Code Placement pane

Selecting C++ class also disables the Code Mapping Editor (see “Configure Default Code Generation for Categories of Model Data and Functions” on page 21-7). You cannot apply default storage classes, memory sections, or function templates to the model.

Among the data exchange interfaces available on the Interface pane of the Configuration Parameters dialog box, only the C API interface is supported for C++ class code generation. If you select External mode or ASAP2 interface, code generation fails with a validation error.

The I/O arguments style of step method specification supports single-rate models and multirate single-tasking models, but not multirate multitasking models.

If you have a Stateflow license, for a Stateflow chart that resides in a root model configured to use the I/O arguments step method function specification, and that uses a model root inport value or calls a subsystem that uses a model root inport value, you must do one of the following to generate code:

- Clear the Execute (enter) Chart At Initialization check box in the Stateflow chart.
- Insert a Simulink Signal Conversion block immediately after the root inport. In the Signal Conversion block parameters dialog box, select Exclude this block from 'Block reduction' optimization.
- If a model root inport value connects to a Simscape conversion block, you must insert a Simulink Signal Conversion block between the root inport and the Simscape conversion block. In the Signal Conversion block parameters dialog box, select Exclude this block from 'Block reduction' optimization.
- When building a referenced model that is configured to generate a C++ class interface:
  - Do not use a C++ class interface in cases when a referenced model cannot have a combined output/update function. Cases include a model that has a continuous sample time or saves states.
  - Do not use virtual buses as inputs or outputs to the referenced model when the referenced model uses the I/O arguments step method. When bus signals cross referenced model boundaries, either use nonvirtual buses or use the Default step method.
- If the C++ encapsulation interface is not the default, the value is ignored for the Configuration Parameters > Model Referencing > Pass fixed-size scalar root
inputs by value for code generation parameter. For more information, see “Pass fixed-size scalar root inputs by value for code generation” (Simulink).

Generate Modular Function Code

The Embedded Coder software provides a Subsystem Parameters dialog box option, **Function with separate data**, that allows you to generate modular function code for nonvirtual subsystems, including atomic subsystems and conditionally executed subsystems.

By default, the generated code for a nonvirtual subsystem does not separate a subsystem's internal data from the data of its parent Simulink model. This can make it difficult to trace and test the code, particularly for nonreusable subsystems. Also, in large models containing nonvirtual subsystems, data structures can become large and potentially difficult to compile.

About Nonvirtual Subsystem Code Generation

**Function with separate data** allows you to generate subsystem function code in which the internal data for a nonvirtual subsystem is separated from its parent model and is owned by the subsystem. The subsystem data structure is declared independently from the parent model data structures. A subsystem with separate data has its own block I/O and DWork data structure. As a result, the generated code for the subsystem is easier to trace and test. The data separation also tends to reduce the maximum size of global data structures throughout the model, because they are split into multiple data structures.

To use the **Function with separate data** parameter,

- Your model must use an ERT-based system target file (requires a Embedded Coder license).
- Your subsystem must be configured to be atomic or conditionally executed. For more information, see “Systems and Subsystems” (Simulink).
- Your subsystem must use the Nonreusable function setting for **Code Generation > Function packaging**.

To configure your subsystem for generating modular function code, you invoke the Subsystem Parameters dialog box and make a series of selections to display and enable the **Function with separate data** option. See “Configure Subsystem for Generating Modular Function Code” on page 29-66 and “Modular Function Code for Nonvirtual Subsystems” on page 29-70 for details. For limitations that apply, see “Nonvirtual Subsystem Modular Function Code Limitations” on page 29-75.
For more information about generating code for atomic subsystems, see the sections “Control Generation of Subsystem Functions” (Simulink Coder) and “Generate Code and Executables for Individual Subsystems” (Simulink Coder).

**Configure Subsystem for Generating Modular Function Code**

This section summarizes the steps to configure a nonvirtual subsystem in a Simulink model for modular function code generation.

1. Verify that the Simulink model containing the subsystem uses an ERT-based system target file (see the **System target file** parameter on the **Code Generation** pane of the Configuration Parameters dialog box).

2. In your Simulink model, select the subsystem for which you want to generate modular function code and open the Subsystem Parameters dialog box (for example, right-click the subsystem and select **Block Parameters (Subsystem)**). The dialog box for an atomic subsystem is shown below. (In the dialog box for a conditionally executed subsystem, the dialog box option **Treat as atomic unit** is greyed out, and you can skip Step 3.)

3. If the Subsystem Parameters dialog box option **Treat as atomic unit** is available for selection but not selected, the subsystem is neither atomic nor conditionally
executed. Select the option **Treat as atomic unit**, which enables **Function packaging** on the **Code Generation** tab. Select the **Code Generation** tab.

4 For the **Function packaging** parameter, select the value **Nonreusable function**. After you make this selection, the **Function with separate data** option is displayed.
Note Before you generate nonvirtual subsystem function code with the **Function with separate data** option selected, you might want to generate function code with the option *deselected* and save the generated function .c and .h files in a separate directory for later comparison.

Select the **Function with separate data** option. After you make this selection, additional configuration parameters are displayed.
Note To control the naming of the subsystem function and the subsystem files in the generated code, you can modify the subsystem parameters Function name options and File name options.

