This example shows how to generate code that reads the value of a signal by dereferencing a memory address that you specify. With this technique, you can generate a control algorithm that interacts with memory that your hardware populates (for example, memory that stores the output of an analog-to-digital converter in a microcontroller).

In this example, you generate an algorithm that acquires input data from a 16-bit block of memory at address \(0x8675309\). Assume that a hardware device asynchronously populates only the lower 10 bits of the address. The algorithm must treat the address as read-only (\(\text{const}\)), volatile (\(\text{volatile}\)) data, and ignore the upper 6 bits of the address.

The generated code can access the data by defining a macro that dereferences \(0x8675309\) and masks the unnecessary bits:

\[
\text{#define A2D_INPUT } \left(\left(\left(\text{volatile const uint16_T } \ast\right)0x8675309\right)\&0x03FF\right)
\]

To configure a model to generate code that defines and uses this macro, you must create an advanced custom storage class and write Target Language Compiler (TLC) code. For an example that shows how to use the Custom Storage Class Designer without writing TLC code, see “Create and Apply a Custom Storage Class” on page 35-35.

As an alternative to writing TLC code, you can use memory sections to generate code that includes pragmas. Depending on your build toolchain, you can use pragmas to specify a literal memory address for storing a global variable. For more information about memory sections, see “Control Data and Function Placement in Memory by Inserting Pragmas” on page 39-2.
**Derivation of Macro Syntax**

In this example, you configure the generated code to define and use the dereferencing macro. To determine the correct syntax for the macro, start by recording the target address.

0x8675309

Cast the address as a pointer to a 16-bit integer. Use the Simulink Coder data type name `uint16_T`.

`(uint16_T *)0x8675309`

Add the storage type qualifier `const` because the generated code must not write to the address. Add `volatile` because the hardware can populate the address at an arbitrary time.

`(volatile const uint16_T *)0x8675309`

Dereference the address.

`*(volatile const uint16_T *)0x8675309`

After the dereference operation, apply a mask to retain only the 10 bits that the hardware populates. Use explicit parentheses to control the order of operations.

`(*(volatile const uint16_T *)0x8675309)&0x03FF`

As a safe coding practice, wrap the entire construct in another layer of parentheses.

`((*(volatile const uint16_T *)0x8675309)&0x03FF)`

**Create Example Model**

Create the example model `ex_memmap_simple`.

For the Inport block, set the output data type to `uint16`. Name the signal as `A2D_INPUT`. The Inport block and the signal line represent the data that the hardware populates.
For the Gain block, set the output data type to `double`.

**Create Package to Contain Definitions of Data Class and Custom Storage Class**

In your current folder, create a folder named `+MemoryMap`. The folder defines a package named `MemoryMap`.

To make the package available for use outside of your current folder, you can add the folder containing the `+MemoryMap` folder to the MATLAB path.

**Create Custom Storage Class**

To generate code that defines and reads `A2D_INPUT` as a macro, you must create a custom storage class that you can apply to the signal line in the model. Later, you write TLC code that complements the custom storage class.

Open the Custom Storage Class designer in advanced mode. To design a custom storage class that operates through custom TLC code, you must use the advanced mode.

```
cscdesigner('MemoryMap','-advanced');
```

In the Custom Storage Class Designer, click **New**. A new custom storage class, `NewCSC_1`, appears in the list of custom storage class definitions.

Rename the new custom storage class `MemoryMappedAddress`.

For `MemoryMappedAddress`, on the **General** tab, set:

- **Type** to `Other`. The custom storage class can operate through custom TLC code that you write later.
- **Data scope** to `Exported`. For data items that use this custom storage class, Simulink Coder generates the definition (for example, the `#define` statement that defines a macro).
- **Data initialization** to `None`. Simulink Coder does not generate code that initializes the data item. Use this setting because this custom storage class represents read-only data. You do not select `Macro` because the Custom Storage Class Designer does not allow you to use `Macro` for signal data.
- **Definition file** to `Specify` (leave the text box empty). For data items that consume memory in the generated code, `Definition file` specifies the `.c` source file that allocates the memory. However, this custom storage class yields a macro, which does not require memory. Typically, header files (.h), not `.c` files, define macros. Setting
**Definition file** to Specify instead of Instance specific prevents users of the custom storage class from unnecessarily specifying a definition file.

- **Header file** to Instance specific. To control the file placement of the macro definition, the user of the custom storage class must specify a header file for each data item that uses this custom storage class.

- **Owner** to Specify (leave the text box empty). **Owner** applies only to data items that consume memory.

After you finish selecting the settings, click **Apply** and **Save**.

Now, when you apply the custom storage class to a data item, such as the A2D_INPUT signal line, you can specify a header file to contain the generated macro definition. However, you cannot yet specify a memory address for the data item. To enable specification of a memory address, create a custom attributes class that you can associate with the MemoryMappedAddress custom storage class.

**Define Class to Store Custom Attributes for Custom Storage Class**

Define a MATLAB class to store additional information for data items that use the custom storage class. In this case, the additional information is the memory address.

In the MemoryMap package (the +MemoryMap folder), create a folder named @MemoryMapAttribs.

In the @MemoryMapAttribs folder, create a file named MemoryMapAttribs. The file defines a class that derives from the built-in class Simulink.CustomStorageClassAttributes.

```
classdef MemoryMapAttribs < Simulink.CustomStorageClassAttributes
    properties( PropertyType = 'char' )
        MemoryAddress = '';
    end
end
```

Later, you associate this MATLAB class with the MemoryMappedAddress custom storage class. Then, when you apply the custom storage class to a data item, you can specify a memory address.
Write TLC Code That Emits Correct C Code

Write TLC code that uses the attributes of the custom storage class, such as `HeaderFile` and `MemoryAddress`, to generate correct C code for each data item.

In the `+MemoryMap` folder, create a folder named `tlc`.

Navigate to the new folder.

Inspect the built-in template TLC file, `TEMPLATE_v1.tlc`.

```matlab
edit(fullfile(matlabroot,...
    'toolbox','rtw','targets','ecoder','csc_templates','TEMPLATE_v1.tlc'))
```

Save a copy of `TEMPLATE_v1.tlc` in the `tlc` folder. Rename the copy `memory_map_csc.tlc`.

In `memory_map_csc.tlc`, find the portion that controls the generation of C-code data declarations.

```matlab
%case "declare"
    % LibDefaultCustomStorageDeclare is the default declare function to
    % declares a global variable whose identifier is the name of the data.
    %return "extern %<LibDefaultCustomStorageDeclare(record)>">
    %break
    %=============================================================================
```

The `case` construct (`%case`) constructs a return value (`%return`), which the code generator emits into the header file that you specify for each data item. To control the C code that declares each data item, adjust the return value in the `case` construct.

Replace the existing `case` content with this new code, which specifies a different return value:

```matlab
%case "declare"
    % In TLC code, a 'record' is a data item (for example, a signal line).
    % 'LibGetRecordIdentifier' returns the name of the data item.
    %assign id = LibGetRecordIdentifier(record)
```

The `assign` statement assigns the value of `LibGetRecordIdentifier` to `id`. The `case` construct then emits a C-code declaration using the `id` variable.
%assign dt = LibGetRecordCompositeDataTypeName(record)

%% The 'CoderInfo' property of a data item stores a
%% 'Simulink.CoderInfo' object, which stores code generation settings
%% such as the storage class or custom storage class that you specify
%% for the item.
%assign ci = record.Object.ObjectProperties.CoderInfo
%% The 'ci' variable now stores the 'Simulink.CoderInfo' object.

%% By default, the 'CustomAttributes' property of a 'Simulink.CoderInfo'
%% object stores a 'Simulink.CustomStorageClassAttributes' object.
%% This nested object stores specialized code generation settings
%% such as the header file and definition file that you specify for
%% the data item.
%%
%% The 'MemoryMap' package derives a new class,
%% 'MemoryMapAttribs', from 'Simulink.CustomStorageClassAttributes'.
%% The new class adds a property named 'MemoryAddress'.
%% This TLC code determines the memory address of the data item by
%% acquiring the value of the 'MemoryAddress' property.
%assign ca = ci.Object.ObjectProperties.CustomAttributes
%assign address = ca.Object.ObjectProperties.MemoryAddress

%assign width = LibGetDataWidth(record)
%% This TLC code constructs the full macro, with correct C syntax,
%% based on the values of TLC variables such as 'address' and 'dt'.
%% This TLC code also asserts that the data item must be a scalar.
%if width == 1
  %assign macro = ...
    "#define %<id> (((volatile const %<dt>*)%<address>) & 0x03FF)"
%else
  %error( "Non scalars are not supported yet." )
%endif
%return "%<macro>"
%break

%% ===================================================================

The new TLC code uses built-in, documented TLC functions, such as
LibGetRecordIdentifier, and other TLC commands and operations to access
information about the data item. Temporary variables such as dt and address store that
information. The TLC code constructs the full macro, with the correct C syntax, by expanding the variables, and stores the macro in the variable macro.

In the same file, find the portion that controls the generation of data definitions.

```plaintext
%case "define"

   %% LibDefaultCustomStorageDefine is the default define function to define
   %% a global variable whose identifier is the name of the data. If the
   %% data is a parameter, the definition is also statically initialized to
   %% its nominal value (as set in MATLAB).
   %return "<LibDefaultCustomStorageDefine(record)>
%%break

%% ================
```

The `define` case derives a return value that the code generator emits into a `.c` file, which defines data items that consume memory.

Replace the existing `case` content with this new content:

```plaintext
%case "define"
   %return ""
%%break

%% ================
```

MemoryMappedAddress yields a macro in the generated code, so you use the `declare` case instead of the `define` case to construct and emit the macro. To prevent the `define` case from emitting a duplicate macro definition, the new TLC code returns an empty string.

Find the portion that controls the generation of code that initializes data.

```plaintext
%case "initialize"

   %% LibDefaultCustomStorageInitialize is the default initialization
   %% function that initializes a scalar element of a global variable to 0.
   %return LibDefaultCustomStorageInitialize(record, idx, reim)
%%break

%% ================
```
The initialize case generates code that initializes data items (for example, in the model_initialize function).

Replace the existing %case content with this new content:

```matlab
%case "initialize"
%return ""
%break
```

MemoryMappedAddress yields a macro, so the generated code must not attempt to initialize the value of the macro. The new TLC code returns an empty string.

**Complete the Definition of the Custom Storage Class**

Your new MATLAB class, MemoryMapAttribs, can enable users of your new custom storage class, MemoryMappedAddress, to specify a memory address for each data item. To allow this specification, associate MemoryMapAttribs with MemoryMappedAddress. To generate correct C code based on the information that you specify for each data item, associate the customized TLC file, memory_map_csc.tlc, with MemoryMappedAddress.

Navigate to the folder that contains the +MemoryMap folder.

Open the Custom Storage Class Designer again.

cscdesigner('MemoryMap','-advanced');

For MemoryMappedAddress, on the Other Attributes tab, set:

- **TLC file name** to memory_map_csc.tlc.
- **CSC attributes class** to MemoryMap.MemoryMapAttribs.

Click **Apply** and **Save**.

**Define Signal Data Class**

To apply the custom storage class to a signal in a model, in the MemoryMap package, you must create a MATLAB class that derives from Simulink.Signal. When you configure the signal in the model, you select this new data class instead of the default class, Simulink.Signal.

In the MemoryMap package, create a folder named @Signal.
In the @Signal folder, create a file named Signal.m.

```matlab
classdef Signal < Simulink.Signal
    methods
        function setupCoderInfo( this )
            useLocalCustomStorageClasses( this, 'MemoryMap' );
            return;
        end
    end
end
```

The file defines a class named MemoryMap.Signal. The class definition overrides the setupCoderInfo method, which the Simulink.Signal class already implements. The new implementation specifies that objects of the MemoryMap.Signal class use custom storage classes from the MemoryMap package (instead of custom storage classes from the Simulink package). When you configure a signal in a model by selecting the MemoryMap.Signal class, you can select the new custom storage class, MemoryMappedAddress.

**Apply Custom Storage Class to Signal Line**

Navigate to the folder that contains the example model and open the model.

In the model, select **View > Property Inspector**.

Click the signal named A2D_INPUT.

In the Property Inspector, under **Code Generation**, set **Signal object class** to MemoryMap.Signal. If you do not see MemoryMap.Signal, select Customize class lists and use the dialog box to enable the selection of MemoryMap.Signal.

In the Property Inspector, set **Storage class** to MemoryMappedAddress.

Set **Header file** to memory_mapped_addresses.h.

Set **MemoryAddress** to 0x8675309.

**Generate and Inspect Code**

Generate code from the model.
Starting build procedure for model: ex_memmap_simple

Successful completion of build procedure for model: ex_memmap_simple

Inspect the generated header file memory_mapped_addresses.h. The file defines the macro A2D_INPUT, which corresponds to the signal line in the model.

/* Declaration of data with custom storage class MemoryMappedAddress */
#define A2D_INPUT                      (*((volatile const uint16_T*)0x8675309) & 0x03FF)

Inspect the generated file ex_memmap_simple.c. The generated algorithmic code (which corresponds to the Gain block) calculates the model output, rtY.Out1, by operating on A2D_INPUT.

/* Model step function */
void ex_memmap_simple_step(void)
{
    /* Outport: '<Root>/Out1' incorporates:
     * Gain: '<Root>/Gain'
     * Inport: '<Root>/In1'
     */
    rtY.Out1 = 42.0 * (real_T)A2D_INPUT;
}

Generate Main Program for Deployment to Bare Board Target (No Operating System)

This example shows how to configure a model such that the code generator produces an example main program that you can customize for deployment on bare-board target hardware (has no operating system). When you select the model configuration parameter **Generate an example main program**, the code generator produces the example file `ert_main.c` or `ert_main.cpp`. This file includes:

- main() function for the generated program
- Task scheduling code that determines how and when block computations execute on each time step of the model

Operation of the main program and the scheduling algorithm depend primarily on:

- Whether the model is a single-rate or multirate model
- Whether the model solver mode is set to single-tasking or multitasking

For more information, see “Deploy Generated Standalone Executable Programs To Target Hardware” on page 62-2.

Alternatively, you can configure a model to generate an example main program for deployment on target hardware that is running the VxWorks® operating system or threaded code that runs on your host operating system. The example file `ert_main.c` that the code generator produces, shows how to deploy the generated example code.

You can customize a generated main program by using a custom file processing (CFP) template. Consider using a template file to:

- Assemble generated code in buffers
- Call an API to emi buffered code intro specific sections of generated source and header files

For more information, see “File customization template”.

**Open Example Model**

Open the example model `rtwdemo_examplemain`.

```matlab
open_system('rtwdemo_examplemain');
```
**Configure Model**

1. Select the model configuration parameter **Generate an example main program**. When you select this parameter, you enable the parameter **Target operating system**.

2. Set the parameter **Target operating system** to BareBoardExample, VxWorksExample, or NativeThreadsExample. For more information, see “Target operating system”.

3. Consider whether you want to specify a custom file processing template. To configure a template, specify the file name and extension for your template TLC file as a string for the **File customization template** parameter.

**Generate Code**

Generate code for the model.

**Add Hand-Coded Customizations**

Augment the generated code with hand code as needed.
Deploy Generated Component Software to Application Target Platforms

The code generator supports integration of generated code with operating systems and processors. For details, see “Embedded Coder Supported Hardware” on page 81-2.

**Interface to an Example Real-Time Operating System (VxWorks®)**

This example shows how to simulate and generate code for asynchronous events on an example RTOS (VxWorks).

The operating system integration techniques that are demonstrated in this example use one or more blocks in the vxlib1 library. These blocks provide starting point examples to help you develop custom blocks for your target environment.

**Example Model**

Open the `rtwdemo_vxworks` model.

```matlab
model = 'rtwdemo_vxworks';
open_system(model);
```
Model Description

The example model contains two asynchronously executed subsystems, Count and Algorithm. Count executes at interrupt level. Algorithm executes in an asynchronous task. The generated code for these blocks is tailored for the VxWorks® operating system. However, you can modify the Async Interrupt and Task Sync blocks to generate code specific to your environment whether you are using an operating system or not.

Multirate Modeling in Multitasking Mode (VxWorks® OS)

This example generates code for a multirate discrete-time model configured for a multitasking operating system target (VxWorks®). The model contains two sample times. Inport block 1 and Inport block 2 specify 1-second and 2-second sample times, respectively, which are enforced by the Periodic sample time constraint solver configuration parameter setting. The solver is set for multitasking operation, which means a Rate Transition block is required to ensure that data integrity is enforced when the 1-second task preempts the 2-second task. Simulink® and the code generator enforce proper rate transitions. This model specifies an explicit Rate Transition block. Alternatively, you can instruct Simulink® to insert this block for you by setting the model configuration parameter Automatically handle rate transition for data transfer.

The model is configured to display sample-time colors upon diagram update. Red represents the fastest discrete sample time in the model, green represents the second fastest, and yellow represents mixed sample times. Click the Display Sample Time Colors button to update the diagram and show sample-time colors.

Example Model

```matlab
model = 'rtwdemo_mrmtos';
open_system(model);
```
The model is configured to display sample-time colors upon diagram update. Red represents the fastest discrete sample time in the model, green represents the second fastest, and yellow represents mixed sample times. Click the yellow button to the right to update the diagram and show sample-time colors.

This model shows the code generated for a multirate discrete-time model configured for a multitasking operating system target (VxWorks). The model contains two sample times. Inport block 1 and Inport block 2 specify 1-second and 2-second sample times, respectively, which are enforced by the "Periodic sample time constraint" option on the Solver configuration page. The solver is set for multitasking operation, which means a rate transition block is required to ensure that data integrity is enforced when the 1-second task preempts the 2-second task. Proper rate transitions are always enforced by Simulink and Simulink Coder. This model specifies an explicit rate transition block. Alternatively, this block could be automatically inserted by Simulink using the "Automatically handle data transfers between tasks" option on the Solver configuration page.

This example uses a Embedded Coder feature to generate an example VxWorks main (i.e., "Target operating system" on the Template configuration page.) Simulink Coder also supports VxWorks via the Tornado target.
Export Code Generated from Model to External Application in Embedded Coder
Control Generation of C++ Class Interfaces

Using the **Code interface packaging** (Simulink Coder) option C++ class, on the **Code Generation > Interface** pane of the Configuration Parameters dialog box, you can generate a C++ class interface to model code. The generated interface encapsulates required model data into C++ class attributes and model entry point functions into C++ class methods. The benefits of C++ class encapsulation include:

- Greater control over access to model data
- Ability to multiply instantiate model classes
- Easier integration of model code into C++ programming environments

C++ class encapsulation also works for right-click builds of nonvirtual subsystems. (For information on requirements that apply, see “Configure C++ Class Interfaces for Nonvirtual Subsystems” on page 38-55.)

The general procedure for generating C++ class interfaces to model code is as follows:

1. Configure your model to use an ert.tlc system target file provided by MathWorks.
2. Select the C++ language for your model.
3. Select C++ class code interface packaging for your model.
4. Optionally, configure related C++ class interface settings for your model code, using either a graphical user interface (GUI) or application programming interface (API).
5. Generate model code and examine the results.

To get started with an example, see “Simple Use of C++ Class Control” on page 38-37. For more details about configuring C++ class interfaces for your model code, see “Customize C++ Class Interfaces Using Graphical Interfaces” on page 38-44 and “Customize C++ Class Interfaces Programmatically” on page 38-55. For limitations that apply, see “C++ Class Interface Control Limitations” on page 38-62.

**Note** For an example of C++ class code generation, see the example model rtwdemo_cppclass.

What Is Code Replacement Customization?

Customize how and when the code generator replaces C/C++ code that it generates by default for functions and operators by developing a custom code replacement library. You can develop libraries interactively with the Code Replacement Tool or programmatically.

- Develop libraries tailored to specific application requirements
- Add identifiers to the list of reserved keywords the code generator considers during code replacement
- Customize the code generator’s match and replacement process for functions

To get started, “Quick Start Code Replacement Library Development - Simulink®” on page 64-28.

Code Replacement Match and Replacement Process

When the code generator encounters a call site for a function or operator, it:

1. Creates and partially populates a code replacement entry object with the function or operator name or key and conceptual arguments.

2. Uses the entry object to query the configured code replacement library for a conceptual representation match. The code generator searches the tables in a code replacement library for a match in the order that the tables appear in the library. When searching for a match, the code generator takes into account:
   - Conceptual name or key
   - Arguments, including quantity, type, type qualifiers, and complexity
   - Algorithm (computation method)
   - Fixed-point saturation and rounding modes
   - Priority

3. When a match exists, the code generator returns a code replacement object, fully populated with the conceptual representation, implementation representation, and priority. If the code generator finds multiple matches within a table, the entry priority determines the match. The priority can range from 0 to 100. The highest priority is 0. The code generator uses a higher-priority entry over a similar entry with a lower priority.
4 Uses the C or C++ replacement function prototype in the code replacement object to generate code.

**Code Replacement Customization Limitations**

- Code replacement verification — It is possible that code replacement behaves differently than you expect. For example, data types that you observe in code generator input might not match what the code generator uses as intermediate data types during an operation. Verify code replacements by examining generated code. See “Verify Code Replacements” on page 64-79.

- Tokens in file paths—You can include tokens in file paths when specifying build information for a code replacement entry by using the programming interface only. The ability to include tokens is not available from the Code Replacement Tool. See “Specify Build Information for Replacement Code” on page 64-61.

- Data alignment—
  - Not supported for
    - Arguments associated with a built-in custom storage class with DataScope set to Exported or the imported built-in custom storage class GetSet
    - Software-in-the-loop (SIL)
    - Processor-in-the-loop (PIL)
    - Model reference parameters
    - Exported functions in Stateflow charts
    - Replaced functions that are generated with C function prototype control or C++ class I/O arguments step method and that use root-level I/O variables
    - Replaced functions that are generated with the AUTOSAR system target file and that use root-level I/O or AUTOSAR inter-runnable access functions
  - If the following conditions exist, the code generator includes data alignment directives for root-level I/O variables in the ert_main.c or ert_main.cpp file it produces:
    - Compiler supports global variable alignment
    - Generate an example main program (select Configuration Parameters > Generate an example main program)
• Generate a reusable function interface for the model (set Configuration Parameters > Code Generation > Interface > Code interface packaging to Reusable function)

• Function uses root-level I/O variables that are passed in as individual arguments (set Configuration Parameters > Code Generation > Interface > Pass root-level I/O asto Individual arguments)

• Replaced function uses a root-level I/O variable

• Replaced function imposes alignment requirements

If you discard the generated example main program, align used root-level I/O variables correctly.

If you choose not to generate an example main program in this case, the code generator does not replace the function.

• If a replacement imposes alignment requirements on the shared utility interface arguments, the code generator does not honor data alignment. Under these conditions, replacement does not occur. Replacement is allowed if the registered data alignment type specification supports alignment of local variables, and the replacement involves only local variables.

• For Simulink.Bus:

  • If user registered alignment specifications do not support structure field alignment, aligning Simulink.Bus objects is not supported unless the Simulink.Bus is imported.

  • When aligning a Simulink.Bus data object, the elements in the bus object are aligned on the same boundary. The boundary is the lowest common multiple of the alignment requirements for each individual bus element.

• When you specify alignment for functions that occur in a model reference hierarchy, and multiple models in the hierarchy operate on the same function data, the bottommost model dictates alignment for the rest of the hierarchy. If the alignment requirement for a function in a model higher in the hierarchy cannot be honored due to the alignment set by a model lower in the hierarchy, the replacement in the higher model does not occur. In some cases, an error message is generated. To work around this issue, if the shared data is represented by a bus or signal object, manually set the alignment property on the shared data by setting the alignment property of the Simulink.Bus or Simulink.Signal object.

• It is your responsibility to honor the Alignment property setting for custom storage classes that you create.
See “Data Alignment for Code Replacement” on page 64-136.
• coder.replace function — See coder.replace for relevant limitations.

Code You Can Replace From Simulink Models

Code that the code generator replaces depends on the code replacement library (CRL) that you use. By default, the code generator does not apply a code replacement library. Your choice of libraries is dependent on product licensing and whether you have access to custom libraries.

For information on how to explore functions and operators that a code replacement library supports, see “Choose a Code Replacement Library” on page 51-8 license and want to develop a custom code replacement library, see Code Replacement Customization.

Math Functions – Simulink Support

When generating C/C++ code from a Simulink model, depending on code replacement libraries available in your development environment, you can configure the code generator to replace instances of the following math functions with application-specific implementations.

<table>
<thead>
<tr>
<th>Function</th>
<th>Data Type Support</th>
<th>Scalar, Vector, Matrix Support</th>
<th>Real, Complex Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>abs¹</td>
<td>Integer</td>
<td>Scalar</td>
<td>Real</td>
</tr>
<tr>
<td></td>
<td>Floating point</td>
<td>Vector</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Fixed point</td>
<td>Matrix</td>
<td></td>
</tr>
<tr>
<td>acos</td>
<td>Floating point</td>
<td>Scalar</td>
<td>Real complex input/complex output</td>
</tr>
</tbody>
</table>

¹ Note: The abs function is defined for both integer and floating point data types.

1. Wrap on integer overflow only. Clear block parameter **Saturate on integer overflow**.

2. Only when used with the MATLAB Function block.

3. Supports the CORDIC approximation method.

4. Stateflow support only.
**Math Functions - Stateflow Support**

When generating C/C++ code from Stateflow charts, depending on code replacement libraries available in your development environment, you can configure the code generator to replace instances of the following math functions with application-specific implementations.

Memory Functions

Depending on code replacement libraries available in your development environment, you can configure the code generator to replace instances of the following memory functions with application-specific implementations.

<table>
<thead>
<tr>
<th>Function</th>
<th>Data Type Support</th>
<th>Scalar, Vector, Matrix Support</th>
<th>Real, Complex Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>memcmp</td>
<td>Void pointer (void*)</td>
<td>Scalar Vector Matrix</td>
<td>Real Complex</td>
</tr>
<tr>
<td>memcpy</td>
<td>Void pointer (void*)</td>
<td>Scalar Vector Matrix</td>
<td>Real Complex</td>
</tr>
<tr>
<td>memset</td>
<td>Void pointer (void*)</td>
<td>Scalar Vector Matrix</td>
<td>Real Complex</td>
</tr>
<tr>
<td>memset2zero</td>
<td>Void pointer (void*)</td>
<td>Scalar Vector Matrix</td>
<td>Real Complex</td>
</tr>
</tbody>
</table>
Some target processors provide optimized functions to set memory to zero. Use the code replacement library programming interface to replace the `memset2zero` function with more efficient target-specific functions.

**Nonfinite Functions**

Depending on code replacement libraries available in your development environment, you can configure the code generator to replace instances of the following nonfinite functions with application-specific implementations.

<table>
<thead>
<tr>
<th>Function</th>
<th>Data Type Support</th>
<th>Scalar, Vector, Matrix Support</th>
<th>Real, Complex Support</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>getInf</code></td>
<td>Floating point</td>
<td>Scalar</td>
<td>Real</td>
</tr>
<tr>
<td><code>getMinusInf</code></td>
<td>Floating point</td>
<td>Scalar</td>
<td>Real</td>
</tr>
<tr>
<td><code>getNaN</code></td>
<td>Floating point</td>
<td>Scalar</td>
<td>Real</td>
</tr>
<tr>
<td><code>rtIsInf</code></td>
<td>Floating point</td>
<td>Scalar</td>
<td>Real, Complex</td>
</tr>
<tr>
<td><code>rtIsNaN</code></td>
<td>Floating point</td>
<td>Scalar</td>
<td>Real, Complex</td>
</tr>
</tbody>
</table>

**Mutex and Semaphore Functions**

Mutex and semaphore functions control access to resources shared by multiple processes in multicore target environments. MathWorks provides code replacement libraries that support mutex and semaphore replacement for Rate Transition and Task Transition blocks on Windows, Linux, Mac, and VxWorks platforms.

Generated mutex and semaphore code typically consists of:

- In model initialization code, an initialization function call to create a mutex or semaphore to control entry to a critical section of code.
- In model step code:
  - Before code for a data transfer between tasks enters the critical section, mutex lock or semaphore wait function calls to reserve a critical section of code.
  - After code for a data transfer between tasks finishes executing the critical section, mutex unlock or semaphore post function calls to release the critical section of code.
• In model termination code, an optional destroy function call to explicitly delete the mutex or semaphore.

Depending on code replacement libraries available in your development environment, you can configure the code generator to replace instances of the following mutex and semaphore functions with application-specific implementations.

<table>
<thead>
<tr>
<th>Function</th>
<th>Key</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mutex Destroy</td>
<td>RTW_MUTEX_DESTROY</td>
</tr>
<tr>
<td>Mutex Init</td>
<td>RTW_MUTEX_INIT</td>
</tr>
<tr>
<td>Mutex Lock</td>
<td>RTW_MUTEX_LOCK</td>
</tr>
<tr>
<td>Mutex Unlock</td>
<td>RTW_MUTEX_UNLOCK</td>
</tr>
<tr>
<td>Semaphore Destroy</td>
<td>RTW_SEM_DESTROY</td>
</tr>
<tr>
<td>Semaphore Init</td>
<td>RTW_SEM_INIT</td>
</tr>
<tr>
<td>Semaphore Post</td>
<td>RTW_SEM_POST</td>
</tr>
<tr>
<td>Semaphore Wait</td>
<td>RTW_SEM_WAIT</td>
</tr>
</tbody>
</table>

### Operators

When generating C/C++ code from a Simulink model, depending on code replacement libraries available in your development environment, you can configure the code generator to replace instances of the following operators with application-specific implementations.

Mixed data type support indicates that you can specify different data types for different inputs.

<table>

</tbody>
</table>

1. See “Addition and Subtraction Operator Code Replacement” on page 64-177 for details to consider when defining mappings for addition and subtraction code replacements.

2. Can map to Basic Linear Algebra Subroutine (BLAS) multiplication functions.

3. Scaled floating point is not supported.

4. Shift operator replacement with matrix data is supported for shift values that you specify with an input port. Replacement is not supported for shift values that you specify in a block parameter dialog.

5. The code generator converts some arithmetic shift rights to logical shift rights. To avoid unexpected results, when creating a code replacement library that includes a table entry for an arithmetic shift right implementation, also include an entry for a logical shift right implementation.

6. Use the multiplication (*) operator (RTW\_OP\_MUL) for scalar multiplication.

7. Requires scalar, real, or fixed-point data types with zero bias; output type of the multiplication operation to accommodate all possible output values; shift operand is an unsigned integer; and net slope is equal to 1 ($U1\_slope \times U2\_slope = Mul\_output\_slope$ and $Mul\_output\_slope = output\_slope\_of\_shift\_operation$).

8. Requires scalar, real, or fixed-point data types with zero bias; output type of the multiplication operation to accommodate all possible output values; and net slope is equal to 1 ($U1\_slope \times U2\_slope = Mul\_output\_slope = U3\_slope \times Div\_output\_slope$).

Develop a Code Replacement Library

Iterate through the following steps, as necessary, to develop a code replacement library:

1. “Identify Code Replacement Requirements” on page 64-39
2. “Prepare for Code Replacement Library Development” on page 64-42
3. “Define Code Replacement Mappings” on page 64-43
4. “Specify Build Information for Replacement Code” on page 64-61
5. “Register Code Replacement Mappings” on page 64-70
6. “Verify Code Replacements” on page 64-79
7. “Deploy Code Replacement Library” on page 64-96

To get started, see “Identify Code Replacement Requirements” on page 64-39.

To experiment with the process and tools, see “Quick Start Code Replacement Library Development - Simulink®” on page 64-28.

Quick Start Code Replacement Library Development - Simulink®

This example shows how to develop a code replacement library that includes an entry for generating replacement code for the math function sin. You use the Code Replacement Tool.

**Prerequisites**

To complete this example, install the following software:

- MATLAB®
- MATLAB Coder™
- Simulink®
- Simulink Coder™
- Embedded Coder®
- Compiler

For instructions on installing MathWorks® products, see the MATLAB installation documentation. If you have installed MATLAB and want to see what other MathWorks products are installed, in the Command Window, enter `ver`.

For a list of supported compilers, see [https://www.mathworks.com/support/compilers/current_release/](https://www.mathworks.com/support/compilers/current_release/).

**Open the Code Replacement Tool**

1. Start a MATLAB session.

2. Create or navigate (`cd`) to an empty folder.

3. At the command prompt, enter the `crtool` command. The Code Replacement Tool window opens.

**Create Code Replacement Table**

1. In the Code Replacement Tool window, select **File > New table**

2. In the right pane, name the table `crl_table_sinfcn` and click **Apply**. When you save the table, the tool saves it with the file name `crl_table_sinfcn.m`. 
Create Table Entry

Create a table entry that maps a \( \sin \) function with double input and double output to a custom implementation function.

1. In the left pane, select table \( \text{crl_table_sinfcn} \). Then, select File > New entry > Function. The entry appears in the middle pane, initially without a name.

2. In the middle pane, select the new entry.

3. In the right pane, on the Mapping Information tab, from the Function menu, select \( \text{sin} \).

4. Leave Algorithm set to Unspecified, and leave parameters in the Conceptual function group set to default values.

5. In the Replacement function group, name the replacement function \( \text{sin_dbl} \).

6. Leave the remaining parameters in the Replacement function group set to default values.
7. Click **Apply**. The tool updates the **Function signature preview** to reflect the specified replacement function name.

8. Scroll to the bottom of the **Mapping Information** tab and click **Validate entry**. The tool validates your entry.

The following figure shows the completed mapping information.
Quick Start Code Replacement Library Development - Simulink®

Mapping Information

Function: sin

Entry Information

Algorithm: Unspecified

Conceptual function

Used by code generation process for matching purposes

Conceptual arguments

Argument properties

Data type: double

Complex

Argument type: Scalar

Make conceptual and implementation argument types the same

Replacement function

Function prototype

Name: sin_db1

C++ namespace:

Function returns void

Function arguments

Argument properties

Data type: double

I/O type: OUTPUT

Const

Pointer

Complex

Function signature preview

double sin_db1(double u1);

Implementation attributes

Integer saturation mode: Unspecified Saturation

Rounding mode:

Unspecified Rounding

Floor

Ceil

Zap

Allow expressions as inputs

Function modifies internal or global state
Specify Build Information for Replacement Code

1. On the **Build Information** tab, for the **Implementation header file** parameter, enter `sin_dbl.h`.

2. Leave the remaining parameters set to default values.

3. Click **Apply**.

4. Optionally, you can revalidate the entry. Return to the **Mapping Information** tab and click **Validate entry**.

Create Another Table Entry

Create an entry that maps a `sin` function with **single** input and **double** output to a custom implementation function named `sin_sgl`. Create the entry by copying and pasting the `sin_dbl` entry.

1. In the middle pane, select the `sin_dbl` entry.

2. Select **Edit > Copy**.

3. Select **Edit > Paste**.

4. On the **Mapping Information** tab, in the **Conceptual function** section, set the data type of input argument `u1` to **single**.

5. In the **Replacement function** section, name the function `sin_sgl`. Set the data type of input argument `u1` to **single**.

6. Click **Apply**. Note the changes that appear for the **Function signature preview**.
7. On the **Build Information** tab, for the **Implementation header file** parameter, enter `sin_sgl.h`. Leave the remaining parameters set to default values and click **Apply**.

**Validate the Code Replacement Table**

1. Select **Actions > Validate table**.

2. If the tool reports errors, fix them, and rerun the validation. Repeat fixing and validating errors until the tool does not report errors. The following figure shows a validation report.

![Validation Report](image)

**Save the Code Replacement Table**

Save the code replacement table to a MATLAB file in your working folder. Select **File > Save table**. By default, the tool uses the table name to name the file. For this example, the tool saves the table in the file `crl_table_sinfcn.m`.

**Review the Code Replacement Table Definition**

Consider reviewing the MATLAB code for your code replacement table definition. After using the tool to create an initial version of a table definition file, you can update, enhance, or copy the file in a text editor.

To review it, in MATLAB or another text editor, open the file `crl_table_sinfcn.m`.

**Generate a Registration File**

Before you can use your code replacement table, you must register it as part of a code replacement library. Use the Code Replacement Tool to generate a registration file.

1. In the Code Replacement Tool, select **File > Generate registration file**.

2. In the **Generate registration file** dialog box, edit the dialog box fields to match the following figure, and click **OK**.
3. In the **Select location to save the registration file** dialog box, specify a location for the registration file. The location must be on the MATLAB path or in the current working folder. Save the file. The tool saves the file as `rtwTargetInfo.m`.

**Register the Code Replacement Table**

At the command prompt, enter:

```matlab
RTW.TargetRegistry.getInstance('reset');
```

**Review and Test Code Replacements**

Apply your code replacement library. Verify that the code generator makes code replacements that you expect.

1. Check for errors. At the command line, invoke the table definition file. For example:

```matlab
|tbl = crl_table_sinfcn

tbl =

```

**TflTable with properties:**

- **Version**: '1.0'
- **ReservedSymbols**: []
If an error exists in the definition file, the invocation triggers a message. Fix the error and try again.

2. Use the Code Replacement Viewer to check your code replacement entries. For example:

```matlab
crviewer('Sin Function Example')
```

In the viewer, select entries in your table and verify that the content is what you expect. The viewer can help you detect issues such as:

- Incorrect argument order.
- Conceptual argument names that do not match what the code generator expects.
- Incorrect priority settings.

3. Identify existing model or create a model that includes a Trigonometric block that is set to the `sin` function. For example:

```
1
double
In1

Trigonometric Function

sin
double

Out1
```

4. Open the model and configure it for code generation with an Embedded Coder (ERT-based) target.

5. See whether your library is listed as an available option for the **Code Generation > Interface > Code replacement library** model configuration parameter. If it is, select it.

If it is not listed, open the registration file, `rtwTargetInfo.m`. See whether you entered the correct code replacement table name when you created the file. If you hover the
cursor over the selected library, a tool tip appears. This tip contains information derived from your code replacement library registration file, such as the library description and the list of tables it contains.

6. To find parameters quickly, in the Configuration Parameters dialog box **Search** field, type the parameter name. Configure the code generation report for code replacement analysis by selecting the following parameters:

- **Create code generation report**
- **Open report automatically**
- **Code-to-model**
- **Model-to-code**
- **Summarize which blocks triggered code replacements**
- **Include comments**
- **Simulink block comments**
- **Simulink block descriptions**

7. Configure the model to generate code only. Before you build an executable program, confirm that the code generator is replacing code as expected.

8. Generate code for the model.

The report indicates that the code generator found a match and applied the replacement code for the function `sin_dbl`.

10. Review the code replacements. In the model window, right-click the Trigonometric Function block. Select **C/C++ Code > Navigate to C/C++ Code**. The code generation report opens and highlights the code replacement in `my_sin_func.c`. In this case, the code generator replaced `sin` with `sin_dbl`.

Identify Code Replacement Requirements

The first step to developing a code replacement library is to consider the following types of requirements for the library.

Mapping Information Requirements

- Are you defining a code replacement mapping for the first time?
- Are you updating code replacement entries in an existing library? Or, are you creating a new library?
- Are you rapid prototyping code replacements?
- Can you base your mappings on existing mappings?
- What type of code do you want to replace? Options include:
  - Math operation
  - Function
  - BLAS operation
  - CBLAS operation
  - Net slope fixed-point operation
  - Semaphore or mutex functions
- Do you want to change the inline or nonfinite behavior for functions?
- What specific functions and operations do you want to replace?
- What input and output arguments does the function or operator that you are replacing take? For each argument, what is the data type, complexity, and dimensionality?
- What does the prototype for your replacement code look like?
  - What is the replacement function name?
  - What are the input and output arguments?
  - Are there return values?
  - What is the data type, complexity, and dimensionality of each argument and return value?
Build Information Requirements

- Does your replacement function implementation require a header file? If yes, specify the header file.
- If the replacement function implementation requires a header file, what is the path for that file?
- Is the source file for the replacement function in your working folder? If not, you can explicitly specify the source file name and extension. For example, if the file is required in the generated makefile or specified in a build information object, specify the source file.
- Does the replacement function use additional include files? If yes, what are they and what are the paths for those files?
- Does the replacement function use additional source files? If yes, what are they and what are the paths for those files?
- What compiler flags are required for compiling code that includes the replacement code?
- What linker flags are required for building an executable that includes the replacement code?
- Are the required header, source, and object files for building an executable that includes your replacement code in the working folder for your project? If not, before starting the build process, do you want the code generator to copy required files to the build folder?

Registration Information Requirements

- What do you want to name your code replacement library?
- What code replacement tables do you want to include in the library? What are the file names and paths for the tables?
- What is the purpose of the library? You can document the purpose as the library description.
- Does the library apply to specific hardware devices? If yes, what devices?
- Are you developing a hierarchy of code replacement libraries? Is the library that you are developing based (dependent) on another library? For example, you can specify a general TI device library as the base library for a more specific TI C28x device library.
• Do you need to specify data alignment for the library? What data alignments are required? For each specification, what type of alignment is required and for what programming language?

Next, prepare for developing a library by reviewing a code replacement library development checklist.

• “What Is Code Replacement Customization?” on page 64-3
Prepare for Code Replacement Library Development

After you identify your code replacement requirements, prepare for library development by reviewing this checklist:

- Get familiar with the library development process.
- Decide whether to define code replacement mappings and produce a registration file interactively with the Code Replacement Tool or programmatically.
- Identify or develop MATLAB code and Simulink models to test your code replacement library.
- Consider the hierarchy and organization of your library. A library can consist of multiple tables and each table can include multiple entries. How do you want to organize the library to optimize reuse of tables and entries? For example, a registration file can define code replacement tables organized in a hierarchy of code replacement libraries based on entries that increase in specificity:
  - Common entries
  - Entries for TI devices
  - Entries for TI C6xx devices
  - Entries specific to the TI C67x device
- If support files, such as header files, additional source files, and dynamically linked libraries are not in your current working folder, note their location. You need to specify the paths for such files.

Next, based on your requirements and preparation, define code replacement mappings.

- “What Is Code Replacement Customization?” on page 64-3
Define Code Replacement Mappings

After you prepare for library development, use your requirements to define code replacement mappings. A code replacement mapping associates a conceptual representation of a function or operator that is familiar to the code generator with a custom implementation representation that specifies a C or C++ replacement function prototype. You capture a mapping as an entry in a code replacement table:

- Interactively, by using the Code Replacement Tool.
- Programmatically, by using a MATLAB programming interface.

Choose an Approach for Defining Code Replacement Mappings

The following table lists situations to help you decide when to use the interactive or programmatic approach.

<table>
<thead>
<tr>
<th>Situation</th>
<th>Approach</th>
</tr>
</thead>
<tbody>
<tr>
<td>Defining mappings for the first time.</td>
<td>Code Replacement Tool.</td>
</tr>
<tr>
<td>Rapid prototyping mappings.</td>
<td>Code Replacement Tool to quickly generate, register, and test mappings.</td>
</tr>
<tr>
<td>Developing a mapping as a template or starting point for defining similar mappings.</td>
<td>Code Replacement Tool to generate definition code that you can copy and modify.</td>
</tr>
<tr>
<td>Modifying a registration file, including copying and pasting content.</td>
<td>MATLAB Editor to update the programming interface directly.</td>
</tr>
<tr>
<td>Defining mappings that specify attributes not available from the Code Replacement Tool (for example, sets of algorithm parameters).</td>
<td>Programming interface.</td>
</tr>
<tr>
<td>Reusing existing code for new mappings by copying, pasting, and editing existing mappings.</td>
<td>Programming interface.</td>
</tr>
</tbody>
</table>
Define Mappings Interactively with the Code Replacement Tool

This example shows how to use the Code Replacement Tool to develop code replacement mappings. The tool is ideal for getting started with developing mappings, rapid prototyping, and developing a mapping to use as a starting point for defining similar mappings.