6 To save your subsystem parameter settings and exit the dialog box, click OK.

This completes the subsystem configuration for generating modular function code. You can now generate the code for the subsystem and examine the generated files, including the function .c and .h files named according to your subsystem parameter specifications. For more information on generating code for nonvirtual subsystems, see “Control Generation of Subsystem Functions” (Simulink Coder). For examples of generated subsystem function code, see “Modular Function Code for Nonvirtual Subsystems” on page 29-70.
Modular Function Code for Nonvirtual Subsystems

To illustrate the selection of the Function with separate data option for a nonvirtual subsystem, the following procedure generates atomic subsystem function code with and without the option selected and compares the results.

1  Open MATLAB and open the model rtwdemo_atomic using the MATLAB command rtwdemo_atomic.

Examine the Simulink model. This model shows how to preserve the boundary of a virtual subsystem. By selecting the Subsystem Parameters option Treat as atomic unit, you guarantee that the code for that subsystem executes as an atomic unit. When a system is marked as atomic, you can specify how the subsystem is represented in code with the Subsystem Parameters option Code Generation Function Packaging. You can specify that the subsystem is translated to any of the following types of implementation:

- Inline: Inline the subsystem code at the call sites
- Function: A void/void function with I/O and internal data in global data structure
- Reusable Function: A reentrant function with data passed in as part of function arguments
- Auto: Let the code generator optimize the implementation based on context

2  Double-click the SS1 subsystem and examine the contents.
Close the subsystem window when you are finished.

3 Right-click the SS1 subsystem, select Block Parameters (Subsystem) from the context menu, and examine the settings. Simulink and the code generator can avoid "artificial" algebraic loops when the subsystem is made atomic with the subsystem option **Minimize algebraic loop occurrences**.

Close the Block Parameters dialog box when you are finished.

4 Change the **System target file** for the mode from `grt.tlc` to `ert.tlc`. Select the **Configuration Parameters > Code Generation** tab and specify `ert.tlc` for the **System target file** parameter. Click OK twice to confirm the change. Using the ERT target provides more code generation options for the atomic subsystem.

5 Create a variant of `rtwdemo_atomic` that illustrates function code **without** data separation.

   a In the `rtwdemo_atomic` model, right-click the SS1 subsystem and select **Block Parameters (Subsystem)**. In the Subsystem Parameters dialog box that appears, verify that

      • On the **Main** tab, **Treat as atomic unit** is selected
      • On the **Code Generation** tab, **User specified** is selected for **Function name options**
      • On the **Code Generation** tab, `myfun` is specified for **Function name**

   b In the Subsystem Parameters dialog box, on the **Code Generation** tab verify that

      i **Nonreusable function** is selected for the **Function packaging** parameter. After this selection, additional parameters and options appear.
      ii **Use function name** is selected for the **File name options** parameter. This selection is optional but simplifies the later task of code comparison by causing the atomic subsystem function code to be generated into the files `myfun.c` and `myfun.h`.

      Do **not** select the option **Function with separate data**. Click **Apply** to apply the changes and click **OK** to exit the dialog box.

   c Save this model variant to a personal work directory, for example, `rtwdemo_atomic1` in `d:/atomic`.

6 Create a variant of `rtwdemo_atomic` that illustrates function code **with** data separation.
In the rtwdemo_atomic1 model (or rtwdemo_atomic with step 3 reapplied), right-click the SS1 subsystem and select **Block Parameters (Subsystem)**. In the Subsystem Parameters dialog box, verify that

- On the **Main** tab, **Treat as atomic unit** is selected
- On the **Code Generation** tab, **Function** is selected for **Function packaging**
- On the **Code Generation** tab, **User specified** is selected for **Function name options**
- On the **Code Generation** tab, **myfun** is specified for **Function name**
- On the **Code Generation** tab, **Use function name** is specified for **File name options**

In the Subsystem Parameters dialog box, on the **Code Generation** tab, select the option **Function with separate data**. Click **Apply** to apply the change and click **OK** to exit the dialog box.

Save this model variant, using a different name than the first variant, to a personal work directory, for example, rtwdemo_atomic2 in d:/atomic.

Generate code for each model, rtwdemo_atomic1 and rtwdemo_atomic2.

In the generated code directories, compare the `model.c`/`.h` and `myfun.c`/`.h` files generated for the two models. For code comparison discussion, see “H File Differences for Nonvirtual Subsystem Function Data Separation” on page 29-72 and “C File Differences for Nonvirtual Subsystem Function Data Separation” on page 29-72.

In this example, there are not significant differences in the generated variants of `ert_main.c`, `model_private.h`, `model_types.h`, or `rtwtypes.h`.

### H File Differences for Nonvirtual Subsystem Function Data Separation

The differences between the H files generated for rtwdemo_atomic1 and rtwdemo_atomic2 help illustrate the selection of the **Function with separate data** option for nonvirtual subsystems.