Open the Code Replacement Tool

Do one of the following:

- In the Command Window, enter the command `crtool`.
- In the Configuration Parameters dialog box, navigate to Code Generation pane. In the Advanced parameters section, scroll down and click Custom CRL... button.

An Embedded Coder license is not required to create a custom code replacement library. However, you must have an Embedded Coder license to use such a library.

By default, the tool displays, left to right, a root pane, a list pane, and a dialog pane. You can manipulate the display:

- Drag boundaries to widen, narrow, shorten, or lengthen panes, and to resize table columns.
- Select View > Show dialog pane to hide or display the right-most pane.
- Click a table column heading to sort the table based on contents of the selected column.
- Right-click a table column heading and select Hide to remove the column from the display. (You cannot hide the Name column.)

Create a Code Replacement Table

1. In the Code Replacement Tool window, select File > New table.
2. In the right pane, name the table and click Apply. Later, when you save the table, the tool uses the table name that you specify to name the file. For example, if you enter the name `my_sinfcn`, the tool names the file `my_sinfcn.m`. 
Create Table Entries

Create one or more table entries. Each entry maps the conceptual representation of a function or operator to your implementation representation. The information that you enter depends on the type of entry you create. Enter the following information:

1. In the left pane, select the table to which you want to add the entry.
2. Select **File > New entry > entry-type**, where *entry-type* is one of:
   - Math Operation
   - Function
   - BLAS Operation
   - CBLAS Operation
   - Net Slope Fixed-Point Operation
   - Semaphore entry
   - Customization entry

   The new entry appears in the middle pane, initially without a name.

3. In the middle pane, select the new entry.
4. In the right pane, on the **Mapping Information** tab, from the **Function** or **Operation** menu, select the function or operation that you want the code generator to replace. Regardless of the entry type, make a selection from this menu. Your selection determines what other information you specify.

   Except for customization entries, you also specify information for your replacement function prototype. You can also specify implementation attributes, such as the rounding modes to apply.

5. If prompted, specify additional entry information that you want the code generator to use when searching for a match. For example, when you select an addition or subtraction operation, the tool prompts you to specify an algorithm (**Cast before operation** or **Cast after operation**).

6. Review the conceptual argument information that the tool populates for the function or operation. Conceptual input and output arguments represent arguments for the function or operator being replaced. Conceptual arguments observe naming conventions (\(y^1\), \(u^1\), \(u^2\), ...) and data types familiar to the code generator.
When validating the entry, the code generator validates that each conceptual argument has an I/O type that is compatible with the argument name. For example, an input must have `IOType` of `RTW_IO_INPUT`.

If you do not want the data types for your implementation to be the same as the conceptual argument types, clear the **Make the conceptual and implementation argument types the same** check box. For example, most ANSI-C functions operate on and return `double` data. Clear the check box if you want to map a conceptual representation of the function to an implementation representation that specifies an argument and return value. For example, clear the check box to map the conceptual representation of the function `sin` to an implementation representation that specifies an argument and return value of type `single` (**single sin(single)**) or type `double` (**double sin(double)**). In this case, the code generator produces the following code:

\[
y = \text{(single)} \sin(u1);
\]

If you select Custom for a function entry, specify only conceptual argument information.

7 Specify the name and argument information for your replacement function. As you enter the information and click **Apply**, the tool updates the **Function signature preview**.

When validating the entry, the code generator validates that each implementation argument has an I/O type that is compatible with the conceptual argument to which it is mapped. For example, an conceptual argument of type `RTW_IO_OUTPUT` requires a compatible implementation argument of type `RTW_IO_OUTPUT` or `RTW_IO_INPUT_OUTPUT`. The default I/O type is `RTW_IO_INPUT`.

8 Specify additional implementation attributes that apply. For example, depending on the type and name of the entry that you specify, the tool prompts you to specify:

- Integer saturation modes
- Rounding modes
- Whether to allow inputs that include expressions
- Whether a function modifies internal or global state

9 Click **Apply**.

**Validate Tables and Entries**

The Code Replacement Tool provides a way to validate the syntax of code replacement tables and table entries as you define them. If the tool finds validation errors, you can
address them and retry the validation. Repeat the process until the tool does not report errors.

<table>
<thead>
<tr>
<th>To</th>
<th>Do</th>
</tr>
</thead>
<tbody>
<tr>
<td>Validate table entries</td>
<td>Select an entry, scroll to the bottom of the <strong>Mapping Information</strong> tab, and click <strong>Validate entry</strong>. Alternatively, select one or more entries, right-click, and select <strong>Validate entries</strong>.</td>
</tr>
<tr>
<td>Validate a table</td>
<td>Select the table. Then, select <strong>Actions &gt; Validate table</strong>.</td>
</tr>
</tbody>
</table>

**Save a Table**

When you save a table, the tool validates unvalidated content.

1. Select **File > Save table**.
2. In the Browse For Folder dialog box, specify a location and name for the file. Typically, you select a location on the MATLAB path. By default, the tool names the file using the name that you specify for the table with the extension **.m**.
3. Click **Save**.

**Open and Modify Tables**

After saving a code replacement table, to make changes in the table:

1. Select **File > Open table**.
2. In the Import file dialog box, browse to the MATLAB file that contains the table.

Repeat the sequence to open and work on multiple tables.

If you open multiple tables, you can manage the tables together. For example, use the tool to:

- Create new table entries.
- Delete entries.
- Copy and paste or cut and paste information between tables.

**Define Mappings Programmatically**

This example shows how to define a code replacement mapping programmatically. The programming interface for defining code replacement table mappings is ideal for
• Modifying tables that you create with the Code Replacement Tool.
• Defining mappings for specialized entries that you cannot create with the Code Replacement Tool.
• Replicating and modifying similar entries and tables.

Steps for defining a mapping programmatically are:

• “Create Code Replacement Table” on page 64-48
• “Create Table Entry” on page 64-48
• “Set Entry Parameters” on page 64-50
• “Create Conceptual Arguments” on page 64-52
• “Create Implementation Arguments” on page 64-54
• “Add Entry to Table” on page 64-58
• “Validate Entry” on page 64-58
• “Save Table” on page 64-59

Create Code Replacement Table

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_sinfcn()
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

Create Table Entry

For each function or operator that you want the code generator to replace, map a conceptual representation of the function or operator to an implementation representation as a table entry.

1. Within the body of a table definition file, create a code replacement entry object. Call one of the following functions.

<table>
<thead>
<tr>
<th>Entry Type</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>Math operation</td>
<td><code>RTW.TflCOperationEntry</code></td>
</tr>
<tr>
<td>Function</td>
<td><code>RTW.TflCFunctionEntry</code></td>
</tr>
<tr>
<td>BLAS operation</td>
<td><code>RTW.TflBlasEntryGenerator</code></td>
</tr>
</tbody>
</table>
### Entry Type & Function

<table>
<thead>
<tr>
<th>Entry Type</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>CBLAS operation</td>
<td>RTW.TflCBlasEntryGenerator</td>
</tr>
<tr>
<td>Fixed-point addition and subtraction operations (support for SlopesMustBeTheSame and MustHaveZeroNetBias parameters)</td>
<td>RTW.TflCOperationEntryGenerator</td>
</tr>
<tr>
<td>Net slope fixed-point operation</td>
<td>RTW.TflCOperationEntryGenerator_NetSlope</td>
</tr>
<tr>
<td>Semaphore or mutex entry</td>
<td>RTW.TflCSemaphoreEntry</td>
</tr>
<tr>
<td>Custom function entry</td>
<td>MyCustomFunctionEntry (where MyCustomFunctionEntry is a class derived from RTW.TflCFunctionEntryML)</td>
</tr>
<tr>
<td>Custom operation entry</td>
<td>MyCustomOperationEntry (where MyCustomOperationEntry is a class derived from RTW.TflCOperationEntryML)</td>
</tr>
</tbody>
</table>

For example:

```c
hEnt = RTW.TflCFunctionEntry;
```

You can combine steps of creating the entry, setting entry parameters, creating conceptual and implementation arguments, and adding the entry to a table with a single function call to `registerCFunctionEntry`, `registerCPPFunctionEntry`, or `registerCPromotableMacroEntry` if you are creating an entry for a function and the function implementation meets the following criteria:

- Implementation argument names and order match the names and order of corresponding conceptual arguments.
- Input arguments are of the same type.
- The return and input argument names follow the code generator’s default naming conventions:
  - Return argument is `y1`.
  - Input arguments are `u1`, `u2`, ..., `un`.

For example:
As another alternative, you can significantly reduce the amount of code that you write by combining the steps of creating the entry and conceptual and implementation arguments with a call to the createCRLEntry function. In this case, specify the conceptual and implementation information as character vector or string scalar specifications.

For example:

```matlab
hEnt = createCRLEntry(hTable, ...
   'double y1 = sin(double u1)', ...
   'mySin');
```

This approach does not support:

- C++ implementations
- Data alignment
- Operator replacement with net slope arguments
- Entry parameter specifications (for example, priority, algorithm, building information)
- Semaphore and mutex function replacements

**Set Entry Parameters**

Set entry parameters, such as the priority, algorithm information, and implementation (replacement) function name. Call the function listed in the following table for the entry type that you created.

<table>
<thead>
<tr>
<th>Entry Type</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>Math operation</td>
<td>setTflCOperationEntryParameters</td>
</tr>
<tr>
<td>Function</td>
<td>setTflCFuntionEntryParameters</td>
</tr>
<tr>
<td>BLAS operation</td>
<td>setTflCOperationEntryParameters</td>
</tr>
<tr>
<td>CBLAS operation</td>
<td>setTflCOperationEntryParameters</td>
</tr>
<tr>
<td>Entry Type</td>
<td>Function</td>
</tr>
<tr>
<td>---------------------------------------------------------------------------</td>
<td>------------------------------------------------------</td>
</tr>
<tr>
<td>Fixed-point addition and subtraction operations where there is a many-to-one mapping, such as a mapping for a range of fixed-point types to the same replacement function (support for SlopesMustBeTheSame and MustHaveZeroNetBias parameters)</td>
<td>setTflCOperationEntryParameters</td>
</tr>
<tr>
<td>Net slope fixed-point operation</td>
<td>setTflCOperationEntryParameters</td>
</tr>
<tr>
<td>Semaphore or mutex entry</td>
<td>setTflCSemaphoreEntryParameters</td>
</tr>
<tr>
<td>Custom function entry</td>
<td>setTflCFunctionEntryParameters</td>
</tr>
<tr>
<td>Custom operation entry</td>
<td>setTflCOperationEntryParameters</td>
</tr>
</tbody>
</table>

To see a list of the parameters that you can set, at the command line, create a new entry and omit the semicolon at the end of the command. For example:

```matlab
hEnt = RTW.TflCFunctionEntry
```

```matlab
tflCFunctionEntry with properties:

    Implementation: [1x1 RTW.CImplementation]
    SlopesMustBeTheSame: 0
    BiasMustBeTheSame: 0
    AlgorithmParams: []
    ImplType: 'FCN IMPL FUNCT'
    AdditionalHeaderFiles: {0x1 cell}
    AdditionalSourceFiles: {0x1 cell}
    AdditionalIncludePaths: {0x1 cell}
    AdditionalSourcePaths: {0x1 cell}
    AdditionalLinkObjs: {0x1 cell}
    AdditionalLinkObjsPaths: {0x1 cell}
    AdditionalLinkFlags: {0x1 cell}
    AdditionalCompileFlags: {0x1 cell}
    SearchPaths: {0x1 cell}
    Key: ''
    Priority: 100
    ArrayLayout: 'COLUMN_MAJOR'
    ConceptualArgs: [0x1 handle]
    EntryInfo: []
```
To see the implementation parameters, enter:

    hEnt.Implementation

ans =

    CImplementation with properties:

        HeaderFile: ''
        SourceFile: ''
        HeaderPath: ''
        SourcePath: ''
        Return: []
        StructFieldMap: []
        Name: ''
        Arguments: [0x1 RTW.Argument]
        ArgumentDescriptor: []

For example, to set entry parameters for the sin function and name your replacement function sin_dbl, use the following function call:

    setTflCFunctionEntryParameters(hEnt, ...
        'Key', 'sin', ...
        'ImplementationName', 'sin_dbl');

Create Conceptual Arguments

Create conceptual arguments and add them to the entry’s array of conceptual arguments.

- Specify output arguments before input arguments.
• Specify argument names that comply with code generator argument naming conventions:
  • \( y_1 \) for a return argument
  • \( u_1, u_2, \ldots, u_n \) for input arguments
• Specify data types that are familiar to the code generator.
• The function signature, including argument naming, order, and attributes, must fulfill the signature match sought by function or operator callers.
• The code generator determines the size of the value for an argument with an unsized type, such as integer, based on hardware implementation configuration settings.

For each argument:

1. Identify whether the argument is for input or output, the name, and data type. If you do not know what arguments to specify for a supported function or operation, use the Code Replacement Tool to find them. For example, to find the conceptual arguments for the \( \text{sin} \) function, open the tool, create a table, create a function entry, and in the Function menu select \( \text{sin} \).

When validating the entry, the code generator validates that each conceptual argument has an I/O type that is compatible with the argument name. For example, an input must have IOType of RTW_I0_INPUT.

2. Create and add the conceptual argument to an entry. You can choose a method from the methods listed in this table.

<table>
<thead>
<tr>
<th>If</th>
<th>Then</th>
</tr>
</thead>
<tbody>
<tr>
<td>You want simpler code or want to explicitly specify whether the argument is scalar or nonscalar (vector or matrix).</td>
<td>Call the function createAndAddConceptualArg. For example: createAndAddConceptualArg(hEnt, ... 'RTW.TflArgNumeric', ..., 'Name', 'y1', ..., 'IOType', 'RTW_I0_OUTPUT', ..., 'DataTypeMode', 'double'); The second argument specifies whether the argument is scalar (RTW.TflArgNumeric orRTW.TflArgMatrix).</td>
</tr>
<tr>
<td>If</td>
<td>Then</td>
</tr>
<tr>
<td>-------------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>You want to create an argument based on a built-in argument</td>
<td>Call <code>getTflArgFromString</code> to create the argument. Then, call <code>addConceptualArg</code> to add the argument to the entry.</td>
</tr>
<tr>
<td>definition (for example, scalar or nonscalar).</td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>arg = getTflArgFromString(hEnt, 'y1','double'); arg.IOType = 'RTW_IO_OUTPUT'; addConceptualArg(hEnt, arg);</code></td>
</tr>
<tr>
<td>You need to define several similar mappings, you want to</td>
<td>Call <code>createCRLEntry</code> to create the entry and specify conceptual and implementation arguments in a single function call.</td>
</tr>
<tr>
<td>minimize the code to write, and the entries do not require data</td>
<td></td>
</tr>
<tr>
<td>alignment, use net slope arguments, or involve semaphore or mutex</td>
<td></td>
</tr>
<tr>
<td>replacements.</td>
<td><code>hEnt = createCRLEntry(hTable, ... 'double y1 = sin(double u1)', ... 'mySin');</code></td>
</tr>
</tbody>
</table>

The following code shows the second approach listed in the table for specifying the conceptual output and input argument definitions for the `sin` function.

```matlab
% Conceptual Args

arg = getTflArgFromString(hEnt, 'y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEnt, arg);

arg = getTflArgFromString(hEnt, 'u1','double');
addConceptualArg(hEnt, arg);
```

**Create Implementation Arguments**

Create implementation arguments for the C or C++ replacement function and add them to the entry.

- When replacing code, the code generator uses the argument names to determine how it passes data to the implementation function.
- For function replacements, the order of implementation argument names must match the order of the conceptual argument names.
• For operator replacements, the order of implementation argument names do not have to match the order of the conceptual argument names. For example, for an operator replacement for addition, \( y_1 = u_1 + u_2 \), the conceptual arguments are \( y_1, u_1, \) and \( u_2 \), in that order. If the signature of your implementation function is \( t \_myAdd(t \_u2, t \_u1) \), where \( t \) is a valid C type, based on the argument name matches, the code generator passes the value of the first conceptual argument, \( u_1 \), to the second implementation argument of \( myAdd \). The code generator passes the value of the second conceptual argument, \( u_2 \), to the first implementation argument of \( myAdd \).

• For operator replacements, you can remap operator output arguments to implementation function input arguments.

For each argument:

1. Identify whether the argument is for input or output, the name, and the data type.

   When validating the entry, the code generator validates that each implementation argument has an I/O type that is compatible with the conceptual argument to which it is mapped. For example, an conceptual argument of type \( RTW\_IO\_OUTPUT \) requires a compatible implementation argument of type \( RTW\_IO\_OUTPUT \) or \( RTW\_IO\_INPUT\_OUTPUT \). The default I/O type is \( RTW\_IO\_INPUT \).

2. Create and add the implementation argument to an entry. You can choose a method from the methods listed in this table.

<table>
<thead>
<tr>
<th>If</th>
<th>Then</th>
</tr>
</thead>
<tbody>
<tr>
<td>You want to populate implementation arguments as copies of previously created matching conceptual arguments</td>
<td>Call the function <code>copyConceptualArgsToImplementation</code>. For example: <code>copyConceptualArgsToImplementation(hEnt);</code></td>
</tr>
<tr>
<td>If</td>
<td>Then</td>
</tr>
<tr>
<td>-------------------------------------------------------------------</td>
<td>----------------------------------------------------------------------</td>
</tr>
<tr>
<td>You want to create and add implementation arguments individually, or vary argument attributes, while maintaining conceptual argument order</td>
<td>Call functions createAndSetCImplementationReturn and createAndAddImplementationArg. For example:</td>
</tr>
<tr>
<td></td>
<td>createAndSetCImplementationReturn(hEnt, 'RTW.TflArgNumeric', ...</td>
</tr>
<tr>
<td></td>
<td>'Name', 'y1', ...</td>
</tr>
<tr>
<td></td>
<td>'IOType', 'RTW_IO_OUTPUT', ...</td>
</tr>
<tr>
<td></td>
<td>'IsSigned', true, ...</td>
</tr>
<tr>
<td></td>
<td>'WordLength', 32, ...</td>
</tr>
<tr>
<td></td>
<td>'FractionLength', 0);</td>
</tr>
<tr>
<td></td>
<td>createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric', ...</td>
</tr>
<tr>
<td></td>
<td>'Name', 'u1', ...</td>
</tr>
<tr>
<td></td>
<td>'IOType', 'RTW_IO_INPUT', ...</td>
</tr>
<tr>
<td></td>
<td>'IsSigned', true, ...</td>
</tr>
<tr>
<td></td>
<td>'WordLength', 32, ...</td>
</tr>
<tr>
<td></td>
<td>'FractionLength', 0 );</td>
</tr>
<tr>
<td>If</td>
<td>Then</td>
</tr>
<tr>
<td>---</td>
<td>---</td>
</tr>
<tr>
<td>You want to minimize the amount of code, or specify constant arguments to pass to the implementation function</td>
<td>Create the argument with a call to the function <code>getTflArgFromString</code>. Then, use the convenience method <code>setReturn</code> or <code>addArgument</code> to specify whether an argument is a return value or argument and to add the argument to the entry’s array of implementation arguments. For example:</td>
</tr>
</tbody>
</table>

```matlab
arg = getTflArgFromString(hEnt,...
   'y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);

arg = getTflArgFromString(hEnt,...
   'u1','double');
hEnt.Implementation.addArgument(arg);
```

The following call to `getTflArgFromString` passes the constant 0 to argument `u2`:

```matlab
arg = getTflArgFromString(hEnt,...
   'u2', 'int16', 0)
hEnt.Implementation.addArgument(arg);
```

For semaphore and mutex entries, use the functions `getTflDWorkFromString` and `addDWorkArg` to create and add a DWork argument to the entry. Then create implementation arguments as shown above with `getTflArgFromString` and the convenience methods `setReturn` and `addArgument`. For example:

```matlab
arg = getTflDWorkFromString(...
   'd1', 'void*')
hEnt.addDWorkArg(arg);

arg = hEnt.getTflArgFromString(...
   'y1', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);

arg = hEnt.getTflArgFromString(...
   'u1', 'integer');
hEnt.Implementation.addArgument(arg);
```
If | Then
---|---
arg = hEnt.getTflArgFromString(...
   'd1', 'void**');
hEnt.Implementation.addArgument(arg);

You need to define several similar mappings, you want to minimize the code to write, and the entries do not require data alignment, use net slope arguments, or involve semaphore or mutex replacements.

Call `createCRLEntry` to create the entry and specify conceptual and implementation arguments in a single function call.

```
hEnt = createCRLEntry(hTable, ...
   'double y1 = sin(double u1)', ...
   'mySin');
```

The following code shows the third approach listed in the table for specifying the implementation output and input argument definitions for the `sin` function:

```
% Implementation Args

arg = hEnt.getTflArgFromString('y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);

arg = hEnt.getTflArgFromString('u1','double');
hEnt.Implementation.addArgument(arg);
```

Add Entry to Table

Add an entry to a code replacement table by calling the function `addEntry`.

```
addEntry(hTable, hEnt);
```

Validate Entry

After you create or modify a code replacement table entry, validate it by invoking it at the MATLAB command line. For example:

```
hTbl = crl_table_sinfcn

hTbl = 64
```
If the table includes errors, MATLAB reports them. The following examples shows how MATLAB reports a typo in a data type name:

```matlab
hTbl = crl_table_sinfcn
??? RTW_CORE:tfl:TflTable: Unsupported data type, 'dooble'.
Error in ==> crl_table_sinfcn at 7
hTable.registerCFunctionEntry(100, 1, 'sin', 'dooble', 'sin_dbl', ...)
```

**Save Table**

Save the table definition file. Use the name of the table definition function to name the file, for example, `crl_table_sinfcn.m`.

Next, from your requirements, determine whether you need to specify build information for your replacement code.

Specify Build Information for Replacement Code

After you define code replacement mappings, determine whether you need to specify build information for your replacement code. A code replacement table entry can specify build information for the code generator to use when replacing code for a match. For example, specify files for implementation replacement code if you are using a generated makefile and the code generation software compiles the code.

Add build information to an entry:

- Interactively, by using the **Build Information** tab in the **Code Replacement Tool**.
- Programmatically, by using a MATLAB programming interface.

**Build Information**

The build information can include:

- Paths and file names for header files
- Paths and file names for source files
- Paths and file names for object files
- Compile flags
- Link flags

**Choose an Approach for Specifying Build Information**

The following table lists situations to help you decide when to use an interactive or programmatic approach to specifying build information:

<table>
<thead>
<tr>
<th>Situation</th>
<th>Approach</th>
</tr>
</thead>
<tbody>
<tr>
<td>Creating code replacement entries for the first time.</td>
<td>Code Replacement Tool.</td>
</tr>
<tr>
<td>You used the Code Replacement Tool to create the entries for which the build information applies.</td>
<td>Code Replacement Tool to specify the build information quickly.</td>
</tr>
<tr>
<td>Situation</td>
<td>Approach</td>
</tr>
<tr>
<td>-----------------------------------------------</td>
<td>--------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Rapid prototyping entries.</td>
<td>Code Replacement Tool to generate, register, and test entries quickly.</td>
</tr>
<tr>
<td>Developing an entry to use as a template or</td>
<td>Code Replacement Tool to generate entry code that you can copy and modify.</td>
</tr>
<tr>
<td>starting point for defining similar entries.</td>
<td></td>
</tr>
<tr>
<td>Modifying existing mappings.</td>
<td>MATLAB Editor to update the programming interface directly.</td>
</tr>
</tbody>
</table>

- If an entry uses header, source, or object files, consider whether to make the files accessible to the code generator. You can copy files to the build folder or you can specify individual file names and paths explicitly.

- If you specify additional header files/include paths or source files/paths and you copy files, the compiler and utilities such as packNGo might find duplicate instances of files (an instance in the build folder and an instance in the original folder).

- If you choose to copy files to the build folder and you are using the packNGo function to relocate static and generated code files to another development environment:

  - In the call to packNGo, specify the property-value pair 'minimalHeaders' true (the default). That setting instructs the function to include the minimal header files required to build the code in the zip file.
  
  - Do not collocate files that you copy with files that you do not copy. If the packNGo function finds multiple instances of the same file, the function returns an error.

- If you use the programming interface, paths that you specify can include tokens. A token is a variable defined as a character vector, cell array of character vectors, or string array in the MATLAB workspace that you enclose with dollar signs ($variable$). The code generator evaluates and replaces a token with the defined value. For example, consider the path $myfolder\folder1$, where myfolder is a character vector or string scalar variable defined in the MATLAB workspace as 'd:\work \source\module1'. The code generator generates the custom path as d:\work \source\module1\folder1.

### Specify Build Information Interactively with the Code Replacement Tool

The Code Replacement Tool provides a quick, easy way for you to specify build information for code replacement table entries. It is ideal for getting started with defining
a table entry, rapid prototyping, and developing table entries to use as a starting point for defining similar mappings.

1. Determine the information that you must specify.
2. Open the Code Replacement Tool.
3. Select the code replacement table entry for which you want to specify the build information. In the left pane, select the table that contains the entry. In the middle pane, select the entry that you want to modify.
4. In the right pane, select the **Build Information** tab.
5. On the **Build Information** tab, specify your build information.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Specify</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Implementation header file</strong></td>
<td>File name and extension for the header file the code generator needs to generate the replacement code. For example, sin_dbl.h.</td>
</tr>
<tr>
<td><strong>Implementation source file</strong></td>
<td>File name and extension for the C or C++ source file the code generator needs to generate the replacement code. For example, sin_dbl.c.</td>
</tr>
<tr>
<td><strong>Additional header files/ include paths</strong></td>
<td>Paths and file names for additional header files the code generator needs to generate the replacement code. For example, C:\libs\headerFiles and C:\libs\headerFiles\common.h. This parameter adds -I to the compile line in the generated makefile.</td>
</tr>
<tr>
<td><strong>Additional source files/ paths</strong></td>
<td>Paths and file names for additional source files the code generator needs to generate the replacement code. For example, C:\libs\srcFiles and C:\libs\srcFiles\common.c. This parameter adds -I to the compile line in the generated makefile.</td>
</tr>
<tr>
<td><strong>Additional object files/ paths</strong></td>
<td>Paths and file names for additional object files the linker needs to build the replacement code. For example, C:\libs\objFiles and C:\libs\objFiles\common.obj.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Specify</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Additional link flags</td>
<td>Flags the linker needs to generate an executable file for the replacement code.</td>
</tr>
<tr>
<td>Additional compile flags</td>
<td>Flags the compiler needs to generate object code for the replacement code.</td>
</tr>
<tr>
<td>Copy files to build directory</td>
<td>Whether to copy header, source, or object files, which are required to generate replacement code, to the build folder before code generation. If you specify files with Additional header files/include paths or Additional source files/paths and you copy files, the compiler and utilities such as packNGo might find duplicate instances of files.</td>
</tr>
</tbody>
</table>

6 Click **Apply**.

7 Select the **Mapping Information** tab. Scroll to the bottom of that table and click **Validate entry**. The tool validates the changes that you made to the entry.

8 Save the table that includes the entry that you just modified.

**Specify Build Information Programmatically**

The programming interface for specifying build information for a code replacement entry is ideal for:

- Modifying entries created with the Code Replacement Tool.
- Replicating and then modifying similar entries and tables.

The basic workflow for specifying build information programmatically is:

1 Identify or create the code replacement entry that you want to specify the build information.

2 Determine what information to specify.

3 Specify your build information.
<table>
<thead>
<tr>
<th>Specify</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td></td>
<td>such as packNGo might find duplicate instances of files.</td>
</tr>
</tbody>
</table>

4  Save the table that includes the entry that you added or modified.

The following example defines a table entry for an optimized multiplication function that takes signed 32-bit integers and returns a signed 32-bit integer, taking saturation into account. Multiplications in the generated code are replaced with calls to the optimized function. The optimized function does not reside in the build folder. For the code generator to access the files, copy them into the build folder to be compiled and linked into the application.

The table entry specifies the source and header file names and paths. To request the copy operation, the table entry sets the genCallback property to 'RTW.copyFileToBuildDir' in the call to the setTflCOperationEntryParameters function. In this example, the header file s32_mul.h contains an inlined function that invokes assembly functions contained in s32_mul.s. If a match occurs for the table entry,
the function `RTW.copyFileToBuildDir` copies the specified source and header files to the build folder for use during the remainder of the build process.

```matlab
function hTable = make_my_crl_table
    hTable = RTW.TflTable;

    op_entry = RTW.TflCOperationEntry;
    setTflCOperationEntryParameters(op_entry,
        'Key',                      'RTW_OP_MUL', ...
        'Priority',                 100, ...
        'SaturationMode',           'RTW_SATURATE_ON_OVERFLOW', ...
        'RoundingModes',            {'RTW_ROUND_UNSPECIFIED'}, ...
        'ImplementationName',       's32_mul_s32_s32_sat', ...
        'ImplementationHeaderFile', 's32_mul.h', ...
        'ImplementationSourceFile', 's32_mul.s', ...
        'ImplementationHeaderPath', {fullfile('$(MATLAB_ROOT)','crl')}, ...
        'ImplementationSourcePath', {fullfile('$(MATLAB_ROOT)','crl')}, ...
        'GenCallback',              'RTW.copyFileToBuildDir');

    addEntry(hTable, op_entry);

    The following example uses the functions addAdditionalHeaderFile, addAdditionalIncludePath, addAdditionalSourceFile, addAdditionalSourcePath, addAdditionalLinkObj, and addAdditionalLinkObjPath in addition to the code generation callback function `RTW.copyFileToBuildDir`.

```
addEntry(hTable, op_entry);

Next, include your code replacement table in a code replacement library and register the library with the code generator.

Register Code Replacement Mappings

After you define code replacement entries and specify build information in a code replacement table, you can include the table in a code replacement library that you register with the code generator. When registered, a library appears in the list of available code replacement libraries that you can choose from when configuring the code generator.

Register a code replacement table as a code replacement library:

- Interactively, by using the Code Replacement Tool
- Programmatically, by using a MATLAB programming interface

Choose an Approach for Creating the Registration File

The following table lists situations to help you decide when to use an interactive or programmatic approach to creating a registration file:

<table>
<thead>
<tr>
<th>If...</th>
<th>Then...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Registering a code replacement table for the first time</td>
<td>Use the Code Replacement Tool.</td>
</tr>
<tr>
<td>You used the Code Replacement Tool to create the table</td>
<td>Use the Code Replacement Tool to quickly register the table.</td>
</tr>
<tr>
<td>Rapid prototyping code replacement</td>
<td>Use the Code Replacement Tool to quickly generate, register, and test entries.</td>
</tr>
<tr>
<td>Creating registration file to use as a template or starting point for defining similar registration files</td>
<td>Use the Code Replacement Tool to generate code that you can copy and modify.</td>
</tr>
<tr>
<td>Modifying existing registration files</td>
<td>Use the MATLAB Editor to update the registration file.</td>
</tr>
<tr>
<td>Defining multiple code replacement libraries in one registration file</td>
<td>Use the MATLAB Editor to create a new or extend an existing registration file.</td>
</tr>
<tr>
<td>Defining code replacement library hierarchy in a registration file</td>
<td>Use the MATLAB Editor to create a new or extend an existing registration file.</td>
</tr>
</tbody>
</table>
Create Registration File Interactively with the Code Replacement Tool

The Code Replacement tool provides a quick, easy way for you to create a registration file for a code replacement table. It is ideal for getting started, rapid prototyping, and generating a registration file that you want to use as a starting point for similar registrations.

1 After you validate and save a code replacement table, select File > Generate registration file to open the Generate registration file dialog box.

2 Enter the registration information. Minimally, specify:

<table>
<thead>
<tr>
<th>For...</th>
<th>Specify...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Registry name</td>
<td>Text naming the code replacement library. For example, Sin Function Example.</td>
</tr>
</tbody>
</table>
Table list

Text naming one or more code replacement tables to include in the library. Specify each table as one of the following:

- Name of a table file on the MATLAB search path
- Absolute path to a table file
- Path to a table file relative to $(MATLAB_ROOT)$

You can specify multiple tables. If you do, separate the table specifications with a comma. For example:

crl_table_sinfcn, c:/work_crl/crl_table_muldiv

See “Registration Files That Define Multiple Code Replacement Libraries” on page 65-62 for examples of each type of table specification.

Optionally, you can specify:

<table>
<thead>
<tr>
<th>For...</th>
<th>Specify...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table list</td>
<td>Text naming one or more code replacement tables to include in the library. Specify each table as one of the following:</td>
</tr>
<tr>
<td></td>
<td>- Name of a table file on the MATLAB search path</td>
</tr>
<tr>
<td></td>
<td>- Absolute path to a table file</td>
</tr>
<tr>
<td></td>
<td>- Path to a table file relative to $(MATLAB_ROOT)$</td>
</tr>
<tr>
<td>Description</td>
<td>Text that describes the purpose and content of the library.</td>
</tr>
<tr>
<td>Target HW device</td>
<td>Text naming one or more hardware devices the code replacement library supports. Separate names with a comma. To support all device types, enter an asterisk (*). For example, TI C28x, TI C62x.</td>
</tr>
<tr>
<td>Base CRL</td>
<td>Text naming a code replacement library that you want to serve as a base library for the library you are registering. Use this field to specify library hierarchies. For example, you can specify a general TI device library as the base library for a more specific TI C28x device library.</td>
</tr>
<tr>
<td>Generate data alignment specification</td>
<td>Flag that enables data alignment specification.</td>
</tr>
</tbody>
</table>
Create Registration File Programmatically

The programming interface for creating a registration file for a code replacement table is ideal for:

- Modifying registration files created with the Code Replacement Tool
- Replicating and modifying similar registration files
- Defining multiple code replacement libraries in one registration file

The basic workflow for creating a registration file programmatically consists of the following steps:

1. Define an `rtwTargetInfo` function. The code generator recognizes this function as a customization file. The function definition must include at least the following content:

   ```matlab
   function rtwTargetInfo(cm)
       cm.registerTargetInfo(@loc_register_crl);

   function this = loc_register_crl
       this(1) = RTW.TflRegistry;
       this(1).Name = 'crl-name';
       this(1).TableList = {'table',...};
   ```

<table>
<thead>
<tr>
<th>For...</th>
<th>Replace...</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>this(1).Name = 'crl-name';</code></td>
<td><code>crl-name</code> with text naming the code replacement library. For example, <code>Sin Function Example</code>.</td>
</tr>
</tbody>
</table>

Register Code Replacement Mappings
For...

this(1).TableList = {'table',...};

Replace...

`table` with text that identifies the code replacement table that contains your code replacement entries. Specify a table as one of the following:

- Name of a table file on the MATLAB search path
- Absolute path to a table file
- Path to a table file relative to `$MATLAB_ROOT$`

You can specify multiple tables. If you do, separate the table specifications with commas.

Optionally, you can specify:

For...

this(1).Description = 'text'

this(1).TargetHWDeviceType = {'device-type',...}

Replace...

text with text that describes the purpose and content of the library.

device-type with text that names a hardware device the code replacement library supports. You can specify multiple device types. Separate device types with a comma. For example, TI C28x, TI C62x. To support all device types, enter an asterisk (*).
For... | Replace...
---|---
this(1).BaseTfl = 'base-lib' | *base-lib* with text that names a code replacement library that you want to serve as a base library for the library you are registering. Use this field to specify library hierarchies. For example, you can specify a general TI device library as the base library for a TI C28x device library.

See “Registration Files That Define Code Replacement Library Hierarchies” on page 65-62 for an example.

For example:

```matlab
function rtwTargetInfo(cm)
    cm.registerTargetInfo(@loc_register_crl);

function this = loc_register_crl

    this(1) = RTW.TflRegistry;
    this(1).Name = 'Sin Function Example';
    this(1).TableList = {'crl_table_sinfcn'};
    this(1).TargetHWDeviceType = {'*'};
    this(1).Description = 'Example - sin function replacement';
```

2 Save the file with the name rtwTargetInfo.m.
3 Place the file on the MATLAB path. When the file is on the MATLAB path, the code generator reads the file after starting and applies the customizations during the current MATLAB session.

**Register a Code Replacement Library**

Before you can use the code replacement tables defined in a registration file, refresh Simulink customizations within the current MATLAB session. To initiate a refresh, enter the following command:

```matlab
sl_refresh_customizations
```
Register a Library that Includes Multiple Code Replacement Tables

Use the programming interface to create a registration file that defines a code replacement library that includes multiple code replacement tables. The following example defines a library that includes multiple tables. The TableList fields specify tables that reside at different locations. The tables reside on the MATLAB search path or at locations specified with a path.

```matlab
function rtwTargetInfo(cm)
    cm.registerTargetInfo(@locCrlRegFcn);

    function thisCrl = locCrlRegFcn
        % Register a code replacement library for use with model: rtwdemo_crladdsub
        thisCrl(1) = RTW.TflRegistry;
        thisCrl(1).Name = 'Addition & Subtraction Examples';
        thisCrl(1).Description = 'Example of addition/subtraction op replacement';
        thisCrl(1).TableList = {'crl_table_addsub'};
        thisCrl(1).TargetHWDeviceType = {'*'};

        % Register a code replacement library for use with model: rtwdemo_crlmuldiv
        thisCrl(2) = RTW.TflRegistry;
        thisCrl(2).Name = 'Multiplication & Division Examples';
        thisCrl(2).Description = 'Example of mult/div op repl for built-in integers';
        thisCrl(2).TableList = {'c:/work_crl/crl_table_muldiv'};
        thisCrl(2).TargetHWDeviceType = {'*'};

        % Register a code replacement library for use with model: rtwdemo_crlfixpt
        thisCrl(3) = RTW.TflRegistry;
        thisCrl(3).Name = 'Fixed-Point Examples';
        thisCrl(3).Description = 'Example of fixed-point operator replacement';
        thisCrl(3).TableList = {fullfile('$(MATLAB_ROOT)', ...
                                  'toolbox','rtw','rtwdemos','crl_demo','crl_table_fixpt')};
        thisCrl(3).TargetHWDeviceType = {'*'};
    
    Registration Files That Define Code Replacement Library Hierarchies

Using the programming interface, you can organize multiple code replacement libraries in a hierarchy. The following example shows a registration file that defines four code replacement tables organized in a hierarchy of four code replacement libraries. The tables include entries that increase in specificity: common entries, entries for TI devices, entries for TI C6xx devices, and entries specific to the TI C67x device.

```
function thisCrl = locCrlRegFcn

% Register a code replacement library that includes common entries
thisCrl(1) = RTW.TflRegistry;
thisCrl(1).Name = 'Common Replacements';
thisCrl(1).Description = 'Common code replacement entries shared by other libraries';
thisCrl(1).TableList = {'crl_table_general'};
thisCrl(1).TargetHWDeviceType = {'*'};

% Register a code replacement library for TI devices
thisCrl(2) = RTW.TflRegistry;
thisCrl(2).Name = 'TI Device Replacements';
thisCrl(2).Description = 'Code replacement entries shared across TI devices';
thisCrl(2).TableList = {'crl_table_TI_devices'};
thisCrl(2).TargetHWDeviceType = {'TI C28x', 'TI C55x', 'TI C62x', 'TI C64x', 'TI 67x'};
thisCrl(1).BaseTfl = 'Common Replacements'

% Register a code replacement library for TI c6xx devices
thisCrl(3) = RTW.TflRegistry;
thisCrl(3).Name = 'TI c6xx Device Replacements';
thisCrl(3).Description = 'Code replacement entries shared across TI C6xx devices';
thisCrl(3).TableList = {'crl_table_TIC6xx_devices'};
thisCrl(3).TargetHWDeviceType = {'TI C62x', 'TI C64x', 'TI 67x'};

% Register a code replacement library for the TI c67x device
thisCrl(3) = RTW.TflRegistry;
thisCrl(3).Name = 'TI c67x Device Replacements';
thisCrl(3).Description = 'Code replacement entries for the TI C67x device';
thisCrl(3).TableList = {'crl_table_TIC67x_device'};
thisCrl(3).TargetHWDeviceType = {'TI 67x'};

After registering your code replacement mappings, verify that code replacements occur.

Troubleshoot Code Replacement Library Registration

If a code replacement library is not listed as a configuration option or does not appear in the Code Replacement Viewer:

- Refresh the library registration information within the current MATLAB session (RTW.TargetRegistry.getInstance('reset'); or for the Simulink environment, sl_refresh_customizations).
- See whether the registration file, rtwTargetInfo.m, contains an error.

See Also

More About

- “Register Code Replacement Mappings” on page 64-70
Verify Code Replacements

After you create or modify and register a code replacement table, use the following techniques to examine and verify the table and its entries.

- Invoke the table definition file at the command prompt.
- Use the Code Replacement Viewer to examine libraries, tables, and entries.
- Trace code replacements from the source where you applied the code replacement library.
- Examine code replacement hits and misses logged during code generation.

Code Replacement Hits and Misses

The code generator logs code replacement table entries for which it finds and does not find matches in the hit cache and miss cache, respectively. When a code replacement entry match fails and code is not replaced, the code generator logs the call site object (CSO) for the miss in the miss cache. When an entry match succeeds, the code generator logs the matched entry in the hit cache.

The code generator overwrites the hit and miss cache data each time it produces code. The cache data reflects hits and misses for only the last application component (MATLAB code or Simulink model) for which you generate code.

You can use the Code Replacement Viewer to review trace information based on logged hit and miss trace data. The hit cache provides trace information that helps to verify code replacements.

The miss cache and related miss data collected and stored in code replacement tables provide trace information for misses. Use this information for misses to troubleshoot expected code replacements that do not occur. Trace information for a miss:

- Identifies the call site object.
- Provides a link to the relevant source location for the miss.
- Includes information about the reason for the miss.
Validate Table Definition File

After you create or modify a code replacement table definition file, validate it. At the command prompt, specify the name of the table in a call to the isvalid function. For example:

```matlab
isvalid(crl_table_sinfcn)
ans =
  1
```

MATLAB displays errors that occur. In the following example, MATLAB detects a typo in a data type name.

```matlab
isvalid(crl_table_sinfcn)
??? RTW_CORE:tfl:TflTable: Unsupported data type, 'dooble'.
Error in ==> crl_table_sinfcn at 7
hTable.registerCFunctionEntry(100, 1, 'sin', 'dooble', 'sin_dbl', ...
```

Review Library Content

After you create or modify a code replacement library, use the Code Replacement Viewer to review and verify the list of tables in the library and the entries in each table.

1. Open the viewer to display the contents of your library. At the command prompt, enter the following command:

```matlab
crviewer('library')
```

For example:

```matlab
crviewer('Addition & Subtraction Examples')
```
2 Review the list of tables in the left pane. Are tables missing? Are the tables listed in the correct relative order? By default, the viewer displays tables in search order.

3 In the left pane, click each table and review the list of entries in the center pane. Are entries missing? Does the list include extraneous or unexpected entries?
Review Table Content

After you create or modify a code replacement table, use the **Code Replacement Viewer** to review and verify table entries.

1. Open the viewer to display the contents of your table. At the command prompt, enter the following command. `table` is a MATLAB file that defines code replacement tables. The file must be in the current folder or on the MATLAB path.

   ```matlab
crviewer(table)
   ```

   For example:

   ```matlab
crviewer(crl_table_addsub)
   ```
2 Review the list of entries in the center pane. Are entries missing? Does the list include extraneous or unexpected entries? By default, the viewer displays entries in search order.

3 In the center pane, click each entry and verify the entry information in the right pane.
• Argument order is correct.
• Conceptual argument names match code generator naming conventions.
• Implementation argument names are correct.
• Algorithm properties (for example, saturation and rounding mode) are set correctly.
• Header or source file specification is not missing.
• I/O types are correct.
• Relative priority of entries is correct.

Review Code Replacements

After you review the content of your code replacement library and tables, generate code and a code generation report. Verify that the code generator replaces code as you expect.

The Code Replacements Report details the code replacement library functions that the code generator uses for code replacements. The report provides a mapping between each replacement instance and the model element that triggered the replacement.