Selecting **Function with separate data** causes typedefs for subsystem data to be generated in the `myfun.h` file for rtwdemo_atomic2:

```c
/* Block signals for system '<Root>/SS1' */
typedef struct {
```
real_T Integrator; /* '<S1>/Integrator' */
} rtB_myfun;

/* Block states (auto storage) for system '<Root>/SS1'; */
typedef struct {
    real_T Integrator_DSTATE; /* '<S1>/Integrator' */
} rtDW_myfun;

By contrast, for rtwdemo_atomic1, typedefs for subsystem data belong to the
model and appear in rtwdemo_atomic1.h:

/* Block signals (auto storage) */
typedef struct {
    ...
    real_T Integrator; /* '<S1>/Integrator' */
} BlockIO_rtwdemo_atomic1;

/* Block states (auto storage) for system '<Root>' */
typedef struct {
    real_T Integrator_DSTATE; /* '<S1>/Integrator' */
} D_Work_rtwdemo_atomic1;

**Selecting Function with separate data** generates the following external
declarations in the myfun.h file for rtwdemo_atomic2:

/* Extern declarations of internal data for 'system '<Root>/SS1'' */
extern rtB_myfun rtwdemo_atomic2_myfunB;
extern rtDW_myfun rtwdemo_atomic2_myfunDW;
extern void myfun_initialize(void);

By contrast, the generated code for rtwdemo_atomic1 contains model-level external
declarations for the subsystem's BlockIO and D_Work data, in
rtwdemo_atomic1.h:

/* Block signals (auto storage) */
extern BlockIO_rtwdemo_atomic1 rtwdemo_atomic1_B;

/* Block states (auto storage) */
extern D_Work_rtwdemo_atomic1 rtwdemo_atomic1_DWork;

**C File Differences for Nonvirtual Subsystem Function Data Separation**

The differences between the C files generated for rtwdemo_atomic1 and
rtwdemo_atomic2 illustrate the selection of the Function with separate data option
for nonvirtual subsystems.
Selecting **Function with separate data** causes a separate subsystem initialize function, myfun_initialize, to be generated in the myfun.c file for rtwdemo_atomic2:

```c
void myfun_initialize(void) {
    {((real_T*)&rtwdemo_atomic2_myfunB.Integrator)[0] = 0.0;
    }
    rtwdemo_atomic2_myfunDW.Integrator_DSTATE = 0.0;
}
```

The subsystem initialize function in myfun.c is invoked by the model initialize function in rtwdemo_atomic2.c:

```c
/* Model initialize function */
void rtwdemo_atomic2_initialize(void) {
    ...

    /* Initialize subsystem data */
    myfun_initialize();
}
```

By contrast, for rtwdemo_atomic1, subsystem data is initialized by the model initialize function in rtwdemo_atomic1.c:

```c
/* Model initialize function */
void rtwdemo_atomic1_initialize(void) {
    ...

    /* block I/O */
    {
      ...
      ((real_T*)&rtwdemo_atomic1_B.Integrator)[0] = 0.0;
    }

    /* states (dwork) */
    rtwdemo_atomic1_DWork.Integrator_DSTATE = 0.0;
    ...
}
```
2 Selecting **Function with separate data** generates the following declarations in the myfun.c file for rtwdemo_atomic2:

```c
/* Declare variables for internal data of system '<Root>/SS1' */
rtB_myfun rtwdemo_atomic2_myfunB;
rtDW_myfun rtwdemo_atomic2_myfunDW;
```

By contrast, the generated code for rtwdemo_atomic1 contains model-level declarations for the subsystem's BlockIO and D_Work data, in rtwdemo_atomic1.c:

```c
/* Block signals (auto storage) */
BlockIO_rtwdemo_atomic1 rtwdemo_atomic1_B;

/* Block states (auto storage) */
D_Work_rtwdemo_atomic1 rtwdemo_atomic1_DWork;
```

3 Selecting **Function with separate data** generates identifier naming that reflects the subsystem orientation of data items. Notice the references to subsystem data in subsystem functions such as myfun and myfun_update or in the model's `model_step` function. For example, compare this code from myfun for rtwdemo_atomic2

```c
/* DiscreteIntegrator: '<S1>/Integrator' */
rtwdemo_atomic2_myfunB.Integrator = rtwdemo_atomic2_myfunDW.Integrator_DSTATE;
```

to the corresponding code from myfun for rtwdemo_atomic1.

```c
/* DiscreteIntegrator: '<S1>/Integrator' */
rtwdemo_atomic1_B.Integrator = rtwdemo_atomic1_DWork.Integrator_DSTATE;
```

### Nonvirtual Subsystem Modular Function Code Limitations

The nonvirtual subsystem option **Function with separate data** has the following limitations:

- The **Function with separate data** option is available only in ERT-based Simulink models (requires a Embedded Coder license).
- The nonvirtual subsystem to which the option is applied cannot have multiple sample times or continuous sample times; that is, the subsystem must be single-rate with a discrete sample time.
- The nonvirtual subsystem cannot contain continuous states.
• The nonvirtual subsystem cannot output function call signals.
• The nonvirtual subsystem cannot contain noninlined S-functions.
• The generated files for the nonvirtual subsystem will reference model-wide header files, such as model.h and model_private.h.
• The Function with separate data option is incompatible with the Classic call interface option, located on the Code Generation > Interface pane of the Configuration Parameters dialog box. Selecting both generates an error.
• The Function with separate data option is incompatible with setting Code interface packaging to Reusable function (Code Generation > Interface pane). Selecting both generates an error.
• When you select Function with separate data for a subsystem, the model that contains the subsystem cannot contain a Data Store Memory block with Share across model instances selected. See Data Store Memory.

Control Data and Function Placement in Memory by Inserting Pragmas

For some applications, you can use pragmas and other code decorations to control the placement of data (global variables) and function definitions in memory. For example, a linker configuration file can define named sections in a `SECTIONS` directive and map each section to a range of memory addresses. In the C code, you include pragmas that assign global variables and functions to these named sections and, by extension, to the memory ranges. By controlling memory placement, you can:

- Generate code that is more efficient for your hardware.
- Modularize your application code for easier maintenance and modification later in the development process and after deployment.

With Embedded Coder and memory sections, you can:

- Apply default pragmas or other decorations to categories of model data and entry-point functions. To configure these defaults, use the Code Mapping Editor. For example, you can:
  - Apply a default pragma to internal data, which includes block states that the code generator cannot eliminate through optimizations. You can apply a different default pragma to constant parameters, such as nonscalar parameters that the generated code must store in memory.
  - Apply a default pragma to categories of generated functions, including entry-point functions such as `model_step`.
- Override the default pragmas for individual data items such as block parameters, states, and signals. To do so, create your own storage class.
- Override the default pragmas for individual functions that correspond to atomic subsystems, which you can configure to appear in the generated code as separate functions with separate data. Use the subsystem parameters dialog box.

Insert Pragmas by Using Memory Sections

In this example, you configure the default memory placement for all of the data and functions of the algorithm represented by the example model `rtwdemo_roll`. Then, for some signal data, you override the default placement.
Explore Example Model and Inspect Default Generated Code

1. Open the example model.

   ```matlab
   open_system('rtwdemo_roll')
   ```

The model is configured to generate efficient production code. For example, the configuration parameter **Default parameter behavior** is set to **Inlined**.

2. Generate code from the model.

3. In the code generation report, inspect the file `rtwdemo_roll.h`. The file defines structure types that represent data that the algorithm needs. For example, the file defines a structure type that represents block states such as the states of Discrete-Time Integrator blocks.

   ```c
   /* Block states (default storage) for system '<Root>' */
   typedef struct {
     real32_T FixPtUnitDelay1_DSTATE;  /* '<S7>/FixPt Unit Delay1' */
     real32_T Integrator_DSTATE;       /* '<S1>/Integrator' */
     int8_T Integrator_PrevResetState; /* '<S1>/Integrator' */
   } DW_rtwdemo_roll_T;
   ```

The file also declares entry-point functions for the model.

   ```c
   /* Model entry point functions */
   extern void rtwdemo_roll_initialize(void);
   ```
extern void rtwdemo_roll_step(void);
extern void rtwdemo_roll_terminate(void);

4 Inspect rtwdemo_roll.c. This file defines global structure variables to store the data. The file also defines the functions.

In this example, assume your linker configuration file defines named sections MYALGORITHM_DATA and MYALGORITHM_CODE in a SECTIONS directive. You can configure the model so that the generated code includes pragmas, placing the memory allocated for the data and functions in these named sections.

- For a global variable named myVar, the pragma syntax is:

  #pragma SEC_MYALGORITHM_DATA("myVar")

  double myVar;
- For a function named myFunction, the pragma syntax is the same except for the section name:

  #pragma SEC_MYALGORITHM_CODE("myFunction")

  void myFunction(void)

Create Memory Sections

In this example, you use two pragmas with different syntaxes, so you must create two memory sections.

1 In the model window, select Code > C/C++ Code > Configure Model in Code Perspective. Simulink places the model in the code perspective, which you can use to configure code generation settings for the model.

2 Underneath the block diagram, under Code Mappings > Data Defaults, click the Embedded Coder Dictionary icon.

3 In the Embedded Coder Dictionary dialog box, select the Memory Sections tab.

4 Click the Add button.

5 For the new memory section, set these options:

- Name to MYALGORITHM_DATA.
- Statements Surround to Each variable.
- Pre Statement to #pragma SEC_MYALGORITHM_DATA("$N"). The token $N stands for the name of each variable that uses the memory section.

6 Create another, similar memory section that corresponds to MYALGORITHM_CODE.
Configure Default Pragmas for Data and Functions

1. In the model, inspect the Code Mappings > Data Defaults tab.
2. In the table, select the Inports row.
3. In the Property Inspector, set Memory Section to MYALGORITHM_DATA.
4. For the other rows in the table, set Memory Section to MYALGORITHM_DATA.
5. Under Function Defaults, for each row in the table, set Memory Section to MYALGORITHM_CODE.
6. In your current folder, delete the existing slprj folder.
7. Configure the model to generate only code. Select the configuration parameter Configuration Parameters > Generate code only.
8. Generate code from the model.

Now, the rtwdemo_roll.c file applies the pragmas to the definitions of the structure variables and the functions. For each category of data and functions that you configured in the Code Mapping Editor, the code applies a pragma. For example, the code applies the MYALGORITHM_DATA pragma to each of the structures that store block states, root-level inputs, and root-level outputs.

```c
/* Block states (default storage) */
#pragma SEC_MYALGORITHM_DATA("rtwdemo_roll_DW")

DW_rtwdemo_roll_T rtwdemo_roll_DW;

/* External inputs (root inport signals with default storage) */
#pragma SEC_MYALGORITHM_DATA("rtwdemo_roll_U")

ExtU_rtwdemo_roll_T rtwdemo_roll_U;

/* External outputs (root outports fed by signals with default storage) */
#pragma SEC_MYALGORITHM_DATA("rtwdemo_roll_Y")

ExtY_rtwdemo_roll_T rtwdemo_roll_Y;
```

Retain Default Memory Section After Applying a Default Storage Class or Function Template

In the Code Mapping Editor, you can use the Storage Class and Function Customization Template columns to control the default appearance of data and functions in the generated code. When you use these columns to apply a setting other than Default, the Code Mapping Editor discards the memory section that you applied in the Property Inspector. To retain the memory section, use the Embedded Coder Dictionary to create a storage class or function template, then apply the memory section to that storage class or function template.
In this example, you configure the nonparameter data of the model, such as signals and states, to appear in the same structure by creating a storage class. To retain the MYALGORITHM_DATA memory section, you apply the memory section to the storage class.