The following example illustrates two complementary approaches to reviewing code replacements:

• Check the Code Replacements Report section of the code generation report for expected replacements.
• Trace code replacements.

For models that consist of model hierarchies, repeat the following procedure for each model in the hierarchy. Generate code for and review the trace information of each referenced model separately. Logged cache hit and miss information captured in the Code Replacement Viewer is valid for the last model for which code was generated. As you generate code for each model in the hierarchy, the code generator overwrites logged information.

1. Open the model where you anticipate that a function or operator replacement occurs. This example uses the model rtwdemo_crladdsub.
2. Configure the code generator to use your code replacement library. For this example, set the library to Addition & Subtraction Examples.
4 Configure comments for the generated code. On the Code Generation > Comments pane, select:

- **Include comments**
- Either or both of **Simulink block comments** and **Simulink block descriptions**

In the **Code Replacements Report**, these options include Simulink block information.

5 Configure the code generator to generate only code. Before you build an executable file, review your code replacements in the generated code.

6 Generate code and a report.

7 Open the **Code Replacements Report** section of the code generation report.

The report lists the replacement functions that the code generator used. It provides a mapping between each replacement instance and the Simulink block that triggered the replacement.
Review the report:

- Check whether expected function and operator code replacements occurred.
- In the replacements sections, click each block link to see the source that triggered the reported code replacement.

In the Simulink model window, use model-to-code highlighting to trace code replacements. Identify and right-click a block where you expected code replacement to occur. Select **C/C++ Code > Navigate to C/C++ Code**. The code generation report appears with the corresponding replacement code highlighted. In the example model `rtwdemo_crladdsub`, right-click the Add8 block and select **C/C++ Code > Navigate to C/C++ Code**.

```c
/* Real-time model */
RT_MODEL rtM;
RT_MODEL *const rtM = &rtM;

/* Model step function */
void rtwdemo_crladdsub_step(void) {
    /* Outport: '<Root>/Out1' incorporates:
        * Inport: '<Root>/In1'
        * Inport: '<Root>/In2'
        * Sum: '<Root>/Add8'
    */
    rtY.Out1 = u8_add_u8_u8(rtU.In1, rtU.In2);

    /* Outport: '<Root>/Out2' incorporates:
        * Inport: '<Root>/In3'
        * Inport: '<Root>/In4'
        * Sum: '<Root>/Add16'
    */
    rtY.Out2 = u16_add_u16_u16(rtU.In3, rtU.In4);
}
```

Inspect the generated code to see if the function or operator replacement occurred as you expected.

If a function or operator is not replaced as expected, the code generator used a higher-priority (lower-priority value) match or did not find a match.
To analyze and troubleshoot code replacement misses, use the trace information that the Code Replacement Viewer provides. See “Troubleshoot Code Replacement Misses” on page 64-89.

Next, deploy your code replacement library for others to use.

• “What Is Code Replacement Customization?” on page 64-3
Troubleshoot Code Replacement Misses

Use miss reason messages that appear in the Code Replacement Viewer to analyze and correct code replacement misses.

Miss Reason Messages

The Code Replacement Viewer displays miss reason messages in trace information for code replacement misses. A legend listing each message that appears in the miss report precedes the report details. A message consists of:

- Numeric identifier, which identifies the message in the report details.
- Message text, which in some cases includes placeholders for names of arguments, call site object values, table entry values, and property names.

For example:

1. Mismatched data types (argument name, CSO value, table entry value)

The parenthetical information represents placeholders for actual values that appear in the report details.

In the Miss Source Locations table that lists the miss details, the Reason column includes:

- The message identifier, as listed in the legend.
- The placeholder values for that instance of the miss reason message.

The following Reason details indicate a data type mismatch because the call site object specifies data type int8 for arguments y1, u1, and u2, while the code replacement table entry specifies uint32.

1. y1, int8, uint32
   u1, int8, uint32
   u2, int8, uint32

Depending on your situation and the reported miss reason, troubleshoot reported misses by looking for instances of the following:

- A typo in the code replacement table entry definition or a source parameter setting.
• Information missing from the code replacement table entry or a source parameter setting.
• Invalid or incorrect information in the code replacement table entry definition or a source parameter setting.
• Arguments incorrectly ordered in the code replacement table entry definition or the source being replaced with replacement code.
• Failed algorithm classification for an addition or subtraction operation due to:
  • An ideal accumulator not being calculated because the type of an input argument is not fixed-point or the slope adjustment factors of the input arguments are not equal.
  • Input or output casts with a floating-point cast type.
  • Input or output casts with cast types that have different slope adjustment factors or biases.
  • Output casts not being convertible to a single output cast.
  • Input casts resulting in loss of bits.

**Analyze and Correct Code Replacement Misses**

The following example shows how to use Code Replacement Viewer trace information to troubleshoot code replacement misses. You must have already reviewed and tested code replacements for your model.

1. Review the code generated for a model element, looking for expected code replacements. For this example, examine the code generated for block Sub32 in model `rtwdemo_crladdsub`. Right-click the block and select **C/C++ Code > Navigate to C/C++ Code**.

The Code Generation Report opens to the location of the generated code for that block.

```c
/* Output: 'crladdsub/s13' incorporates:
   * Import: 'crladdsub/s10'
   * Import: 'crladdsub/s11'
   * Sum: 'crladdsub/s12'
   */
real_T * rtwpxc_Cut5 = s32_sub_e32_e32(rtwpx_In9, rtwpx_In10);
```

The code generator replaced code, but the replacement was for the signed version of the 32-bit subtraction operation. You expected an unsigned operation.
2 Regenerate or reopen the Code Replacements Report for your model. If you already generated the code generation report that includes the Code Replacements Report for model rtwdemo_crladdsub, open the file rtwdemo_crladdsub_ert_rtw/html/rtwdemo_crladdsub_codegen_rpt.html. For information on how to regenerate the report, see “Review Code Replacements” on page 64-85.

3 Click the link to open the Code Replacement Viewer.

4 In the viewer left pane, select your code replacement table. The following display shows entries for code replacement table crl_table_addsub.

5 In the middle pane, select table entry RTW_OP_MINUS with implementation function u32_sub_u32_u32.

6 In the right pane, select the Trace Information tab.
The Trace Information is a table that lists the following information for each miss:

- Call site object preview. The call site object is the conceptual representation of a subtraction operator. The code generator uses this object to query the code replacement library for a match.
• A link to the source location in the model for which the code generator considered replacing code.
• The reasons that the miss occurred. For the list of reasons that misses occur, see “Miss Reason Messages” on page 64-89.

For this example, the report shows misses for two blocks: Sub32 and Sub8.

7 Find that source in the trace information. Depending on your situation and the reported miss reason, consider looking for a condition such as a typo in the code replacement table entry definition or in a source parameter setting. “Miss Reason Messages” on page 64-89 lists conditions to consider.

For this example, determine why code for the Sub32 block was not replaced with code for an unsigned 32-bit subtraction operation. The miss reason for the Sub32 block indicates a data type mismatch. The data type in the call site object for the three arguments is a signed 32-bit integer. The code replacement entry specifies an unsigned 32-bit integer.

8 Correct the model or code replacement table entry. If the issue is in the model, use the source location link in the trace information to find the model element to correct. For this example, you expected an unsigned subtraction operation for the Sub32 block. Click the link in the trace report for the Sub32 block.

The model opens with the Sub32 block highlighted.
Change the data type setting for the two input signals and the output signal for the Sub32 block to `uint32`.

9 Regenerate code. Use the Code Replacement Viewer trace information to verify that your model or code replacement table entry corrects the code replacement issue. In the following display, the trace information shows a hit for block Sub32.

More About

• “Verify Code Replacements” on page 64-79
Deploy Code Replacement Library

After you verify code replacements and are ready to package and deploy a code replacement library for others to use:

1. Move your code replacement table files to an area that is on the MATLAB search path and that is accessible to and shared by other users.

2. Move the `rtwTargetInfo.m` registration file, to an area that is on the MATLAB search path and that is accessible to and shared by other users. If you are deploying a library to a folder in a development environment that already contains a `rtwTargetInfo.m` file, copy the registration code from your code replacement library version of `rtwTargetInfo.m` and paste it into the shared version of that file.

3. Register the library customizations or restart MATLAB.

4. Verify that the libraries are available for configuring the code generator and that code replacements occur as expected.

5. Inform users that the libraries are available and provide direction on when and how to apply them.

Math Function Code Replacement

This example shows how to define a code replacement mapping for a math function. The example defines a mapping for the sin function programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

```matlab
function hTable = crl_table_sinfcn2()
%CRL_TABLE_SINFCN2 - Define function entry for code replacement table.
```

2. Within the function body, create the table by calling the function RTW.TflTable.

```matlab
hTable = RTW.TflTable;
```

3. Create an entry for the function mapping with a call to the RTW.TflCFunctionEntry function.

```matlab
% Create entry for sin function replacement
fcn_entry = RTW.TflCFunctionEntry;
```

4. Set function entry parameters with a call to the setTflCFunctionEntryParameters function.

```matlab
setTflCFunctionEntryParameters(fcn_entry, ...
    'Key',                      'sin', ...
    'Priority',                 30, ...
    'ImplementationName',       'mySin', ...
    'ImplementationHeaderFile', 'basicMath.h',...
    'ImplementationSourceFile', 'basicMath.c');
```

5. Create conceptual arguments y1 and u1. There are multiple ways to set up the conceptual arguments. This example uses calls to the createAndAddConceptualArg function to create and add an argument with one function call.

```matlab
createAndAddConceptualArg(fcn_entry, 'RTW.TflArgNumeric', ..., ...
    'Name',         'y1', ...
    'IOType',       'RTW_IO_OUTPUT',...
    'DataTypeMode', 'double');
```

```matlab
createAndAddConceptualArg(fcn_entry, 'RTW.TflArgNumeric', ..., ...
    'Name',         'u1', ...
    'IOType',       'RTW_IO_INPUT',...
    'DataTypeMode', 'double');
```

6. Copy the conceptual arguments to the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses a call to the copyConceptualArgsToImplementation function to create and add implementation arguments to the entry by copying matching conceptual arguments.
copyConceptualArgsToImplementation(fcn_entry);

7 Add the entry to a code replacement table with a call to the `addEntry` function.
   
   ```
   addEntry(hTable, fcn_entry);
   ```

8 Save the table definition file. Use the name of the table definition function to name the file.

Memory Function Code Replacement

This example shows how to define a code replacement mapping for a memory function. The example defines a mapping for the `memcpy` function programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   function hTable = crl_table_memcpy()

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   hTable = RTW.TflTable;

3. Create an entry for the function mapping with a call to the `RTW.TflCFunctionEntry` function.

   % Create entry for void* memcpy(void*, void*, size_t)
   fcn_entry = RTW.TflCFunctionEntry;

4. Set function entry parameters with a call to the `setTflCFunctionEntryParameters` function.

   % Set SideEffects to 'true' for function returning void to prevent it from
   % being optimized away.
   setTflCFunctionEntryParameters(fcn_entry, ...
   'Key',                      'memcpy', ...
   'Priority',                 90, ...
   'ImplementationName',       'memcpy_int', ...
   'ImplementationHeaderFile', 'memcpy_int.h',...
   'SideEffects',              true);

5. Create conceptual arguments `y1`, `u1`, `u2`, and `u3`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create and add the arguments.

   arg = getTflArgFromString(hTable, 'y1', 'void*');
   arg.IOType = 'RTW_IO_OUTPUT';
   addConceptualArg(fcn_entry, arg);

   arg = getTflArgFromString(hTable, 'u1', 'void*');
   addConceptualArg(fcn_entry, arg);

   arg = getTflArgFromString(hTable, 'u2', 'void*');
   addConceptualArg(fcn_entry, arg);

   arg = getTflArgFromString(hTable, 'u3', 'size_t');
   addConceptualArg(fcn_entry, arg);

6. Copy the conceptual arguments to the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses a call to the...
copyConceptualArgsToImplementation function to create and add implementation arguments to the entry by copying matching conceptual arguments.

```matlab
copyConceptualArgsToImplementation(fcn_entry);
```

7. Add the entry to a code replacement table with a call to the `addEntry` function.

```matlab
addEntry(hTable, fcn_entry);
```

8. Save the table definition file. Use the name of the table definition function to name the file.

To test this example:

1. Register the code replacement mapping.

2. Create a model that uses the `memcpy` function for vector assignments. For example, use In, Out, and Mux blocks to create the following model. (Alternatively, open the example model `rtwdemo_crlmath` and copy the contents of Subsystem1 to a new model.)

3. Select the diagram and use **Edit > Subsystem** to make it a subsystem.

4. Configure the subsystem with the following settings:
   - On the **Solver** pane, select a fixed-step solver.
   - On the **Optimization** pane, select **Use memcpy for vector assignment** and set **Memcpy threshold (bytes)** to 64.
   - On the **Code Generation** pane, select an ERT-based system target file.
   - On the **Code Generation > Interface** pane, select the code replacement library that contains your memory function entry.
5 In the Model Explorer, configure the Signal Attributes for the In1, In2, and In3 source blocks. For each, set Port dimensions to [1, 100], and set Data type to int32. Apply the changes. Save the model.

6 Generate code and a code generation report.

7 Review the code replacements.

Nonfinite Function Code Replacement

This example shows how to define a code replacement mapping for nonfinite utility functions.

1. Create a table definition file that contains a function definition. For example:

   ```matlab
   function hTable = crl_table_nonfinite()
   
   2. Within the function body, create the table by calling the function RTW.TflTable.

   hTable = RTW.TflTable;

3. Create entries for the function mappings. To minimize the size of this function, the example uses a local function, `locAddFcnEnt`, to group lines of code repeated for each entry. A call to the RTW.TflCFunctionEntry function creates an entry for the collection of local function entry definitions.

   ```matlab
   %% Create entries for nonfinite utility functions
   % locAddFcnEnt(hTable, key, implName, out, in1, hdr)
   locAddFcnEnt(hTable, 'getNaN', 'getNaN', 'double', 'void', 'nonfin.h');
   locAddFcnEnt(hTable, 'getNaN', 'getNaNF', 'single', 'void', 'nonfin.h');
   locAddFcnEnt(hTable, 'getInf', 'getInf', 'double', 'void', 'nonfin.h');
   locAddFcnEnt(hTable, 'getInf', 'getInfF', 'single', 'void', 'nonfin.h');
   locAddFcnEnt(hTable, 'getMinusInf', 'getMinusInf', 'double', 'void', 'nonfin.h');
   locAddFcnEnt(hTable, 'getMinusInf', 'getMinusInfF', 'single', 'void', 'nonfin.h');
   
   %% Local Function
   function locAddFcnEnt(hTable, key, implName, out, in1, hdr)
     if isempty(hTable)
       return;
     end
     
     fcn_entry = RTW.TflCFunctionEntry;
   
4. Set function entry parameters with a call to the `setTflCFunctionEntryParameters` function.

   ```matlab
   setTflCFunctionEntryParameters(fcn_entry, ...
       'Key', key, ...
       'Priority', 90, ...
       'ImplementationName', implName, ...
       'ImplementationHeaderFile', hdr);
   
5. Create conceptual arguments y1 and u1. There are multiple ways to set up the conceptual arguments. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create and add the arguments.

   ```matlab
   arg = getTflArgFromString(hTable, 'y1', out);
   arg.IOType = 'RTW IO_OUTPUT';
   addConceptualArg(fcn_entry, arg);
arg = getTflArgFromString(hTable, 'u1', in1);
addConceptualArg(fcn_entry, arg);

6 Copy the conceptual arguments to the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses a call to the copyConceptualArgsToImplementation function to create and add implementation arguments to the entry by copying matching conceptual arguments.

copyConceptualArgsToImplementation(fcn_entry);

7 Add the entry to a code replacement table with a call to the addEntry function.

addEntry(hTable, fcn_entry);

8 Save the table definition file. Use the name of the table definition function to name the file.

To test this example:

1 Register the code replacement mapping.

2 Create a model that uses a nonfinite function. For example, create a model that includes a Math Function block that is set to the rem function. For example:

3 Configure the model with the following settings:
   - On the Solver pane, select a fixed-step solver.
   - On the Code Generation pane, select an ERT-based system target file.
   - On the Code Generation > Interface pane, select the code replacement library that contains your memory function entry and select Support: non-finite numbers.

4 In the Model Explorer, configure the Signal Attributes for the In1 and Constant source blocks. For each source block, set Data type to double. Apply the changes. Save the model.

5 Generate code and a code generation report.

6 Review the code replacements.

Semaphore and Mutex Function Replacement

You can create a code replacement table for a custom target that supports concurrent execution. Create table entries that specify custom implementations of semaphore or mutex operations. The table must have four semaphore entries, four mutex entries, or both, and include the table in a custom code replacement library. (The semaphore or mutex entries are mutually dependent. Provide them in complete sets of four.)

**Note** A custom target that supports concurrent multitasking must set the target configuration parameter `ConcurrentExecutionCompliant`. For more information, see “Support Concurrent Execution of Multiple Tasks” (Simulink Coder).

If the build process generates semaphore or mutex function calls for data transfer between tasks during code generation for a multicore target environment, use a custom library. The library can specify code replacements for custom semaphore or mutex implementations that are optimal for your target environment. Using the Code Replacement Tool (`crtool`) or equivalent code replacement functions, you can:

- Configure code replacement table entries for custom semaphore or mutex functions. During system startup, execution of the code for data transfer between tasks, and system shutdown the generated code calls these functions.
- Configure DWork arguments that represent global data, which the semaphore or mutex functions access. A DWork pointer is passed to the model entry functions.

Generated mutex and semaphore code typically consists of these elements:

<table>
<thead>
<tr>
<th>Code</th>
<th>Generated Code</th>
</tr>
</thead>
<tbody>
<tr>
<td>Model initialization</td>
<td>Initialization function call that creates a mutex or semaphore function to control entry to a critical section of code.</td>
</tr>
</tbody>
</table>
| Model step       | • Before code for a data transfer between tasks enters the critical section, mutex lock or semaphore wait function calls reserve the critical section of code.  
                      • After code for a data transfer between tasks finishes executing the critical section, mutex unlock or semaphore post function calls release the critical section of code. |
Model termination | Optional destroy function call to delete the mutex or semaphore explicitly.

This example shows how to create code replacement table entries for a mutex replacement scenario. You configure a multicore target model for concurrent execution and for data transfer between tasks of differing rates, which Rate Transition blocks handle. In the generated code for the model, each Rate Transition block has a separate, unique mutex. Mutex lock and unlock operations within the Rate Transition block generated code share access to the same global data. They achieve this by using the unique mutex created for that Rate Transition block.

1. Open the **Code Replacement Tool**.
2. Create and open a new table.
3. Name the table `crl_table_rt_mutex`.
4. Create an entry for a mutex initialization function replacement.
   a. Select **File > New entry > Semaphore entry** to open a new table entry for configuring a semaphore or mutex replacement.
   b. In the **Mapping Information** tab, use the **Function** parameter to select `Mutex Init`. Initial default values for the table entry appear. In the **Conceptual function** section, typically you can leave the argument settings at their defaults.
   c. In the **DWork attributes** section, the **Allocate DWork** option is selected. The dialog box provides a unique entry tag for the DWork argument `d1`.  

<table>
<thead>
<tr>
<th>Code</th>
<th>Generated Code</th>
</tr>
</thead>
</table>
On the **DWork attributes** pane, configure a DWork argument to the replacement function. The DWork argument supports sharing of a semaphore or mutex between:

- Code that creates the semaphore or mutex
- Code that requests and relinquishes access
- Code that deletes the semaphore or mutex

In this example, the DWork argument for the **Mutex Init** function defines a unique entry tag, *entry_25576*. That function also defines DWork arguments for **Mutex Lock**, **Mutex Unlock**, and **Mutex Destroy**, which reference the entry tag to share the DWork data.

The only data type supported for the DWork **Data type** parameter is **void**.

In the **Replacement function** section, enter a function name in the **Name** field. This example uses `myMutexCreate`. In the list of **Function arguments**, leave the DWork argument `d1` data type as `void**`.

The C function signature preview is:

```c
void myMutexCreate (void** d1);
```
e In the **Replacement function** section, select **Function modifies internal or global state**. This option instructs the code generator not to optimize away the implementation function described by this entry because it accesses global memory values. Click **Apply**. Optionally, you can click **Validate entry** to validate the information entered in the **Mapping Information** tab.

To create a sample table entry, configure the replacement function signature without the replacement function and its build information. If header and source files for these functions are available, select the **Build Information** table to specify them.

f The **Mutex Init** table entry is complete. Optionally, you can save the table to a file, and inspect the MATLAB code created for the table definition so far.

5 Repeat the following sequence to create the table entries for the mutex lock, unlock, and destroy function replacements. Each table entry references the DWork unique tag entry, entry_25576, defined in the **Mutex Init** table entry.

a Select **File > New entry > Semaphore entry**.

b In the **Mapping Information** tab, use the **Function** parameter to select **Mutex Lock**, **Mutex Unlock**, or **Mutex Destroy**. Initial default values for the table entry appear. In the **Conceptual function** section, typically you can leave the argument settings at their defaults.

c For a Rate Transition block mutex, the wait, post, and destroy functions operate on the DWork allocated at system startup by the mutex initialization function. In the **DWork attributes** section, verify that the **Allocate DWork** option is cleared. From the **DWork Allocator entry** drop-down list, select the entry tag matching the value in the **Mutex Init** table entry. In this example, the entry tag is **entry_25576**.

d In the **Replacement function** section, **Name** field, enter a function name. This example uses **myMutexLock**, **myMutexUnlock**, and **myMutexDelete**. In the list of **Function arguments**, leave the DWork argument **d1 data type as void**.*
6 In the **Implementation attributes** section, select the option **Function modifies internal or global state**. This option instructs the code generator not to optimize away the implementation function described by this entry because it accesses global memory values.

f Optionally, supply build information for the replacement function on the **Build Information** tab.

g Click **Apply**. In the middle pane, right-click the table entry and select **Validate entry(s)**.

6 When you have added the table entries for **Mutex Lock**, **Mutex Unlock**, and **Mutex Destroy** to the entry for **Mutex Init**, the rate transition mutex replacement table is complete. In the left-most pane, right-click the table name and select **Validate table**. Address errors and repeat the table validation.
7 Save the table to a MATLAB file in your working folder, for example, using **File > Save table**. The name of the saved file is the table name, `crl_table_rt_mutex`, with an `.m` extension. Optionally, you can open the saved file and examine the MATLAB code for the code replacement table definition.

To test this example:

1 Register the code replacement mapping.
2 Create a model that contains a rate transition for which the build process generates mutex function calls. For example:

3 Configure the model for a multicore target environment and the following settings:
   - On the **Solver** pane, select a fixed-step solver.
   - On the **Code Generation** pane, select an ERT-based system target file.
   - On the **Code Generation > Interface** pane, select the code replacement library that contains your mutex entry.

Algorithm-Based Code Replacement

For some math function blocks, you can control code replacement based on the computation or approximation algorithm configured for that block. For example, you can configure:

- The Reciprocal Sqrt block to use the Newton-Raphson or Exact computation method.
- The Trigonometric Function block, with Function set to sin, cos, or sincos, to use the approximation method CORDIC or None.

You can define code replacement entries to replace these functions for one or all of the available computation methods. For example, you can define an entry to replace only Newton-Raphson instances of the rSqrt function.

To set the algorithm for a function in an entry definition, use the EntryInfoAlgorithm property in a call to the function setTflCFunctionEntryParameters. The following table lists arguments for specifying the computation method to match during code generation.

<table>
<thead>
<tr>
<th>Function</th>
<th>Argument</th>
</tr>
</thead>
</table>
| rSqrt    | • 'RTW_DEFAULT' (match the default computation method, Exact)  
|          | • 'RTW_NEWTON_RAPHSON'  
|          | • 'RTW_UNSPECIFIED' (match any computation method) |
| sin      | • 'RTW_CORDIC'                                |
| cos      | • 'RTW_DEFAULT' (match the default approximation method, None) |
| sincos   | • 'RTW_UNSPECIFIED' (match any approximation method) |

For example, to replace only Newton-Raphson instances of the rSqrt function, create an entry as follows:

1. Create a table definition file that contains a function definition. For example:
   ```matlab
   function hTable = crl_rsqrt()
   %CRL_TABLE_RSQRT - Define function entry for code replacement table.
   ```

2. Within the function body, create the table by calling the function RTW.TflTable.
hTable = RTW.TflTable;

3. Create an entry for the function mapping with a call to the RTW.TflCFunctionEntry function.

% Create entry for rsqrt function replacement
fcn_entry = RTW.TflCFunctionEntry;

4. Set function entry parameters with a call to the setTflCFunctionEntryParameters function.

setTflCFunctionEntryParameters(fcn_entry, ...
   'Key',                      'rSqrt', ...
   'Priority',                 80, ...
   'ImplementationName',       'rsqrt_newton', ...
   'ImplementationHeaderFile', 'rsqrt.h', ...
   'EntryInfoAlgorithm',       'RTW_NEWTON_RAPHSON');

5. Create conceptual arguments y1 and u1. This example uses calls to the createAndAddConceptualArg function to create and add an argument with one function call.

createAndAddConceptualArg(fcn_entry, 'RTW.TflArgNumeric', ...
   'Name',         'y1', ...
   'IOType',       'RTW_IO_OUTPUT', ...
   'DataTypeMode', 'double');

createAndAddConceptualArg(e, 'RTW.TflArgNumeric', ...
   'Name',         'u1', ...
   'DataTypeMode', 'double');

6. Copy the conceptual arguments to the implementation arguments. This example uses a call to the copyConceptualArgsToImplementation function to create and add implementation arguments to the entry by copying matching conceptual arguments.

copyConceptualArgsToImplementation(fcn_entry);

7. Add the entry to a code replacement table with a call to the addEntry function.

addEntry(hTable, fcn_entry);

8. Save the table definition file. Use the name of the table definition function to name the file.

The generated code for a Newton-Raphson instance of the rsqrt function looks like the following code:

/* Model step function */
void mrsqrt_step(void)
{

Lookup Table Function Code Replacement

You can configure the algorithm for table lookup operations and index searches to better meet your application code requirements. Use the Algorithm tab of lookup table blocks. For example, you can specify the interpolation, extrapolation, and index search methods.

Lookup Table Algorithm Replacement

If the code generated for available algorithm options does not meet requirements for your application, create custom code replacement table entries to replace generated algorithm code. You can create the table entries programmatically or interactively by using the Code Replacement Tool.

For more information about using lookup table blocks, see “Nonlinearity” (Simulink).

Lookup Table Function Signatures

To create code replacement table entries for a function corresponding to a lookup table algorithm, you must have:

- Information about the conceptual function signature.
- Relevant algorithm parameters.

The following table provides the conceptual function signature information.

<table>
<thead>
<tr>
<th>Conceptual Function Signature</th>
<th>Argument Summary</th>
</tr>
</thead>
<tbody>
<tr>
<td>$y_1 = \text{interp1D}(u_1, u_2, u_3, u_4)$</td>
<td>$y_1$ - output\n$u_1$ - index\n$u_2$ - fraction\n$u_3$ - table data\n$u_4$ - table dimension length</td>
</tr>
<tr>
<td>$y_1 = \text{interp2D}(u_1, u_2, u_3, u_4, u_5, u_6, u_7)$</td>
<td>$y_1$ - output\n$u_1, u_3$ - index\n$u_2, u_4$ - fraction\n$u_5$ - table data\n$u_6, u_7$ - table dimension lengths</td>
</tr>
<tr>

</tbody>
</table>

When defining a table entry programmatically, you might also need to change the values of required (primary) and optional algorithm parameters.

- Set values for required parameters to achieve code replacement.
- If you do not set a value for an optional parameter, the algorithm parameter software applies don't care. The code replacement software ignores the parameter while searching for matches.

To look up algorithm parameter information for a lookup table function:

1. Create a table entry for a function.
   
   ```
   tableEntry = RTW.TflCFunctionEntry;
   ```
Identify the lookup table function in the table entry. Use the Key table entry parameter in a call to `setTflCFunctionEntryParameters`. The following example identifies an entry for the prelookup function.

```matlab
setTflCFunctionEntryParameters(tableEntry, ...
    'Key', 'prelookup', ...
    'Priority', 100, ...
    'ImplementationName', 'myPrelookup');
```

Get the algorithm parameter set for the entry with a call to `getAlgorithmParameters`.

```matlab
algParams = getAlgorithmParameters(tableEntry);
```

Examine information available for each parameter.

```matlab
algParams.ExtrapMethod
ans =
    ExtrapMethod with properties:
        Name: 'ExtrapMethod'
        Options: {'Linear'  'Clip'}
        Primary: 1
        Value: {'Linear'}

algParams.RndMeth
ans =
    RndMeth with properties:
        Name: 'RndMeth'
        Options: {1x7 cell}
        Primary: 0
        Value: {1x7 cell}

algParams.RndMeth.Value
ans =
    Columns 1 through 6
        'Ceiling'    'Convergent'    'Floor'    'Nearest'    'Round'    'Simplest'
    Column 7
        'Zero'
```

Examine information available for each parameter.

```matlab
algParams.IndexSearchMethod
```
ans =
IndexSearchMethod with properties:
    Name: 'IndexSearchMethod'
    Options: {'Linear search' 'Binary search' 'Evenly spaced points'}
    Primary: 0
    Value: {'Binary search' 'Evenly spaced points' 'Linear search'}
algParams.UseLastBreakpoint
ans =
UseLastBreakpoint with properties:
    Name: 'UseLastBreakpoint'
    Options: {'off' 'on'}
    Primary: 0
    Value: {'off' 'on'}
algParams.RemoveProtectionInput
ans =
RemoveProtectionInput with properties:
    Name: 'RemoveProtectionInput'
    Options: {'off' 'on'}
    Primary: 0
    Value: {'off' 'on'}

Interactive Mapping with Code Replacement Tool

This example shows how to specify a code replacement table entry for a lookup table algorithm by using the Code Replacement Tool.

Open and Examine Example Replacement Function

Identify or create the C or C++ replacement function for the algorithm that you want to use in place of a Simulink software algorithm.

This example uses the following C replacement function header and source files, which are in the folder \texttt{matlab/toolbox/rtw/rtwdemos/crl\_demo}:

- myLookup1D.h
- myLookup1D.c

Place a copy of these files in your working folder.

Open and examine the code for myLookup1D.h.

\texttt{
#include "rtwtypes.h"
real\_T my\_Lookup1D\_Repl(real\_T u0, const real\_T *bp0, const real\_T *table, uint32\_T tdl);}

64-121
Open and examine the code in `myLookup1D.c`. Note the function signature. When you enter the implementation argument specification in the Code Replacement Tool, specify argument properties.

```c
#include "myLookup1D.h"
real_T my_Lookup1D_Repl(real_T u0, const real_T *bp0, const real_T *table, uint32_T tdl)
{
    real_T y;
    uint16_T frac;
    uint32_T bpIdx;
    uint32_T maxIndex=tdl-1;
    if (u0 <= bp0[0U]) {
        bpIdx = 0U;
        frac = 0U;
    } else if (u0 < bp0[maxIndex]) {
        bpIdx = maxIndex >> 1U;
        while ((u0 < bp0[bpIdx]) && (bpIdx > 0U)) {
            bpIdx--;
        }
        while ((bpIdx < maxIndex - 1U) && (u0 >= bp0[bpIdx + 1U])) {
            bpIdx++;
        }
        frac = (uint16_T)((u0 - bp0[bpIdx]) / (bp0[bpIdx + 1U] -
            bp0[bpIdx]) * 32768.0);
    } else {
        bpIdx = maxIndex;
        frac = 0U;
    }
    if (bpIdx == maxIndex) {
        y = table[bpIdx];
    } else {
        y = (table[bpIdx + 1U] - table[bpIdx]) * ((real_T)frac * 3.0517578125E-5) +
            table[bpIdx];
    }
    return y;
}
```

Open and Examine the Example Model

This example uses the model `rtwdemo_crllookup1D` to test your code replacement specification. Place a copy of the model in your working folder and name it `my_lookup1d.slx`.

Open and examine the model. Note input and output specifications and block parameter settings. To achieve a match, you must specify conceptual arguments based on how the 1-D Lookup Table block is configured in the example model.
Create Code Replacement Table

1. At the command prompt, enter `crtool` to open the Code Replacement Tool.
2. Add a new table, select that table, and add a new function entry.
3. On the **Mapping Information** tab, select **Custom** for the **Function** parameter.
4. Look up the call signature and algorithm parameter information for the lookup table function that you want to update with an algorithm replacement. See “Lookup Table Function Signatures” on page 64-115.

   For this example, you replace the algorithm for the conceptual function associated with the 1-D Lookup Table block. The signature for that function is:

   \[ y_1 = \text{lookup1D}(u_1, u_2, u_3, u_4) \]

   Arguments \( u_1, u_2, u_3, u_4 \) represent input, breakpoint data, table data, and table dimension length, respectively. The function returns output to \( y_1 \).

5. To the right of the **Function** drop-down list, in the function-name text box, enter the name of the Simulink lookup table function. For this example, type the name `lookup1D`. Type the name exactly as it appears in the documented signature, including character casing. Press **Enter**.

   The tool displays algorithm parameter settings that trigger a match for the 1-D Lookup Table block in the example model. Required parameters appear with only one value. For this example, do not change the values. Optional parameters appear with multiple values. Changes to optional parameters do not affect the match process.

6. Specify the conceptual arguments. Under the **Conceptual arguments** list box, click + to add the arguments that are in the documented function signature. The `lookup1D` function takes one output argument and four input arguments. Click + five times.
The tool creates an output argument \( y_1 \) and four input arguments \( u_1, u_2, u_3, \) and \( u_4 \). By default, the four arguments are scalars of type double.

You can adjust the conceptual argument properties. For this example, you do not make changes for \( y_1 \) and \( u_1 \). However, as the block parameter dialog box for the example model shows, you must adjust the argument properties for the breakpoint and table data arguments.

Adjust the conceptual argument properties by using the following table. Click Apply.

<table>
<thead>
<tr>
<th>Signature Argument Name</th>
<th>Conceptual Argument Name</th>
<th>Data type</th>
<th>I/O type</th>
<th>Argument type</th>
<th>Lower range</th>
<th>Upper range</th>
</tr>
</thead>
<tbody>
<tr>
<td>y</td>
<td>( y_1 )</td>
<td>double</td>
<td>OUTPUT</td>
<td>Scalar</td>
<td>Not applicable</td>
<td>Not applicable</td>
</tr>
<tr>
<td>u1</td>
<td>( u_1 )</td>
<td>double</td>
<td>INPUT</td>
<td>Scalar</td>
<td>Not applicable</td>
<td>Not applicable</td>
</tr>
<tr>
<td>bp1</td>
<td>( u_2 )</td>
<td>double</td>
<td>INPUT</td>
<td>Matrix</td>
<td>[0 0]</td>
<td>[Inf Inf]</td>
</tr>
<tr>
<td>table</td>
<td>( u_3 )</td>
<td>double</td>
<td>INPUT</td>
<td>Matrix</td>
<td>[0 0]</td>
<td>[Inf Inf]</td>
</tr>
</tbody>
</table>
7 Enter information for the replacement function prototype. The prototype for the example function is:

```c
real_T my_Lookup1D_Repl(real_T u0, const real_T *bp0, const real_T *table, uint32_T tdl)
```

In the **Replacement function > Function prototype** section, type the function name `my_Lookup1D_Repl` in the **Name** text box.

8 Specify the arguments for the replacement function. Under the **Function arguments** list box, click + five times to add five implementation arguments.

You might need to adjust the function argument properties. As the replacement function signature shows, adjust the argument properties for the breakpoint, table data, and table dimension length arguments. For `u2` (breakpoints) and `u3` (table), select the **Const** check box. For `u4`, set **Data type** to `uint32`.

The function signature preview should appear as follows:

```c
double my_Lookup1D_Repl(double u1, const double* u2, const double* u3, uint32 u4)
```

9 Set relevant implementation attributes. Use the default settings.

10 Validate the entry. If the tool reports errors, fix them, and retry the validation. Repeat the procedure until the tool does not report errors.

11 Save the code replacement table in your working folder as `my_lookup_replacement_table.m`.

**Specify Build Information**

On the **Build Information** tab, specify information relevant to generating C or C++ code and building an executable from the model. Enter `myLookup1D.h` for **Implementation Header File** and `myLookup1D.c` for **Implementation Source File**.

<table>
<thead>
<tr>
<th>Signature Argument Name</th>
<th>Conceptual Argument Name</th>
<th>Data type</th>
<th>I/O type</th>
<th>Argument Type</th>
<th>Lower range</th>
<th>Upper range</th>
</tr>
</thead>
<tbody>
<tr>
<td>tdl</td>
<td>u4</td>
<td>uint32</td>
<td>INPUT</td>
<td>Scalar</td>
<td>Not applicable</td>
<td>Not applicable</td>
</tr>
</tbody>
</table>

74-125
If you copied the example files to a folder other than the working folder containing the test model, lookup1d.s1x, specify the source and header file paths. Otherwise, leave the other Build Information parameters set to default values. Click Apply.

Test the Entry

To test this example:

1. Register the code replacement mapping.
2. Use the example model rtwdemo_crllookup1D.
3. Configure the model with the following settings:
   - On the Solver pane, select a fixed-step solver.
   - On the Code Generation pane, select an ERT-based system target file.
   - On the Code Generation > Interface pane, select the code replacement library that contains your lookup table function entry.

Programmatic Specification

This example shows how to specify code replacement table entries for lookup table functions programmatically.

Open and Examine Example Replacement Function

Identify or create the C or C++ replacement function for the algorithm that you want to use in place of a Simulink software algorithm.

This example uses the following C replacement function header and source files, which are in the folder matlab/toolbox/rtw/rtwdemos/crl_demo:

- myLookup1D.h
- myLookup1D.c

Place a copy of these files in your working folder.

Open and examine the code for myLookup1D.h.

```c
#include "rtwtypes.h"
real_T my.Lookup1D_Repl(real_T u0, const real_T *bp0, const real_T *table, uint32_T tdl);
```
Open and examine the code in `myLookup1D.c`. Note the function signature. When you enter the implementation argument specification in the Code Replacement Tool, specify argument properties.

```c
#include "myLookup1D.h"
real_T my_Lookup1D_Repl(real_T u0, const real_T *bp0, const real_T *table, uint32_T tdl)
{
    real_T y;
    uint16_T frac;
    uint32_T bpIdx;
    uint32_T maxIndex=tdl-1;

    if (u0 <= bp0[0U]) {
        bpIdx = 0U;
        frac = 0U;
    } else if (u0 < bp0[maxIndex]) {
        bpIdx = maxIndex >> 1U;
        while (((u0 < bp0[bpIdx]) && (bpIdx > 0U)) {
            bpIdx--;
        }

        while ((bpIdx < maxIndex - 1U) && (u0 >= bp0[bpIdx + 1U])) {
            bpIdx++;
        }

        frac = (uint16_T)((u0 - bp0[bpIdx]) / (bp0[bpIdx + 1U] -
            bp0[bpIdx]) * 32768.0);
    } else {
        bpIdx = maxIndex;
        frac = 0U;
    }

    if (bpIdx == maxIndex) {
        y = table[bpIdx];
    } else {
        y = (table[bpIdx + 1U] - table[bpIdx]) * ((real_T)frac * 3.0517578125E-5) +
            table[bpIdx];
    }

    return y;
}
```

**Review Lookup Function Signature**

Look up the call signature information for the lookup function that you want to update with an algorithm replacement. See “Lookup Table Function Signatures” on page 64-115.

Replace the algorithm for the function associated with the 1-D Lookup Table block. The signature for that function is:

\[ y1 = \text{lookup1D}(u1, u2, u3, u4) \]

Arguments \( u1, u2, u3, \) and \( u4 \) represent input, breakpoint data, table data, and table dimension length, respectively. The function returns output to \( y1 \).
Create Code Replacement Entry

Create a code replacement table file as a MATLAB function, that describes the lookup table function code replacement table entries. Place a copy of the file `matlab/toolbox/rtw/rtwdeemos/crl_demo/crl_table_lookup1D.m` in your working folder. This file defines a code replacement table for the C function `my_Lookup1D_Repl`.

Open `crl_table_lookup1D.m` and examine the definition.

1. Create a table definition file that contains a function definition. For example:

   ```matlab
   function hLib = my_lookup_replacement_table
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```matlab
   hLib = RTW.TflTable;
   ```

3. Create an entry for the function mapping with a call to the `RTW.TflCFunctionEntry` function.

   ```matlab
   hEnt = RTW.TflCFunctionEntry;
   ```

4. Set function entry parameters with a call to the `setTflCFunctionEntryParameters` function. The function key, implementation name, and header and source files in the function call identify the Simulink lookup table function name, `lookup1D`, and the following information for replacement function `my_Lookup1D_Repl`:

   - Function name
   - Header file
   - Source file

Specify the Simulink lookup table function name exactly as it appears in the documented signature, including character casing (see “Lookup Table Function Signatures” on page 64-115). If you copied the example files to a folder other than the working folder that contains the test model, `rtwdeemo_crllookup1D`, specify the source and header file paths.

```matlab
setTflCFunctionEntryParameters(hEnt, ...
    'Key', 'lookup1D', ...
    'Priority', 100, ...
    'ImplementationName', 'my_Lookup1D_Repl', ...
    'ImplementationHeaderFile', 'myLookup1D.h', ...
    'ImplementationSourceFile', 'myLookup1D.c', ...
    'GenCallback', 'RTW.copyFileToBuildDir');
```
5 Create conceptual arguments and add them to the entry. This example uses calls to
the getTflArgFromString and addConceptualArg functions to create and add
the arguments.