1. In the Embedded Coder Dictionary for the model, select the Storage Classes tab and click the Add button.
2. For the new storage class, set:
   - **Name** to STRUCT_DATA.
   - **Storage Type** to Structured.
   - **Memory Section** to MYALGORITHM_DATA.
3. In the Code Mapping Editor, under Data Defaults, in the Storage Class column, select STRUCT_DATA for all of the rows except:
   - Global parameters
   - Local parameters
   - Global data stores
   - Constants
4. Generate code from the model.
5. Inspect rtwdemo_roll.c. Now, the file defines a single structure variable that contains the nonparameter data, applying the pragma to that variable.

```c
/* Storage class 'STRUCT_DATA' */
#pragma SEC_MYALGORITHM_DATA("STRUCT_DATA_rtwdemo_roll")

rtwdemo_roll_STRUCT_DATA STRUCT_DATA_rtwdemo_roll;
```

**Retain Default Memory Section After Directly Applying a Storage Class**

To override the default storage classes that you specify in Code Mappings > Data Defaults, you can apply a storage class directly to a data item by using the Model Data Editor. Directly applying any storage class other than Auto or Model default bypasses the default memory section that you specify in Data Defaults. To retain the memory section, you must migrate the memory section definition out of the Embedded Coder Dictionary and into a package, which is a folder that can contain storage class and memory section definitions. Then, you can create a storage class in the package, apply the memory section to the storage class, and apply the storage class directly to individual data items in the Model Data Editor.

In rtwdemo_roll, in the BasicRollMode subsystem, the three Gain blocks represent the parameters of a PID control algorithm. In this example, you configure the output
Control Data and Function Placement in Memory by Inserting Pragmas

signals of these blocks so that the generated code allocates memory for them and places the memory in the MYALGORITHM_DATA section. You also configure the signals so that the code defines them in mySigs.c and declares them in mySigs.h.

To create the memory section and the storage class:

1. In your current folder, create a folder named `myPackage`. The folder defines a package named `myPackage`.

To make the package available outside of your current folder, optionally, you can add the folder containing the `myPackage` folder to the MATLAB path.

2. Open the Custom Storage Class designer:

   ```matlab
cscdesigner('myPackage');
```

3. In the Custom Storage Class Designer, select the **Memory Section** tab.

4. Click **New**.

5. For the new memory section, set these options, which match the options that you set for MYALGORITHM_DATA in the Embedded Coder Dictionary:

   - **Name** to MYALGORITHM_DATA.
   - **Statements surround** to Each variable.
   - **Pre statement** to `#pragma SEC_MYALGORITHM_DATA("$N")`.

6. Click **Apply** and **Save**.

7. In the `myPackage` package folder, create a folder named `@Signal`.

8. In the `@Signal` folder, create a file named `Signal.m`.

   ```matlab
classdef Signal < Simulink.Signal

    methods
        function setupCoderInfo(h)
            useLocalCustomStorageClasses(h, 'myPackage');
        end

        function h = Signal()
            % SIGNAL  Class constructor.
        end % End of constructor

    end % methods
end % classdef
```

The file defines a class named `myPackage.Signal`, which is derived from the built-in class `Simulink.Signal`. The class definition overrides the `setupCoderInfo`
method, which the Simulink.Signal class already implements. The new implementation specifies that objects of the myPackage.Signal class use custom storage classes from the myPackage package instead of custom storage classes from the built-in Simulink package.

9. Set your current folder to the folder that contains the +myPackage folder.
10. In the Custom Storage Class Designer for myPackage, select the Custom Storage Class tab.
11. Click New.
12. For the new custom storage class, set these properties:

   • Name to myCSC.
   • Clear For parameters.
   • Memory section to MYALGORITHM_DATA.
   • Data scope to Exported.
   • Header file to mySigs.h.
   • Definition file to mySigs.c.

13. Click Apply and Save.

To apply the storage class in the model:

1. In the model, select View > Model Explorer > Model Explorer.
2. In the Model Explorer Model Hierarchy pane, select Base Workspace.
3. In the Model Explorer toolbar, click the arrow next to the Add Signal button and select Customize class lists.
4. In the Customize class lists dialog box, under Signal classes, select the check box next to myPackage.Signal and click OK.
5. In the Model Explorer, click the arrow next to Add Signal again and select myPackage.Signal. A myPackage.Signal object appears in the base workspace.
6. Delete the myPackage.Signal object from the base workspace. Now, when you use the Model Data Editor to apply storage classes to signals, you can choose storage classes from the myPackage package.
7. In the model, navigate into the BasicRollMode subsystem.
8. Underneath the block diagram, select the Model Data Editor > Signals tab.
9. In the model, select the three Gain blocks.
10. In the Model Data Editor, in the data table, for any of the highlighted rows, set Storage Class to myCSC.
11. Generate code from the model.
Inspect the generated file mySigs.c. The file defines the global variables that correspond to the Gain block outputs in the model. The pragma applies to the definitions.

```c
/* Definition for custom storage class: myCSC */
#pragma SEC_MYALGORITHM_DATA("DispGain")
real32_T DispGain;
#pragma SEC_MYALGORITHM_DATA("IntGain")
real32_T IntGain;
#pragma SEC_MYALGORITHM_DATA("RateGain")
real32_T RateGain;
```

Now, two definitions of the MYALGORITHM_DATA memory section exist: One in the Embedded Coder Dictionary and one in myPackage. When you make changes to the memory section, make the same changes for each definition.