The example defines five conceptual arguments for the lookup1D function, one
output argument $y_1$ and four input arguments $u_1$, $u_2$, $u_3$, and $u_4$. Arguments $y_1$ and
$u_1$ are defined as scalar double data. Arguments $u_2$ and $u_3$ represent $bp_1$ and
table in the signature and are defined as 1x10 matrices of double data. Argument
$u_4$ represents $tdl$ and is defined as scalar of uint32 data. This definition triggers a
match with the example model.

arg = hEnt.getTflArgFromString('y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEnt, arg);

arg = hEnt.getTflArgFromString('u1','double');
addConceptualArg(hEnt, arg);

arg = RTW.TflArgMatrix('u2', 'RTW_IO_INPUT', 'double');
arg.DimRange = [0 0; Inf Inf];
addConceptualArg(hEnt, arg);

arg = RTW.TflArgMatrix('u3', 'RTW_IO_INPUT', 'double');
arg.DimRange = [0 0; Inf Inf];
addConceptualArg(hEnt, arg);

arg = hEnt.getTflArgFromString('u4','uint32');
addConceptualArg(hEnt, arg);

6 Review the algorithm parameter information for the lookup function that you want to
update with an algorithm replacement. Use the getAlgorithmParameters function
to display the parameter information.

algParams = getAlgorithmParameters(hEnt)
algParams =

Lookup with properties:

InterpMethod: [1x1 coder.algorithm.parameter.InterpMethod]
ExtrapMethod: [1x1 coder.algorithm.parameter.ExtrapMethod]
UseRowMajorAlgorithm: [1x1 coder.algorithm.parameter.UseRowMajorAlgorithm]
RndMeth: [1x1 coder.algorithm.parameter.RndMeth]
IndexSearchMethod: [1x1 coder.algorithm.parameter.IndexSearchMethod]
UseLastTableValue: [1x1 coder.algorithm.parameter.UseLastTableValue]
RemoveProtectionInput: [1x1 coder.algorithm.parameter.RemoveProtectionInput]
SaturateOnIntegerOverflow: [1x1 coder.algorithm.parameter.SaturateOnIntegerOverflow]
SupportTunableTableSize: [1x1 coder.algorithm.parameter.SupportTunableTableSize]
BPPower2Spacing: [1x1 coder.algorithm.parameter.BPPower2Spacing]

Examine the information for each parameter. The Options property lists possible
values. Primary indicates whether a parameter is required (1) or optional (0). The
Value property specifies the current value. For required parameters, initially, Value is set to the default value for a given lookup table function.

algParams.InterpMethod

ans =

    InterpMethod with properties:
    Name: 'InterpMethod'
    Options: {'Linear' 'Flat' 'Nearest'}
    Primary: 1
    Value: {'Linear'}

algParams.RndMeth

ans =

    RndMeth with properties:
    Name: 'RndMeth'
    Options: {1x7 cell}
    Primary: 0
    Value: {1x7 cell}

algParams.RndMeth.Options

ans =

    Columns 1 through 5
    'Ceiling' 'Convergent' 'Floor' 'Nearest' 'Round'

    Columns 6 through 7
    'Simplest' 'Zero'

Set the algorithm properties for the lookup1D table entry. Assign a value to each parameter. Update the parameter settings for the entry by calling the function setAlgorithmParameters. The following parameter settings trigger a match with the example model.

algParams.InterpMethod = 'Linear';
algParams.ExtrapMethod = 'Clip';
algParams.UseRowMajorAlgorithm = 'off';
algParams.RndMeth = 'Round';
algParams.IndexSearchMethod = 'Linear search';
algParams.UseLastTableValue = 'Evenly spaced point';
algParams.RemoveProtectionInput = 'off';
algParams.SaturateOnIntegerOverflow = 'off';
algParams.SupportTunableTableSize = 'off';
algParams.BPPower2Spacing = 'off';
setAlgorithmParameters(hEnt, algParams);

To verify your changes, call getAlgorithmParameters to get the parameter set for the table entry. Examine the value of each parameter:

getAlgorithmParameters(hEnt, algParams);
algParams.InterpMethod.Value
ans =
    'Linear'
algParams.ExtrapMethod.Value
ans =
    'Clip'
algParams.UseRowMajorAlgorithm.Value
ans =
    'off'

Create the implementation arguments and add them to the entry. This example uses calls to the getTflArgFromString function to create five implementation arguments that map to arguments in the replacement function prototype: one output argument y1 and four input arguments u1, u2, u3, and u4. The convenience methods setReturn and addArgument specify whether an argument is a return value or argument. The addArgument function also adds each argument to the entry’s array of implementation arguments.

arg = hEnt.getTflArgFromString('y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);

arg = hEnt.getTflArgFromString('u1','double');
hEnt.Implementation.addArgument(arg);
arg = hEnt.getTflArgFromString('u2','double*');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u3','double*');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u4','uint32');
hEnt.Implementation.addArgument(arg);

9 Add the entry to a code replacement table with a call to the addEntry function.
addEntry(hLib, hEnt);

10 Save the table definition file. Use the name of the table definition function to name the file.

Test the Entry

To test this example:

1 Register the code replacement mapping.
2 Use the example model rtwdemo_crllookup1D.
3 Configure the model with the following settings:
   • On the Solver pane, select a fixed-step solver.
   • On the Code Generation pane, select an ERT-based system target file.
   • On the Code Generation > Interface pane, select the code replacement library that contains your lookup table function entry.

Sample Code Replacement Definition for the lookup2D Function

The following code shows a replacement definition for the lookup2D function.

function hLib = my_2dlookup_replacement_table
hLib = RTW.TflTable;

hEnt = RTW.TflCFunctionEntry;
setTflCFunctionEntryParameters(hEnt, ...
   'Key', 'lookup2D', ...
'Priority', 100, ...

'ImplementationName', 'custom_lookup2d', ...
'ImplementationHeaderFile', 'custom_lookup2d.h', ...
'ImplementationSourceFile', 'custom_lookup2d.c', ...
'GenCallback', 'RTW.copyFileToBuildDir');

% Conceptual Args

arg = hEnt.getTflArgFromString('y1', 'double');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEnt, arg);

arg = hEnt.getTflArgFromString('u1', 'double');
addConceptualArg(hEnt, arg);

arg = hEnt.getTflArgFromString('u2', 'double');
addConceptualArg(hEnt, arg);

arg = RTW.TflArgMatrix('u3', 'RTW_IO_INPUT', 'double');
arg.DimRange = [1 1; 10 1];
addConceptualArg(hEnt, arg);

arg = RTW.TflArgMatrix('u4', 'RTW_IO_INPUT', 'double');
arg.DimRange = [1 1; 10 1];
addConceptualArg(hEnt, arg);

arg = RTW.TflArgMatrix('u5', 'RTW_IO_INPUT', 'double');
arg.DimRange = [1 1; 10 1];
addConceptualArg(hEnt, arg);

arg = hEnt.getTflArgFromString('u6', 'uint32');
addConceptualArg(hEnt, arg);

arg = hEnt.getTflArgFromString('u7', 'uint32');
addConceptualArg(hEnt, arg);

% Algorithm Parameters

addAlgorithmProperty(hEnt, 'ExtrapMethod', 'Clip');
addAlgorithmProperty(hEnt, 'IndexSearchMethod', 'Linear search');
addAlgorithmProperty(hEnt, 'InterpMethod', 'Linear');
addAlgorithmProperty(hEnt, 'RemoveProtectionInput', 'off');
addAlgorithmProperty(hEnt, 'UseLastTableValue', 'on');
% Implementation Args

arg = hEnt.getTflArgFromstring('y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);

arg = hEnt.getTflArgFromstring('u1','double');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromstring('u2','double');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromstring('u3','double*');
arg.Type.BaseType.ReadOnly = true;
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromstring('u4','double*');
arg.Type.BaseType.ReadOnly = true;
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromstring('u5','double*');
arg.Type.BaseType.ReadOnly = true;
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromstring('u6','uint32');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromstring('u7','uint32');
hEnt.Implementation.addArgument(arg);

hLib.addEntry(hEnt);

Data Alignment for Code Replacement

Code replacement libraries can align data objects passed into a replacement function to a specified boundary.

Code Replacement Data Alignment

You can take advantage of function implementations that require aligned data to optimize application performance. To configure data alignment for a function implementation:

1. Specify the data alignment requirements in a code replacement entry. Specify alignment separately for each implementation function argument or collectively for all function arguments. See “Specify Data Alignment Requirements for Function Arguments” on page 64-136.

2. Specify the data alignment capabilities and syntax for one or more compilers. Include the alignment specifications in a library registration entry in the rtwTargetInfo.m file. See “Provide Data Alignment Specifications for Compilers” on page 64-138.

3. Register the library containing the table entry and alignment specification object.

4. Configure the code generator to use the code replacement library and generate code. Observe the results.

For examples, see “Basic Example of Code Replacement Data Alignment” on page 64-143 and the “Data Alignment for Function Implementations” section of the “Optimize Generated Code By Developing and Using Code Replacement Libraries - Simulink®” example page.

Specify Data Alignment Requirements for Function Arguments

To specify the data alignment requirement for an argument in a code replacement entry:

- If you are defining a replacement function in a code replacement table registration file, create an argument descriptor object (RTW.ArgumentDescriptor). Use its AlignmentBoundary property to specify the required alignment boundary and assign the object to the argument Descriptor property.

- If you are defining a replacement function using the Code Replacement Tool, on the Mapping Information tab, in the Argument properties section for the replacement function, enter a value for the Alignment value parameter.
The AlignmentBoundary property (or Alignment value parameter) specifies the alignment boundary for data passed to a function argument, in number of bytes. The AlignmentBoundary property is valid only for addressable objects, including matrix and pointer arguments. It is not applicable for value arguments. Valid values are:

- **-1 (default)** — If the data is a `Simulink.Bus`, `Simulink.Signal`, or `Simulink.Parameter` object, specifies that the code generator determines an optimal alignment based on usage. Otherwise, specifies that there is not an alignment requirement for this argument.
- Positive integer that is a power of 2, not exceeding 128 — Specifies number of bytes in the boundary. The starting memory address for the data allocated for the function argument is a multiple of the specified value. If you specify an alignment boundary that is less than the natural alignment of the argument data type, the alignment directive is emitted in the generated code. However, the target compiler ignores the directive.

The following code specifies the AlignmentBoundary for an argument as 16 bytes.

```matlab
hLib = RTW.TflTable;
entry = RTW.TflCOperationEntry;
arg = getTflArgFromString(hLib, 'u1','single*');
desc = RTW.ArgumentDescriptor;
desc.AlignmentBoundary = 16;
arg.Descriptor = desc;
entry.Implementation.addArgument(arg);
```
The equivalent alignment boundary specification in the Code Replacement Tool dialog box is in this figure.

![Alignment Spec](image)

**Note** If your model imports Simulink.Bus, Simulink.Parameter, or Simulink.Signal objects, specify an alignment boundary in the object properties, using the **Alignment** property. For more information, see Simulink.Bus, Simulink.Parameter, and Simulink.Signal.

## Provide Data Alignment Specifications for Compilers

To support data alignment in generated code, describe the data alignment capabilities and syntax for your compilers in the code replacement library registration. Provide one or more alignment specifications for each compiler in a library registry entry.

To describe the data alignment capabilities and syntax for a compiler:

- If you are defining a code replacement library registration entry in a rtwTargetInfo.m customization file, add one or more AlignmentSpecification objects to an RTW.DataAlignment object. Attach the RTW.DataAlignment object to the TargetCharacteristics object of the registry entry.

  The RTW.DataAlignment object also has the property DefaultMallocAlignment, which specifies the default alignment boundary, in bytes, that the compiler uses for dynamically allocated memory. If the code generator uses dynamic memory allocation for a data object involved in a code replacement, this value determines if the memory satisfies the alignment requirement of the replacement. If not, the code generator does not use the replacement. The default value for DefaultMallocAlignment is -1, indicating that the default alignment boundary used for dynamically allocated memory is unknown. In this case, the code generator uses the natural alignment of the data type to determine whether to allow a replacement.
Additionally, you can specify the alignment boundary for complex types by using the `addComplexTypeAlignment` function.

- If you are generating a customization file function using the Code Replacement Tool, fill out the following fields for each compiler.

![Generate data alignment specification](image)

Click the plus (+) symbol to add additional compiler specifications.

For each data alignment specification, provide the following information.
<table>
<thead>
<tr>
<th>Alignment- Specification Property</th>
<th>Dialog Box Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AlignmentType</td>
<td>Alignment type</td>
<td>Cell array of predefined enumerated strings, specifying which types of alignment this specification supports.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• DATA_ALIGNMENT_LOCAL_VAR — Local variables.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• DATA_ALIGNMENT_GLOBAL_VAR — Global variables.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• DATA_ALIGNMENT_STRUCT_FIELD — Individual structure fields.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• DATA_ALIGNMENT_WHOLE_STRUCT — Whole structure, with padding (individual structure field alignment, if specified, is favored and takes precedence over whole structure alignment).</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Each alignment specification must specify at least DATA_ALIGNMENT_GLOBAL_VAR and DATA_ALIGNMENT_STRUCT_FIELD.</td>
</tr>
<tr>
<td>Alignment-Specification Property</td>
<td>Dialog Box Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------</td>
<td>----------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>AlignmentPosition</td>
<td>Alignment position</td>
<td>Predefined enumerated string specifying the position in which you must place the compiler alignment directive for alignment type DATA_ALIGNMENT_WHOLE_STRUCT:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- DATA_ALIGNMENT_PREDIRECTIVE — The alignment directive is emitted before struct st_tag{...}, as part of the type definition statement (for example, MSVC).</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- DATA_ALIGNMENT_POSTDIRECTIVE — The alignment directive is emitted after struct st_tag{...}, as part of the type definition statement (for example, gcc).</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- DATA_ALIGNMENT_PRECEDING_STATEMENT — The alignment directive is emitted as a standalone statement immediately preceding the definition of the structure type. A semicolon (;) must terminate the registered alignment syntax.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- DATA_ALIGNMENT_FOLLOWING_STATEMENT — The alignment directive is emitted as a standalone statement immediately following the definition of the structure type. A semicolon (;) must terminate the registered alignment syntax.</td>
</tr>
</tbody>
</table>

For alignment types other than DATA_ALIGNMENT_WHOLE_STRUCT, code generation uses alignment position DATA_ALIGNMENT_PREDIRECTIVE.
## Alignment-Specification Property

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>Dialog Box Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| AlignmentSyntax-Template | Specifies the alignment directive string that the compiler supports. The string is registered as a syntax template that has placeholders in it. These placeholders are supported:  
  - `%n` — Replaced by the alignment boundary for the replacement function argument.  
  - `%s` — Replaced by the aligned symbol, usually the identifier of a variable.  
  
  For example, for the gcc compiler, you can specify `__attribute__((aligned(%n)))`, or for the MSVC compiler, `__declspec(align(%n))`. | Alignment syntax | Specifies the alignment directive string that the compiler supports. The string is registered as a syntax template that has placeholders in it. These placeholders are supported:  
  - `%n` — Replaced by the alignment boundary for the replacement function argument.  
  - `%s` — Replaced by the aligned symbol, usually the identifier of a variable.  
  
  For example, for the gcc compiler, you can specify `__attribute__((aligned(%n)))`, or for the MSVC compiler, `__declspec(align(%n))`. |
| SupportedLanguages | Cell array specifying the languages to which this alignment specification applies, among c and c++. Sometimes alignment syntax and position differ between languages for a compiler. | Supported languages | Cell array specifying the languages to which this alignment specification applies, among c and c++. Sometimes alignment syntax and position differ between languages for a compiler. |

Here is a data alignment specification for the GCC compiler:

```matlab
da = RTW.DataAlignment;

as = RTW.AlignmentSpecification;
as.AlignmentType = {'DATA ALIGNMENT_LOCAL_VAR', ...
    'DATA ALIGNMENT_STRUCT_FIELD', ...
    'DATA ALIGNMENT_GLOBAL_VAR'};
as.AlignmentSyntaxTemplate = '__attribute__((aligned(%n)))';
as.AlignmentPosition = 'DATA_ALIGNMENT_PREDIRECTIVE';
as.SupportedLanguages = {'c', 'c++'};
da.addAlignmentSpecification(as);

tc = RTW.TargetCharacteristics;
tc.DataAlignment = da;
```

Here is the corresponding specification in the **Generate customization** dialog box of the Code Replacement Tool.
Basic Example of Code Replacement Data Alignment

A simple example of the complete workflow for data alignment specified for code replacement is:

1. Create and save the following code replacement table definition file, `crl_table_mmul_4x4_single_align.m`. This table defines a replacement entry for the * (multiplication) operator, the single data type, and input dimensions [4,4]. The entry also specifies a data alignment boundary of 16 bytes for each replacement function argument. The entry expresses the requirement that the starting memory address for the data allocated for the function arguments during code generation is a multiple of 16.

   ```matlab
   function hLib = crl_table_mmul_4x4_single_align
   %CRL_TABLE_MMUL_4x4_SINGLE_ALIGN - Describe matrix operator entry with data alignment
   hLib = RTW.TflTable;
   entry = RTW.TflCOperationEntry;
   setTflCOperationEntryParameters(entry, ...
   % conceptual arguments
   createAndAddConceptualArg(entry, 'RTW.TflArgMatrix', ...
   )
   ```
createAndAddConceptualArg(entry, 'RTW.TflArgMatrix', ...
    'Name', 'u1', ...
    'BaseType', 'single', ...
    'DimRange', [4 4]);

createAndAddConceptualArg(entry, 'RTW.TflArgMatrix', ...
    'Name', 'u2', ...
    'BaseType', 'single', ...
    'DimRange', [4 4]);

% implementation arguments
arg = getTflArgFromString(hLib, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
entry.Implementation.setReturn(arg);

arg = getTflArgFromString(hLib, 'y1','single*');
desc = RTW.ArgumentDescriptor;
desc.AlignmentBoundary = 16;
arg.Descriptor = desc;
entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hLib, 'u1','single*');
desc = RTW.ArgumentDescriptor;
desc.AlignmentBoundary = 16;
arg.Descriptor = desc;
entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hLib, 'u2','single*');
desc = RTW.ArgumentDescriptor;
desc.AlignmentBoundary = 16;
arg.Descriptor = desc;
entry.Implementation.addArgument(arg);

hLib.addEntry(entry);

2

Create and save the following registration file, rtwTargetInfo.m. If you want to compile the code generated in this example, first modify the AlignmentSyntaxTemplate property for the compiler that you use. For example, for the MSVC compiler, replace the gcc template specification
__attribute__((aligned(%n))) with __declspec(align(%n)).

function rtwTargetInfo(cm)
% rtwTargetInfo function to register a code replacement library (CRL)
% for use with code generation

    % Register the CRL defined in local function locCrlRegFcn
    cm.registerTargetInfo(@locCrlRegFcn);

end % End of RTWTARGETINFO

% Local function to define a CRL containing crl_table_mmul_4x4_single_align
function thisCrl = locCrlRegFcn

    % create an alignment specification object, assume gcc
as = RTW.AlignmentSpecification;
as.AlignmentType = {'DATA_ALIGNMENT_LOCAL_VAR', ...
'DATA_ALIGNMENT_GLOBAL_VAR', ...
'DATA_ALIGNMENT_STRUCT_FIELD'};
as.AlignmentSyntaxTemplate = '__attribute__((aligned(%n)))';
as.SupportedLanguages={'c', 'c++'};

% add the alignment specification object
da = RTW.DataAlignment;
da.addAlignmentSpecification(as);

% add the data alignment object to target characteristics
tc = RTW.TargetCharacteristics;
tc.DataAlignment = da;

% Instantiate a CRL registry entry
thisCrl = RTW.TflRegistry;

% Define the CRL properties
thisCrl.Name = 'Data Alignment Example';
thisCrl.Description = 'Example of replacement with data alignment';
thisCrl.TableList = {'crl_table_mmul_4x4_single_align'};
thisCrl.TargetCharacteristics = tc;

end % End of LOCCRLREGFCN

3 To register your library with code generator without having to restart MATLAB, enter this command:

    RTW.TargetRegistry.getInstance('reset');

4 Configure the code generator to use your code replacement library.

5 Generate code and a code generation report.

6 Review the code replacements. For example, check whether a multiplication operation is replaced with a matrix_mul_4x4_s function call. In mmalign.h, check whether the gcc alignment directive __attribute__((aligned(16))) is generated to align the function variables.

Replace MATLAB Functions with Custom Code Using `coder.replace`

The `coder.replace` function provides the ability to replace a specified MATLAB function with a code replacement function in generated code. Use `coder.replace` in MATLAB code from which you want to generate C code using:

- MATLAB Coder
- MATLAB code in a Simulink MATLAB Function block

You can replace MATLAB functions that have:

- Single or multiple inputs
- Single or multiple outputs
- Scalar and matrix inputs and outputs

Supported types include:

- `single`, `double` (complex and noncomplex)
- `int8`, `uint8` (complex and noncomplex)
- `int16`, `uint16` (complex and noncomplex)
- `int32`, `uint32` (complex and noncomplex)
- Fixed-point integers
- Mixed types (different type on each input)

Replace coder.ceval Calls to External Functions

The `coder.ceval` function calls external C/C++ functions from code generated from MATLAB code. The code replacement software supports replacement of the function that you specify in a call to `coder.ceval`. An application of this code replacement scenario is to write generic MATLAB code that you can customize for different platforms with code replacements. A code replacement library can define hardware-specific code replacements for the function call. Use `coder.ceval` in MATLAB code from which you want to generate C code using:

- MATLAB Coder
- MATLAB code in a Simulink MATLAB Function block

Example Files

For the examples in “Interactive External Function Call Replacement Specification with Code Replacement Tool” on page 65-112 and “Programmatic External Function Call Replacement Specification” on page 65-114 you must have set up the following:

- Custom C function `my_add.c`.

```c
/* my_add.c */

#include "my_add.h"

double my_add(double in1, double in2)
{
    return in1 + in2;
}
```

- Custom C header file `my_add.h`.

```c
/* my_add.h */

double my_add(double in1, double in2);
```

- MATLAB function `call_my_add.m`, which uses `coder.ceval` to invoke `my_add.c`.

```matlab
function y = call_my_add(in1, in2) %#codegen
y=0.0;
if ~coder.target('Rtw')
% Executing in MATLAB, call MATLAB equivalent of C function my_add
  y = in1 + in2;
else
  % Executing in generated code, call C function my_add
  y = coder.ceval('my_add', in1, in2);
end

• MATLAB test function call_my_add_test.m, which calls call_my_add.m.
  in1 = 10;
in2 = 20;
y = call_my_add(in1, in2);
  disp('Output')
  disp('y =')
  disp(y);

• Replacement C function my_addReplacement.c.

  /* my_addReplacement.c */
  
  #include "my_addReplacement.h"

  double my_addReplacement(double in1, double in2)
  {
    return in1 + in2;
  }

• Replacement C header file my_addReplacement.h.

  /* my_addReplacement.h */
  
  double my_addReplacement(double in1, double in2);

Interactive External Function Call Replacement Specification
with Code Replacement Tool

This example shows how to define a code replacement table entry for a MATLAB function that calls coder.ceval to invoke an external C function. The example shows how to define the entry interactively with the Code Replacement Tool.

1 Identify or create the C/C++ code and relevant header files, the MATLAB function that calls coder.ceval, a MATLAB test function, and the source and header files for
your replacement code. To follow along with this example, set up the files identified in “Example Files” on page 65-111.

2 In the Code Replacement Tool, add a table, select that table, and add a function entry. For more information, see “Define Code Replacement Mappings” on page 65-29.

3 On the **Mapping Information** tab, select Custom for the **Function** parameter.

4 In the **function-name** text box, type the custom function name. For this example, type the name `my_add`.

5 Under the **Conceptual arguments** list box, click + to add three arguments. By default, the tool creates an output argument `y1` and input arguments `u1` and `u2` of type `double`.

6 In the **Replacement function > Function prototype** section, type the name `my_add_replacement` in the **Name** text box.

7 Under the **Function arguments** list box, click + to add three function implementation arguments. By default, the tool creates an output argument `y1` and input arguments `u1` and `u2` of type `double`. Use the default settings.

8 In the **Function signature preview** box, if you see the expected function signature, click **Apply**. The function signature for this example, appears as:

   ```
   double my_add_replacement(double u1, double u2);
   ```

9 On the **Build Information** tab, specify `my_add_replacement.h` for the **Implementation header file** parameter and `my_add_replacement.c` for the **Implementation source file**.

10 Click **Validate entry**.

11 Save the code replacement table in the same folder as `my_add_replacement.c`. Name the file `crl_table_my_add.m`.

To test the example:

1 Register the table that contains the entry in a code replacement library.

2 Configure the code generator to use the code replacement library and to include the Code Replacements Report in the code generation report.

3 Generate code and the report.

4 Review the code replacements.
Programmatic External Function Call Replacement Specification

This example shows how to define a code replacement table entry for a MATLAB function that calls `coder.ceval` to invoke an external C function. The example shows how to define the entry programmatically.

1. Identify or create the C/C++ code and relevant header files, the MATLAB function that calls `coder.ceval` to invoke the C/C++ function, a MATLAB test function, and the source and header files for your replacement code. To follow along with this example, set up the files identified in “Example Files” on page 65-111.

2. Create a table definition file that contains a function definition. For example:

   ```matlab
   function hLib = crl_table_my_add
   ```

3. Within the function body, create the table by calling the function `RTW.TflTable`.

4. Create an entry for the function mapping with a call to the `RTW.TflCFunctionEntry` function.

   ```matlab
   hEnt = RTW.TflCFunctionEntry;
   ```

5. Set function entry parameters with a call to the `setTflCFunctionEntryParameters` function.

   ```matlab
   hEnt.setTflCFunctionEntryParameters( ...
       'Key', 'my_add', ...
       'Priority', 100, ...
       'ImplementationName', 'my_add_replacement', ...
       'ImplementationHeaderFile', 'my_add_replacement.h', ...
       'ImplementationSourceFile', 'my_add_replacement.c');
   ```

6. Create conceptual arguments `y1`, `u1`, and `u2`. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create and add the arguments.

   ```matlab
   arg = hEnt.getTflArgFromString('y1','double');
   arg.IOType = 'RTW_IO_OUTPUT';
   hEnt.addConceptualArg(arg);

   arg = hEnt.getTflArgFromString('u1','double');
   hEnt.addConceptualArg(arg);

   arg = hEnt.getTflArgFromString('u2','double');
   hEnt.addConceptualArg(arg);
   ```
Create the implementation arguments and add them to the entry. This example uses calls to the `getTflArgFromString` function to create implementation arguments. These functions map to arguments in the replacement function prototype: output argument `y1` and input arguments `u1` and `u2`. For each argument, the example uses the convenience method `setReturn` or `addArgument` to specify whether an argument is a return value or argument. For each argument, this example adds the argument to the entry array of implementation arguments.

```matlab
arg = hEnt.getTflArgFromString('y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);

arg = hEnt.getTflArgFromString('u1','double');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u2','double');
hEnt.Implementation.addArgument(arg);
```

Add the entry to a code replacement table with a call to the `addEntry` function.

```matlab
hLib.addEntry(hEnt);
```

Save the table definition file. Use the name of the table definition function to name the file.

To test the example:

1. Register the table that contains the entry in a code replacement library.
2. Configure the code generator to use the code replacement library and to include the Code Replacements Report in the code generation report.
3. Generate code and the report.
4. Review the code replacements.

Replace MATLAB Functions Specified in MATLAB Function Blocks

This example shows how to use code replacement to replace a MATLAB function specified in a MATLAB Function block.

1. Open the ex_replace model. At the command prompt, enter:

   addpath(fullfile(docroot,'toolbox','ecoder','examples'))
ex_replace

2. View the MATLAB Function Block code. In the model, double-click the MATLAB Function block to view the code in the MATLAB editor.

   ```matlab
   function y = customFcn(u1, u2) %#codegen
   % This block supports MATLAB for code generation.
   % Replace this MATLAB function with CRL replacement function and if no % CRL replacement is found, generate an error during code generation.
   coder.replace('-errorifnoreplacement');
   assert(isa(u1,'int32'));
   assert(isa(u2,'int32'));
   
   y = power(u1,u2);
   
   The coder.replace('-errorifnoreplacement') statement instructs the code generator to replace this MATLAB function with a code replacement library function. The code generator produces an error if it does not find a match.

3. Create a table definition file that contains a function definition. For example:

   ```matlab
   function hTable = crl_table_coderreplace()
   
   4. Within the function body, create the table by calling the function RTW.TflTable.

      hTable = RTW.TflTable;
   
   5. Create an entry for the function mapping with a call to the RTW.TflCFunctionEntry function.

      hEnt = RTW.TflCFunctionEntry;
   
   6. Set function entry parameters with a call to the setTflCFunctionEntryParameters function.
setTflCFunctionEntryParameters(hEnt, ...  
    'Key',                      'customFcn', ...  
    'Priority',                 100, ...  
    'ImplementationName',       'scalarFcnReplacement', ...  
    'ImplementationHeaderFile', 'MyMath.h', ...  
    'ImplementationSourceFile', 'MyMath.c')

7 Create conceptual arguments \(y_1\), \(u_1\), and \(u_2\). This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create and add the arguments.

```matlab
arg = getTflArgFromString(hEnt, 'y1','int32');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEnt, arg);

arg = getTflArgFromString(hEnt, 'u1','int32');
addConceptualArg(hEnt, arg);

arg = getTflArgFromString(hEnt, 'u2','int32');
addConceptualArg(hEnt, arg);
```

8 Create the implementation arguments and add them to the entry. This example uses calls to the `getTflArgFromString` function to create implementation arguments that map to arguments in the replacement function prototype: output argument `void`, input arguments \(u_1\) and \(u_2\), and output argument \(y_1\). The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument. The `addArgument` function also adds each argument to the entry's array of implementation arguments.

```matlab
arg = getTflArgFromString(hEnt, 'void','void');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);

arg = getTflArgFromString(hEnt, 'u1','int32');
hEnt.Implementation.addArgument(arg);

arg = getTflArgFromString(hEnt, 'u2','int32');
hEnt.Implementation.addArgument(arg);

arg = getTflArgFromString(hEnt, 'y1','int32*');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.addArgument(arg);
```

9 Add the entry to a code replacement table with a call to the `addEntry` function.

```matlab
addEntry(hLib, hEnt);
```

10 Save the table definition file. Use the name of the table definition function to name the file.
To test the example:

1. Register the code replacement mapping.
2. Create files MyMath.c and MyMath.h that define the replacement function, scalarFcnReplacement, which has two int32 inputs and one int32 output.

MyMath.c

```c
#include "MyMath.h"

void scalarFcnReplacement(int32_T u1, int32_T u2, int32_T* y1) {
    *y1 = u1^u2;
}
```

MyMath.h

```c
#ifndef _ScalarMath_h
#define _ScalarMath_h
#include "rtwtypes.h"
#ifdef __cplusplus
extern "C" {
#endif
extern void scalarFcnReplacement(int32_T u1, int32_T u2, int32_T* y1);
#ifdef __cplusplus
}
#endif
#endif
```

3. Open the ex_replace model.
4. Configure the code generator to use the code replacement library and to include the Code Replacements Report in the code generation report.
5. Generate the replacement code and a code generation report.
6. Review the code replacements. In the code generation report, view the generated code for ex_replace.c.

```c
void ex_replace_step(void) {
    int32_T y;
}```
scalarFcnReplacement(ex_replace_U.In1, ex_replace_U.In2, &y);
ex_replace_Y.Out1 = y;
}

Reserved Identifiers and Code Replacement

The code generator and C programming language use, internally, reserved keywords for code generation. Do not use reserved keywords as identifiers or function names. Reserved keywords for code generation include many code replacement library identifiers, the majority of which are function names, such as acos.

To view a list of reserved identifiers for the code replacement library that you use to generate code, specify the name of the library in a call to the function RTW.TargetRegistry.getInstance.getTflReservedIdentifiers. For example:

crl_ids = RTW.TargetRegistry.getInstance.getTflReservedIdentifiers('GNU99 (GNU)')

In a code replacement table, the code generator registers each function implementation name defined by a table entry as a reserved identifier. You can register additional reserved identifiers for the table on a per-header-file basis. Providing additional reserved identifiers can help prevent duplicate symbols and other identifier-related compile and link issues.

To register additional code replacement reserved identifiers, use the setReservedIdentifiers function. This function registers specified reserved identifiers to be associated with a code replacement table.

You can register up to four reserved identifier structures in a code replacement table. You can associate one set of reserved identifiers with a code replacement library, while the other three (if present) must be associated with ANSI C. The following example shows a reserved identifier structure that specifies two identifiers and the associated header file.

d{1}.LibraryName = 'ANSI C';
d{1}.HeaderInfos{1}.HeaderName = 'math.h';
d{1}.HeaderInfos{1}.ReservedIds = {'y0', 'y1'};

The code generator adds the identifiers to the list of reserved identifiers and honors them during the build procedure.

Customize Match and Replacement Process

During the build process, the code generator uses:

- Preset match criteria to identify functions and operators for which application-specific implementations replace default implementations.
- Preset replacement function signatures.

It is possible that preset match criteria and preset replacement function signatures do not completely meet your function and operator replacement needs. For example:

- You want to replace an operator with a particular fixed-point implementation function only when fraction lengths are within a particular range.
- When a match occurs, you want to modify your replacement function signature based on compile-time information, such as passing fraction-length values into the function.

To add extra logic into the code replacement match and replacement process, create custom code replacement table entries. With custom entries, you can specify additional match criteria and modify the replacement function signature to meet application needs.

To create a custom code replacement entry:

1. Create a custom code replacement entry class, derived from RTW.TflCFunctionEntryML (for function replacement) or RTW.TflCOperationEntryML (for operator replacement).

2. In your derived class, implement a do_match method with a fixed preset signature as a MATLAB function. In your do_match method, provide either or both of the following customizations that instantiate the class:

   - Add match criteria that the base class does not provide. The base class provides a match based on:
     - Argument number
     - Argument name
     - Signedness
     - Word size
     - Slope (if not specified with wildcards)
     - Bias (if not specified with wildcards)
• Math modes, such as saturation and rounding
• Operator or function key
• Modify the implementation signature by adding additional arguments or setting constant input argument values. You can inject a constant value, such as an input scaling value, as an additional argument to the replacement function.

3 Create code replacement entries that instantiate the custom entry class.
4 Register a library containing the code replacement table that includes your entries.

During code generation, the code replacement match process tries to match function or operator call sites with the base class of your derived entry class. If the process finds a match, the software calls your `do_match` method to execute your additional match logic (if any) and your replacement function customizations (if any).

**Customize Code Match and Replacement for Functions**

This example shows how to use custom code replacement table entries to refine the match and replacement logic for functions. The example shows how to:

• Modify a sine function replacement only if the integer size on the current target platform is 32 bits.
• Change the replacement such that the implementation function passes in a degrees-versus-radians flag as an input argument.

1 To exercise the table entries that you create in this example, create an ERT-based model with a sine function block. For example:

   ![Sine Function Block Diagram]

   In the Inport block parameters, set the signal **Data type** to `double`. If the value selected for **Configuration Parameters > Hardware Implementation > Device type** supports an integer size other than 32, do one of the following:

   • Select a temporary target platform with a 32-bit integer size.
   • Modify the code to match the integer size of your target platform.

2 Create a class, for example `TflCustomFunctionEntry`, that is derived from the base class `RTW.TflCFunctioEntryML`. The derived class defines a `do_match` method with the signature:
function ent = do_match(hThis, ...
    hCSO, ...
    targetBitPerChar, ...
    targetBitPerShort, ...
    targetBitPerInt, ...
    targetBitPerLong, ...
    targetBitPerLongLong)

In the do_match signature:

- ent is the return handle, which is returned either as empty (indicating that the match failed) or as a TflCFunctionEntry handle.
- hThis is a handle to the class instance.
- hCSO is a handle to an object that the code generator creates for querying the library for a replacement.
- Remaining arguments are the number of bits for various data types of the current target.

The do_match method:

- Adds required additional match criteria that the base class does not provide.
- Makes required modifications to the implementation signature.

In this case, the do_match method must match only targetBitPerInt, representing the number of bits in the C int data type for the current target, to the value 32. If the code generator finds a match, the method sets the return handle and creates and adds an input argument. The input argument represents whether units are expressed as degrees or radians, to the replacement function signature.

Alternatively, create and add the additional implementation function argument for passing a units flag in each code replacement table definition file that instantiates this class. In that case, this class definition code does not create the argument. That code sets only the argument value. For an example of creating and adding additional implementation function arguments in a table definition file, see “Customize Code Match and Replacement for Scalar Operations” on page 64-167.
% DO MATCH - Create a custom match function. The base class checks the types of the arguments prior to calling this method. This will check additional data and perhaps modify the implementation function.

ent = []; % default the return to empty, indicating the match failed.

% Match sine function only if the target int size is 32 bits
if targetBitPerInt == 32
    % Need to modify the default implementation, starting from a copy of the standard TflCFunctionEntry.
    ent = RTW.TflCFunctionEntry(hThis);

    % If the target int size is 32 bits, the implementation function takes an additional input flag argument indicating degrees vs. radians. The additional argument can be created and added either in the CRL table definition file that instantiates this class, or here in the class definition, as follows:
    createAndAddImplementationArg(ent, 'RTW.TflArgNumericConstant', ...
        'Name', 'u2', ...
        'IsSigned', true, ...
        'WordLength', 32, ...
        'FractionLength', 0, ...
        'Value', 1);
end
end
end

Exit the class folder and return to the previous working folder.

Create and save the following code replacement table definition file, crl_table_custom_sinfcn_double.m. This file defines a code replacement table that contains a function table entry for sine with double input and output. This entry instantiates the derived class from the previous step, TflCustomFunctionEntry.

```matlab
function hTable = crl_table_custom_sinfcn_double

hTable = RTW.TflTable;

% Add TflCustomFunctionEntry
fcn_entry = TflCustomFunctionEntry;
setTflCFunctionEntryParameters(fcn_entry, ...
    'Key', 'sin', ...
    'Priority', 30, ...
    'ImplementationName', 'mySin', ...
    'ImplementationHeaderFile', 'mySin.h', ...
    'ImplementationSourceFile', 'mySin.c');

createAndAddConceptualArg(fcn_entry, 'RTW.TflArgNumeric', ...
    'Name', 'y1', ...
    'IOType', 'RTW_IO_OUTPUT', ...
Create an implementation function argument during code generation if the supported integer size on the current target is 32 bits.

Copy conceptual arguments to implementation.

Add the entry to the code replacement table.

Check the validity of the code replacement table entry.

- At the command prompt, invoke the table definition file.

- In the Code Replacement Viewer, view the table definition file.

Customize Code Match and Replacement for Nonscalar Operations

This example shows how to create custom code replacement entries that add logic to the code match and replacement process for a nonscalar operation. Custom entries specify additional match criteria or modify the replacement function signature to meet application needs.

This example restricts the match criteria for an element-wise multiplication replacement to entries with a specific dimension range. When a match occurs, the custom do_match method modifies the replacement signature to pass the number of elements into the function.

Files for developing and testing this code replacement library example are available in 
matlab/help/toolbox/ecoder/examples/code_replacement/custom_elemmult:

- do_match method — @MyElemMultEntry/MyElemMultEntry.m
- Replacement function source and header files — src/myMulImplLib.c and src/myMulImplLib.h
- Model — myElemMul.slx
To create custom code replacement entries that add logic to the code replacement match and replacement process:

1. Create a class, for example MyElemMultEntry, which is derived from the base class RTW.TflCOperationEntryML. The derived class defines a do_match method with the following signature:

   ```matlab
   function ent = do_match(hThis, ...
                             hCSO, ...
                             targetBitPerChar, ...
                             targetBitPerShort, ...
                             targetBitPerInt, ...
                             targetBitPerLong, ...
                             targetBitPerLongLong)
   ```

   In the do_match signature:

   - `ent` is the return handle, which is returned as empty (indicating that the match failed) or as a TflCOperationEntry handle.
   - `hThis` is the handle to the derived instance.
   - `hCSO` is a handle to an object that the code generator creates for querying the library for a replacement.
   - Remaining arguments are the number of bits for various data types of the current target.

   The do_match method:

   - Adds match criteria that the base class does not provide.
   - Makes changes to the implementation signature.

   The do_match method relies on the base class for checking data types and dimension ranges. If the code generator finds a match, do_match:

   - Sets the return handle.
   - Uses the conceptual arguments to compute the number of elements in the array. In the replacement entry returned, sets the value of the constant implementation argument as the number of elements of the array.
• Updates the code replacement entry such that it matches CSOs that have the
same argument dimensions.

classdef MyElemMulyEntry < RTW.TflCOperationEntryML
    methods
        function obj = MyElemMultEntry(varargin)
            mlock;
            obj@RTW.TflCOperationEntryML(varargin{:});
        end

        function ent = do_match(hThis, ...
            hCSO, ... %#ok
            targetBitPerChar, ... %#ok
            targetBitPerShort, ... %#ok
            targetBitPerInt, ... %#ok
            targetBitPerLong, ... %#ok
            targetBitPerLongLong ) %#ok

            % Fourth implementation arg represents number of elements for producing matches.
            assert(strcmp(hThis.Implementation.Arguments(4).Name,'numElements'));

            ent = RTW.TflCOperationEntry(hThis);

            % Calculate number of elements and set value of injected constant.
            ent.Implementation.Arguments(4).Value = prod(hCSO.ConceptualArgs(1).DimRange(1,:));

            % Since implementation has been modified for specific DimRange, update
            % returned entry to match similar CSOs only.
            for idx =1:3
                ent.ConceptualArgs(idx).DimRange = hCSO.ConceptualArgs(idx).DimRange;
            end
        end
    end
end

2 Create and save the following code replacement table definition file,
myElemMultCrlTable.m. This file defines a code replacement table that contains an
operator entry generator for element-wise multiplication. The table entry:

• Instantiates the derived class myElemMultEntry from the previous step.
• Sets operator entry parameters with the call to
the setTflCOperationEntryParameters function.
• Creates conceptual arguments y1, u1, and u2. The argument class
RTW.TflArgMatrix specifies matrix arguments to match. The three arguments
are set up to match 2-dimensional matrices with at least two elements in each
dimension.
• Calls the getTflArgFromString function to create a return value and four
implementation arguments. Arguments u1 and u2 are the operands, y1 is the
product, and the fourth argument is the number of elements.
Alternatively, the `do_match` method of the derived class `myElemMultEntry` can create and add the implementation arguments. When the number of additional implementation arguments required can vary based on compile-time information, use the alternative approach.

- Calls `addEntry` to add the entry to a code replacement table.