**ConfigurePragma to Surround Groups of Definitions**

If your build toolchain requires that a pragma or other decoration surround multiple definitions of variables or functions at once, in an Embedded Coder Dictionary or the Custom Storage Class Designer, set **Statements surround to Group of variables** (the default in the Custom Storage Class Designer).

**Override Default Memory Placement for Individual Data Elements**

After you configure memory section defaults in the Code Mapping Editor (see “Configure Default Code Generation for Categories of Model Data and Functions” on page 21-7), to override these default settings for individual data elements (signals, parameters, and states), create a storage class and any required memory sections by using the Custom Storage Class Designer. In the Designer, when you create the storage class, set the **Memory section** property to the appropriate memory section. Then, use the Model Data Editor to apply the storage class to individual data elements.
Choose Where to Create and Store Memory Section Definition

To define a memory section, you must choose where to create it: in an Embedded Coder Dictionary or in a package (by using the Custom Storage Class Designer).

- If you need to use the memory section only in the Code Mapping Editor, define the memory section in an Embedded Coder Dictionary.
- If you need to use the memory section outside of the Code Mapping Editor, for example, in the Model Data Editor, define the memory section in a package.

Optionally, you can enable use of the package memory section in the Code Mapping Editor by loading the package into an Embedded Coder Dictionary (see “Refer to Code Generation Definitions in a Package”). However, if you create storage classes in the dictionary, you cannot apply the package memory section to them. To associate a memory section with storage classes that you define in an Embedded Coder Dictionary and with other storage classes that you define in a package, maintain two definitions of the memory section: one in the dictionary and one in the package.

Share Memory Section Definition Between Models

- If you define the memory section in the Embedded Coder Dictionary of a model, you cannot use the memory section in other models. To share the memory section, migrate the definition to a Simulink data dictionary (sldd). Then, share the dictionary between the target models. For more information, see “Share Embedded Coder Dictionary Definition Between Models” on page 20-6.
- If you define the memory section in a package, any model can use the memory section. Add the folder containing the package folder to the MATLAB path (see “What Is the MATLAB Search Path?” (MATLAB)).

Share Memory Section Between Packages (Package Memory Sections Only)

Packages can access and use memory sections that are defined in other packages, including custom packages and built-in packages such as Simulink. Only one copy of the memory section exists, in the package that defines it. Other packages refer to the memory section by pointing to it in its original location. Changes to the memory section, including changes to a built-in memory section in later MathWorks product releases, are immediately available in every referencing package.
To configure a package to refer to a memory section that is defined in another package:

1. Open the Custom Storage Class Designer. At the command prompt, enter `cscdesigner`.
2. Select the **Memory Section** tab.
3. Use **Select Package** to select the package in which you want to reference a class or section defined in some other package.
4. In the **Memory section definitions** pane, select the existing definition below which you want to insert the reference.
5. Click **New Reference**.

A new reference with a default name and properties appears below the previously selected definition. The new reference is selected, and a **Reference** tab appears that shows the reference's initial properties.

6. Use the **Name** field to enter a name for the new reference. The name must be unique in the importing package, but can duplicate the name in the source package.
7. Set **Refer to memory section in package** to specify the package that contains the memory section that you want to reference.
8. Set **Memory section to reference** to specify the memory section to be referenced.
9. Click **OK** or **Apply** to save the changes to memory. To save the changes permanently, click **Save**.

**Control Appearance of Memory Section Drop-Down List (Package Memory Sections Only)**

When you apply a package memory section, you select the memory section from a drop-down list. To control the order of the memory sections in the list, in the Custom Storage Class Designer, use the **Up** and **Down** buttons. The order of memory sections in drop-down lists matches the order in the Custom Storage Class Designer.

**Protect Definitions of Package Memory Sections (Package Memory Sections Only)**

When you click **Save** in the Custom Storage Class Designer, the Designer saves memory section and custom storage class definitions into the `csc_registration.m` file in the package folder. To determine the location of this file, in the Custom Storage Class Designer, inspect the value of **Filename**.
You can prevent changes to the memory section definitions of an entire package by converting the `csc_registration.m` file from a MATLAB file to a P-file. Use the `pcode` function.

A best practice is to keep `csc_registration.m` and `csc_registration.p` in your package folder. That way, if you need to modify the memory sections by using the Designer, you can delete `csc_registration.p` and later regenerate it after you finish the modifications. Because the P-coded version of the file takes precedence, while both files exist in the package, the memory sections are protected.

### Override Default Memory Placement for Subsystem Functions and Data

When you use atomic subsystems to partition the generated code into functions (see “Generate Subsystem Code as Separate Function and Files” on page 3-11), you can apply different memory sections to the functions and data of each subsystem. You can also specify that a subsystem use no memory section.

- To use different memory sections to override the model-level defaults that you set in the Code Mapping Editor, see “Override Memory Section for Atomic Subsystem” on page 30-12.
- To specify that a subsystem use no memory section (in other words, to prevent the subsystem from inheriting the model-level defaults), see “Specify That Atomic Subsystem Use No Memory Section” on page 30-13.