```matlab
function hLib = myElemMultCrlTable

libPath = fullfile(fileparts(which(mfilename)),'src');

hLib = RTW.TflTable;
%---------- entry: RTW_OP_ELEM_MUL ----------
hEnt = MyElemMultEntry;
hEnt.setTflCOperationEntryParameters( ...
    'Key', 'RTW_OP_ELEM_MUL', ...
    'Priority', 100, ...
    'SaturationMode', 'RTW_WRAP_ON_OVERFLOW', ...
    'ImplementationName', 'myElemMul_s32', ...
    'ImplementationSourceFile', 'myMulImplLib.c', ...
    'ImplementationSourcePath', libPath, ...
    'ImplementationHeaderFile', 'myMulImplLib.h', ...
    'ImplementationHeaderPath', libPath, ...
    'SideEffects', true, ...
    'GenCallback','RTW.copyFileToBuildDir');

% Conceptual Args
arg = RTW.TflArgMatrix('y1', 'RTW_IO_OUTPUT', 'int32');
arg.DimRange = [2 2; Inf Inf];
hEnt.addConceptualArg(arg);

arg = RTW.TflArgMatrix('u1', 'RTW_IO_INPUT', 'int32');
arg.DimRange = [2 2; Inf Inf];
hEnt.addConceptualArg(arg);

arg = RTW.TflArgMatrix('u2', 'RTW_IO_INPUT', 'int32');
arg.DimRange = [2 2; Inf Inf];
hEnt.addConceptualArg(arg);

% Implementation Args
arg = hEnt.getTflArgFromString('unused','void');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);
```
arg = hEnt.getTflArgFromString('u1','int32*');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u2','int32*');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('y1','int32*');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('numElements','uint32',0);
hEnt.Implementation.addArgument(arg);

hLib.addEntry( hEnt );

3 Check the validity of the code replacement table entry.

• At the command prompt, invoke the table definition file.
  tbl = myElemMultCrlTable

• In the Code Replacement Viewer, view the table definition file.
  crviewer(myElemMultCrlTable)

Customize Code Match and Replacement for Scalar Operations

This example shows how to create custom code replacement entries that add logic to the code match and replacement process for a scalar operation. Custom entries specify additional match criteria or modify the replacement function signature to meet application needs.

For example:

• When fraction lengths are within a specific range, replace an operator with a fixed-point implementation function.

• When a match occurs, modify the replacement function signature based on compile-time information, such as passing fraction-length values into the function.

This example modifies a fixed-point addition replacement such that the implementation function passes in the fraction lengths of the input and output data types as arguments.
To create custom code replacement entries that add logic to the code replacement match and replacement process:

1. Create a class, for example `TflCustomOperationEntry`, that is derived from the base class `RTW.TflCOperationEntryML`. The derived class defines a `do_match` method with the following signature:

```matlab
function ent = do_match(hThis, ...
    hCSO, ...
    targetBitPerChar, ...
    targetBitPerShort, ...
    targetBitPerInt, ...
    targetBitPerLong, ...
    targetBitPerLongLong)
```

In the `do_match` signature:

- `ent` is the return handle, which is returned as empty (indicating that the match failed) or as a `TflCOperationEntry` handle.
- `hThis` is the handle to the class instance.
- `hCSO` is a handle to an object that the code generator creates for querying the library for a replacement.
- Remaining arguments are the number of bits for various data types of the current target.

The `do_match` method adds match criteria that the base class does not provide. The method makes modifications to the implementation signature. In this case, the `do_match` method relies on the base class for checking word size and signedness. `do_match` must match only the number of conceptual arguments to the value 3 (two inputs and one output) and the bias for each argument to value 0. If the code generator finds a match, `do_match`:

- Sets the return handle.
- Removes slope and bias wild cards from the conceptual arguments (the match is for specific slope and bias values).
- Writes fraction-length values for the inputs and output into replacement function arguments 3, 4, and 5.

You can create and add three additional implementation function arguments for passing fraction lengths in the class definition or in each code replacement entry definition that instantiates this class. This example creates the arguments, adds them
to a code replacement table definition file, and sets them to specific values in the class definition code.

classdef TflCustomOperationEntry < RTW.TflCOperationEntryML
methods
    function ent = do_match(hThis, ... 
        hCSO, ... %#ok 
        targetBitPerChar, ... %#ok 
        targetBitPerShort, ... %#ok 
        targetBitPerInt, ... %#ok 
        targetBitPerLong, ... %#ok 
        targetBitPerLongLong) %#ok

    % DO_MATCH - Create a custom match function. The base class 
    % checks the types of the arguments prior to calling this 
    % method. This class will check additional data and can 
    % modify the implementation function.

    % The base class checks word size and signedness. Slopes and biases 
    % have been wildcarded, so the only additional checking to do is 
    % to check that the biases are zero and that there are only three 
    % conceptual arguments (one output, two inputs)

    ent = []; % default the return to empty, indicating the match failed

    if length(hCSO.ConceptualArgs) == 3 && ... 
        hCSO.ConceptualArgs(1).Type.Bias == 0 && ... 
        hCSO.ConceptualArgs(2).Type.Bias == 0 && ... 
        hCSO.ConceptualArgs(3).Type.Bias == 0

        % Modify the default implementation. Since this is a 
        % generator entry, a concrete entry is created using this entry 
        % as a template. The type of entry being created is a standard 
        % TflCOperationEntry. Using the standard operation entry 
        % provides required information, and you do not need 
        % a custom match function.
        ent = RTW.TflCOperationEntry(hThis);

        % Since this entry is modifying the implementation for specific 
        % fraction-length values (arguments 3, 4, and 5), the conceptual argument 
        % wild cards must be removed (the wildcards were inherited from the 
        % generator when it was used as a template for the concrete entry). 
        % This concrete entry is now for a specific slope and bias. 
        % hCSO holds the slope and bias values (created by the code generator).
        for idx=1:3
            ent.ConceptualArgs(idx).CheckSlope = true;
            ent.ConceptualArgs(idx).CheckBias = true;

            % Set the specific Slope and Biases
            ent.ConceptualArgs(idx).Type.Slope = hCSO.ConceptualArgs(idx).Type.Slope;
            ent.ConceptualArgs(idx).Type.Bias = 0;
        end

        % Set the fraction-length values in the implementation function.
        ent.Implementation.Arguments(3).Value = ...
Exit the class folder and return to the previous working folder.

2 Create and save the following code replacement table definition file, `crl_table_custom_sinfcn_double.m`. This file defines a code replacement table that contains a single operator entry, an entry generator for unsigned 32-bit fixed-point addition operations, with arbitrary fraction-length values on the inputs and the output. The table entry:

- Instantiates the derived class `TflCustomOperationEntry` from the previous step. If you want to replace word sizes and signedness attributes, you can use the same derived class, but not the same entry, because you cannot use a wild card with the `WordLength` and `IsSigned` arguments. For example, to support `uint8`, `int8`, `uint16`, `int16`, and `int32`, add five other distinct entries. To use different implementation functions for saturation and rounding modes other than overflow and round to floor, add entries for those match permutations.
- Sets operator entry parameters with the call to the `setTflCOperationEntryParameters` function.
- Calls the `createAndAddConceptualArg` function to create conceptual arguments `y1`, `u1`, and `u2`.
- Calls `createAndSetCImplementationReturn` and `createAndAddImplementationArg` to define the signature for the replacement function. Three of the calls to `createAndAddImplementationArg` create implementation arguments to hold the fraction-length values for the inputs and output. Alternatively, the entry can omit those argument definitions. Instead, the `do_match` method of the derived class `TflCustomOperationEntry` can create and add the three implementation arguments. When the number of additional implementation arguments required can vary based on compile-time information, use the alternative approach.
- Calls `addEntry` to add the entry to a code replacement table.

```matlab
function hTable = crl_table_custom_sinfcn_double

hTable = RTW.TflTable;
```
```matlab
%% Add TflCustomOperationEntry
op_entry = TflCustomOperationEntry;

setTflCOperationEntryParameters(op_entry, ...
    'Key',                      'RTW_OP_ADD', ...
    'Priority',                 30, ... 
    'SaturationMode',           'RTW_SATURATE_ON_OVERFLOW', ... 
    'RoundingModes',            {'RTW_ROUND_FLOOR'}, ... 
    'ImplementationName',       'myFixptAdd', ... 
    'ImplementationHeaderFile', 'myFixptAdd.h', ... 
    'ImplementationSourceFile', 'myFixptAdd.c');

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',       'y1', ...
    'IOType',     'RTW_IO_OUTPUT', ... 
    'CheckSlope', false, ... 
    'CheckBias',  false, ...
    'DataType',   'Fixed', ...
    'Scaling',    'BinaryPoint', ...
    'IsSigned',   false, ...
    'WordLength', 32);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',       'u1', ...
    'IOType',     'RTW_IO_INPUT', ...
    'CheckSlope', false, ...
    'CheckBias',  false, ...
    'DataType',   'Fixed', ...
    'Scaling',    'BinaryPoint', ...
    'IsSigned',   false, ...
    'WordLength', 32);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',       'u2', ...
    'IOType',     'RTW_IO_INPUT', ...
    'CheckSlope', false, ...
    'CheckBias',  false, ...
    'DataType',   'Fixed', ...
    'Scaling',    'BinaryPoint', ...
    'IsSigned',   false, ...
    'WordLength', 32);

% Specify replacement function signature
```
createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...
   'Name',       'y1', ...
   'IOType',     'RTW_IO_OUTPUT', ...
   'IsSigned',   false, ...
   'WordLength', 32, ...
   'FractionLength', 0);
createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric', ...
   'Name',       'u1', ...
   'IOType',     'RTW_IO_INPUT', ...
   'IsSigned',   false, ...
   'WordLength', 32, ...
   'FractionLength', 0);
createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric', ...
   'Name',       'u2', ...
   'IOType',     'RTW_IO_INPUT', ...
   'IsSigned',   false, ...
   'WordLength', 32, ...
   'FractionLength', 0);

% Add 3 fraction-length args. Actual values are set during code generation.
createAndAddImplementationArg(op_entry, 'RTW.TflArgNumericConstant', ...
   'Name',       'fl_in1', ...
   'IOType',     'RTW_IO_INPUT', ...
   'IsSigned',   false, ...
   'WordLength', 32, ...
   'FractionLength', 0, ...
   'Value',       0);
createAndAddImplementationArg(op_entry, 'RTW.TflArgNumericConstant', ...
   'Name',       'fl_in2', ...
   'IOType',     'RTW_IO_INPUT', ...
   'IsSigned',   false, ...
   'WordLength', 32, ...
   'FractionLength', 0, ...
   'Value',       0);
createAndAddImplementationArg(op_entry, 'RTW.TflArgNumericConstant', ...
   'Name',       'fl_out', ...
   'IOType',     'RTW_IO_INPUT', ...
   'IsSigned',   false, ...
   'WordLength', 32, ...
   'FractionLength', 0, ...
addEntry(hTable, op_entry);
3   Check the validity of the operator entry.

   • At the command prompt, invoke the table definition file.
     tbl = crl_table_custom_sinfcn_double
   • In the Code Replacement Viewer, view the table definition file.
     crviewer(crl_table_custom_sinfcn_double)

Scalar Operator Code Replacement

This example shows how to define a code replacement mapping for a scalar operator. The example defines a mapping for the + (addition) operator programmatically. Alternatively, you can use the **Code Replacement Tool** to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_add_uint8
   ```

2. Within the function body, create the table by calling the function RTW.TflTable.

   ```
   hTable = RTW.TflTable;
   ```

3. Create an entry for the operator mapping with a call to the RTW.TflCOperationEntry function.

   ```
   % Create operation entry
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set function entry parameters with a call to the setTflCOperationEntryParameters function.

   ```
   % Define addition operation of built-in uint8 data type
   % Saturation on, Rounding unspecified
   setTflCOperationEntryParameters(op_entry, ...)
   ```

5. Create conceptual arguments y1, u1, and u2. There are multiple ways to set up the conceptual arguments. This example uses calls to the getTflArgFromString and addConceptualArg functions to create and add the arguments.

   ```
   arg = getTflArgFromString(hTable, 'y1', 'uint8');
   arg.IOType = 'RTW_IO_OUTPUT';
   addConceptualArg(op_entry, arg);
   arg = getTflArgFromString(hTable, 'u1', 'uint8');
   addConceptualArg(op_entry, arg);
   arg = getTflArgFromString(hTable, 'u2', 'uint8');
   addConceptualArg(op_entry, arg);
   ```

6. Copy the conceptual arguments to the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses a call to the
The `copyConceptualArgsToImplementation` function is used to add implementation arguments to the entry by copying matching conceptual arguments. This can be achieved by calling:

```
copyConceptualArgsToImplementation(op_entry);
```

Afterward, the entry should be added to a code replacement table with a call to the `addEntry` function:

```
addEntry(hTable, op_entry);
```

Finally, save the table definition file. The name of the table definition function is used to name the file.

To test this example:

1. Register the code replacement mapping.
2. Create a model that includes an Add block, such as this model.

![Add block model diagram](image)

3. Configure the model with the following settings:
   - On the **Solver** pane, select a fixed-step solver.
   - On the **Code Generation** pane, select an ERT-based system target file.
   - On the **Code Generation > Interface** pane, select the code replacement library that contains your addition operation entry.

4. Generate code and a code generation report.
5. Review the code replacements.

Addition and Subtraction Operator Code Replacement

Consider the following when defining mappings for addition and subtraction operator code replacements.

Algorithm Options

When creating a code replacement table entry for an addition or subtraction operator, first determine the type of algorithm that your library function implements.

- Cast-before-operation (CBO), default — Prior to performing the addition or subtraction operation, the algorithm type casts input values to the output type. If the output data type cannot exactly represent the input values, losses can occur as a result of the cast to the output type. Additional loss can occur when the result of the operation is cast to the final output type.

- Cast-after-operation (CAO) — The algorithm computes the ideal result of the addition or subtraction operation of the two inputs. The algorithm then type casts the result to the output data type. Loss occurs during the type cast. This algorithm behaves similarly to the C language except when the signedness of the operands does not match. For example, when you add a signed long operand to an unsigned long operand, standard C language rules convert the signed long operand to an unsigned long operand. The result is a value that is not ideal.

Interactive Specification with Code Replacement Tool

When you use the Code Replacement Tool to create a code replacement table entry for an addition or subtraction operation, the tool displays an Algorithm menu. Use that menu to specify the Cast before operation or Cast after operation algorithm for that entry.
Programmatic Specification

Create a code replacement table file, as a MATLAB function, that describes the addition or subtraction code replacement table entry. In the call to `setTflCOperationEntryParameters`, set at least these parameters:

- **Key** to `RTW_OP_ADD` or `RTW_OP_MINUS`
- **ImplementationName** to the name of your replacement function
- **EntryInfoAlgorithm** to `RTW_CAST_BFORE_OP` (cast-before-operation) or `RTW_CAST_AFTER_OP` (cast-after-operation)

This example sets parameters for a code replacement operator entry for a cast-after-operation implementation of a `uint8` addition.

```matlab
op_entry = RTW.TflCOperationEntry;
setTflCOperationEntryParameters(op_entry, ...
    'Key',                      'RTW_OP_ADD', ...
    'EntryInfoAlgorithm',       'RTW_CAST_AFTER_OP', ...
    'ImplementationName',       'u8_add_u8_u8');
```

For more information, see `setTflCOperationEntryParameters`.

Algorithm Classification

During code generation, the code generator examines addition and subtraction operations, including adjacent type cast operations, to determine the type of algorithm to compute the expression result. Based on the data types in the expression and the type of the accumulator (type used to hold the result of the addition or subtraction operation), the code generator uses these rules.

- Floating-point and fixed-point types on the immediate addition or subtraction operation

<table>
<thead>
<tr>
<th>Algorithm</th>
<th>Conditions</th>
</tr>
</thead>
</table>
| CBO       | One of the following is true:  
  - Operation type is double.  
  - Operation type is single and input types are single or fixed-point.  

<table>
<thead>
<tr>
<th>Algorithm</th>
<th>Conditions</th>
</tr>
</thead>
<tbody>
<tr>
<td>CAO</td>
<td>Operation type is a superset of input types—that is, output type can represent values of input types without loss of data.</td>
</tr>
</tbody>
</table>

- Fixed-point types only

<table>
<thead>
<tr>
<th>Algorithm</th>
<th>Conditions</th>
</tr>
</thead>
</table>
| CBO       | At least one of the following is true:  
  - Accumulator type equals output type ($T_{acc} == T_{out}$).  
  - Output type is a superset of input types ($T_{acc} >= \{T_{in1}, T_{in2}\}$) and accumulator type is a superset of output type ($T_{acc} >= T_{out}$).  
  - Operation does not incur range or precision loss. |
In many cases, the numerical result of a CBO operation is equal to that of a CAO operation. For example, if the input and output types are such that the operation produces the ideal result, as in the case of \texttt{int8 + int8 -> int16}. To maximize the probability of code replacement occurring in such cases, set the algorithm to cast-after-operation.

**Limitations**

- The code generator does not replace operations with nonzero net bias.
- When classifying an operation as a CAO operation, the code generator includes the adjacent casts in the expression when the expression involves only fixed-point types. Otherwise, the code generator classifies and replaces only the immediate addition or subtraction operation. Casts that the code generator excludes from the classification appear in the generated code.
- To enable the code generator to include multiple cast operations, which follow an addition or subtraction of fixed-point data, in the classification of an expression, the rounding mode must be \texttt{simplest} or \texttt{floor}. Consider the expression \(y=(\text{cast A}) (\text{cast B})(u1+u2)\). If the rounding mode of \((\text{cast A}), (\text{cast B})\), and the addition operator (+) are set to \texttt{simplest} or \texttt{floor}, the code generator takes into account \((\text{cast A})\) and \((\text{cast B})\) when classifying the expression and performing the replacement only.

**Small Matrix Operation to Processor Code Replacement**

This example shows how to define code replacement mappings that replace nonscalar small matrix operations with processor-specific intrinsic functions. The example defines a table containing two matrix operator replacement entries for the + (addition) operator and the double data type. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_matrix_add_double
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Create the entry for the first operator mapping with a call to the `RTW.TflCOperationEntry` function.

   ```
   % Create table entry for matrix_sum_2x2_double
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The code generator ignores saturation and rounding modes for floating-point nonscalar addition and subtraction. For code replacement entries for nonscalar addition and subtraction operations that do not involve fixed-point data, in the call to `setTflCOperationEntryParameters`, specify 'RTW_SATURATE_UNSPECIFIED' for the SaturationMode property and {'RTW_ROUND_UNSPECIFIED'} for RoundingModes.

   ```
   setTflCOperationEntryParameters(op_entry, ...
       'Key',                      'RTW_OP_ADD', ...
       'Priority',                 30, ...
       'SaturationMode',           'RTW_WRAP_ON_OVERFLOW', ...
       'ImplementationName',       'matrix_sum_2x2_double', ...
       'ImplementationHeaderFile', 'MatrixMath.h', ...
       'ImplementationSourceFile', 'MatrixMath.c', ...
       'ImplementationHeaderPath', LibPath, ...
       'ImplementationSourcePath', LibPath, ...
       'AdditionalIncludePaths',   {LibPath}, ...
       'GenCallback',              'RTW.copyFileToBuildDir', ...
       'SideEffects',              true);
   ```

5. Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. To specify a matrix argument in the function call, use the argument class `RTW.TflArgMatrix`. Specify the base type and the dimensions for which the
argument is valid. The first table entry specifies \([2 \ 2]\) and the second table entry specifies \([3 \ 3]\).

% Specify operands and result
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...'Name',         'y1', ...'IOType',       'RTW_IO_OUTPUT', ...'BaseType',     'double', ...'DimRange',     [2 2]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix',...'Name',         'u1', ...'BaseType',     'double', ...'DimRange',     [2 2]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix',...'Name',         'u2', ...'BaseType',     'double', ...'DimRange',     [2 2]);

Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the getTflArgFromString to create the arguments. The convenience methods setReturn and addArgument specify whether an argument is a return value or argument and adds the argument to the entry's array of implementation arguments.

arg = getTflArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);
arg = getTflArgFromString(hTable, 'u1', ['double' '*']);
op_entry.Implementation.addArgument(arg);
arg = getTflArgFromString(hTable, 'u2', ['double' '*']);
op_entry.Implementation.addArgument(arg);
arg = getTflArgFromString(hTable, 'y1', ['double' '*']);
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.addArgument(arg);

Add the entry to a code replacement table with a call to the addEntry function.

addEntry(hTable, op_entry);

Create the entry for the second operator mapping.

% Create table entry for matrix_sum_3x3_double
op_entry = RTW.TflCOperationEntry;
setTflCOperationEntryParameters(op_entry, ...
    'Key',                      'RTW_OP_ADD', ...'
    'Priority',                 30, ...'
    'SaturationMode',           'RTW_WRAP_ON_OVERFLOW', ...'
    'ImplementationName',       'matrix_sum_3x3_double', ...'
    'ImplementationHeaderFile', 'MatrixMath.h', ...
% Specify operands and result
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ... 'Name', 'y1', ...
           'IOType', 'RTW_IO_OUTPUT', ...
           'BaseType', 'double', ...
           'DimRange', [3 3]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ... 'Name', 'u1', ...
           'BaseType', 'double', ...
           'DimRange', [3 3]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ... 'Name', 'u2', ...
           'BaseType', 'double', ...
           'DimRange', [3 3]);
% Specify replacement function signature
arg = getTflArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturnType(arg);
arg = getTflArgFromString(hTable, 'u1', ['double' '*']);
op_entry.Implementation.addArgument(arg);
arg = getTflArgFromString(hTable, 'u2', ['double' '*']);
op_entry.Implementation.addArgument(arg);
arg = getTflArgFromString(hTable, 'y1', ['double' '*']);
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.addArgument(arg);
addEntry(hTable, op_entry);
9  Save the table definition file. Use the name of the table definition function to name the file.

To test this example:
1  Register the code replacement mapping.
2  Create a model that includes an Add block.
3 Configure the model with the following settings:

- On the **Solver** pane, select a fixed-step, discrete solver with a fixed-step size such as 0.1.
- On the **Code Generation** pane, select an ERT-based system target file.
- On the **Code Generation > Interface** pane, select the code replacement library that contains your addition operation entry.

4 In the Model Explorer, configure the **Signal Attributes** for the In1 and In2 source blocks. For each source block, set **Port dimensions** to [3, 3], and set **Data type** to double. Apply the changes. Save the model.

5 Generate code and a code generation report.

6 Review the code replacements. The code generator replaces the + operator with `matrix_sum_3x3_double` in the generated code.

7 Reconfigure **Port dimensions** for In1 and In2 to [2 2], regenerate code. Observe that code containing the + operator is replaced with `matrix_sum_2x2_double`.

Matrix Multiplication Operation to MathWorks BLAS Code Replacement

This example shows how to define code replacement mappings that replace nonscalar multiplication operations with Basic Linear Algebra Subroutine (BLAS) multiplication functions xgemm and xgemv. The example defines code replacement entries that map floating-point matrix/matrix and matrix/vector multiplication operations to MathWorks BLAS library multiplication functions dgemm and dgemv. The example defines the function mappings programmatically. Alternatively, you can use the Code Replacement Tool to define the same mappings.

BLAS libraries support matrix/matrix multiplication in the form of

\[ C = a(\text{op}(A) \times \text{op}(B)) + bC \]

where \( \text{op}(X) \) means \( X \), transposition of \( X \), or Hermitian transposition of \( X \). However, code replacement libraries support only the limited case of

\[ C = \text{op}(A) \times \text{op}(B) \quad (a = 1.0, b = 0.0) \]

Correspondingly, although BLAS libraries support matrix/vector multiplication in the form of

\[ y = a(\text{op}(A) \times x) + by \]

code replacement libraries support only the limited case of

\[ y = \text{op}(A) \times x \quad (a = 1.0, b = 0.0) \]

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_tmwblas_mmult_double
   ```

2. Within the function body, create the table by calling the function RTW.TflTable.

   ```
   hTable = RTW.TflTable;
   ```

3. Define the path for the BLAS function library. If your replacement functions are on the MATLAB search path or are in your working folder, you can skip this step.

   ```
   arch = computer('arch');
   if ~ispc
       LibPath = fullfile('$(MATLAB_ROOT)', 'bin', arch);
   else
       % Use Stateflow to get the compiler info
       compilerInfo = sf('Private','compilerman','get_compiler_info');
       compilerName = compilerInfo.compilerName;
       if strcmp(compilerName, 'msvc90') || ...
           strcmp(compilerName, 'msvc80') || ...
           strcmp(compilerName, 'msvc71') || ...
           strcmp(compilerName, 'msvc60'), ...
       compilerName = 'microsoft';
   ```
4 Create an entry for the first mapping with a call to the RTW.TflBlasEntryGenerator function.

```matlab
% Create table entry for dgemm32
op_entry = RTW.TflBlasEntryGenerator;
```

5 Set operator entry parameters with a call to the setTflCF Bun cation EntryParameters function. The function call sets matrix multiplication operator entry properties. The code generator ignores saturation and rounding modes for floating-point nonscalar addition and subtraction. For code replacement entries for nonscalar addition and subtraction operations that do not involve fixed-point data, in the call to setTflCFuctionEntryParameters, specify 'RTW_SATURATE_UNSPECIFIED' for the SaturationMode property and {'RTW_ROUND_UNSPECIFIED'} for RoundingModes.

```matlab
if ispc
    libExt = 'lib';
elseif ismac
    libExt = 'dylib';
else
    libExt = 'so';
end
setTflCOperationEntryParameters(op_entry, ...
    'Key', 'RTW_OP_MUL', ...
    'Priority', 100, ...
    'ImplementationName', 'dgemm32', ...
    'ImplementationHeaderFile', 'blascompat32_crl.h', ...
    'ImplementationHeaderPath', fullfile('$(MATLAB_ROOT)','extern','include'), ...
    'AdditionalLinkObjs', [{'libmwblascompat32.' libExt}], ...
    'AdditionalLinkObjsPaths', {LibPath}, ...
    'SideEffects', true);
```

6 Create conceptual arguments y1, u1, and u2. There are multiple ways to set up the conceptual arguments. This example uses calls to the createAndAddConceptualArg function to create and add an argument with one function call. To specify a matrix argument in the function call, use the argument class RTW.TflArgMatrix and specify the base type and the dimensions for which the argument is valid. This type of table entry supports a range of dimensions specified in the format [Dim1Min Dim2Min ... DimNMin; Dim1Max Dim2Max ... DimNMax]. For example, [2 2; inf inf] means a two-dimensional matrix of size 2x2 or larger. The conceptual output argument for the dgemm32 entry for matrix/matrix multiplication replacement specifies dimensions [2 2; inf inf], while the conceptual output argument for the dgemv32 entry for matrix/vector multiplication replacement specifies dimensions [2 1; inf 1].
% Specify operands and result
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
  'Name',         'y1', ...
  'IOType',       'RTW_IO_OUTPUT', ...
  'BaseType',     'double', ...
  'DimRange',     [2 2; inf inf]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
  'Name',         'u1', ...
  'BaseType',     'double', ...
  'DimRange',     [2 2; inf inf]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
  'Name',         'u2', ...
  'BaseType',     'double', ...
  'DimRange',     [1 1; inf inf]);

Create the implementation arguments. There are multiple ways to set up the
implementation arguments. This example uses calls to the `getTflArgFromString`
and `RTW.TflArgCharConstant` functions to create the arguments. The example
code configures special implementation arguments that are required for `dgemm`
and `dgemv` function replacements. The convenience methods `setReturn` and
`addArgument` specify whether an argument is a return value or argument and adds
the argument to the entry’s array of implementation arguments.

% Using `RTW.TflBlasEntryGenerator` for xgemm requires the following
% implementation signature:
% void f(char* TRANSA, char* TRANSB, int* M, int* N, int* K,
%      type* ALPHA, type* u1, int* LDA, type* u2, int* LDB,
%      type* BETA, type* y, int* LDC)
% When a match occurs, the code generator computes the
% values for M, N, K, LDA, LDB, and LDC and inserts them into the
% generated code. TRANSA and TRANSB are set to 'N'.

% Specify replacement function signature
arg = getTflArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);
arg = RTW.TflArgCharConstant('TRANSA');
arg.PassByType = 'RTW_PASSBY_POINTER';
op_entry.Implementation.addArgument(arg);

arg = RTW.TflArgCharConstant('TRANSB');
arg.PassByType = 'RTW_PASSBY_POINTER';
op_entry.Implementation.addArgument(arg);
arg = getTflArgFromString(hTable, 'M', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
arg = getTflArgFromString(hTable, 'M', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'N', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'K', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'ALPHA', 'double', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u1', ['double' '*.']);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDA', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u2', ['double' '*.']);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDB', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'BETA', 'double', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'y1', ['double' '*.']);
arg.IOType = 'RTW_IO_OUTPUT';
arg.PassByType = 'RTW_PASSBY_POINTER';
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDC', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

8

Add the entry to a code replacement table with a call to the addEntry function.

addEntry(hTable, op_entry);
64

Code Replacement Customization for Simulink Models in Embedded Coder

9

Create the entry for the second mapping.
% Create table entry for dgemv32
op_entry = RTW.TflBlasEntryGenerator;

Using RTW.TflBlasEntryGenerator for xgemv requires the following
implementation signature:
void f(char* TRANS, int* M, int* N,
type* ALPHA, type* u1, int* LDA, type* u2, int* INCX,
type* BETA, type* y, int* INCY)
Upon a match, the CRL entry will compute the
values for M, N, LDA, INCX, and INCY, and insert them into the
generated code. TRANS will be set to 'N'.

% Specify replacement function signature
arg = getTflArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);
arg = RTW.TflArgCharConstant('TRANS');
arg.PassByType = 'RTW_PASSBY_POINTER';

Matrix Multiplication Operation to MathWorks BLAS Code Replacement

```java
op_entry.Implementation.addArgument(arg);
arg = getTflArgFromString(hTable, 'M', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'N', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'ALPHA', 'double', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u1', ['double' '*']);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDA', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u2', ['double' '*']);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'INCX','integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'BETA', 'double', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'y1', ['double' '*']);
arg.IOType = 'RTW_IO_OUTPUT';
arg.PassByType = 'RTW_PASSBY_POINTER';
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'INCY', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

addEntry(hTable, op_entry);
```
10 Save the table definition file. Use the name of the table definition function to name the file.

To test this example:

1 Register the code replacement mapping.
2 Create a model that includes two Product blocks.

3 For each Product block, set the block parameter Multiplication to the value Matrix(*).

4 Configure the model with the following settings:
   • On the Solver pane, select a fixed-step, discrete solver with a fixed-step size such as 0.1.
   • On the Code Generation pane, select an ERT-based system target file.
   • On the Code Generation > Interface pane, select the code replacement library that contains your addition operation entry.

5 In the Model Explorer, configure the Signal Attributes for the In1, In2, and In3 source blocks. For In1 and In2, set Port dimensions to [3 3] and set the Data type to double. For In3, set Port dimensions to [3 1] and set the Data type to double.

6 Generate code and a code generation report.
7 Review the code replacements.

Matrix Multiplication Operation to ANSI/ISO C BLAS Code Replacement

This example shows how to define code replacement mappings that replace nonscalar multiplication operations with ANSI/ISO C BLAS multiplication functions xgemm and xgemv. The example defines code replacement entries that map floating-point matrix/matrix and matrix/vector multiplication operations to ANSI/ISO C BLAS library multiplication functions dgemm and dgemv. The example defines the function mappings programmatically. Alternatively, you can use the Code Replacement Tool to define the same mappings.

BLAS libraries support matrix/matrix multiplication in the form of
\[ C = a(\text{op}(A) \times \text{op}(B)) + bC \] . \text{op}(X) means X, transposition of X, or Hermitian transposition of X. However, code replacement libraries support only the limited case of
\[ C = \text{op}(A) \times \text{op}(B) \] \( a = 1.0, b = 0.0 \). Correspondingly, although BLAS libraries support matrix/vector multiplication in the form of \[ y = a(\text{op}(A) \times x) + b y \] , code replacement libraries support only the limited case of \[ y = \text{op}(A) \times x \] \( a = 1.0, b = 0.0 \).

1. Create a table definition file that contains a function definition. For example:

   ```matlab
   function hTable = crl_table_cblas_mmult_double
   ```

2. Within the function body, create the table by calling the function RTW.TflTable.

   ```matlab
   hTable = RTW.TflTable;
   ```

3. Define the path for the CBLAS function library. For example:

   ```matlab
   LibPath = fullfile(matlabroot, 'toolbox', 'rtw', 'rtwdemos', 'crl_demo');
   ```

4. Create an entry for the first mapping with a call to the RTW.TflBlasEntryGenerator function.

   ```matlab
   % Create table entry for cblas_dgemm
   op_entry = RTW.TflCBlasEntryGenerator;
   ```

5. Set operator entry parameters with a call to the setTflCOperationEntryParameters function. The function call sets matrix multiplication operator entry properties. The code generator ignores saturation and rounding modes for floating-point nonscalar addition and subtraction.

   ```matlab
   setTflCOperationEntryParameters(op_entry, ...
      'Key',                          'RTW_OP_MUL', ...
   ```
Create conceptual arguments \( y_1 \), \( u_1 \), and \( u_2 \). There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. To specify a matrix argument in the function call, use the argument class `RTW.TflArgMatrix` and specify the base type and the dimensions for which the argument is valid. This type of table entry supports a range of dimensions specified in the format \([\text{Dim1Min Dim2Min ... DimNMin; Dim1Max Dim2Max ... DimNMax}]\). For example, \([2 2; \infty \infty]\) means a two-dimensional matrix of size 2x2 or larger. The conceptual output argument for the `dgemm32` entry for matrix/matrix multiplication replacement specifies dimensions \([2 2; \infty \infty]\). The conceptual output argument for the `dgemv32` entry for matrix/vector multiplication replacement specifies dimensions \([2 1; \infty 1]\).

```matlab
% Specify operands and result
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
    'Name',         'y1', ...
    'IOType',       'RTW_IO_OUTPUT', ...
    'BaseType',     'double', ...
    'DimRange',     [2 2; inf inf]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
    'Name',         'u1', ...
    'BaseType',     'double', ...
    'DimRange',     [2 2; inf inf]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
    'Name',         'u2', ...
    'BaseType',     'double', ...
    'DimRange',     [1 1; inf inf]);
```

Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `getTflArgFromString` function to create the arguments. The example code configures special implementation arguments that are required for `dgemm` and `dgemv` function replacements. The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument and adds the argument to the entry's array of implementation arguments.

```matlab
% Using RTW.TflCBlasEntryGenerator for xgemm requires the following
% implementation signature:
%
% void f(enum ORDER, enum TRANSA, enum TRANSB, int M, int N, int K,
%    type ALPHA, type* u1, int LDA, type* u2, int LDB,
%    type BETA, type* y, int LDC)
```
% Since CRLs do not have the ability to specify enums, you must
% use integer. (This will cause problems with C++ code generation,
% so for C++, use a wrapper function to cast each int to the
% corresponding enumeration type.)
%
% When a match occurs, the code generator computes the
% values for M, N, K, LDA, LDB, and LDC and insert them into the
% generated code.

% Specify replacement function signature
arg = getTflArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW IO_OUTPUT';
op_entry.Implementation.setReturn(arg);

arg = getTflArgFromString(hTable, 'ORDER', 'integer', 102);
% arg.Type.ReadOnly=true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'TRANSA', 'integer', 111);
% arg.Type.ReadOnly=true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'TRANSB', 'integer', 111);
% arg.Type.ReadOnly=true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'M', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'N', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'K', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'ALPHA', 'double', 1);
arg = getTflArgFromString(hTable, 'u1', ['double' '*']);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDA', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u2', ['double' '*']);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDB', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'BETA', 'double', 0);
op_entry.Implementation.addArgument(arg);
arg = getTflArgFromString(hTable, 'y1', ['double' '*']);
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDC', 'integer', 0);
op_entry.Implementation.addArgument(arg);

8 Add the entry to a code replacement table with a call to the addEntry function.
addEntry(hTable, op_entry);

9 Create the entry for the second mapping.

% Create table entry for cblas_dgemv
op_entry = RTW.TflCBlasEntryGenerator;
setTflCOperationEntryParameters(op_entry, ...
   'Key',                      'RTW_OP_MUL', ...   
   'Priority',                 100, ...           
   'ImplementationName',       'cblas_dgemv', ...  
   'ImplementationHeaderFile', 'cblas.h', ...      
   'ImplementationHeaderPath', LibPath, ...       
   'AdditionalIncludePaths',   {LibPath}, ...     
   'GenCallback',              'RTW.copyFileToBuildDir', ...  
   'SideEffects',              true);

% Specify operands and result
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
   'Name',         'y1', ...  
   'IOType',       'RTW_IO_OUTPUT', ...  
   'BaseType',     'double', ...  
   'DimRange',     [2 1; inf 1]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
   'Name',         'u1', ...  
   'BaseType',     'double', ...  
   'DimRange',     [2 2; inf inf]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
   'Name',         'u2', ...  
   'BaseType',     'double', ...  
   'DimRange',     [1 1; inf 1]);

% Using RTW.TflCBlasEntryGenerator for xgemv requires the following
% implementation signature:
%
% void f(enum ORDER, enum TRANSNA, int M, int N,  
%    type ALPHA, type* u1, int LDA, type* u2, int INCX,  
%    type BETA, type* y, int INCY)
%
% Since CRLs do not have the ability to specify enums, you must
% use integer. (This will cause problems with C++ code generation,
% so for C++, use a wrapper function to cast each int to the
% corresponding enumeration type.)
%
% Upon a match, the CRL entry will compute the
% values for M, N, LDA, INCX, and INCY and insert them into the
% generated code.
% Specify replacement function signature

arg = getTflArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);

arg = getTflArgFromString(hTable, 'ORDER', 'integer', 102);
% arg.Type.ReadOnly=true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'TRANSA', 'integer', 111);
% arg.Type.ReadOnly=true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'M', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'N', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'ALPHA', 'double', 1);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u1', ['double' '*']);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDA', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u2', ['double' '*']);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'INXC', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'BETA', 'double', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'y1', ['double' '*']);
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'INCY', 'integer', 0);
op_entry.Implementation.addArgument(arg);

addEntry(hTable, op_entry);

10 Save the table definition file. Use the name of the table definition function to name the file.

To test this example:

1 Register the code replacement mapping.
2 Create a model that includes two Product blocks.

3 Configure the model with the following settings:
   - On the Solver pane, select a fixed-step, discrete solver with a fixed-step size such as 0.1.
   - On the Code Generation pane, select an ERT-based system target file.
   - On the Code Generation > Interface pane, select the code replacement library that contains your addition operation entry.

4 For each Product block, set the block parameter Multiplication to the value Matrix(*).

5 In the Model Explorer, configure the Signal Attributes for the In1, In2, and In3 source blocks. For In1 and In2, set Port dimensions to [3 3]. Set the Data type to double. For In3, set Port dimensions to [3 1]. Set the Data type to double.

6 Generate code and a code generation report.

7 Review the code replacements.

Remap Operator Output to Function Input

If your generated code must meet a specific coding pattern or you want more flexibility, for example, to further improve performance, you can remap operator outputs to input positions in an implementation function argument list.

**Note** Remapping outputs to implementation function inputs is supported only for operator replacement.

For example, for a sum operation, the code generator produces code similar to:

```c
add8_Y.Out1 = u8_add_u8_u8(add8_U.In1, add8_U.In2);
```

If you remap the output to the first input, the code generator produces code similar to:

```c
u8_add_u8_u8(&add8_Y.Out1;, add8_U.In1, add8_U.In2);
```

The following table definition file for a sum operation remaps operator output `y1` as the first function input argument.

1. Create a table definition file that contains a function definition. For example:

   ```matlab
   function hTable = crl_table_add_uint8
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```matlab
   hTable = RTW.TflTable;
   ```

3. Create an entry for the operator mapping with a call to the `RTW.TflCOperationEntry` function.

   ```matlab
   % Create operation entry
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. In the function call, set the property `SideEffects` to true.

   ```matlab
   setTflCOperationEntryParameters(op_entry, ...
   'Key',                      'RTW_OP_ADD', ...,
   'Priority',                 90, ...,
   'ImplementationName',       'u8_add_u8_u8', ...,
   'ImplementationHeaderFile', 'u8_add_u8_u8.h', ...,
   'ImplementationSourceFile', 'u8_add_u8_u8.c', ...,
   'SideEffects',              true );
   ```
Create conceptual arguments \( y_1, u_1, \) and \( u_2 \). There are multiple ways to set up the conceptual arguments. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create and add the arguments.

```matlab
arg = getTflArgFromString(hTable, 'y1', 'uint8');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(op_entry, arg);

arg = getTflArgFromString(hTable, 'u1', 'uint8');
addConceptualArg(op_entry, arg);

arg = getTflArgFromString(hTable, 'u2', 'uint8');
addConceptualArg(op_entry, arg);
```

Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `getTflArgFromString` function to create the arguments. When defining the implementation function return argument, create a new `void` output argument, for example, \( y_2 \). When defining the implementation function argument for the conceptual output argument \( (y_1) \), set the operator output argument as an additional input argument. Mark its IOType as output. Make its type a pointer type. The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument and adds the argument to the entry’s array of implementation arguments.

```matlab
% Create new void output \( y_2 \)
arg = getTflArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);

% Set \( y_1 \) as first input arg, mark IOType as output, and use pointer type
arg = getTflArgFromString(hTable, 'y1', 'uint8*');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u1', 'uint8');
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u2', 'uint8');
op_entry.Implementation.addArgument(arg);
```

Add the entry to a code replacement table with a call to the `addEntry` function.

```matlab
addEntry(hTable, op_entry);
```

Save the table definition file. Use the name of the table definition function to name the file.

To test this example:

1. Register the code replacement mapping.
2 Create a model that includes an Add block.

3 Configure the model with the following settings:
   - On the Solver pane, select a fixed-step solver.
   - On the Code Generation pane, select an ERT-based system target file.
   - On the Code Generation > Interface pane, select the code replacement library that contains your addition operation entry.
   - Set the Optimize global data access parameter to Use global to hold temporary results to reduce data copies in the generated code.

4 Generate code and a code generation report.

5 Review the code replacements.

Fixed-Point Operator Code Replacement

If you have a Fixed-Point Designer license, you can define fixed-point operator code replacement entries to match:

- A binary-point-only scaling combination on the operator inputs and output.
- A slope bias scaling combination on the operator inputs and output.
- Relative scaling or net slope between multiplication or division operator inputs and output. Use one of these methods to map a range of slope and bias values to a replacement function for multiplication or division.
- Equal slope and zero net bias across addition or subtraction operator inputs and output. Use this method to disregard specific slope and bias values and map relative slope and bias values to a replacement function for addition or subtraction.

Common Ways to Match Fixed-Point Operator Entries

The following table maps common ways to match fixed-point operator code replacement entries with the associated fixed-point parameters that you specify in a code replacement table definition file.

<table>
<thead>

Fixed-Point Numbers and Arithmetic

Fixed-point numbers use integers and integer arithmetic to represent real numbers and arithmetic with the following encoding scheme:

\[ V = \tilde{V} = SQ + B \]

- \( V \) is an arbitrarily precise real-world value.
- \( \tilde{V} \) is the approximate real-world value that results from fixed-point representation.
- \( Q \) is an integer that encodes \( \tilde{V} \), referred to as the quantized integer.
- \( S \) is a coefficient of \( Q \), referred to as the slope.
- \( B \) is an additive correction, referred to as the bias.

The general equation for an operation between fixed-point operands is:

\[
(S_o Q_o + B_o) = (S_1 Q_1 + B_1) < op > (S_2 Q_2 + B_2)
\]

The objective of fixed-point operator replacement is to replace an operator that accepts and returns fixed-point or integer inputs and output with a function that accepts and returns built-in C numeric data types. The following sections provide additional programming information for each supported operator.

**Addition**

The operation \( V_0 = V_1 + V_2 \) implies that

\[
Q_0 = \left( \frac{S_1}{S_0} \right) Q_1 + \left( \frac{S_2}{S_0} \right) Q_2 + \left( \frac{B_1 + B_2 - B_0}{S_0} \right)
\]

If an addition replacement function is defined such that the scaling on the operands and sum are equal and the net bias
is zero (for example, a function `s8_add_s8_s8` that adds two signed 8-bit values and produces a signed 8-bit result), then the operator entry must set the operator entry parameters `SlopesMustBeTheSame` and `MustHaveZeroNetBias` to true. To match for replacement, the slopes must be the same for all addition conceptual arguments. (For parameter descriptions, see the reference page for the function `setTflCOperationEntryParameters`.)

**Subtraction**

The operation $V_0 = V_1 - V_2$ implies that

$$Q_0 = \left( \frac{S_1}{S_0} \right) Q_1 - \left( \frac{S_2}{S_0} \right) Q_2 + \left( \frac{B_1 - B_2 - B_0}{S_0} \right)$$

If a subtraction replacement function is defined such that the scaling on the operands and difference are equal and the net bias

$$\left( \frac{B_1 - B_2 - B_0}{S_0} \right)$$

is zero (for example, a function `s8_sub_s8_s8` that subtracts two signed 8-bit values and produces a signed 8-bit result), then the operator entry must set the operator entry parameters `SlopesMustBeTheSame` and `MustHaveZeroNetBias` to true. To match for replacement, the slopes must be the same for all subtraction conceptual arguments. (For parameter descriptions, see the reference page for the function `setTflCOperationEntryParameters`.)

**Multiplication**

There are different ways to specify multiplication replacements. The most direct way is to specify an exact match of the input and output types. This is feasible if a model contains only a few known slope and bias combinations. Use the `TflCOperationEntry` class and specify the exact values of slope and bias on each argument. For scenarios where there
are numerous slope/bias combinations, it is not feasible to specify each value with a different entry. Use a net slope entry or create a custom entry.

The operation $V_0 = V_1 \times V_2$ implies, for binary-point-only scaling, that

$$S_0Q_0 = (S_1Q_1)(S_2Q_2)$$
$$Q_0 = \left(\frac{S_1S_2}{S_0}\right)Q_1Q_2$$
$$Q_0 = S_nQ_1Q_2$$

where $S_n$ is the net slope.

It is common to replace all multiplication operations that have a net slope of 1.0 with a function that performs C-style multiplication. For example, to replace all signed 8-bit multiplications that have a net scaling of 1.0 with the s8_mul_s8_u8_ replacement function, the operator entry must define a net slope factor, $F^{2E}$. You specify the values for $F$ and $E$ using operator entry parameters NetSlopeAdjustmentFactor and NetFixedExponent. For the s8_mul_s8_u8 function, set NetSlopeAdjustmentFactor to 1 and NetFixedExponent to 0.0. Also, set the operator entry parameter SlopesMustBeTheSame to false and the parameter MustHaveZeroNetBias to true. To match for replacement, the biases must be zero for all multiplication conceptual arguments. (For parameter descriptions, see the reference page for the function setTflCOperationEntryParameters.)

**Note** When an operator entry specifies NetSlopeAdjustmentFactor and NetFixedExponent, matching entries must have arguments with zero bias.