### Override Memory Section for Atomic Subsystem

The memory sections that you specify for a subsystem override the model-level defaults that you set in the Code Mapping Editor. Use this technique to aggregate the data and instruction code for subroutines or subcomponents (represented by subsystems) into different regions of memory. To apply a memory section directly to an atomic subsystem:

1. Define the memory sections in a package. You cannot use a memory section that you define in an Embedded Coder Dictionary.

2. In the target model, set **Configuration Parameters > Code Generation > Advanced parameters > Memory Sections > Package** to the name of the package. If the package does not appear in the list, click **Refresh package list**.
3 Configure the Embedded Coder Dictionary of the model to load the target package as described in “Refer to Code Generation Definitions in a Package”.

4 Configure the target subsystem to use the memory section. In the subsystem parameters dialog box, on the Code Generation tab:

- Set Function packaging to Nonreusable function or Reusable function (for reentrant code).

- If you set Function packaging to Nonreusable function, to enable configuration of memory sections for the subsystem data, select Function with separate data. If you do not select Function with separate data, the subsystem data inherit memory sections from the model or, if applicable, a parent subsystem.

- Use parameters such as Memory section for initialize/terminate functions to apply default memory sections to the subsystem functions and data.

Specify That Atomic Subsystem Use No Memory Section

By default, subsystem functions and data inherit the model-level memory sections that you specify for relevant function and data categories in the Code Mapping Editor. For example, if you specify a function customization template for the Execution category, and that template carries a memory section, the memory section applies to subsystem execution functions as well as model entry-point execution functions.

To specify that a subsystem use no memory section:

1 In the target model, set Configuration Parameters > Code Generation > Advanced parameters > Memory Sections > Package to one of these values:

   - If the Embedded Coder Dictionary of the model does not refer to code generation definitions in a package (see “Refer to Code Generation Definitions in a Package”), set Package to Simulink.

   - If the Embedded Coder Dictionary of the model refers to a package, set Package to that package.

2 In the target subsystem, on the Code Generation tab, set parameters such as Memory section for initialize/terminate functions to Default. With this setting, the subsystem does not use a memory section for the data or functions that each parameter represents.
Limitations and Other Considerations

- The settings that you specify for an atomic, nonreusable subsystem with separate data apply only to the data and functions of that subsystem, not to data in similarly configured child subsystems. Atomic, nonreusable child subsystems with separate data can inherit memory sections from the containing model, not from the parent subsystem.

- If you use **Build This Subsystem** or **Build Selected Subsystem** to generate code for an atomic subsystem that specifies memory sections, the code generator ignores the subsystem-level specifications and uses the model-level specifications instead. For information about building subsystems, see “Generate Code and Executables for Individual Subsystems” (Simulink Coder).

Create Fewer Custom Storage Classes (Package Memory Sections Only)

In the example “Insert Pragmas by Using Memory Sections” on page 30-2, to apply a memory section to individual signal data items, you create a custom storage class by using the Custom Storage Class Designer. Suppose you want to apply a different memory section to each of the signals. Instead of copying the custom storage class (myCSC) and associating a different memory section with the copy, which results in two very similar custom storage classes, in the Custom Storage Class Designer, for myCSC, set **Memory section** to **Instance specific**. Then, when you apply the custom storage class to a data item, you can choose a memory section for that data item.

Limitations

- The code generator does not apply memory sections to data that uses these built-in storage classes:
  - ExportedGlobal
  - ImportedExtern
  - ImportedExternPointer

- In the Custom Storage Class Designer, the storage type qualifier that you specify for a memory section by using the **Qualifier** text box affects only data items that use a storage class setting other than these built-in storage classes:
  - ExportedGlobal
• ImportedExtern
• ImportedExternPointer

The code generator omits the qualifier from other data categories.
• When you create a subsystem in a custom block library, you cannot specify memory sections for the subsystem definition in the library. Instead, specify memory sections for the subsystem instances that you place in your models.

Insert Pragmas for Functions and Data in Generated Code

This model shows how to insert pragmas for functions and data in generated code.

Explore Example Model

Open the example model.

```
open_system('rtwdemo_memsec')
```

Instructions

1. Learn about memory sections by clicking the documentation link in the model.
2. View the memory sections in the ECoderDemos package by clicking the button in the model and then selecting the Memory Sections tab.
3. View the memory sections selected for this model by clicking the button in the model. The model-level settings are also the default settings for atomic subsystems.

4. Open the SubSystem Parameters dialog for the subsystems to see the memory section settings for each of the atomic subsystems in the model.

5. Generate code by clicking the button in the model. An HTML report is displayed automatically. Inspect the data and function definitions in the .c files and observe how the generated pragmas correspond to the specified memory sections.

Protect Global Data with `const` and `volatile` Keywords

In C, you use the keyword `const` to prevent any code in an application from assigning a new value to a variable. In an application where an external actor (for example, a hardware device) can manipulate the value of a variable, you use the keyword `volatile` to prevent your compiler from optimizing the assembly code in a way that compromises the integrity of the variable value. You can also use `volatile` to prevent your compiler from eliminating storage for `const` data, such as a parameter whose value you want to tune during execution.

- To apply the qualifiers to an individual data item in a model, including a custom structure that you create by using a nonvirtual bus or a parameter structure, apply the appropriate built-in custom storage class directly to the data item. The custom storage class prevents optimizations such as Default parameter behavior from eliminating storage for the data item. For an example, see “Type Qualifiers” on page 14-14. For information about optimizations that a directly applied storage class prevents, see “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 22-50.

If the built-in custom storage classes do not meet your requirements, you can create your own custom storage class. To make your custom storage class apply the qualifiers, in the Custom Storage Class Designer, set Memory section to the appropriate built-in memory section or to a memory section that you create. For more information, see “Create Custom Storage Classes by Using the Custom Storage Class Designer” on page 26-26.

- You can apply the qualifiers to a category of model data by default, such as parameters or states. As you add blocks to a model, new data items in these categories carry the qualifiers that you specify. For more information, see “Configure Default Code Generation for Data” on page 21-8.

If the built-in storage classes do not meet your requirements, you can create your own by using an Embedded Coder Dictionary. In the Dictionary, for your new storage class, select the appropriate check boxes under Qualifiers. For more information, see “Create Code Definitions for Use as Default Code Generation Settings” on page 20-2.
Maintain const Correctness for Arguments of Entry-Point Functions

When your external code calls a generated entry-point function and passes const data through an argument (formal parameter) of the function, to make the corresponding argument in the function definition const, use function prototype control.

- To configure function prototype control for a model entry-point function such as model_step, see “Control Generation of Function Interfaces” on page 53-2.
- To configure function prototype control for a Simulink Function block, see “Customize Generated Function Interfaces for Simulink Function and Function Caller Blocks” on page 29-24.

Incorrect Results or Undefined Behavior When Passing Volatile Data to a Generated Function

The generated code can define and call functions other than the model entry-point functions such as model_step and model_initialize. For example, you can configure an atomic subsystem to appear in the code as a separate function. Also, lookup table blocks such as n-D Lookup Table typically yield separate utility functions.

When the generated code defines a function that has an argument (formal parameter), the function definition does not apply volatile to the argument. Therefore, when other generated code or your external code calls the function and passes a volatile variable as the value of the argument, the called function implicitly casts away the volatility.

If your application executes the called function while the value of the volatile data changes, the function can yield incorrect results or undefined behavior. In particular, for lookup table data that you prepare for calibration by applying const and volatile, make sure that you do not calibrate the data while your application executes the lookup utilities.

Code Generation Configuration

When you are ready to generate code for a model, you can modify the model configuration parameters specific to code generation. The code generation parameters determine how the code generator produces code and builds an executable program from your model.

The model configuration parameters for code generation are in the Code Generation and Optimization panes in the Configuration Parameters dialog box. The content of the Code Generation pane and its subpanes can change depending on the target that you specify. Some configuration options are available only with the Embedded Coder product. The Optimization pane includes code generation parameters that help to improve the performance of the generated code.

Your application objectives can include a combination of these code generation objectives: debugging, traceability, execution efficiency, and safety precaution. There are tradeoffs associated with these configuration choices, such as execution speed and memory usage. To help configure a model to achieve your application objectives, use the Model Advisor and the Code Generation Advisor.

Open the Model Configuration for Code Generation

To modify the model configuration parameters for code generation, open the Code Generation pane. There are several different ways to open the Code Generation pane from the Simulink editor:

- To open the Configuration Parameters dialog box, click the model configuration parameters icon.

Then click Code Generation in the Select (left) pane.

- From the Simulation menu, select Model Configuration Parameters. When the Configuration Parameters dialog box opens, click Code Generation in the Select (left) pane.

- From the Code menu, select C/C++ Code > Code Generation Options.

- From the View menu in the model window, select Model Explorer, or from the MATLAB command line, type daexplr and press Enter. In the Model Explorer, expand the node for the current model in the left pane and click Configuration
(active). Click elements in the middle pane to display the corresponding parameters in the right pane.

**Note** In a Configuration Parameters dialog box, when you change the value of a check box, menu selection, or edit field, the white background of the element changes color to indicate that you made an unsaved change. When you click OK, Cancel, or Apply, the background resets to white.

## Configuration Tools

To help you configure your model for code generation and to check your configuration against your code generation objectives, Simulink Coder and Embedded Coder provide several tools.

<table>

Configure Code Generation Parameters for Model Programmatically

You can modify code generation parameters for the active configuration set in the Configuration Parameters dialog box or from the MATLAB command line. Use the command-line approach for creating a script that automates setting parameters for an established model configuration.

Modify Parameters to Support Execution efficiency

In this example, you modify the configuration parameters to support the Code Generation Advisor application objective, Execution efficiency.

Step 1. Open a model.

slexAircraftExample

Step 2. Get the active configuration set.

cs = getActiveConfigSet(model);

Step 3. Select the Generic Real-Time (GRT) target.

switchTarget(cs,'grt.tlc',[]);

Step 4. To optimize execution speed, modify parameters.

If your application objective is Execution efficiency, use set_param to modify these parameters:

set_param(cs,'MatFileLogging','off');
set_param(cs,'SupportNonFinite','off');
set_param(cs,'RTWCompilerOptimization','on');
set_param(cs,'OptimizeBlockI0Storage','on');
set_param(cs,'EnhancedBackFolding','on');
set_param(cs,'ConditionallyExecuteInputs','on');
set_param(cs,'DefaultParameterBehavior','Inlined');
set_param(cs,'BooleanDataType','on');
set_param(cs,'BlockReduction','on');
set_param(cs,'ExpressionFolding','on');
set_param(cs,'LocalBlockOutputs','on');
set_param(cs,'EfficientFloat2IntCast','on');
set_param(cs,'BufferReuse','on');
Step 5. Save the model configuration to a file.

Save the model configuration to a file, 'Exec_efficiency_cs.m', and view the parameter settings.