**Division**

There are different ways to specify division replacements. The most direct way is to specify an exact match of the input and output types. This is feasible if a model contains only a few known slope and bias combinations. Use the TflCOperationEntry class and specify the exact values of slope and bias on each argument. For scenarios where there are numerous slope/bias combinations, it is not feasible to specify each value with a different entry. Use a net slope entry or create a custom entry (see “Customize Match and Replacement Process” on page 64-159).
The operation \( V_0 = \left( \frac{V_1}{V_2} \right) \) implies, for binary-point-only scaling, that

\[
S_0Q_0 = \left( \frac{S_1Q_1}{S_2Q_2} \right)
\]

\[
Q_0 = S_n \left( \frac{Q_1}{Q_2} \right)
\]

where \( S_n \) is the net slope.

It is common to replace all division operations that have a net slope of 1.0 with a function that performs C-style division. For example, to replace all signed 8-bit divisions that have a net scaling of 1.0 with the `s8_mul_s8_u8` replacement function, the operator entry must define a net slope factor, \( F2^E \). You specify the values for \( F \) and \( E \) using operator entry parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`. For the `s16_netslope0p5_div_s16_s16` function, you would set `NetSlopeAdjustmentFactor` to 1 and `NetFixedExponent` to 0.0. Also, set the operator entry parameter `SlopesMustBeTheSame` to `false` and the parameter `MustHaveZeroNetBias` to `true`. To match for replacement, the biases must be zero for all division conceptual arguments. (For parameter descriptions, see the reference page for the function `setTflCOperationEntryParameters`.)

**Note** When an operator entry specifies `NetSlopeAdjustmentFactor` and `NetFixedExponent`, matching entries must have arguments with zero bias.

### Data Type Conversion (Cast)

The data type conversion operation \( V_0 = V_1 \) implies, for binary-point-only scaling, that

\[
Q_0 = \left( \frac{S_1}{S_0} \right) Q_1
\]

\[
Q_0 = S_n Q_1
\]

where \( S_n \) is the net slope. Set the operator entry parameter `SlopesMustBeTheSame` to `false` and the parameter `MustHaveZeroNetBias` to `true`. To match for replacement,
the biases must be zero for all cast conceptual arguments. (For parameter descriptions, see the reference page for the function `setTflCOperationEntryParameters`.)

**Shift**

The shift left or shift right operation \( V_0 = (V_1 / 2^n) \) implies, for binary-point-only scaling, that

\[
S_0Q_0 = \left( \frac{S_1Q_1}{2^n} \right)
\]

\[
Q_0 = \left( \frac{S_1}{S_0} \right) \left( \frac{Q_1}{2^n} \right)
\]

\[
Q_0 = S_n \left( \frac{Q_1}{2^n} \right)
\]

where \( S_n \) is the net slope. Set the operator entry parameter `SlopesMustBeTheSame` to false and the parameter `MustHaveZeroNetBias` to true. To match for replacement, the biases must be zero for all shift conceptual arguments. (For parameter descriptions, see the reference page for the function `setTflCOperationEntryParameters`.)

You can define code replacement entries for operations on fixed-point data types such that they match a binary-point-only scaling combination on operator inputs and output. These binary-point-only scaling entries can map the specified binary-point-scaling combination to a replacement function for addition, subtraction, multiplication, or division.

This example creates a code replacement entry for multiplication of fixed-point data types. You specify arguments using binary-point-only scaling. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```matlab
   function hTable = crl_table_fixed_binptscale
   ```

2. Within the function body, create the table by calling the function RTW.TflTable.

   ```matlab
   hTable = RTW.TflTable;
   ```

3. Create the entry for the operator mapping with a call to the RTW.TflCOperationEntry function.

   ```matlab
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set operator entry parameters with a call to the setTflCOperationEntryParameters function. The parameters specify the type of operation as multiplication, the saturation mode as saturate on integer overflow, rounding modes as unspecified, and the name of the replacement function as `s32_mul_s16_s16_binarypoint`.

   ```matlab
   setTflCOperationEntryParameters(op_entry, ...
   'Key',                    'RTW_OP_MUL', ...
   'Priority',               90, ...
   'SaturationMode',         'RTW_SATURATE_ON_OVERFLOW', ...
   'RoundingModes',          {'RTW_ROUND_UNSPECIFIED'}, ...
   'ImplementationName',    's32_mul_s16_s16_binarypoint', ...
   'ImplementationHeaderFile', 's32_mul_s16_s16_binarypoint.h', ...
   'ImplementationSourceFile', 's32_mul_s16_s16_binarypoint.c');
   ```

5. Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the createAndAddConceptualArg function to create and add an argument with one function call. Each argument specifies that the data type is fixed-point, the mode is binary-point-only scaling, and its derived slope and bias values must exactly match the call-site slope and bias values. The output argument is 32 bits, signed, with a
fraction length of 28. The input arguments are 16 bits, signed, with fraction lengths of 15 and 13.

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
'Name',           'y1', ...
'IOType',         'RTW_IO_OUTPUT', ...
'CheckSlope',     true, ...
'CheckBias',      true, ...
'DatatypeMode',   'Fixed-point: binary point scaling', ...
'IsSigned',       true, ...
'WordLength',     32, ...
'FractionLength', 28);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
'Name',           'u1', ...
'IOType',         'RTW_IO_INPUT', ...
'CheckSlope',     true, ...
'CheckBias',      true, ...
'DatatypeMode',   'Fixed-point: binary point scaling', ...
'IsSigned',       true, ...
'WordLength',     16, ...
'FractionLength', 15);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
'Name',           'u2', ...
'IOType',         'RTW_IO_INPUT', ...
'CheckSlope',     true, ...
'CheckBias',      true, ...
'DatatypeMode',   'Fixed-point: binary point scaling', ...
'IsSigned',       true, ...
'WordLength',     16, ...
'FractionLength', 13);

Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the
createAndSetCImplementationReturn and
createAndAddImplementationArg functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). In this case, the output argument is 32 bits and signed (int32). The input arguments are 16 bits and signed (int16).

createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...
'Name',           'y1', ...
'IOType',         'RTW_IO_OUTPUT', ...
'IsSigned',       true, ...
'WordLength',     32, ...
'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric', ...
'Name',           'u1', ...
'IOType',         'RTW_IO_INPUT', ...
'IsSigned',       true, ...
'WordLength',     16, ...
createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'u2', ...
    'IOType',         'RTW_IO_INPUT', ...
    'IsSigned',       true, ...
    'WordLength',     16, ...
    'FractionLength', 0);

7 Add the entry to a code replacement table with a call to the addEntry function.

    addEntry(hTable, op_entry);

8 Save the table definition file. Use the name of the table definition function to name the file.

To test this example:

1 Register the code replacement mapping.
2 Create a model.

3 For this model:
   • Set the Inport 1 **Data type** to `fixdt(1,16,15)`.
   • Set the Inport 2 **Data type** to `fixdt(1,16,13)`.
   • In the Product block:
     • Set **Output data type** to `fixdt(1,32,28)`.
     • Select the option **Saturate on integer overflow**.
4 Configure the model with the following settings:
   • On the **Solver** pane, select a fixed-step, discrete solver.
   • On the **Code Generation** pane, select an ERT-based system target file.
   • On the **Code Generation > Interface** pane, select the code replacement library that contains your addition operation entry.
5 Generate code and a code generation report.
Review the code replacements.

Slope Bias Scaling Code Replacement

You can define code replacement for operations on fixed-point data types as matching a slope bias scaling combination on the operator inputs and output. The slope bias scaling entries can map the specified slope bias combination to a replacement function for addition, subtraction, multiplication, or division.

This example creates a code replacement entry for division of fixed-point data types. You specify arguments using slope bias scaling. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```matlab
   function hTable = crl_table_fixed_s16divslopebias
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```matlab
   hTable = RTW.TflTable;
   ```

3. Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntry` function.

   ```matlab
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as division, the saturation mode as saturate on integer overflow, rounding modes as round to ceiling, and the name of the replacement function as `s16_div_s16_s16_slopebias`.

   ```matlab
   setTflCOperationEntryParameters(op_entry, ...
      'Key',                      'RTW_OP_DIV', ...
      'Priority',                 90, ...
      'SaturationMode',           'RTW_SATURATE_ON_OVERFLOW', ...
      'RoundingModes',            {'RTW_ROUND_CEILING'}, ...
      'ImplementationName',       's16_div_s16_s16_slopebias', ...
      'ImplementationHeaderFile', 's16_div_s16_s16_slopebias.h', ...
      'ImplementationSourceFile', 's16_div_s16_s16_slopebias.c');
   ```

5. Create conceptual arguments y1, u1, and u2. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Each argument specifies that the data type is fixed-point, the mode is slope bias scaling, and its specified slope and bias values must exactly match the call-site slope and bias values. The output argument and input arguments are 16 bits, signed, each with specific slope bias specifications.
Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `createAndSetCImplementationReturn` and `createAndAddImplementationArg` functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). In this case, the output and input arguments are 16 bits and signed (int16).

```matlab
createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...
    'Name',       'y1',  ...
    'IOType',     'RTW_IO_OUTPUT',  ...
    'IsSigned',   true,  ...
    'WordLength', 16,  ...
    'FractionLength', 0);
createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',       'u1',  ...
    'IOType',     'RTW_IO_INPUT',  ...
    'IsSigned',   true,  ...
    'WordLength', 16,  ...
    'FractionLength', 0);
createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',       'u2',  ...
    'IOType',     'RTW_IO_INPUT',  ...
    'IsSigned',   true,  ...
    'WordLength', 16,  ...
    'FractionLength', 0);
```
createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'u2', ...
    'IOType',         'RTW_IO_INPUT', ...
    'IsSigned',       true, ...
    'WordLength',     16, ...
    'FractionLength', 0);

7 Add the entry to a code replacement table with a call to the addEntry function.

    addEntry(hTable, op_entry);

8 Save the table definition file. Use the name of the table definition function to name the file.

To test this example:

1 Register the code replacement mapping.

2 Create a model.

3 For this model:
   • Set the Inport 1 Data type to fixdt(1,16,15,2).
   • Set the Inport 2 Data type to fixdt(1,16,13,5).
   • In the Divide block:
     • Set Output data type to Inherit: Inherit via back propagation.
     • Set Integer rounding mode to Ceiling.
     • Select the option Saturate on integer overflow.

4 Configure the model with the following settings:
   • On the Solver pane, select a fixed-step, discrete solver.
   • On the Code Generation pane, select an ERT-based system target file.
   • On the Code Generation > Interface pane, select the code replacement library that contains your addition operation entry.
5 Generate code and a code generation report.
6 Review the code replacements.

Net Slope Scaling Code Replacement

Multiplication and Division with Saturation

You can define code replacement entries for operations on fixed-point data types as matching net slope between operator inputs and output. The net slope entries can map a range of slope and bias values to a replacement function for multiplication or division.

This example creates a code replacement entry for division of fixed-point data types, using wrap on overflow saturation mode and a net slope. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   function hTable = crl_table_fixed_netslopesaturate

2. Within the function body, create the table by calling the function RTW.TflTable.

   hTable = RTW.TflTable;

3. Create the entry for the operator mapping with a call to the RTW.TflCOperationEntryGenerator_Netslope function, which provides access to the fixed-point parameters NetSlopeAdjustmentFactor and NetFixedExponent.

   wv = [16,32];
   for iy = 1:2
     for inum = 1:2
       for iden = 1:2
         hTable = getDivOpEntry(hTable, ...
                               fixdt(1,wv(iy)),fixdt(1,wv(inum)),fixdt(1,wv(iden)));
       end
     end
   end

   %---------------------------------------------------------
   function hTable = getDivOpEntry(hTable,dty,dtnum,dtden)
   %---------------------------------------------------------
   % Create an entry for division of fixed-point data types where
   % arguments are specified using Slope and Bias scaling
   % Saturation on, Rounding unspecified
   funcStr = sprintf('user_div_%s_%s_%s',...
                       typeStrFunc(dty),...
                       typeStrFunc(dtnum),...
                       typeStrFunc(dtden));
op_entry = RTW.TflCOperationEntryGenerator_NetSlope;

4 Set operator entry parameters with a call to the setTflCOperationEntryParameters function. The parameters specify the type of operation as division, the saturation mode as wrap on overflow, rounding modes as unspecified, and the name of the replacement function as user_div_*.

NetSlopeAdjustmentFactor and NetFixedExponent specify the F and E parts of the net slope $F2^E$.

setTflCOperationEntryParameters(op_entry, ...
   'Key', 'RTW_OP_DIV', ...
   'Priority', 90, ...
   'SaturationMode', 'RTW_WRAP_ON_OVERFLOW', ...
   'RoundingModes', {'RTW_ROUND_UNSPECIFIED'}, ...
   'NetSlopeAdjustmentFactor', 1.0, ...
   'NetFixedExponent', 0.0, ...
   'ImplementationName', funcStr, ...
   'ImplementationHeaderFile', [funcStr,'.h'], ...
   'ImplementationSourceFile', [funcStr,'.c']);

5 Create conceptual arguments $y_1$, $u_1$, and $u_2$. There are multiple ways to set up the conceptual arguments. This example uses calls to the createAndAddConceptualArg function to create and add an argument with one function call. Specify each argument as fixed-point and signed. Also, for each argument, specify that code replacement request processing does not check for an exact match to the call-site slope and bias values.

createAndAddConceptualArg(op_entry, ...
   'RTW.TflArgNumeric', ...
   'Name', 'y1', ...
   'IOType', 'RTW_IO_OUTPUT', ...
   'CheckSlope', false, ...
   'CheckBias', false, ...
   'DataTypeMode', 'Fixed-point: slope and bias scaling', ...
   'IsSigned', dty.Signed, ...
   'WordLength', dty.WordLength, ...
   'Bias', 0);

createAndAddConceptualArg(op_entry, ...
   'RTW.TflArgNumeric', ...
   'Name', 'u1', ...
   'IOType', 'RTW_IO_INPUT', ...
   'CheckSlope', false, ...
   'CheckBias', false, ...
   'DataTypeMode', 'Fixed-point: slope and bias scaling', ...
   'IsSigned', dtnum.Signed, ...
   'WordLength', dtnum.WordLength, ...
   'Bias', 0);

createAndAddConceptualArg(op_entry, ...
   'RTW.TflArgNumeric', ...
   'Name', 'u2', ...)
Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `getTflArgFromString` function to create the arguments. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument. These methods add the argument to the entry array of implementation arguments.

```matlab
arg = getTflArgFromString(hTable, 'y1', typeStrBase(dty));
op_entry.Implementation.setReturn(arg);
arg = getTflArgFromString(hTable, 'u1', typeStrBase(dtnum));
op_entry.Implementation.addArgument(arg);
arg = getTflArgFromString(hTable, 'u2', typeStrBase(dtden));
op_entry.Implementation.addArgument(arg);
```

Add the entry to a code replacement table with a call to the `addEntry` function.

```matlab
addEntry(hTable, op_entry);
```

Define functions that determine the data type word length.

```matlab
function str = typeStrFunc(dt)
%-------------------------------------------------------------
if dt.Signed
    sstr = 's';
else
    sstr = 'u';
end
str = sprintf('%s%d',sstr,dt.WordLength);
end

function str = typeStrBase(dt)
%-------------------------------------------------------------
if dt.Signed
    sstr = ;
else
    sstr = 'u';
end
str = sprintf('%sint%d',sstr,dt.WordLength);
end
```
9 Save the table definition file. Use the name of the table definition function to name the file.

**Multiplication and Division with Rounding Mode and Additional Implementation Arguments**

You can define code replacement entries for multiplication and division operations on fixed-point data types such that they match the net slope between operator inputs and output. The net slope entries can map a range of slope and bias values to a replacement function for multiplication or division.

This example creates a code replacement entry for division of fixed-point data types, using the ceiling rounding mode and a net slope scaling factor. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1 Create a table definition file that contains a function definition. For example:

```matlab
function hTable = crl_table_fixed_netsloperound
```

2 Within the function body, create the table by calling the function RTW.TflTable.

```matlab
hTable = RTW.TflTable;
```

3 Create the entry for the operator mapping with a call to the RTW.TflCOperationEntryGenerator_Netslope function, which provides access to the fixed-point parameters NetSlopeAdjustmentFactor and NetFixedExponent.

```matlab
op_entry = RTW.TflCOperationEntryGenerator_NetSlope;
```

4 Set operator entry parameters with a call to the setTflCOperationEntryParameters function. The parameters specify the type of operation as division, the saturation mode as saturation off, rounding modes as round to ceiling, and the name of the replacement function as s16_div_s16 s16. NetSlopeAdjustmentFactor and NetFixedExponent specify the $F$ and $E$ parts of the relative scaling factor $F2^E$.

```matlab
setTflCOperationEntryParameters(op_entry, ... 'Key', 'RTW_OP_DIV', ... 'Priority', 90, ... 'SaturationMode', 'RTW_WRAP_ON_OVERFLOW', ... 'RoundingModes', {'RTW_ROUND_CEILING'}, ... 'NetSlopeAdjustmentFactor', 1.0, ... 'NetFixedExponent', 0.0, ...
Create conceptual arguments y1, u1, and u2. There are multiple ways to set up the conceptual arguments. This example uses calls to the createAndAddConceptualArg function to create and add an argument with one function call. Specify each argument as fixed-point, 16 bits, and signed. Also, for each argument, specify that code replacement request processing does not check for an exact match to the call-site slope and bias values.

```matlab
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ... 'Name', 'y1', ... 'IOType', 'RTW_IO_OUTPUT', ... 'CheckSlope', false, ... 'CheckBias', false, ... 'DataType', 'Fixed', ... 'IsSigned', true, ... 'WordLength', 16);
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ... 'Name', 'u1', ... 'IOType', 'RTW_IO_INPUT', ... 'CheckSlope', false, ... 'CheckBias', false, ... 'DataType', 'Fixed', ... 'IsSigned', true, ... 'WordLength', 16);
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ... 'Name', 'u2', ... 'IOType', 'RTW_IO_INPUT', ... 'CheckSlope', false, ... 'CheckBias', false, ... 'DataType', 'Fixed', ... 'IsSigned', true, ... 'WordLength', 16);
```

Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the createAndSetCImplementationReturn and createAndAddImplementationArg functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). In this case, the output and input arguments are 16 bits and signed (int16).

```matlab
createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ... 'Name', 'y1', ... 'IOType', 'RTW_IO_OUTPUT', ... 'IsSigned', true, ... 'WordLength', 16, ... 'FractionLength', 0);
```
createAndAddImplementationArg(op_entry, 'RTW_TflArgNumeric', ... 
   'Name', 'u1', ...
   'IOType', 'RTW_IO_INPUT', ...
   'IsSigned', true, ...
   'WordLength', 16, ...
   'FractionLength', 0);
createAndAddImplementationArg(op_entry, 'RTW_TflArgNumeric', ... 
   'Name', 'u2', ...
   'IOType', 'RTW_IO_INPUT', ...
   'IsSigned', true, ...
   'WordLength', 16, ...
   'FractionLength', 0);

7 Add the entry to a code replacement table with a call to the addEntry function.

   addEntry(hTable, op_entry);

8 Save the table definition file. Use the name of the table definition function to name the file.

To test this example:

1 Register the code replacement mapping.
2 Create a model.

![Model diagram]

3 For this model:
   • Set the Inport 1 Data type to int16.
   • Set the Inport 2 Data type to fixdt(1,16,-5).
   • In the Divide block:
     • Set Output data type to fixdt(1,16,-13).
     • Set Integer rounding mode to Ceiling.
4 Configure the model with the following settings:
   • On the Solver pane, select a fixed-step, discrete solver.
• On the **Code Generation** pane, select an ERT-based system target file.
• On the **Code Generation > Interface** pane, select the code replacement library that contains your addition operation entry.

5 Generate code and a code generation report.
6 Review the code replacements.

• “Develop a Code Replacement Library” on page 64-27
You can define code replacement entries for addition or subtraction of fixed-point data types such that they match the relative slope and bias values (equal slope and zero net bias) across operator inputs and output. These entries allow you to disregard slope and bias values when mapping relative slope and bias values to a replacement function for addition or subtraction.

This example creates a code replacement entry for the addition of fixed-point data types. Slopes must be equal and net bias must be zero across the operator inputs and output. The example defines the function mapping programmatically. Alternatively, you can also use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

```matlab
function hTable = crl_table_fixed_slopeseq_netbiaszero
```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

```matlab
hTable = RTW.TflTable;
```

3. Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntryGenerator` function, which provides access to the fixed-point parameters `SlopesMustBeTheSame` and `MustHaveZeroNetBias`.

```matlab
op_entry = RTW.TflCOperationEntryGenerator;
```

4. Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as addition, the saturation mode as saturation off, rounding modes as unspecified, and the name of the replacement function as `u16_add_SameSlopeZeroBias`. The parameters `SlopesMustBeTheSame` and `MustHaveZeroNetBias` must be set to `true` to indicate that slopes must be equal and net bias must be zero across the addition (or subtraction) of inputs and output.

```matlab
setTflCOperationEntryParameters(op_entry, ...
    'Key',                     'RTW_OP_ADD', ...
    'Priority',                 90, ...
    'SaturationMode',           'RTW_WRAP_ON_OVERFLOW', ...
    'RoundingModes',            {'RTW_ROUND_UNSPECIFIED'}, ...
    'SlopesMustBeTheSame',      true, ...
    'MustHaveZeroNetBias',      true, ...
    'ImplementationName',       'u16_add_SameSlopeZeroBias', ...
    'ImplementationHeaderFile', 'u16_add_SameSlopeZeroBias.h',...
    'ImplementationSourceFile', 'u16_add_SameSlopeZeroBias.c');
```

5. Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the
createAndAddConceptualArg function to create and add an argument with one function call. Each argument is specified as 16 bits and unsigned. Each argument specifies that code replacement request processing does not check for an exact match to the call-site slope and bias values.

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
'Name',           'y1', ...
'IOType',         'RTW_IO_OUTPUT', ...
'CheckSlope',     false, ...
'CheckBias',      false, ...
'IsSigned',       false, ...
'WordLength',     16);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
'Name',           'u1', ...
'IOType',         'RTW_IO_INPUT', ...
'CheckSlope',     false, ...
'CheckBias',      false, ...
'IsSigned',       false, ...
'WordLength',     16);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
'Name',           'u2', ...
'IOType',         'RTW_IO_INPUT', ...
'CheckSlope',     false, ...
'CheckBias',      false, ...
'IsSigned',       false, ...
'WordLength',     16);

6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the createAndSetCImplementationReturn and createAndAddImplementationArg functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). In this case, the output and input arguments are 16 bits and unsigned (uint16).

createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...
'Name',           'y1', ...
'IOType',         'RTW_IO_OUTPUT', ...
'IsSigned',       false, ...
'WordLength',     16, ...
'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',...
'Name',           'u1', ...
'IOType',         'RTW_IO_INPUT', ...
'IsSigned',       false, ...
'WordLength',     16, ...
'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',...
7 Add the entry to a code replacement table with a call to the `addEntry` function.

```matlab
addEntry(hTable, op_entry);
```

8 Save the table definition file. Use the name of the table definition function to name the file.

To test this example:

1 Register the code replacement mapping.

2 Create a model.

![Add Same S Zero B](image)

3 For this model:
   
   - Set the Inport 1 **Data type** to `fixdt(0, 16, 13)`.
   - Set the Inport 2 **Data type** to `fixdt(0, 16, 13)`.
   - In the Add block:
     
     - Verify that **Output data type** is set to its default, Inherit via internal rule.
     - Set **Integer rounding mode** to Zero.

4 Configure the model with the following settings:
   
   - On the **Solver** pane, select a fixed-step, discrete solver.
   - On the **Code Generation** pane, select an ERT-based system target file.
   - On the **Code Generation > Interface** pane, select the code replacement library that contains your addition operation entry.

5 Generate code and a code generation report.

6 Review the code replacements.

Data Type Conversions (Casts) and Operator Code Replacement

You can use code replacement entries to replace code that the code generator produces for data type conversion (cast) operations.

Casts from int32 To int16

This example creates a code replacement entry that replaces int32 to int16 data type conversion (cast) operations. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_cast_int32_to_int16
   ```

2. Within the function body, create the table by calling the function RTW.TflTable.

   ```
   hTable = RTW.TflTable;
   ```

3. Create the entry for the operator mapping with a call to the RTW.TflCOperationEntry function.

   ```
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set operator entry parameters with a call to the setTflCOperationEntryParameters function. The parameters specify the type of operation as cast, the saturation mode as saturate on integer overflow, rounding modes as toward negative infinity, and the name of the replacement function as my_sat_cast.

   ```
   setTflCOperationEntryParameters(op_entry, ...
   'Key',                      'RTW_OP_CAST', ...
   'Priority',                 50, ...
   'ImplementationName',       'my_sat_cast', ...
   'SaturationMode',           'RTW_SATURATE_ON_OVERFLOW', ...
   'RoundingModes',            {'RTW_ROUND_FLOOR'}, ...
   'ImplementationHeaderFile', 'some_hdr.h', ...
   'ImplementationSourceFile', 'some_hdr.c');
   ```

5. Create the int16 argument as conceptual argument y1 and the implementation return value. There are multiple ways to set up the conceptual and implementation arguments. This example uses calls to the getTflArgFromString and addConceptualArg functions to create the conceptual argument and add it to the
entry. Convenience method `setReturn` specifies the argument as the implementation return value.

```matlab
arg = getTflArgFromString(hTable, 'y1', 'int16');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(op_entry, arg);
op_entry.Implementation.setReturn(arg);
```

6 Create the `int32` argument as conceptual and implementation argument `u1`. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create the conceptual argument and add it to the entry. Convenience method `addArgument` specifies the argument as implementation input argument.

```matlab
arg = getTflArgFromString(hTable, 'u1', 'int32');
addConceptualArg(op_entry, arg);
op_entry.Implementation.addArgument(arg);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

```matlab
addEntry(hLib, hEnt);
```

8 Save the table definition file. Use the name of the table definition function to name the file.

### Casts Using Net Slope

You can use code replacement entries to replace code that the code generator produces for data type conversion (cast) operations.

This example creates a code replacement entry to replace data type conversions (casts) of fixed-point data types by using a net slope. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1 Create a table definition file that contains a function definition. For example:

```matlab
function hTable = crl_table_cast_fixpt_net_slope
```

2 Within the function body, create the table by calling the function `RTW.TflTable`.

```matlab
hTable = RTW.TflTable;
```

3 Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntryGenerator_Netslope` function, which provides access to the fixed-point parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`.

```matlab
op_entry = RTW.TflCOperationEntryGenerator_Netslope;
```
4 Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as cast, the saturation mode as saturate on integer overflow, rounding modes as toward negative infinity, and the name of the replacement function as `my_fxp_cast`. `NetSlopeAdjustmentFactor` and `NetFixedExponent` specify the $F$ and $E$ parts of the net slope $F2^E$.

```
InFL = 2;
InWL = 16;
InSgn = true;
OutFL = 4;
OutWL = 32;
OutSgn = true;
setTflCOperationEntryParameters(op_entry, ...
    'Key',                       'RTW_OP_CAST', ...;
    'Priority',                  50, ...;
    'SaturationMode',            'RTW_SATURATE_ON_OVERFLOW', ...;
    'RoundingModes',             {'RTW_ROUND_FLOOR'}, ...;
    'NetSlopeAdjustmentFactor',  1.0, ...;
    'NetFixedExponent',          (OutFL - InFL), ...;
    'ImplementationName',        'my_fxp_cast', ...;
    'ImplementationHeaderFile',  'some_hdr.h', ...;
    'ImplementationSourceFile',  'some_hdr.c');
```

5 Create conceptual arguments $y1$ and $u1$. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Each argument is specified as fixed-point and signed. Each argument specifies that code replacement request processing does not check for an exact match to the call-site slope and bias values.

```
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',         'y1', ...;
    'IOType',       'RTW_IO_OUTPUT', ...;
    'CheckSlope',   false, ...;
    'CheckBias',    false, ...;
    'DataTypeMode', 'Fixed-point: binary point scaling', ...;
    'IsSigned',     OutSgn, ...;
    'WordLength',   OutWL, ...;
    'FractionLength',OutFL);
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',         'u1', ...;
    'IOType',       'RTW_IO_INPUT', ...;
    'CheckSlope',   false, ...;
    'CheckBias',    false, ...;
    'DataTypeMode', 'Fixed-point: binary point scaling', ...;
    'IsSigned',     InSgn, ...;
    'WordLength',   InWL, ...;
    'FractionLength',InFL);
```
Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `createAndSetCImplementationReturn` and `createAndAddImplementationArg` functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types).

```matlab
createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'y1', ...
    'IOType',         'RTW_IO_OUTPUT', ...
    'IsSigned',       OutSgn, ...
    'WordLength',     OutWL, ...
    'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'u1', ...
    'IOType',         'RTW_IO_INPUT', ...
    'IsSigned',       InSgn, ...
    'WordLength',     InWL, ...
    'FractionLength', 0);
```

Add the entry to a code replacement table with a call to the `addEntry` function.

```matlab
addEntry(hTable, op_entry);
```

Save the table definition file. Use the name of the table definition function to name the file.

Shift Left Operations and Code Replacement

You can use code replacement entries to replace code that the code generator produces for shift (<<) operations.

Shift Lefts for int16 Data

This example creates a code replacement entry to replace shift left operations for int16 data. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```matlab
   function hTable = crl_table_shift_left_int16
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```matlab
   hTable = RTW.TflTable;
   ```

3. Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntry` function.

   ```matlab
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as shift left and the name of the replacement function as `my_shift_left`.

   ```matlab
   setTflCOperationEntryParameters(op_entry, ...
   'Key',                      'RTW_OP_SL', ...
   'Priority',                 50, ...
   'ImplementationName',       'my_shift_left', ...
   'ImplementationHeaderFile', 'some_hdr.h', ...
   'ImplementationSourceFile', 'some_hdr.c');
   ```

5. Create the int16 argument as conceptual argument `y1` and the implementation return value. There are multiple ways to set up the conceptual and implementation arguments. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create the conceptual argument and add it to the entry. Convenience method `setReturn` specifies the argument as the implementation return value.

   ```matlab
   arg = getTflArgFromString(hTable, 'y1', 'int16');
   arg.IOType = 'RTW_IO_OUTPUT';
   addConceptualArg(op_entry, arg);
   op_entry.Implementation.setReturn(arg);
   ```
Create the \texttt{int16} argument as conceptual and implementation argument \texttt{u1}. This example uses calls to the \texttt{getTflArgFromString} and \texttt{addConceptualArg} functions to create the conceptual argument and add it to the entry. Convenience method \texttt{addArgument} specifies the argument as the implementation input argument.

```matlab
arg = getTflArgFromString(hTable, 'u1', 'int16');
addConceptualArg(op_entry, arg);
op_entry.Implementation.addArgument(arg);
```

Create the \texttt{int8} argument as conceptual and implementation argument \texttt{u2}. This example uses calls to the \texttt{getTflArgFromString} and \texttt{addConceptualArg} functions to create the conceptual argument and add it to the entry. Because the argument type is not relevant, the example disables type checking by setting the \texttt{CheckType} property to \texttt{false}. Convenience method \texttt{addArgument} specifies the argument as the implementation input argument.

```matlab
arg = getTflArgFromString(hTable, 'u2', 'int8');
arg.CheckType = false;
addConceptualArg(op_entry, arg);
op_entry.Implementation.addArgument(arg);
```

- The function \texttt{getTflArgFromString} is called to create an \texttt{int8} input argument. This argument is added to the operator entry both as the third conceptual argument and the second implementation input argument.
- Add the entry to a code replacement table with a call to the \texttt{addEntry} function.

```matlab
addEntry(hTable, op_entry);
```
- Save the table definition file. Use the name of the table definition function to name the file.

**Shift Lefts Using Net Slope**

You can use code replacement entries to replace code that the code generator produces for shift (\texttt{<<}) operations.

This example creates a code replacement entry to replace shift left operations for fixed-point data using a net slope. The example defines the function mapping programmatically. Alternatively, you can use the \textbf{Code Replacement Tool} to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

```matlab
function hTable = crl_table_shift_left_fixpt_net_slope
```

---

64-237
Within the function body, create the table by calling the function `RTW.TflTable`.

```plaintext```
hTable = RTW.TflTable;
```

Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntryGenerator_Netslope` function. This function provides access to the fixed-point parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`.

```plaintext```
op_entry = RTW.TflCOperationEntryGenerator_NetSlope;
```

Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as shift left, the saturation mode as saturate on integer overflow, rounding modes as toward negative infinity, and the name of the replacement function as `my_fxp_shift_left`. `NetSlopeAdjustmentFactor` and `NetFixedExponent` specify the F and E parts of the net slope $F^{2^E}$.

```plaintext```
InFL = 2;
InWL = 16;
InSgn = true;
OutFL = 4;
OutWL = 32;
OutSgn = true;
setTflCOperationEntryParameters(op_entry, ...
    'Key',                           'RTW_OP_SL', ...
    'Priority',                      50, ... 
    'SaturationMode',                'RTW_SATURATE_ON_OVERFLOW', ...
    'RoundingModes',                 {'RTW_ROUND_FLOOR'}, ...
    'NetSlopeAdjustmentFactor',      1.0, ...
    'NetFixedExponent',              (OutFL - InFL),...
    'ImplementationName',            'my_fxp_shift_left', ...
    'ImplementationHeaderFile',      'some_hdr.h', ...
    'ImplementationSourceFile',      'some_hdr.c');
```

Create conceptual arguments `y1` and `u1`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Each argument is specified as fixed-point and signed. Each argument specifies that code replacement request processing does not check for an exact match to the call-site slope and bias values.

```plaintext```
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',            'y1', ...
    'IOType',          'RTW_IO_OUTPUT', ...
    'CheckSlope',      false, ...
    'CheckBias',       false, ...
    'DataTypeMode',    'Fixed-point: binary point scaling', ...
    'IsSigned',        OutSgn, ...
    'WordLength',      OutWL, ...
    'FractionLength',  OutFL);
```

64-238
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
  'Name', 'u1', ...
  'IOType', 'RTW_IO_INPUT', ...
  'CheckSlope', false, ...
  'CheckBias', false, ...
  'DataTypeMode', 'Fixed-point: binary point scaling', ...
  'IsSigned', InSgn, ...
  'WordLength', InWL, ...
  'FractionLength', InFL);

6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the createAndSetCImplementationReturn and createAndAddImplementationArg functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types).

createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...
  'Name', 'y1', ...
  'IOType', 'RTW_IO_OUTPUT', ...
  'IsSigned', OutSgn, ...
  'WordLength', OutWL, ...
  'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric', ...
  'Name', 'u1', ...
  'IOType', 'RTW_IO_INPUT', ...
  'IsSigned', InSgn, ...
  'WordLength', InWL, ...
  'FractionLength', 0);

7 Create the int8 argument as conceptual and implementation argument u2. This example uses calls to the getTflArgFromString and addConceptualArg functions to create the conceptual argument and add it to the entry. This argument specifies the number of bits to shift the previous input argument. Because the argument type is not relevant, type checking is disabled by setting the CheckType property to false. Convenience method addArgument specifies the argument as implementation input argument.

arg = getTflArgFromString(hTable, 'u2', 'uint8');
arg.CheckType = false;
addConceptualArg(op_entry, arg);
addArgument(op_entry, arg);

8 Add the entry to a code replacement table with a call to the addEntry function.

addEntry(hTable, op_entry);

9 Save the table definition file. Use the name of the table definition function to name the file.

What Is Code Replacement Customization?

Customize how and when the code generator replaces C/C++ code that it generates by default for functions and operators by developing a custom code replacement library. You can develop libraries interactively with the Code Replacement Tool or programmatically.

- Develop libraries tailored to specific application requirements
- Add identifiers to the list of reserved keywords the code generator considers during code replacement
- Customize the code generator’s match and replacement process for functions

To get started, “Quick Start Code Replacement Library Development - Simulink®” on page 64-28.

Code Replacement Match and Replacement Process

When the code generator encounters a call site for a function or operator, it:

1. Creates and partially populates a code replacement entry object with the function or operator name or key and conceptual arguments.
2. Uses the entry object to query the configured code replacement library for a conceptual representation match. The code generator searches the tables in a code replacement library for a match in the order that the tables appear in the library. When searching for a match, the code generator takes into account:
   - Conceptual name or key
   - Arguments, including quantity, type, type qualifiers, and complexity
   - Algorithm (computation method)
   - Fixed-point saturation and rounding modes
   - Priority
3. When a match exists, the code generator returns a code replacement object, fully populated with the conceptual representation, implementation representation, and priority. If the code generator finds multiple matches within a table, the entry priority determines the match. The priority can range from 0 to 100. The highest priority is 0. The code generator uses a higher-priority entry over a similar entry with a lower priority.
4 Uses the C or C++ replacement function prototype in the code replacement object to generate code.

**Code Replacement Customization Limitations**

- Code replacement verification — It is possible that code replacement behaves differently than you expect. For example, data types that you observe in code generator input might not match what the code generator uses as intermediate data types during an operation. Verify code replacements by examining generated code. See “Verify Code Replacements” on page 65-65.
- Tokens in file paths—You can include tokens in file paths when specifying build information for a code replacement entry by using the programming interface only. The ability to include tokens is not available from the Code Replacement Tool. See “Specify Build Information for Replacement Code” on page 65-47.
- `coder.replace` function — See `coder.replace` for relevant limitations.
- `coder.dataAlignment` function — See `coder.dataAlignment` for relevant limitations.

Code You Can Replace from MATLAB Code

Code that the code generator replaces depends on the code replacement library (CRL) that you use. By default, the code generator does not apply a code replacement library. Your choice of libraries is dependent on product licensing and whether you have access to custom libraries.

<tr>
<td>tand</td>
<td>Floating point</td>
<td>Scalar, Vector, Matrix</td>
<td>Real, Complex</td>
</tr>
</tbody>
</table>
**Memory Functions**

Depending on code replacement libraries available in your development environment, you can configure the code generator to replace instances of the following memory functions with application-specific implementations.

<table>
<thead>
<tr>
<th>Function</th>
<th>Data Type Support</th>
<th>Scalar, Vector, Matrix Support</th>
<th>Real, Complex Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>memcmp</td>
<td>Void pointer (void*)</td>
<td>Scalar, Vector, Matrix</td>
<td>Real, Complex</td>
</tr>
<tr>
<td>memcpy</td>
<td>Void pointer (void*)</td>
<td>Scalar, Vector, Matrix</td>
<td>Real, Complex</td>
</tr>
<tr>
<td>memset</td>
<td>Void pointer (void*)</td>
<td>Scalar, Vector, Matrix</td>
<td>Real, Complex</td>
</tr>
<tr>
<td>memset2zero</td>
<td>Void pointer (void*)</td>
<td>Scalar, Vector, Matrix</td>
<td>Real, Complex</td>
</tr>
</tbody>
</table>

Some target processors provide optimized functions to set memory to zero. Use the code replacement library programming interface to replace the `memset2zero` function with more efficient target-specific functions.

**Operators**

When generating C/C++ code from MATLAB code, depending on code replacement libraries available in your development environment, you can configure the code
A code generator allows you to replace instances of the following operators with application-specific implementations.

Mixed data type support indicates you can specify different data types of different inputs.

<table>

Code You Can Replace from MATLAB Code
### Operator Key Data Type Support Scalar, Vector, Matrix Support Real, Complex Support

2. Can map to Basic Linear Algebra Subroutine (BLAS) multiplication functions.

3. Scaled floating point is not supported.

4. Code replacement libraries that provide arithmetic shift right implementations should also provide logical shift right implementations, because some arithmetic shift rights are converted to logical shift rights during code generation.

5. Use the multiplication (*) operator (RTW_OP_MUL) for scalar multiplication.

6. Requires scalar, real, or fixed-point data types with zero bias; output type of the multiplication operation to accommodate all possible output values; shift operand is an unsigned integer; and net slope is equal to 1 (U1_slope * U2_slope == Mul_output_slope and Mul_output_slope == output_slope_of_shift_operation).

7. Requires scalar, real, or fixed-point data types with zero bias; output type of the multiplication operation to accommodate all possible output values; and net slope is equal to 1 (U1_slope * U2_slope == Mul_output_slope == U3_slope * Div_output_slope).

Develop a Code Replacement Library

Iterate through the following steps, as necessary, to develop a code replacement library:

5. “Register Code Replacement Mappings” on page 65-56

To get started, see “Identify Code Replacement Requirements” on page 65-25.

To experiment with the process and tools, see “Quick Start Library Development” on page 65-16.

More About

- “Identify Code Replacement Requirements” on page 65-25
- “Code You Can Replace from MATLAB Code” on page 65-5
- “Quick Start Library Development” on page 65-16
Quick Start Library Development

This example shows how to develop a code replacement library that includes an entry for generating replacement code for the math function \( \sin \). You use the **Code Replacement Tool**.

**Prerequisites**

To complete this example, install the following software:

- MATLAB
- MATLAB Coder
- Embedded Coder
- C compiler

For instructions on installing MathWorks products, see “Installation, Licensing, and Activation”. If you have installed MATLAB and want to see what other MathWorks products are installed, in the Command Window, enter `ver`.

For a list of supported compilers, see [https://www.mathworks.com/support/compilers/current_release/](https://www.mathworks.com/support/compilers/current_release/).

**Open the Code Replacement Tool**

1. Start a new MATLAB session.
2. Create or navigate (cd) to an empty folder.
3. At the command prompt, enter the `crtool` command. The **Code Replacement Tool** window opens.

**Create Code Replacement Table**

1. In the **Code Replacement Tool** window, select **File > New table**.
2. In the right pane, name the table `crl_table_sinfcn` and click **Apply**. Later, when you save the table, the tool saves it with the file name `crl_table_sinfcn.m`. 
Create Table Entry

Create a table entry that maps a \( \sin \) function with double input and double output to a custom implementation function.

1. In the left pane, select table `crl_table_sinfcn`. Then, select **File > New entry > Function**. The new entry appears in the middle pane, initially without a name.
2. In the middle pane, select the new entry.
3. In the right pane, on the **Mapping Information** tab, from the **Function** menu, select \( \sin \).
4. Leave **Algorithm** set to Unspecified, and leave parameters in the **Conceptual function** group set to default values.
5. In the **Replacement function** group, name the replacement function `sin_dbl`.
6. Leave the remaining parameters in the **Replacement function** group set to default values.
7. Click **Apply**. The tool updates the **Function signature preview** to reflect the specified replacement function name.
8 Scroll to the bottom of the **Mapping Information** tab and click **Validate entry**. The tool validates your entry.

The following figure shows the completed mapping information.
Specify Build Information for Replacement Code

1. On the Build Information tab, for the Implementation header file parameter, enter sin_dbl.h.
2. Leave the remaining parameters set to default values.
3. Click Apply.
4. Optionally, you can revalidate the entry. Return to the Mapping Information tab and click Validate entry.

Create Another Table Entry

Create an entry that maps a sin function with single input and double output to a custom implementation function named sin_sgl. Create the entry by copying and pasting the sin_dbl entry.

1. In the middle pane, select the sin_dbl entry.
2. Select Edit > Copy
3. Select Edit > Paste
4. On the Mapping Information tab, in the Conceptual function section, set the data type of input argument u1 to single.
5. In the Replacement function section, name the function sin_sgl. Set the data type of input argument u1 to single.
6. Click Apply. Note the changes that appear for the Function signature preview.
7. On the Build Information tab, for the Implementation header file parameter, enter sin_sgl.h. Leave the remaining parameters set to default values and click Apply.

Validate the Code Replacement Table

1. Select Actions > Validate table.
2 If the tool reports errors, fix them, and rerun the validation. Repeat fixing and validating errors until the tool does not report errors. The following figure shows a validation report.

![Validation Report](image)

**Save the Code Replacement Table**

Save the code replacement table to a MATLAB file in your working folder. Select **File > Save table**. By default, the tool uses the table name to name the file. For this example, the tool saves the table in the file `crl_table_sinfcn.m`.

**Review the Code Replacement Table Definition**

Consider reviewing the MATLAB code for your code replacement table definition. After using the tool to create an initial version of a table definition file, you can update, enhance, or copy the file in a text editor.

To review it, in MATLAB or another text editor, open the file `crl_table_sinfcn.m`.

**Generate a Registration File**

Before you can use your code replacement table, you must register it as part of a code replacement library. Use the Code Replacement Tool to generate a registration file.

1 In the Code Replacement Tool, select **File > Generate registration file**.
2 In the **Generate registration file** dialog box, edit the dialog box fields to match the following figure, and then click **OK**.
3 In the **Select location to save the registration file** dialog box, specify a location for the registration file. The location must be on the MATLAB path or in the current working folder. Save the file. The tool saves the file as `rtwTargetInfo.m`.

**Register the Code Replacement Table**

At the command prompt, enter:

```matlab
RTW.TargetRegistry.getInstance('reset');
```

**Review and Test Code Replacements**

Apply your code replacement library. Verify that the code generator makes code replacements that you expect.

1 Check for errors. At the command line, invoke the table definition file. For example:

```matlab
tbl = crl_table_sinfcn

tbl =

TflTable with properties:

    Version: '1.0'
    ReservedSymbols: []
    StringResolutionMap: []
    AllEntries: [2x1 RTW.TflCFunctionEntry]
    EnableTrace: 1
```

If an error exists in the definition file, the invocation triggers a message to appear. Fix the error and try again.

2 Use the Code Replacement Viewer to check your code replacement entries. For example:

```matlab
crviewer('Sin Function Example')
```

In the viewer, select entries in your table and verify that the content is what you expect. The viewer can help you detect issues such as:

- Incorrect argument order.
- Conceptual argument names that do not match what is expected by the code generator.
• Incorrect priority settings.

3 Identify existing or create new MATLAB code that calls the \( \text{sin} \) function. For example:

```matlab
function y = my_sin_fnc(x)
    y = \text{sin}(x);
end
```

4 Open the MATLAB Coder app.

5 Add the function that includes a call to the \( \text{sin} \) function as an entry-point file. For example, add `my_sin_func.m`. The app creates a project named `my_sin_func.prj`.

6 Click **Next** to go to the **Define Input Type** step. Define the types for the entry-point function inputs.

7 Click **Next** to go to the **Check for Run-Time Issues** step. This step is optional. However, it is a best practice to perform this step. Provide a test file that calls your entry-point function. The app generates a MEX function from your entry-point function. Then, the app runs the test file, replacing calls to the MATLAB function with calls to the generated MEX function.

8 Click **Next** to go to the **Generate Code** step. To open the **Generate** dialog box, click the **Generate** arrow ◀️.

9 Set **Build type** to generate a library or executable.

10 Click **More Settings**.

11 Configure the code generator to use your code replacement library. On the **Custom Code** tab, set the **Code replacement library** parameter to the name of your library. For example, `Sin Function Example`.

12 Configure the code generation report. On the **Debug** tab, set the **Always create a code generation report**, **Code replacements**, and **Automatically launch a report if one is generated** parameters.

13 Configure the code generator to generate code only. For **Build type**, select **Source code**. You want to review your code replacements in the generated code before building an executable.

14 Click **Generate** to generate C code and a report.

15 Review code replacement results in the Code Replacements Report section of the code generation report.

The report indicates that the code generator found a match and applied the replacement code for the function \( \text{sin}_{\text{dbl}} \).
16 Review the code replacements. In the report, click the MATLAB function that triggered the replacement, `my_sin_func.m`. The MATLAB Editor opens and highlights the function call that triggers the code replacement.

Identify Code Replacement Requirements

The first step to developing a code replacement library is to consider the following types of requirements for your code replacement library.

Mapping Information Requirements

- Are you defining a code replacement mapping for the first time?
- Are you updating code replacement entries in an existing library? Or, are you creating a new library?
- Are you rapid prototyping code replacements?
- Can you base your mappings on existing mappings?
- What type of code do you want to replace? Options include:
  - Math operation
  - Function
  - BLAS operation
  - CBLAS operation
  - Net slope fixed-point operation
  - Semaphore or mutex functions
- Do you want to change the inline or nonfinite behavior for functions?
- What specific functions and operations do you want to replace?
- What input and output arguments does the function or operator that you are replacing take? For each argument, what is the data type, complexity, and dimensionality?
- What does the prototype for your replacement code look like?
  - What is the replacement function name?
  - What are the input and output arguments?
  - Are there return values?
  - What is the data type, complexity, and dimensionality of each argument and return value?
Build Information Requirements

- Does your replacement function implementation require a header file? If yes, specify the header file.
- If the replacement function implementation requires a header file, what is the path for that file?
- Is the source file for the replacement function in your working folder? If not, you can explicitly specify the source file name and extension. For example, if the file is required in the generated makefile or specified in a build information object, specify the source file.
- Does the replacement function use additional include files? If yes, what are they and what are the paths for those files?
- Does the replacement function use additional source files? If yes, what are they and what are the paths for those files?
- What compiler flags are required for compiling code that includes the replacement code?
- What linker flags are required for building an executable that includes the replacement code?
- Are the required header, source, and object files for building an executable that includes your replacement code in the working folder for your project? If not, before starting the build process, do you want the code generator to copy required files to the build folder?

Registration Information Requirements

- What do you want to name your code replacement library?
- What code replacement tables do you want to include in the library? What are the file names and paths for the tables?
- What is the purpose of the library? You can document the purpose as the library description.
- Does the library apply to specific hardware devices? If yes, what devices?
- Are you developing a hierarchy of code replacement libraries? Is the library that you are developing based (dependent) on another library? For example, you can specify a general TI device library as the base library for a more specific TI C28x device library.
• Do you need to specify data alignment for the library? What data alignments are required? For each specification, what type of alignment is required and for what programming language?

Next, prepare for developing a library by reviewing a code replacement library development checklist.

• “Prepare for Code Replacement Library Development” on page 65-28
• “Code You Can Replace from MATLAB Code” on page 65-5
Prepare for Code Replacement Library Development

After you identify your code replacement requirements, prepare for library development by reviewing this checklist:

- Get familiar with the library development process.
- Decide whether to define code replacement mappings and produce a registration file interactively with the Code Replacement Tool or programmatically.
- Identify or develop MATLAB code and Simulink models to test your code replacement library.
- Consider the hierarchy and organization of your library. A library can consist of multiple tables and each table can include multiple entries. How do you want to organize the library to optimize reuse of tables and entries? For example, a registration file can define code replacement tables organized in a hierarchy of code replacement libraries based on entries that increase in specificity:
  - Common entries
  - Entries for TI devices
  - Entries for TI C6xx devices
  - Entries specific to the TI C67x device
- If support files, such as header files, additional source files, and dynamically linked libraries are not in your current working folder, note their location. You need to specify the paths for such files.

Next, based on your requirements and preparation, define code replacement mappings.

- “Develop a Code Replacement Library” on page 65-15
Define Code Replacement Mappings

After you prepare for library development, use your requirements to define code replacement mappings. A code replacement mapping associates a conceptual representation of a function or operator that is familiar to the code generator with a custom implementation representation that specifies a C or C++ replacement function prototype. You capture a mapping as an entry in a code replacement table:

- Interactively, by using the Code Replacement Tool.
- Programmatically, by using a MATLAB programming interface.

Choose an Approach for Defining Code Replacement Mappings

The following table lists situations to help you decide when to use the interactive or programmatic approach.

<table>
<thead>
<tr>
<th>Situation</th>
<th>Approach</th>
</tr>
</thead>
<tbody>
<tr>
<td>Defining mappings for the first time.</td>
<td>Code Replacement Tool.</td>
</tr>
<tr>
<td>Rapid prototyping mappings.</td>
<td>Code Replacement Tool to quickly generate, register, and test mappings.</td>

<tr>
<td>Reusing existing code for new mappings by copying, pasting, and editing existing mappings.</td>
<td>Programming interface.</td>
</tr>
</tbody>
</table>
Define Mappings Interactively with the Code Replacement Tool

This example shows how to use the Code Replacement Tool to develop code replacement mappings. The tool is ideal for getting started with developing mappings, rapid prototyping, and developing a mapping to use as a starting point for defining similar mappings.

Open the Code Replacement Tool

Do one of the following:

- In the Command Window, enter the command crtool.
- In the Configuration Parameters dialog box, navigate to Code Generation pane. In the Advanced parameters section, scroll down and click Custom CRL... button.

An Embedded Coder license is not required to create a custom code replacement library. However, you must have an Embedded Coder license to use a such a library.

By default, the tool displays, left to right, a root pane, a list pane, and a dialog pane. You can manipulate the display:

- Drag boundaries to widen, narrow, shorten, or lengthen panes, and to resize table columns.
- Select View > Show dialog pane to hide or display the right-most pane.
- Click a table column heading to sort the table based on contents of the selected column.
- Right-click a table column heading and select Hide to remove the column from the display. (You cannot hide the Name column.)

Create a Code Replacement Table

1. In the Code Replacement Tool window, select File > New table.
2. In the right pane, name the table and click Apply. Later, when you save the table, the tool uses the table name that you specify to name the file. For example, if you enter the name my_sinfcn, the tool names the file my_sinfcn.m.
Create Table Entries

Create one or more table entries. Each entry maps the conceptual representation of a function or operator to your implementation representation. The information that you enter depends on the type of entry you create. Enter the following information:

1. In the left pane, select the table to which you want to add the entry.
2. Select File > New entry > entry-type, where entry-type is one of:
   - Math Operation
   - Function
   - BLAS Operation
   - CBLAS Operation
   - Net Slope Fixed-Point Operation
   - Semaphore entry
   - Customization entry

   The new entry appears in the middle pane, initially without a name.

3. In the middle pane, select the new entry.
4. In the right pane, on the Mapping Information tab, from the Function or Operation menu, select the function or operation that you want the code generator to replace. Regardless of the entry type, make a selection from this menu. Your selection determines what other information you specify.

   Except for customization entries, you also specify information for your replacement function prototype. You can also specify implementation attributes, such as the rounding modes to apply.

5. If prompted, specify additional entry information that you want the code generator to use when searching for a match. For example, when you select an addition or subtraction operation, the tool prompts you to specify an algorithm (Cast before operation or Cast after operation).

6. Review the conceptual argument information that the tool populates for the function or operation. Conceptual input and output arguments represent arguments for the function or operator being replaced. Conceptual arguments observe naming conventions ('y1', 'u1', 'u2', ...) and data types familiar to the code generator.
When validating the entry, the code generator validates that each conceptual argument has an I/O type that is compatible with the argument name. For example, an input must have `IOType` of `RTW_IO_INPUT`.

If you do not want the data types for your implementation to be the same as the conceptual argument types, clear the **Make the conceptual and implementation argument types the same** check box. For example, most ANSI-C functions operate on and return `double` data. Clear the check box if want to map a conceptual representation of the function to an implementation representation that specifies an argument and return value. For example, clear the check box to map the conceptual representation of the function `sin` to an implementation representation that specifies an argument and return value of type `single` (`single sin(single)`), of type `double` (`double sin(double)`). In this case, the code generator produces the following code:

```
y = (single) sin(u1);
```

If you select **Custom** for a function entry, specify only conceptual argument information.

7 Specify the name and argument information for your replacement function. As you enter the information and click **Apply**, the tool updates the **Function signature preview**.

When validating the entry, the code generator validates that each implementation argument has an I/O type that is compatible with the conceptual argument to which it is mapped. For example, an conceptual argument of type `RTW_IO_OUTPUT` requires a compatible implementation argument of type `RTW_IO_OUTPUT` or `RTW_IO_INPUT_OUTPUT`. The default I/O type is `RTW_IO_INPUT`.

8 Specify additional implementation attributes that apply. For example, depending on the type and name of the entry that you specify, the tool prompts you to specify:

- Integer saturation mode
- Rounding modes
- Whether to allow inputs that include expressions
- Whether a function modifies internal or global state

9 Click **Apply**.

**Validate Tables and Entries**

The Code Replacement Tool provides a way to validate the syntax of code replacement tables and table entries as you define them. If the tool finds validation errors, you can
address them and retry the validation. Repeat the process until the tool does not report errors.

<table>
<thead>
<tr>
<th>To</th>
<th>Do</th>
</tr>
</thead>
<tbody>
<tr>
<td>Validate table entries</td>
<td>Select an entry, scroll to the bottom of the <strong>Mapping Information</strong> tab, and click <strong>Validate entry</strong>. Alternatively, select one or more entries, right-click, and select <strong>Validate entries</strong>.</td>
</tr>
<tr>
<td>Validate a table</td>
<td>Select the table. Then, select <strong>Actions &gt; Validate table</strong>.</td>
</tr>
</tbody>
</table>

**Save a Table**

When you save a table, the tool validates unvalidated content.

1. Select **File > Save table**.
2. In the Browse For Folder dialog box, specify a location and name for the file. Typically, you select a location on the MATLAB path. By default, the tool names the file using the name that you specify for the table with the extension `.m`.
3. Click **Save**.

**Open and Modify Tables**

After saving a code replacement table, to make changes in the table:

1. Select **File > Open table**.
2. In the Import file dialog box, browse to the MATLAB file that contains the table.

Repeat the sequence to open and work on multiple tables.

If you open multiple tables, you can manage the tables together. For example, use the tool to:

- Create new table entries.
- Delete entries.
- Copy and paste or cut and paste information between tables.

**Define Mappings Programmatically**

This example shows how to define a code replacement mapping programmatically. The programming interface for defining code replacement table mappings is ideal for
- Modifying tables that you create with the Code Replacement Tool.
- Defining mappings for specialized entries that you cannot create with the Code Replacement Tool.
- Replicating and modifying similar entries and tables.

Steps for defining a mapping programmatically are:

- “Create Code Replacement Table” on page 65-34
- “Create Table Entry” on page 65-34
- “Set Entry Parameters” on page 65-36
- “Create Conceptual Arguments” on page 65-38
- “Create Implementation Arguments” on page 65-40
- “Add Entry to Table” on page 65-44
- “Validate Entry” on page 65-44
- “Save Table” on page 65-45

**Create Code Replacement Table**

1. Create a table definition file that contains a function definition. For example:

   ```matlab
   function hTable = crl_table_sinfcn()
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`

   ```matlab
   hTable = RTW.TflTable;
   ```

**Create Table Entry**

For each function or operator that you want the code generator to replace, map a conceptual representation of the function or operator to an implementation representation as a table entry.

1. Within the body of a table definition file, create a code replacement entry object. Call one of the following functions.

<table>
<thead>
<tr>
<th>Entry Type</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>Math operation</td>
<td><code>RTW.TflCOperationEntry</code></td>
</tr>
<tr>
<td>Function</td>
<td><code>RTW.TflCFunctionEntry</code></td>
</tr>
<tr>
<td>BLAS operation</td>
<td><code>RTW.TflBlasEntryGenerator</code></td>
</tr>
</tbody>
</table>
### Entry Type | Function
---|---
CBLAS operation | RTW.TflCBlasEntryGenerator
Fixed-point addition and subtraction operations (support for SlopesMustBeTheSame and MustHaveZeroNetBias parameters) | RTW.TflCOperationEntryGenerator
Net slope fixed-point operation | RTW.TflCOperationEntryGenerator.NetSlope
Semaphore or mutex entry | RTW.TflCSemaphoreEntry
Custom function entry | MyCustomFunctionEntry (where MyCustomFunctionEntry is a class derived from RTW.TflCFunctionEntryML)
Custom operation entry | MyCustomOperationEntry (where MyCustomOperationEntry is a class derived from RTW.TflCOperationEntryML)

For example:

```c
hEnt = RTW.TflCFunctionEntry;
```

You can combine steps of creating the entry, setting entry parameters, creating conceptual and implementation arguments, and adding the entry to a table with a single function call to `registerCFunctionEntry`, `registerCPPFunctionEntry`, or `registerCPromotableMacroEntry` if you are creating an entry for a function and the function implementation meets the following criteria:

- Implementation argument names and order match the names and order of corresponding conceptual arguments.
- Input arguments are of the same type.
- The return and input argument names follow the code generator’s default naming conventions:
  - Return argument is `y1`.
  - Input arguments are `u1`, `u2`, ..., `un`.

For example:
registerCFunctionEntry(hTable, 100, 1, 'sin', 'double', ...
  'sin_dbl', 'double', 'sin_dbl.h', '', '');

As another alternative, you can significantly reduce the amount of code that you write by combining the steps of creating the entry and conceptual and implementation arguments with a call to the createCRLEntry function. In this case, specify the conceptual and implementation information as character vector or string scalar specifications.

For example:

hEnt = createCRLEntry(hTable, ...
  'double y1 = sin(double u1)', ...
  'mySin');

This approach does not support:

• C++ implementations
• Data alignment
• Operator replacement with net slope arguments
• Entry parameter specifications (for example, priority, algorithm, building information)
• Semaphore and mutex function replacements

**Set Entry Parameters**

Set entry parameters, such as the priority, algorithm information, and implementation (replacement) function name. Call the function listed in the following table for the entry type that you created.

<table>
<thead>
<tr>
<th>Entry Type</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>Math operation</td>
<td>setTflCOperationEntryParameters</td>
</tr>
<tr>
<td>Function</td>
<td>setTflCFunctionEntryParameters</td>
</tr>
<tr>
<td>BLAS operation</td>
<td>setTflCOperationEntryParameters</td>
</tr>
<tr>
<td>CBLAS operation</td>
<td>setTflCOperationEntryParameters</td>
</tr>
<tr>
<td>Entry Type</td>
<td>Function</td>
</tr>
<tr>
<td>---------------------------------------------------------------------------</td>
<td>-----------------------------------------------------------------</td>
</tr>
<tr>
<td>Fixed-point addition and subtraction operations where there is a many-to-one mapping, such as a mapping for a range of fixed-point types to the same replacement function (support for SlopesMustBeTheSame and MustHaveZeroNetBias parameters)</td>
<td>setTflCOperationEntryParameters</td>
</tr>
<tr>
<td>Net slope fixed-point operation</td>
<td>setTflCOperationEntryParameters</td>
</tr>
<tr>
<td>Semaphore or mutex entry</td>
<td>setTflCSemaphoreEntryParameters</td>
</tr>
<tr>
<td>Custom function entry</td>
<td>setTflCFunctionEntryParameters</td>
</tr>
<tr>
<td>Custom operation entry</td>
<td>setTflCOperationEntryParameters</td>
</tr>
</tbody>
</table>

To see a list of the parameters that you can set, at the command line, create a new entry and omit the semicolon at the end of the command. For example:

```matlab
hEnt = RTW.TflCFunctionEntry
hEnt =

TflCFunctionEntry with properties:

    Implementation: [1x1 RTW.CImplementation]
    SlopesMustBeTheSame: 0
    BiasMustBeTheSame: 0
    AlgorithmParams: []
        ImplType: 'FCN IMPL FUNCT'
    AdditionalHeaderFiles: {0x1 cell}
    AdditionalSourceFiles: {0x1 cell}
    AdditionalIncludePaths: {0x1 cell}
    AdditionalSourcePaths: {0x1 cell}
    AdditionalLinkObjs: {0x1 cell}
    AdditionalLinkObjsPaths: {0x1 cell}
    AdditionalLinkFlags: {0x1 cell}
    AdditionalCompileFlags: {0x1 cell}
    SearchPaths: {0x1 cell}
        Key: ''
    Priority: 100
    ArrayLayout: 'COLUMN_MAJOR'
    ConceptualArgs: [0x1 handle]
    EntryInfo: []
```
To see the implementation parameters, enter:

```
  hEnt.Implementation
```

```
ans =

  CImplementation with properties:
      HeaderComponent: '
      SourceFilename: '
      HeaderComponentPath: '
      SourceFilenamePath: '
      Return: []
      StructFieldNameMap: []
      Name: ''
      Arguments: [0x1 RTW.Argument]
      ArgumentDescriptor: []
```

For example, to set entry parameters for the \texttt{sin} function and name your replacement function \texttt{sin\_dbl}, use the following function call:

```
  setTflCFunctionEntryParameters(hEnt, ...  
    'Key', 'sin', ...  
    'ImplementationName', 'sin\_dbl');
```

**Create Conceptual Arguments**

Create conceptual arguments and add them to the entry’s array of conceptual arguments.

- Specify output arguments before input arguments.
• Specify argument names that comply with code generator argument naming conventions:
  • y1 for a return argument
  • u1, u2, ..., un for input arguments
• Specify data types that are familiar to the code generator.
• The function signature, including argument naming, order, and attributes, must fulfill the signature match sought by function or operator callers.
• The code generator determines the size of the value for an argument with an unsized type, such as integer, based on hardware implementation configuration settings.

For each argument:

1 Identify whether the argument is for input or output, the name, and data type. If you do not know what arguments to specify for a supported function or operation, use the Code Replacement Tool to find them. For example, to find the conceptual arguments for the sin function, open the tool, create a table, create a function entry, and in the Function menu select sin.

When validating the entry, the code generator validates that each conceptual argument has an I/O type that is compatible with the argument name. For example, an input must have IOType of RTW_IO_INPUT.

2 Create and add the conceptual argument to an entry. You can choose a method from the methods listed in this table.

<table>
<thead>
<tr>
<th>If</th>
<th>Then</th>
</tr>
</thead>
</table>
| You want simpler code or want to explicitly specify whether the argument is scalar or nonscalar (vector or matrix). | Call the function createAndAddConceptualArg. For example: createAndAddConceptualArg(hEnt, ...
|                                                      | 'RTW.TflArgNumeric', ...
|                                                      | 'Name',         'y1',...
|                                                      | 'IOType',       'RTW_IO_OUTPUT',...
|                                                      | 'DataTypeMode', 'double');                                           |
|                                                      | The second argument specifies whether the argument is scalar (RTW.TflArgNumeric orRTW.TflArgMatrix). |
**If**

You want to create an argument based on a built-in argument definition (for example, scalar or nonscalar).

**Then**

Call `getTflArgFromString` to create the argument. Then, call `addConceptualArg` to add the argument to the entry.

```matlab
arg = getTflArgFromString(hEnt, 'y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEnt, arg);
```

You need to define several similar mappings, you want to minimize the code to write, and the entries do not require data alignment, use net slope arguments, or involve semaphore or mutex replacements.

**Then**

Call `createCRLEntry` to create the entry and specify conceptual and implementation arguments in a single function call.

```matlab
hEnt = createCRLEntry(hTable, ...
   'double y1 = sin(double u1)', ...
   'mySin');
```

---

The following code shows the second approach listed in the table for specifying the conceptual output and input argument definitions for the `sin` function.

```matlab
% Conceptual Args
arg = getTflArgFromString(hEnt, 'y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEnt, arg);
arg = getTflArgFromString(hEnt, 'u1','double');
addConceptualArg(hEnt, arg);

Create Implementation Arguments

Create implementation arguments for the C or C++ replacement function and add them to the entry.

- When replacing code, the code generator uses the argument names to determine how it passes data to the implementation function.
- For function replacements, the order of implementation argument names must match the order of the conceptual argument names.
For operator replacements, the order of implementation argument names do not have to match the order of the conceptual argument names. For example, for an operator replacement for addition, \( y_1 = u_1 + u_2 \), the conceptual arguments are \( y_1, u_1, \) and \( u_2 \), in that order. If the signature of your implementation function is \( t \ myAdd(t \ u_2, t \ u_1) \), where \( t \) is a valid C type, based on the argument name matches, the code generator passes the value of the first conceptual argument, \( u_1 \), to the second implementation argument of \( myAdd \). The code generator passes the value of the second conceptual argument, \( u_2 \), to the first implementation argument of \( myAdd \).

- For operator replacements, you can remap operator output arguments to implementation function input arguments.

For each argument:

1. Identify whether the argument is for input or output, the name, and the data type.

   When validating the entry, the code generator validates that each implementation argument has an I/O type that is compatible with the conceptual argument to which it is mapped. For example, an conceptual argument of type \( \text{RTW\_IO\_OUTPUT} \) requires a compatible implementation argument of type \( \text{RTW\_IO\_OUTPUT} \) or \( \text{RTW\_IO\_INPUT\_OUTPUT} \). The default I/O type is \( \text{RTW\_IO\_INPUT} \).

2. Create and add the implementation argument to an entry. You can choose a method from the methods listed in this table.

<table>
<thead>
<tr>
<th>If</th>
<th>Then</th>
</tr>
</thead>
<tbody>
<tr>
<td>You want to populate implementation arguments as copies of previously created matching conceptual arguments</td>
<td>Call the function ( \text{copyConceptualArgsToImplementation} ). For example: ( \text{copyConceptualArgsToImplementation(hEnt);} )</td>
</tr>
<tr>
<td><strong>If</strong></td>
<td><strong>Then</strong></td>
</tr>
<tr>
<td>-------</td>
<td>----------</td>
</tr>
<tr>
<td>You want to create and add implementation arguments individually, or vary argument attributes, while maintaining conceptual argument order.</td>
<td>Call functions <code>createAndSetCImplementationReturn</code> and <code>createAndAddImplementationArg</code>. For example:</td>
</tr>
<tr>
<td></td>
<td><code>createAndSetCImplementationReturn(hEnt, 'RTW.TflArgNumeric', ... 'Name', 'y1', ... 'IOType', 'RTW_IO_OUTPUT', ... 'IsSigned', true, ... 'WordLength', 32, ... 'FractionLength', 0);</code></td>
</tr>
<tr>
<td></td>
<td><code>createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',... 'Name', 'u1', ... 'IOType', 'RTW_IO_INPUT',... 'IsSigned', true,... 'WordLength', 32, ... 'FractionLength', 0 );</code></td>
</tr>
<tr>
<td><strong>If</strong></td>
<td><strong>Then</strong></td>
</tr>
<tr>
<td>---</td>
<td>---</td>
</tr>
<tr>
<td>You want to minimize the amount of code, or specify constant arguments to pass to the implementation function</td>
<td>Create the argument with a call to the function <code>getTflArgFromString</code>. Then, use the convenience method <code>setReturn</code> or <code>addArgument</code> to specify whether an argument is a return value or argument and to add the argument to the entry’s array of implementation arguments. For example:</td>
</tr>
</tbody>
</table>
|  | `arg = getTflArgFromString(hEnt,...
|  |   'y1','double');
|  |   arg.IOType = 'RTW_IO_OUTPUT';
|  |   hEnt.Implementation.setReturn(arg);` |
|  | `arg = getTflArgFromString(hEnt,...
|  |   'u1','double');
|  |   hEnt.Implementation.addArgument(arg);` |
|  | The following call to `getTflArgFromString` passes the constant 0 to argument u2: |
|  | `arg = getTflArgFromString(hEnt,...
|  |   'u2', 'int16', 0)
|  |   hEnt.Implementation.addArgument(arg);` |
|  | For semaphore and mutex entries, use the functions `getTflDWorkFromString` and `addDWorkArg` to create and add a DWork argument to the entry. Then create implementation arguments as shown above with `getTflArgFromString` and the convenience methods `setReturn` and `addArgument`. For example: |
|  | `arg = getTflDWorkFromString(...
|  |   'd1', 'void*')
|  |   hEnt.addDWorkArg(arg);` |
|  | `arg = hEnt.getTflArgFromString(...
|  |   'y1', 'void');
|  |   arg.IOType = 'RTW_IO_OUTPUT';
|  |   hEnt.Implementation.setReturn(arg);` |
|  | `arg = hEnt.getTflArgFromString(...
|  |   'u1', 'integer');
|  |   hEnt.Implementation.addArgument(arg);` |
If Then

<table>
<thead>
<tr>
<th>If</th>
<th>Then</th>
</tr>
</thead>
</table>
| arg = hEnt.getTflArgFromstring(...)  
  'd1', 'void**');  
hEnt.Implementation.addArgument(arg); | You need to define several similar mappings, you want to minimize the code to write, and the entries do not require data alignment, use net slope arguments, or involve semaphore or mutex replacements. |
| Call createCRLEntry to create the entry and specify conceptual and implementation arguments in a single function call.  
hEnt = createCRLEntry(hTable, ...  
  'double y1 = sin(double u1)', ...  
  'mySin'); | |

The following code shows the third approach listed in the table for specifying the implementation output and input argument definitions for the sin function:

```matlab
% Implementation Args

arg = hEnt.getTflArgFromstring('y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);

arg = hEnt.getTflArgFromstring('u1','double');
hEnt.Implementation.addArgument(arg);
```

**Add Entry to Table**

Add an entry to a code replacement table by calling the function `addEntry`.

```matlab
addEntry(hTable, hEnt);
```

**Validate Entry**

After you create or modify a code replacement table entry, validate it by invoking it at the MATLAB command line. For example:

```matlab
hTbl = crl_table_sinfcn
hTbl =
```
If the table includes errors, MATLAB reports them. The following examples shows how MATLAB reports a typo in a data type name:

```matlab
hTbl = crl_table_sinfcn
??? RTW_CORE:tfl:TflTable: Unsupported data type, 'dooble'.
Error in ==> crl_table_sinfcn at 7
hTable.registerCFunctionEntry(100, 1, 'sin', 'dooble', 'sin_dbl', ...)
```

**Save Table**

Save the table definition file. Use the name of the table definition function to name the file, for example, `crl_table_sinfcn.m`.

Next, from your requirements, determine whether you need to specify build information for your replacement code.

Specify Build Information for Replacement Code

After you define code replacement mappings, determine whether you need to specify build information for your replacement code. A code replacement table entry can specify build information for the code generator to use when replacing code for a match. For example, specify files for implementation replacement code if you are using a generated makefile and the code generation software compiles the code.

Add build information to an entry:

- Interactively, by using the **Build Information** tab in the **Code Replacement Tool**.
- Programmatically, by using a MATLAB programming interface.

**Build Information**

The build information can include:

- Paths and file names for header files
- Paths and file names for source files
- Paths and file names for object files
- Compile flags
- Link flags

**Choose an Approach for Specifying Build Information**

The following table lists situations to help you decide when to use an interactive or programmatic approach to specifying build information:

<table>
<thead>
<tr>
<th>Situation</th>
<th>Approach</th>
</tr>
</thead>
<tbody>
<tr>
<td>Creating code replacement entries for the first time.</td>
<td>Code Replacement Tool.</td>
</tr>
<tr>
<td>You used the Code Replacement Tool to create the entries for which the build information applies.</td>
<td>Code Replacement Tool to specify the build information quickly .</td>
</tr>
</tbody>
</table>
### Situation vs Approach

<table>
<thead>
<tr>
<th>Situation</th>
<th>Approach</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rapid prototyping entries.</td>
<td>Code Replacement Tool to generate, register, and test entries quickly.</td>
</tr>
<tr>
<td>Developing an entry to use as a template or starting point for defining similar entries.</td>
<td>Code Replacement Tool to generate entry code that you can copy and modify.</td>
</tr>
<tr>
<td>Modifying existing mappings.</td>
<td>MATLAB Editor to update the programming interface directly.</td>
</tr>
</tbody>
</table>

- If an entry uses header, source, or object files, consider whether to make the files accessible to the code generator. You can copy files to the build folder or you can specify individual file names and paths explicitly.

- If you specify additional header files/include paths or source files/paths and you copy files, the compiler and utilities such as packNGo might find duplicate instances of files (an instance in the build folder and an instance in the original folder).

- If you choose to copy files to the build folder and you are using the packNGo function to relocate static and generated code files to another development environment:
  - In the call to packNGo, specify the property-value pair 'minimalHeaders' true (the default). That setting instructs the function to include the minimal header files required to build the code in the zip file.
  - Do not collocate files that you copy with files that you do not copy. If the packNGo function finds multiple instances of the same file, the function returns an error.

- If you use the programming interface, paths that you specify can include tokens. A token is a variable defined as a character vector, cell array of character vectors, or string array in the MATLAB workspace that you enclose with dollar signs ($variable$). The code generator evaluates and replaces a token with the defined value. For example, consider the path $myfolder$\folder1, where myfolder is a character vector or string scalar variable defined in the MATLAB workspace as 'd:\work \source\module1'. The code generator generates the custom path as d:\work \source\module1\folder1.

## Specify Build Information Interactively with the Code Replacement Tool

The Code Replacement Tool provides a quick, easy way for you to specify build information for code replacement table entries. It is ideal for getting started with defining...
a table entry, rapid prototyping, and developing table entries to use as a starting point for defining similar mappings.

1. Determine the information that you must specify.
2. Open the Code Replacement Tool.
3. Select the code replacement table entry for which you want to specify the build information. In the left pane, select the table that contains the entry. In the middle pane, select the entry that you want to modify.
4. In the right pane, select the **Build Information** tab.
5. On the **Build Information** tab, specify your build information.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Specify</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Implementation header file</strong></td>
<td>File name and extension for the header file the code generator needs to generate the replacement code. For example, sin_dbl.h.</td>
</tr>
<tr>
<td><strong>Implementation source file</strong></td>
<td>File name and extension for the C or C++ source file the code generator needs to generate the replacement code. For example, sin_dbl.c.</td>
</tr>
<tr>
<td><strong>Additional header files/include paths</strong></td>
<td>Paths and file names for additional header files the code generator needs to generate the replacement code. For example, C:\libs \headerFiles and C:\libs\headerFiles \common.h. This parameter adds -I to the compile line in the generated makefile.</td>
</tr>
<tr>
<td><strong>Additional source files/ paths</strong></td>
<td>Paths and file names for additional source files the code generator needs to generate the replacement code. For example, C:\libs \srcFiles and C:\libs\srcFiles \common.c. This parameter adds -I to the compile line in the generated makefile.</td>
</tr>
<tr>
<td><strong>Additional object files/ paths</strong></td>
<td>Paths and file names for additional object files the linker needs to build the replacement code. For example, C:\libs\objFiles and C:\libs\objFiles\common.obj.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Specify</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Additional link flags</td>
<td>Flags the linker needs to generate an executable file for the replacement code.</td>
</tr>
<tr>
<td>Additional compile flags</td>
<td>Flags the compiler needs to generate object code for the replacement code.</td>
</tr>
<tr>
<td>Copy files to build directory</td>
<td>Whether to copy header, source, or object files, which are required to generate replacement code, to the build folder before code generation. If you specify files with Additional header files/include paths or Additional source files/paths and you copy files, the compiler and utilities such as packNGo might find duplicate instances of files.</td>
</tr>
</tbody>
</table>

6 Click **Apply**.

7 Select the **Mapping Information** tab. Scroll to the bottom of that table and click **Validate entry**. The tool validates the changes that you made to the entry.

8 Save the table that includes the entry that you just modified.

**Specify Build Information Programmatically**

The programming interface for specifying build information for a code replacement entry is ideal for:

- Modifying entries created with the Code Replacement Tool.
- Replicating and then modifying similar entries and tables.

The basic workflow for specifying build information programmatically is:

1 Identify or create the code replacement entry that you want to specify the build information.

2 Determine what information to specify.

3 Specify your build information.
<table>
<thead>
<tr>
<th>Specify</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Implementation header file</td>
<td>Use one of the following:</td>
</tr>
<tr>
<td></td>
<td>• Set properties ImplementationHeaderFile and ImplementationHeaderPath in a call to setTflCFunctionEntryParameters, setTflCOperationEntryParameters, or setTflCSemaphoreEntryParameters. For example:</td>
</tr>
<tr>
<td></td>
<td>setTflCFunctionEntryParameters(hEnt, ...)</td>
</tr>
<tr>
<td></td>
<td>'ImplementationHeaderFile', 'sin_dbl.h', ...</td>
</tr>
<tr>
<td></td>
<td>'ImplementationHeaderPath', 'D:/lib/headerFiles'</td>
</tr>
<tr>
<td></td>
<td>'Key', 'sin', ...</td>
</tr>
<tr>
<td></td>
<td>'ImplementationName', 'sin_dbl');</td>
</tr>
<tr>
<td></td>
<td>• Set argument headerFile in a call to registerCFunctionEntry, registerCPPFunctionEntry, or registerCPromotableMacroEntry.</td>
</tr>
<tr>
<td></td>
<td>Implementation source file</td>
</tr>
<tr>
<td></td>
<td>setTflCFunctionEntryParameters(hEnt, ...)</td>
</tr>
<tr>
<td></td>
<td>'ImplementationHeaderFile', 'sin_dbl.c', ...</td>
</tr>
<tr>
<td></td>
<td>'ImplementationHeaderPath', 'D:/lib/sourceFiles'</td>
</tr>
<tr>
<td></td>
<td>'Key', 'sin', ...</td>
</tr>
<tr>
<td></td>
<td>'ImplementationName', 'sin_dbl');</td>
</tr>
<tr>
<td>Additional header files/include paths</td>
<td>For each file, specify the file name and path in calls to the functions addAdditionalHeaderFile and addAdditionalIncludePath. For example:</td>
</tr>
<tr>
<td></td>
<td>libdir = fullfile('$MATLAB_ROOT','..', '..','lib');</td>
</tr>
<tr>
<td></td>
<td>hEnt = RTW.TflCFunctionEntry;</td>
</tr>
<tr>
<td></td>
<td>addAdditionalHeaderFile(hEnt, 'common.h');</td>
</tr>
<tr>
<td></td>
<td>addAdditionalIncludePath(hEnt, fullfile(libdir, 'include'));</td>
</tr>
<tr>
<td></td>
<td>These functions add -I to the compile line in the generated makefile.</td>
</tr>
</tbody>
</table>
## Specify Action

<table>
<thead>
<tr>
<th>Specify</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Additional source files/paths</td>
<td>For each file, specify the file name and path in calls to the functions <code>addAdditionalSourceFile</code> and <code>addAdditionalSourcePath</code>. For example:</td>
</tr>
<tr>
<td></td>
<td><code>libdir = fullfile('$(MATLAB_ROOT)','..', '..', 'lib');</code></td>
</tr>
<tr>
<td></td>
<td>hEnt = RTW.TflCFunctionEntry;</td>
</tr>
<tr>
<td></td>
<td>addAdditionalSourceFile(hEnt, 'common.c');</td>
</tr>
<tr>
<td></td>
<td>addAdditionalSourcePath(hEnt, fullfile(libdir, 'src'));</td>
</tr>
<tr>
<td></td>
<td>These functions add <code>-I</code> to the compile line in the generated makefile.</td>
</tr>
<tr>
<td>Additional object files/paths</td>
<td>For each file, specify the file name and path in calls to the functions <code>addAdditionalLinkObj</code> and <code>addAdditionalLinkObjPath</code>. For example:</td>
</tr>
<tr>
<td></td>
<td><code>libdir = fullfile('$(MATLAB_ROOT)','..', '..', 'lib');</code></td>
</tr>
<tr>
<td></td>
<td>hEnt = RTW.TflCFunctionEntry;</td>
</tr>
<tr>
<td></td>
<td>addAdditionalLinkObj(hEnt, 'sin.o');</td>
</tr>
<tr>
<td></td>
<td>addAdditionalLinkObjPath(hEnt, fullfile(libdir, 'bin'));</td>
</tr>
<tr>
<td>Compile flags</td>
<td>Set the entry property <code>AdditionalCompileFlags</code> to a cell array of character vectors or string array representing the required compile flags. For example:</td>
</tr>
<tr>
<td></td>
<td>hEnt = RTW.TflCFunctionEntry;</td>
</tr>
<tr>
<td></td>
<td>hEnt.AdditionalCompileFlags = {'-Zi -Wall', '-03'};</td>
</tr>
<tr>
<td>Link flags</td>
<td>Set the entry property <code>AdditionalLinkFlags</code> to a cell array of character vectors or string array representing the required link flags. For example:</td>
</tr>
<tr>
<td></td>
<td>hEnt = RTW.TflCFunctionEntry;</td>
</tr>
<tr>
<td></td>
<td>hEnt.AdditionalCompileFlags = {'-MD -Gy', '-T'};</td>
</tr>
</tbody>
</table>
Specify whether to copy header, source, or object files, which are required to generate replacement code, to the build folder before code generation. Use one of the following:

- Set property GenCallback to 'RTW.copyFileToBuildDir' in a call to setTflCFunctionEntryParameters, setTflCOperationEntryParameters, or setTflCSemaphoreEntryParameters. For example:

  ```
  setTflCFunctionEntryParameters(hEnt, ...
    'ImplementationHeaderFile', 'sin_dbl.h', ...
    'ImplementationHeaderPath', 'D:/lib/headerFiles' 
    'Key',                      'sin', ...
    'ImplementationName',       'sin_dbl' 
    'GenCallback',              'RTW.copyFileToBuildDir');
  ```

- Set argument genCallback in a call to registerCFunctionEntry, registerCPPFunctionEntry, or registerCPromotableMacroEntry to 'RTW.copyFileToBuildDir'.

If a match occurs for a table entry, a call to the function RTW.copyFileToBuildDir copies required files to the build folder.

If you specify additional header files/include paths or additional source files/paths and you copy files, the compiler and utilities such as packNGo might find duplicate instances of files.

4 Save the table that includes the entry that you added or modified.

The following example defines a table entry for an optimized multiplication function that takes signed 32-bit integers and returns a signed 32-bit integer, taking saturation into account. Multiplications in the generated code are replaced with calls to the optimized function. The optimized function does not reside in the build folder. For the code generator to access the files, copy them into the build folder to be compiled and linked into the application.

The table entry specifies the source and header file names and paths. To request the copy operation, the table entry sets the genCallback property to 'RTW.copyFileToBuildDir' in the call to the setTflCOperationEntryParameters function. In this example, the header file s32_mul.h contains an inlined function that invokes assembly functions contained in s32_mul.s. If a match occurs for the table entry,
the function `RTW.copyFileToBuildDir` copies the specified source and header files to the build folder for use during the remainder of the build process.

```matlab
function hTable = make_my_crl_table

hTable = RTW.TflTable;

op_entry = RTW.TflCOperationEntry;
setTflCOperationEntryParameters(op_entry, ...
    'Key',                      'RTW_OP_MUL', ...
    'Priority',                 100, ...
    'SaturationMode',           'RTW_SATURATE_ON_OVERFLOW', ...
    'RoundingModes',            {'RTW_ROUND_UNSPECIFIED'}, ...
    'ImplementationName',       's32_mul_s32_s32_sat', ...
    'ImplementationHeaderFile', 's32_mul.h', ...
    'ImplementationSourceFile', 's32_mul.s', ...
    'ImplementationHeaderPath', {fullfile('$(MATLAB_ROOT)','crl')}, ...
    'ImplementationSourcePath', {fullfile('$(MATLAB_ROOT)','crl')}, ...
    'GenCallback',              'RTW.copyFileToBuildDir');

addEntry(hTable, op_entry);

The following example uses the functions `addAdditionalHeaderFile`, `addAdditionalIncludePath`, `addAdditionalSourceFile`, `addAdditionalSourcePath`, `addAdditionalLinkObj`, and `addAdditionalLinkObjPath` in addition to the code generation callback function `RTW.copyFileToBuildDir`.

```matlab
hTable = RTW.TflTable;

% Path to external source, header, and object files
libdir = fullfile('$(MATLAB_ROOT)','..', '..', 'lib');

op_entry = RTW.TflCOperationEntry;
setTflCOperationEntryParameters(op_entry, ...
    'Key',                      'RTW_OP_ADD', ...
    'Priority',                 90, ...
    'SaturationMode',           'RTW_SATURATE_UNSPECIFIED', ...
    'RoundingModes',            {'RTW_ROUND_UNSPECIFIED'}, ...
    'ImplementationName',       's32_add_s32_s32', ...
    'ImplementationHeaderFile', 's32_add_s32_s32.h', ...
    'ImplementationSourceFile', 's32_add_s32_s32.c'...
    'GenCallback',              'RTW.copyFileToBuildDir');

addAdditionalHeaderFile(op_entry, 'all_additions.h');
addAdditionalIncludePath(op_entry, fullfile(libdir, 'include'));
addAdditionalSourceFile(op_entry, 'all_additions.c');
addAdditionalSourcePath(op_entry, fullfile(libdir, 'src'));
addAdditionalLinkObj(op_entry, fullfile(libdir, 'addition.o'));
addAdditionalLinkObjPath(op_entry, fullfile(libdir, 'bin'));
addEntry(hTable, op_entry);

Next, include your code replacement table in a code replacement library and register the library with the code generator.

Register Code Replacement Mappings

After you define code replacement entries in a code replacement table, you can include the table in a code replacement library that you register with the code generator. When registered, a library appears in the list of available code replacement libraries that you can choose from when configuring the code generator.

Register a code replacement table as a code replacement library:

• Interactively, by using the Code Replacement Tool
• Programmatically, by using a MATLAB programming interface

Choose an Approach for Creating the Registration File

The following table lists situations to help you decide when to use an interactive or programmatic approach to creating a registration file:

<table>
<thead>
<tr>
<th>If...</th>
<th>Then...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Registering a code replacement table for the first time</td>
<td>Use the Code Replacement Tool.</td>
</tr>
<tr>
<td>You used the Code Replacement Tool to create the table</td>
<td>Use the Code Replacement Tool to quickly register the table.</td>
</tr>
<tr>
<td>Rapid prototyping code replacement</td>
<td>Use the Code Replacement Tool to quickly generate, register, and test entries.</td>
</tr>
<tr>
<td>Creating registration file to use as a template or starting point for defining similar registration files</td>
<td>Use the Code Replacement Tool to generate code that you can copy and modify.</td>
</tr>
<tr>
<td>Modifying existing registration files</td>
<td>Use the MATLAB Editor to update the registration file.</td>
</tr>
<tr>
<td>Defining multiple code replacement libraries in one registration file</td>
<td>Use the MATLAB Editor to create a new or extend an existing registration file.</td>
</tr>
<tr>
<td>Defining code replacement library hierarchy in a registration file</td>
<td>Use the MATLAB Editor to create a new or extend an existing registration file.</td>
</tr>
</tbody>
</table>
Create Registration File Interactively with the Code Replacement Tool

The Code Replacement tool provides a quick, easy way for you to create a registration file for a code replacement table. It is ideal for getting started, rapid prototyping, and generating a registration file that you want to use as a starting point for similar registrations.

1. After you validate and save a code replacement table, select **File > Generate registration file** to open the **Generate registration file** dialog box.

![Generate registration file dialog box](image)

2. Enter the registration information. Minimally, specify:

<table>
<thead>
<tr>
<th>For...</th>
<th>Specify...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Registry name</td>
<td>Text naming the code replacement library. For example, Sin Function Example.</td>
</tr>
</tbody>
</table>
## Table List

Text naming one or more code replacement tables to include in the library. Specify each table as one of the following:

- Name of a table file on the MATLAB search path
- Absolute path to a table file
- Path to a table file relative to $(MATLAB_ROOT)$

You can specify multiple tables. If you do, separate the table specifications with a comma. For example:

```
crl_table_sinfcn, c:/work_crl/crl_table_muldiv
```

See “Registration Files That Define Multiple Code Replacement Libraries” on page 65-62 for examples of each type of table specification.

### Optionally, you can specify:

<table>
<thead>
<tr>
<th>For...</th>
<th>Specify...</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Description</strong></td>
<td>Text that describes the purpose and content of the library.</td>
</tr>
<tr>
<td><strong>Target HW device</strong></td>
<td>Text naming one or more hardware devices the code replacement library supports. Separate names with a comma. To support all device types, enter an asterisk (*). For example, TI C28x, TI C62x.</td>
</tr>
<tr>
<td><strong>Base CRL</strong></td>
<td>Text naming a code replacement library that you want to serve as a base library for the library you are registering. Use this field to specify library hierarchies. For example, you can specify a general TI device library as the base library for a more specific TI C28x device library.</td>
</tr>
<tr>
<td><strong>Generate data alignment specification</strong></td>
<td>Flag that enables data alignment specification.</td>
</tr>
</tbody>
</table>
Create Registration File Programmatically

The programming interface for creating a registration file for a code replacement table is ideal for:

- Modifying registration files created with the Code Replacement Tool
- Replicating and modifying similar registration files
- Defining multiple code replacement libraries in one registration file

The basic workflow for creating a registration file programmatically consists of the following steps:

1. Define an `rtwTargetInfo` function. The code generator recognizes this function as a customization file. The function definition must include at least the following content:

   ```matlab
   function rtwTargetInfo(cm)
   cm.registerTargetInfo(@loc_register_crl);
   function this = loc_register_crl
   this(1) = RTW.TflRegistry;
   this(1).Name = 'crl-name';
   this(1).TableList = {'table',...};
   
   For... Replace...
   this(1).Name = 'crl-name';  
crl-name with text naming the code replacement library. For example, Sin Function Example.
   ```
For... | Replace...
--- | ---
```this(1).TableList = {'table',...};```

*table* with text that identifies the code replacement table that contains your code replacement entries. Specify a table as one of the following:

- Name of a table file on the MATLAB search path
- Absolute path to a table file
- Path to a table file relative to `$MATLAB_ROOT$`

You can specify multiple tables. If you do, separate the table specifications with commas.

Optionally, you can specify:

<table>
<thead>
<tr>
<th>For...</th>
<th>Replace...</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>this(1).Description = 'text'</code></td>
<td><em>text</em> with text that describes the purpose and content of the library.</td>
</tr>
<tr>
<td><code>this(1).TargetHWDeviceType = {'device-type',...}</code></td>
<td><em>device-type</em> with text that names a hardware device the code replacement library supports. You can specify multiple device types. Separate device types with a comma. For example, TI C28x, TI C62x. To support all device types, enter an asterisk (*).</td>
</tr>
</tbody>
</table>
For... | Replace...
---|---
this(1).BaseTfl = 'base-lib' | *base-lib* with text that names a code replacement library that you want to serve as a base library for the library you are registering. Use this field to specify library hierarchies. For example, you can specify a general TI device library as the base library for a TI C28x device library.

See “Registration Files That Define Code Replacement Library Hierarchies” on page 65-62 for an example.

For example:

```matlab
function rtwTargetInfo(cm)
    cm.registerTargetInfo(@loc_register_crl);

function this = loc_register_crl

    this(1) = RTW.TflRegistry;
    this(1).Name = 'Sin Function Example';
    this(1).TableList = {'crl_table_sinfcn'};
    this(1).TargetHWDeviceType = {'*'};
    this(1).Description = 'Example - sin function replacement';

Save the file with the name rtwTargetInfo.m.

Place the file on the MATLAB path. When the file is on the MATLAB path, the code generator reads the file after starting and applies the customizations during the current MATLAB session.

## Register a Code Replacement Library

Before you can use the code replacement tables defined in a registration file, you must refresh Simulink customizations within the current MATLAB session. To initiate a refresh, enter the following command:

```matlab
RTW.TargetRegistry.getInstance('reset');
```
Registration Files That Define Multiple Code Replacement Libraries

Use the programming interface to create a registration file that defines a code replacement library that includes multiple code replacement tables. The following example defines a library that includes multiple tables. The TableList fields specify tables that reside at different locations. The tables reside on the MATLAB search path or at locations specified with a path.

```matlab
function rtwTargetInfo(cm)
    cm.registerTargetInfo(@locCrlRegFcn);

    function thisCrl = locCrlRegFcn
        % Register a code replacement library for use with model: rtwdemo_crladdsub
        thisCrl(1) = RTW.TflRegistry;
        thisCrl(1).Name = 'Addition & Subtraction Examples';
        thisCrl(1).Description = 'Example of addition/subtraction op replacement';
        thisCrl(1).TableList = {'crl_table_addsub'};
        thisCrl(1).TargetHWDeviceType = {'*'};

        % Register a code replacement library for use with model: rtwdemo_crlmuldiv
        thisCrl(2) = RTW.TflRegistry;
        thisCrl(2).Name = 'Multiplication & Division Examples';
        thisCrl(2).Description = 'Example of mult/div op repl for built-in integers';
        thisCrl(2).TableList = {'c:/work_crl/crl_table_muldiv'};
        thisCrl(2).TargetHWDeviceType = {'*'};

        % Register a code replacement library for use with model: rtwdemo_crlfixpt
        thisCrl(3) = RTW.TflRegistry;
        thisCrl(3).Name = 'Fixed-Point Examples';
        thisCrl(3).Description = 'Example of fixed-point operator replacement';
        thisCrl(3).TableList = {fullfile('$(MATLAB_ROOT)',...
                             'toolbox','rtw','rtwdemos','crl_demo','crl_table_fixpt')};
        thisCrl(3).TargetHWDeviceType = {'*'};
```

Registration Files That Define Code Replacement Library Hierarchies

Using the programming interface, you can organize multiple code replacement libraries in a hierarchy. The following example shows a registration file that defines four code replacement tables organized in a hierarchy of four code replacement libraries. The tables include entries that increase in specificity: common entries, entries for TI devices, entries for TI C6xx devices, and entries specific to the TI C67x device.

```matlab
function rtwTargetInfo(cm)
```
cm.registerTargetInfo(locCrlRegFcn);

function thisCrl = locCrlRegFcn

% Register a code replacement library that includes common entries
thisCrl(1) = RTW.TflRegistry;
thisCrl(1).Name = 'Common Replacements';
thisCrl(1).Description = 'Common code replacement entries shared by other libraries';
thisCrl(1).TableList = {'crl_table_general'};
thisCrl(1).TargetHWDeviceType = {'*'};

% Register a code replacement library for TI devices
thisCrl(2) = RTW.TflRegistry;
thisCrl(2).Name = 'TI Device Replacements';
thisCrl(2).Description = 'Code replacement entries shared across TI devices';
thisCrl(2).TableList = {'crl_table_TI_devices'};
thisCrl(2).TargetHWDeviceType = {'TI C28x', 'TI C55x', 'TI C62x', 'TI C64x', 'TI 67x'};
thisCrl(1).BaseTfl = 'Common Replacements'

% Register a code replacement library for TI c6xx devices
thisCrl(3) = RTW.TflRegistry;
thisCrl(3).Name = 'TI c6xx Device Replacements';
thisCrl(3).Description = 'Code replacement entries shared across TI C6xx devices';
thisCrl(3).TableList = {'crl_table_TIC6xx_devices'};
thisCrl(3).TargetHWDeviceType = {'TI C62x', 'TI C64x', 'TI 67x'};

% Register a code replacement library for the TI c67x device
thisCrl(3) = RTW.TflRegistry;
thisCrl(3).Name = 'TI c67x Device Replacements';
thisCrl(3).Description = 'Code replacement entries for the TI C67x device';
thisCrl(3).TableList = {'crl_table_TIC67x_device'};
thisCrl(3).TargetHWDeviceType = {'TI 67x'};

After registering your code replacement mappings, verify that code replacements occur.

- “Code You Can Replace from MATLAB Code” on page 65-5
Troubleshoot Code Replacement Library Registration

If a code replacement library is not listed as a configuration option or does not appear in the Code Replacement Viewer:

- Refresh the library registration information within the current MATLAB session (RTW.TargetRegistry.getInstance('reset'); or for the Simulink environment, sl_refresh_customizations).
- See whether the registration file, rtwTargetInfo.m, contains an error.

See Also

More About
- “Register Code Replacement Mappings” on page 65-56
Verify Code Replacements

After you create or modify a code replacement table, use the following techniques to examine and validate the table and its entries.

- Invoke the table definition file at the command prompt.
- Use the Code Replacement Viewer to examine libraries, tables, and entries.
- Trace code replacements from the source where you applied the code replacement library.
- Examine code replacement hits and misses logged during code generation.

Code Replacement Hits and Misses

The code generator logs code replacement table entries for which it finds and does not find matches in the hit cache and miss cache, respectively. When a code replacement entry match fails and code is not replaced, the code generator logs the call site object (CSO) for the miss in the miss cache. When an entry match succeeds, the code generator logs the matched entry in the hit cache.

The code generator overwrites the hit and miss cache data each time it produces code. The cache data reflects hits and misses for only the last application component (MATLAB code or Simulink model) for which you generate code.

You can use the Code Replacement Viewer to review trace information based on logged hit and miss trace data. The hit cache provides trace information that helps to verify code replacements.

The miss cache and related miss data collected and stored in code replacement tables provide trace information for misses. Use this information for misses to troubleshoot expected code replacements that do not occur. Trace information for a miss:

- Identifies the call site object.
- Provides a link to the relevant source location for the miss.
- Includes information about the reason for the miss.
**Validate a Table Definition File**

After you create or modify a code replacement table definition file, validate it. At the command prompt, specify the name of the table in a call to the `isvalid` function. For example:

```matlab
isvalid(crl_table_sinfcn)
ans =
    1
```

MATLAB displays errors that occur. In the following example, MATLAB detects a typo in a data type name.

```matlab
isvalid(crl_table_sinfcn)
??? RTW_CORE:tfl:TflTable: Unsupported data type, 'dooble'.
Error in ==> crl_table_sinfcn at 7
hTable.registerCFunctionEntry(100, 1, 'sin', 'dooble', 'sin_dbl', ...
```

**Review Library Content**

After you create or modify a code replacement library, use the **Code Replacement Viewer** to review and verify the list of tables in the library and the entries in each table.

1. Open the viewer to display the contents of your library. At the command prompt, enter the following command:

```matlab
crviewer('library')
```

For example:

```matlab
crviewer('Addition & Subtraction Examples')
```
2 Review the list of tables in the left pane. Are tables missing? Are the tables listed in the correct relative order? By default, the viewer displays tables in search order.

3 In the left pane, click each table and review the list of entries in the center pane. Are entries missing? Does the list include extraneous or unexpected entries?
Review Table Content

After you create or modify a code replacement table, use the Code Replacement Viewer to review and verify table entries.

1. Open the viewer to display the contents of your table. At the command prompt, enter the following command. `table` is a MATLAB file that defines code replacement tables. The file must be in the current folder or on the MATLAB path.

   ```matlab
crviewer(table)
```

   For example:

   ```matlab
crviewer(crl_table_addsub)
```
2 Review the list of entries in the center pane. Are entries missing? Does the list include extraneous or unexpected entries? By default, the viewer displays entries in search order.

3 In the center pane, click each entry and verify the entry information in the right pane.
• Argument order is correct.
• Conceptual argument names match code generator naming conventions.
• Implementation argument names are correct.
• Algorithm properties (for example, saturation and rounding mode) are set correctly.
• Header or source file specification is not missing.
• I/O types are correct.
• Relative priority of entries is correct.

**Review Code Replacements**

After you review the content of your code replacement library and tables, generate code and a code generation report. Verify that the code generator replaces code as you expect.

The Code Replacements Report details the code replacement library functions that the code generator uses for code replacements. The report provides a mapping between each replacement instance and the line of MATLAB code that triggered the replacement. The Code Replacements report is not available for generated MEX functions.

The following example illustrates two complementary approaches for reviewing code replacements:

- Check the Code Replacements Report section of the code generation report for expected replacements.
- Trace code replacements.

1. Identify the MATLAB function where you anticipate that a function or operator replacement occurs. This example uses the function `matlabroot/toolbox/rtw/rtwdemos/crl_demo/addsub_two_int16.m`.

   ```matlab
   function [y1, y2] = addsub_two_int16(u1, u2)
   
   y1 = int16(u1 + u2);
   y2 = int16(u1 - u2);
   ```

2. Identify or create code or a script to exercise the function. For example, consider test file `addsub_to_int16_test.m`, which includes the following code:

   ```matlab
   disp('Input')
   u1 = int16(10)
   u2 = int16(10)
   
   [y1, y2] = addsub_two_int16(u1, u2);
   ```
disp('Output')
disp('y1 =')
disp(y1);
disp('y2 =')
disp(y2);

3 Open the MATLAB Coder app.

4 On the Select Source Files page, add your function to the project. For this example, add function addsub_two_int16. Click Next.

5 On the Define Input Types page, use the test file addsub_to_int16_test to automatically define the input types. Click Next.

6 On the Check for Run-Time Issues page, specify the test file addsub_to_int16_test. The app runs the test file, replacing calls to addsub_to_int16_test with calls to a MEX version of addsub_to_int16_test. Click Next.

7 To open the Generate dialog box, on the Generate Code page, click the Generate arrow ▼.

8 Set Build type to generate source code. Before you build an executable, you want to review your code replacements in the generated code.

9 In the Generate dialog box, click More Settings.

10 Configure the code generator to use your code replacement library. On the Custom Code tab, set the Code replacement library parameter to the name of your library. For this example, set the library to Addition & Subtraction Examples.

11 Configure the code generation report to include the Code Replacements Report. On the Debugging tab, select:

- Always create a code generation report
- Code replacements
- Automatically launch a report if one is generated

12 To generate code and a report, set Build type to Source Code. Then, click Generate.

13 Open the Code Replacements Report section of the code generation report.

That report lists the replacement functions that the code generator used. The report provides a mapping between each replacement instance and the MATLAB code that triggered the replacement.
Review the report:

- Check whether expected function and operator code replacements occurred.
- In the replacements sections, click each code link to see the source that triggered the reported code replacement.

If a function or operator is not replaced as expected, the code generator used a higher-priority (lower-priority value) match or did not find a match.

To analyze and troubleshoot code replacement misses, use the trace information that the Code Replacement Viewer provides. See “Troubleshoot Code Replacement Misses” on page 65-74.

Troubleshoot Code Replacement Misses

Use miss reason messages that appear in the Code Replacement Viewer to analyze and correct code replacement misses.

Miss Reason Messages

The Code Replacement Viewer displays miss reason messages in trace information for code replacement misses. A legend listing each message that appears in the miss report precedes the report details. A message consists of:

- Numeric identifier, which identifies the message in the report details.
- Message text, which in some cases includes placeholders for names of arguments, call site object values, table entry values, and property names.

For example:

1. Mismatched data types (argument name, CSO value, table entry value)

The parenthetical information represents placeholders for actual values that appear in the report details.

In the Miss Source Locations table that lists the miss details, the Reason column includes:

- The message identifier, as listed in the legend.
- The placeholder values for that instance of the miss reason message.

The following Reason details indicate a data type mismatch because the call site object specifies data type int8 for arguments y1, u1, and u2, while the code replacement table entry specifies uint32.

1. y1, int8, uint32
   u1, int8, uint32
   u2, int8, uint32

Depending on your situation and the reported miss reason, troubleshoot reported misses by looking for instances of the following:

- A typo in the code replacement table entry definition or a source parameter setting.
• Information missing from the code replacement table entry or a source parameter setting.
• Invalid or incorrect information in the code replacement table entry definition or a source parameter setting.
• Arguments incorrectly ordered in the code replacement table entry definition or the source being replaced with replacement code.
• Failed algorithm classification for an addition or subtraction operation due to:
  • An ideal accumulator not being calculated because the type of an input argument is not fixed-point or the slope adjustment factors of the input arguments are not equal.
  • Input or output casts with a floating-point cast type.
  • Input or output casts with cast types that have different slope adjustment factors or biases.
  • Output casts not being convertible to a single output cast.
  • Input casts resulting in loss of bits.

**Analyze and Correct Code Replacement Misses**

The following example shows how to use Code Replacement Viewer trace information to troubleshoot code replacement misses. You must have already reviewed and tested code replacements for your MATLAB code.

1. Review the code generated for a specific code element, looking for expected code replacement. Regenerate or reopen the code generation report for your MATLAB code. If you already generated the code generation report that includes the Code Replacements Report for `matlabroot/toolbox/rtw/rtwdemos/crl_demo/addsub_two_int16.m`, open the file `codegen/lib/addsub_two_int16/html/mldatx.html`. For information on how to regenerate the report, see “Verify Code Replacements” on page 65-65.

To examine the code generated for the function, from the code generation report, open the generated file `addsub_two_int16.h`.

```c
extern void addsub_two_int16(double u1, double u2, short *b_y1, short *y2);
```

The code generator replaced code, but the replacement is for the signed version of the 16-bit addition and subtraction operations. You expected code replacements for operations on unsigned data.
2 Open the Code Replacements Report for the MATLAB code.
3 Click the link to open the Code Replacement Viewer.
4 In the viewer left pane, select your code replacement table. For this example, select code replacement table crl_table_addsub.
5 In the middle pane, select table entry RTW_OP_ADD with implementation function u16_add_u16_u16.
6 In the right pane, select the **Trace Information** tab.

The **Trace Information** is a table that lists the following information for each miss:

- Call site object preview. The call site object is the conceptual representation of addition operator. The code generator uses this object to query the code replacement library for a match.
- A link to the source location in the MATLAB function where the code generator considered replacing code.
- The reasons that the miss occurred. See “Miss Reason Messages” on page 65-74.

For this example, the report shows misses for function addsub_two_int16.m.

7 Find the source in the trace information. Depending on your situation and the reported miss reason, consider looking for a condition such as a typo in the code replacement table entry definition or a source parameter setting. For a list of conditions to consider, see “Miss Reason Messages” on page 65-74.

For this example, determine why code for function addsub_two_int16 is not replaced with code for an unsigned 16-bit addition operation. The miss reasons for the function indicate data type and algorithm mismatches:

- The data type in the call site object is a signed 16-bit integer. The code replacement entry specifies an unsigned 16-bit integer.
- The algorithm property in the call site object is RTW_CAST_AFTER_OP while the code replacement entry specifies RTW_CAST_BEFORE_OP.

8 Fix the specified MATLAB code and relevant specifications or code replacement table entry. If the issue concerns the MATLAB code, use the source location in the trace information to find the code to fix. For this example, you expected an unsigned addition operation to occur for the addsub_two_int16 function.

To fix the mismatches, in the test file addsub_to_int16_test, change the data types definitions for u1 and u2 as follows:
u1 = uint16(10)
u2 = uint16(10)

In the MATLAB Coder app:

• Open the project that contains the addsub_to_int16 function.
• Use the updated test file addsub_to_int16_test to automatically redefine the input types.
• Change the addition and subtraction algorithm setting. Open the code replacement library crl_table_addsub. Change the entry Algorithm parameter setting from Cast before operation (RTW_CAST_BEFORE_OP) to Cast after operation (RTW_CAST_AFTER_OP).
• Regenerate code and a report.
9 From the Code Replacements Report, open the Code Replacement Viewer. Use the Code Replacement Viewer trace information to verify that your MATLAB code or code replacement table entry corrects the code replacement issue. The trace information shows a hit for function addsub_two_int16.

Deploy Code Replacement Library

After you verify code replacements and are ready to package and deploy a code replacement library for others to use:

1. Move your code replacement table files to an area that is on the MATLAB search path and that is accessible to and shared by other users.

2. Move the `rtwTargetInfo.m` registration file, to an area that is on the MATLAB search path and that is accessible to and shared by other users. If you are deploying a library to a folder in a development environment that already contains a `rtwTargetInfo.m` file, copy the registration code from your code replacement library version of `rtwTargetInfo.m` and paste it into the shared version of that file.

3. Register the library customizations or restart MATLAB.

4. Verify that the libraries are available for configuring the code generator and that code replacements occur as expected.

5. Inform users that the libraries are available and provide direction on when and how to apply them.

Math Function Code Replacement

This example shows how to define a code replacement mapping for a math function. The example defines a mapping for the \texttt{sin} function programmatically. Alternatively, you can use the \textbf{Code Replacement Tool} to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   
   ```
   function hTable = crl_table_sinfcn2()
   %CRL_TABLE_SINFCN2 - Define function entry for code replacement table.
   ```

2. Within the function body, create the table by calling the function \texttt{RTW.TflTable}.

   ```
   hTable = RTW.TflTable;
   ```

3. Create an entry for the function mapping with a call to the \texttt{RTW.TflCFunctionEntry} function.

   ```
   % Create entry for sin function replacement
   fcn_entry = RTW.TflCFunctionEntry;
   ```

4. Set function entry parameters with a call to the \texttt{setTflCFunctionEntryParameters} function.

   ```
   setTflCFunctionEntryParameters(fcn_entry,
       'Key', 'sin', ...
       'Priority', 30, ...
       'ImplementationName', 'mySin', ...
       'ImplementationHeaderFile', 'basicMath.h', ...
       'ImplementationSourceFile', 'basicMath.c');
   ```

5. Create conceptual arguments \texttt{y1} and \texttt{u1}. There are multiple ways to set up the conceptual arguments. This example uses calls to the \texttt{createAndAddConceptualArg} function to create and add an argument with one function call.

   ```
   createAndAddConceptualArg(fcn_entry,
       'RTW.TflArgNumeric', ...,
       'Name', 'y1', ...
       'IOType', 'RTW_IO_OUTPUT', ...
       'DataTypeMode', 'double');
   ```

   ```
   createAndAddConceptualArg(fcn_entry,
       'RTW.TflArgNumeric', ...,
       'Name', 'u1', ...
       'IOType', 'RTW_IO_INPUT', ...
       'DataTypeMode', 'double');
   ```

6. Copy the conceptual arguments to the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses a call to the \texttt{copyConceptualArgsToImplementation} function to create and add implementation arguments to the entry by copying matching conceptual arguments.
7 Add the entry to a code replacement table with a call to the addEntry function.

    addEntry(hTable, fcn_entry);

8 Save the table definition file. Use the name of the table definition function to name the file.

Memory Function Code Replacement

This example shows how to define a code replacement mapping for a memory function. The example defines a mapping for the `memcpy` function programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```matlab
   function hTable = crl_table_memcpy()
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```matlab
   hTable = RTW.TflTable;
   ```

3. Create an entry for the function mapping with a call to the `RTW.TflCFunctionEntry` function.

   ```matlab
   % Create entry for void* memcpy(void*, void*, size_t)
   fcn_entry = RTW.TflCFunctionEntry;
   ```

4. Set function entry parameters with a call to the `setTflCFunctionEntryParameters` function.

   ```matlab
   % Set SideEffects to 'true' for function returning void to prevent it from
   % being optimized away.
   setTflCFunctionEntryParameters(fcn_entry, ...
   'Key',                      'memcpy', ...
   'Priority',                 90, ...
   'ImplementationName',       'memcpy_int', ...
   'ImplementationHeaderFile', 'memcpy_int.h',...
   'SideEffects',              true);
   ```

5. Create conceptual arguments `y1`, `u1`, `u2`, and `u3`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create and add the arguments.

   ```matlab
   arg = getTflArgFromString(hTable, 'y1', 'void*');
   arg.IOType = 'RTW_IO_OUTPUT';
   addConceptualArg(fcn_entry, arg);
   arg = getTflArgFromString(hTable, 'u1', 'void*');
   addConceptualArg(fcn_entry, arg);
   arg = getTflArgFromString(hTable, 'u2', 'void*');
   addConceptualArg(fcn_entry, arg);
   arg = getTflArgFromString(hTable, 'u3', 'size_t');
   addConceptualArg(fcn_entry, arg);
   ```

6. Copy the conceptual arguments to the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses a call to the
copyConceptualArgsToImplementation function to create and add implementation arguments to the entry by copying matching conceptual arguments.

copyConceptualArgsToImplementation(fcn_entry);

7 Add the entry to a code replacement table with a call to the `addEntry` function.

    addEntry(hTable, fcn_entry);

8 Save the table definition file. Use the name of the table definition function to name the file.

Specify In-Place Code Replacement

In-place code replacement is an optimization technique that uses a single buffer, that is, the same memory, to store function input and output data, as in \( x = \text{foo}(x) \).

When you generate C or C++ code from MATLAB code, the code generator supports in-place function argument code replacement. When you interactively create a code replacement table entry with the Code Replacement Tool, you can specify in-place function argument replacement. You can also specify in-place function argument replacement programmatically with the Code Replacement Library API.

**Argument Specification Requirements**

- The argument must be a pointer.
- An argument can be in-place with only one other argument.
- Specify an input argument as in-place (shares memory) with an output argument or an output argument as in-place with an input argument.

**Interactive Argument Replacement Specification with Code Replacement Tool**

This example shows how to specify in-place function argument replacement when replacing code for a MATLAB function with the Code Replacement Tool. The tool enforces in-place argument specification requirements as you add arguments and modify argument properties.

1. Create the following MATLAB function, `customFunction.m`.
   ```matlab
   function x = customFunction(x)
   % Function that updates the input and returns it as an output
   coder.replace('-errorifnoreplacement');
   x = sin(x);
   
   2. In the Code Replacement Tool, add a new table, select that table, and add a new function entry. For more information, see “Define Code Replacement Mappings” on page 65-29.

   3. On the Mapping Information tab, select Custom for the Function parameter.

   4. In the function-name text box, name the custom function. For this example, type the name `customFunction`.
5 Under the **Conceptual arguments** list box, click + to add two arguments. By default, the tool creates an output argument $y1$ and an input argument $u1$, both of type double.

6 In the **Replacement function > Function prototype** section, type the name custom_function_inplace_impl in the **Name** text box.

7 Under the **Function arguments** list box, click + to add two function implementation arguments. By default, the tool creates an output argument $y1$ and an input argument $u1$, both of type double.

8 For each input argument that you want to specify as in-place with a corresponding output argument, in the **Argument properties** box, select the **Pointer** check box. The **Argument properties** section of the dialog box expands to include an **In-place argument** drop-down list. For this example, in the **Function arguments** list, select input argument $u1$, and then select the **Pointer** check box.

9 From the **In-place argument** list, select $y1$, the output argument for the code replacement mapping. The **Function arguments** list box is updated to show possible in-place argument mappings.
10 Select and delete one of the two possible argument mappings. For this example, delete the mapping \( y_1 \leftarrow u_1 \).

11 In the **Function signature preview** box, if the function signature appears as expected, click **Apply**. Otherwise, make adjustments, and then click **Apply**. The function signature for this example, appears as

\[
\text{void custom_function_inplace_impl(double* u1);}\]

12 Click **Validate entry**.

13 Save the code replacement table in the same folder as `customFunction.m`. Name the file `htfl_inplace_table.m`.

To test the example:

1 Register the table that contains the entry in a code replacement library.
2 Configure the code generator to use a code replacement library and to include the Code Replacements Report in the code generation report.
3 Generate the replacement code and a code generation report.
4 Review the code replacements.
Programmatic Argument Replacement Specification

This example shows how to specify in-place function argument replacement when replacing code for a MATLAB function programmatically. For the input implementation argument that shares the memory buffer, the example:

- Sets the name of the implementation argument to the same name as the corresponding conceptual argument.
- Associates the corresponding implementation argument with the argument property ArgumentForInPlaceUse.

1. Create the following MATLAB function, `customFunction.m`.
   ```matlab
   function y = customFunction(x)
   % Function that updates the input and returns it as an output
   coder.replace('-errorifnoreplacement');
   x = sin(x);
   ```

2. Create a table definition file that contains a function definition. For example:
   ```matlab
   function hTable = crl_table_inplace()
   ```

3. Within the function body, create the table by calling the function `RTW.TflTable`.
   ```matlab
   hTable = RTW.TflTable;
   ```

4. Create an entry for the function mapping with a call to the `RTW.TflCFunctionEntry` function.
   ```matlab
   hEnt = RTW.TflCFunctionEntry;
   ```

5. Set function entry parameters with a call to the `setTflCFunctionEntryParameters` function.
   ```matlab
   setTflCFunctionEntryParameters(hEnt, ...
       'Key', 'customFunction', ...
       'Priority', 100, ...
       'ImplementationName', 'custom_function_inplace_impl', ...
       'SideEffects', true);
   ```

6. Create conceptual arguments `y1` and `u1`. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create and add the arguments.
   ```matlab
   arg = getTflArgFromString(hEnt, 'y1','double');
   arg.IOType = 'RTW_IO_OUTPUT';
   addConceptualArg(hEnt, arg);
   ```
arg = getTflArgFromString(hEnt, 'u1','double');
addConceptualArg(hEnt, arg);

7 Create the implementation arguments and add them to the entry. This example uses calls to the getTflArgFromString function to create implementation arguments that map to arguments in the replacement function prototype: output argument y1 and input argument u1. For each argument, the example uses the convenience method setReturn or addArgument to specify whether an argument is a return value or argument. For each argument, this example adds the argument to the entry array of implementation arguments.

arg = getTflArgFromString(hEnt, 'y2','void');
arg.IOType = 'RTW IO_OUTPUT';
hEnt.Implementation.setReturn(arg);

arg = getTflArgFromString(hEnt, 'u1','double*');
arg.ArgumentForInPlaceUse = 'y1';
hEnt.Implementation.addArgument(arg);

8 Add the entry to a code replacement table with a call to the addEntry function.

addEntry(hLib, hEnt);

9 Save the table definition file. Use the name of the table definition function to name the file.

To test the example:

1 Register the table that contains the entry in a code replacement library.
2 Configure the code generator to use a code replacement library and to include the Code Replacements Report in the code generation report.
3 Generate the replacement code and a code generation report.
4 Review the code replacements.

Data Alignment for Code Replacement

Code replacement libraries can align data objects passed into a replacement function to a specified boundary.

Code Replacement Data Alignment

You can take advantage of function implementations that require aligned data to optimize application performance when using MATLAB Coder. To configure data alignment for a function implementation:

1. Specify the data alignment requirements in a code replacement entry. Specify alignment separately for each implementation function argument or collectively for all function arguments. See “Specify Data Alignment Requirements for Function Arguments” on page 64-136.

2. Specify the data alignment capabilities and syntax for one or more compilers. Include the alignment specifications in a library registration entry in the rtwTargetInfo.m file. See “Provide Data Alignment Specifications for Compilers” on page 64-138.

3. Register the library containing the table entry and alignment specification object.

4. Configure the code generator to use the code replacement library and generate code. Observe the results.

For examples, see “Basic Example of Code Replacement Data Alignment” on page 64-143 and the “Data Alignment for Function Implementations” section of the “Optimize Generated Code By Developing and Using Code Replacement Libraries - Simulink®” example page.

Note If replacement that requires alignment uses imported data (for example, I/O of an entry-point function or exported function), specify the data alignment with coder.dataAlignment statements in the MATLAB code. Specify alignment separately for each instance of imported data. See “Specify Data Alignment in MATLAB Code for Imported Data” on page 65-95.

Specify Data Alignment Requirements for Function Arguments

To specify the data alignment requirement for an argument in a code replacement entry:
• If you are defining a replacement function in a code replacement table registration file, create an argument descriptor object (RTW.ArgumentDescriptor). Use its AlignmentBoundary property to specify the required alignment boundary and assign the object to the argument Descriptor property.

• If you are defining a replacement function using the Code Replacement Tool, on the Mapping Information tab, in the Argument properties section for the replacement function, enter a value for the Alignment value parameter.

The AlignmentBoundary property (or Alignment value parameter) specifies the alignment boundary for data passed to a function argument, in number of bytes. The AlignmentBoundary property is valid only for addressable objects, including matrix and pointer arguments. It is not applicable for value arguments. Valid values are:

- -1 (default) — If the data is a Simulink.Bus, Simulink.Signal, or Simulink.Parameter object, specifies that the code generator determines an optimal alignment based on usage. Otherwise, specifies that there is not an alignment requirement for this argument.

- Positive integer that is a power of 2, not exceeding 128 — Specifies number of bytes in the boundary. The starting memory address for the data allocated for the function argument is a multiple of the specified value. If you specify an alignment boundary that is less than the natural alignment of the argument data type, the alignment directive is emitted in the generated code. However, the target compiler ignores the directive.

The following code specifies the AlignmentBoundary for an argument as 16 bytes.
hLib = RTW.TflTable;
entry = RTW.TflCOperationEntry;
arg = getTflArgFromString(hLib, 'u1','single*');
desc = RTW.ArgumentDescriptor;
desc.AlignmentBoundary = 16;
arg.Descriptor = desc;
entry.Implementation.addArgument(arg);

The equivalent alignment boundary specification in the Code Replacement Tool dialog box is in this figure.

![Argument properties]

**Note** If your model imports Simulink.Bus, Simulink.Parameter, or Simulink.Signal objects, specify an alignment boundary in the object properties, using the **Alignment** property. For more information, see Simulink.Bus, Simulink.Parameter, and Simulink.Signal.

**Provide Data Alignment Specifications for Compilers**

To support data alignment in generated code, describe the data alignment capabilities and syntax for your compilers in the code replacement library registration. Provide one or more alignment specifications for each compiler in a library registry entry.

To describe the data alignment capabilities and syntax for a compiler:

- If you are defining a code replacement library registration entry in a `rtwTargetInfo.m` customization file, add one or more `AlignmentSpecification` objects to an `RTW.DataAlignment` object. Attach the `RTW.DataAlignment` object to the `TargetCharacteristics` object of the registry entry.

  The `RTW.DataAlignment` object also has the property `DefaultMallocAlignment`, which specifies the default alignment boundary, in bytes, that the compiler uses for dynamically allocated memory. If the code generator uses dynamic memory allocation...
for a data object involved in a code replacement, this value determines if the memory satisfies the alignment requirement of the replacement. If not, the code generator does not use the replacement. The default value for DefaultMallocAlignment is -1, indicating that the default alignment boundary used for dynamically allocated memory is unknown. In this case, the code generator uses the natural alignment of the data type to determine whether to allow a replacement.

Additionally, you can specify the alignment boundary for complex types by using the addComplexTypeAlignment function.

- If you are generating a customization file function using the Code Replacement Tool, fill out the following fields for each compiler.

Click the plus (+) symbol to add additional compiler specifications.

For each data alignment specification, provide the following information.
<table>
<thead>
<tr>
<th>Alignment-Specification Property</th>
<th>Dialog Box Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>AlignmentType</strong></td>
<td><strong>Alignment type</strong></td>
<td>Cell array of predefined enumerated strings, specifying which types of alignment this specification supports.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• DATA_ALIGNMENT_LOCAL_VAR — Local variables.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• DATA_ALIGNMENT_GLOBAL_VAR — Global variables.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• DATA_ALIGNMENT_STRUCT_FIELD — Individual structure fields.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• DATA_ALIGNMENT_WHOLE_STRUCT — Whole structure, with padding (individual structure field alignment, if specified, is favored and takes precedence over whole structure alignment).</td>
</tr>
</tbody>
</table>

Each alignment specification must specify at least DATA_ALIGNMENT_GLOBAL_VAR and DATA_ALIGNMENT_STRUCT_FIELD.
<table>
<thead>
<tr>
<th>Alignment-Specification Property</th>
<th>Dialog Box Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| AlignmentPosition                | Alignment position   | Predefined enumerated string specifying the position in which you must place the compiler alignment directive for alignment type `DATA_ALIGNMENT_WHOLE_STRUCT`:

- **DATA_ALIGNMENT_PREDIRECTIVE** — The alignment directive is emitted before `struct st_tag{...}`, as part of the type definition statement (for example, MSVC).
- **DATA_ALIGNMENT_POSTDIRECTIVE** — The alignment directive is emitted after `struct st_tag{...}`, as part of the type definition statement (for example, gcc).
- **DATA_ALIGNMENT_PRECEDING_STATEMENT** — The alignment directive is emitted as a standalone statement immediately preceding the definition of the structure type. A semicolon (;) must terminate the registered alignment syntax.
- **DATA_ALIGNMENT_FOLLOWING_STATEMENT** — The alignment directive is emitted as a standalone statement immediately following the definition of the structure type. A semicolon (;) must terminate the registered alignment syntax.

For alignment types other than `DATA_ALIGNMENT_WHOLE_STRUCT`, code generation uses alignment position `DATA_ALIGNMENT_PREDIRECTIVE`. |
<table>

</tr>
</tbody>
</table>

SupportedLanguages | Supported languages | Cell array specifying the languages to which this alignment specification applies, among c and c++. Sometimes alignment syntax and position differ between languages for a compiler. |

Here is a data alignment specification for the GCC compiler:

```matlab
da = RTW.DataAlignment;
as = RTW.AlignmentSpecification;
as.AlignmentType = {'DATA_ALIGNMENT_LOCAL_VAR', ...
  'DATA_ALIGNMENT_STRUCT_FIELD', ...
  'DATA_ALIGNMENT_GLOBAL_VAR'};
as.AlignmentSyntaxTemplate = '__attribute__((aligned(%n)))';
as.AlignmentPosition = 'DATA_ALIGNMENT_PREDIRECTIVE';
as.SupportedLanguages = {'c', 'c++'};
da.addAlignmentSpecification(as);
tc = RTW.TargetCharacteristics;
tc.DataAlignment = da;
```

Here is the corresponding specification in the **Generate customization** dialog box of the Code Replacement Tool.
Specify Data Alignment in MATLAB Code for Imported Data

If MATLAB Coder code replacements that require data alignment use imported data, such as an entry-point or exported function I/O, specify data alignment to external code with `coder.dataAlignment` statements in the MATLAB code.

If MATLAB Coder code replacements occur that require data alignment (uses imported data), such as an entry-point or exported function with I/O, specify code replacement data alignment with `coder.DataAlignment` statements in the MATLAB code.

To specify the data alignment requirements for imported data in a MATLAB code:

- For each instance of imported data that requires data alignment, specify the alignment in the function with a `coder.dataAlignment` statement of the form:

  ```matlab
coder.dataAlignment('varName', align_value)
  ``

- The `varName` is a character array of the variable name that requires alignment information specification. The `align_value` is an integer number which should be a power of 2, from 2 through 128. This number specifies the power-of-2 byte alignment boundary.

- An example function that specifies data alignment is:

  ```matlab
  function y = testFunction(x1,x2)
  coder.dataAlignment('x1',16); % Specifies information
  ```
coder.dataAlignment('x2',16);    % Specifies information
coder.dataAlignment('y',16);     % Specifies information

y = x1 + x2;

end

If `testFunction` is an entry-point or exported function, imported data `x1`, `x2`, and `y` are not aligned automatically by the code generator. The `coder.DataAlignment` statements for these variables are only meant as information for the code generator. The call sites allocating memory for the data need to ensure that the data is aligned as specified.

You also can specify code replacement data alignment for exported data, such as a global variable or an `ExportedGlobal` custom storage class. For more information, see “Built-In Storage Classes You Can Choose” on page 31-86 and “Choose Storage Class for Controlling Data Representation in Generated Code” on page 31-69.

### Replacing Math Functions and Operators with Implementations that require Data Alignment - MATLAB®

This example shows how to develop and use code replacement library entries for target-specific function implementations that require data to be aligned to optimize application performance. To configure data alignment for a function implementation:

- Specify the data alignment requirements in a table entry. You can specify alignment for implementation function arguments individually or collectively.
- Specify the data alignment capabilities and syntax for your compiler. Attach an `AlignmentSpecification` object to the `TargetCharacteristics` object of the registry entry specified in your `rtwTargetInfo.m` file.

If externally allocated data (e.g. entry-point function arguments) are used in an operation that can be replaced with an implementation that requires alignment, use the `coder.dataAlignment` directive to specify alignment so that replacement occurs.

This example is configured to use the GCC, Clang, or MSVC compiler.

### Create a New Folder and Copy Relevant Files

The following code creates a folder in your current working folder (pwd). The new folder will contain the files that are relevant for this example. If you do not want to affect the
current folder (or if you cannot generate files in this folder), you should change your working folder.

**Run Command: Create a New Folder and Copy Relevant Files**

coderdemo_setup('coderdemo_crlalign');
cleanupObj = {};
mlpath = addpath(fullfile(...
    matlabroot,'toolbox','coder','codegendemos','coderdemo_crlalign'));
cleanupObj{end+1} = onCleanup(@()path(mlpath));

**Check selected compiler**

This example is configured to use either GCC, Clang, or MSVC to compile the generated code.

cc = rtwprivate('getMexCompilerInfo');
isDaDemoSupported = strcmpi(cc.comp.Manufacturer,'GNU') || ...
    strcmpi(cc.comp.Manufacturer,'Apple') || ...
    strcmpi(cc.comp.Manufacturer,'Microsoft');
if ~isDaDemoSupported
    recMsg = ['Use "mex -setup" to select either GCC, Clang,'...
        ' or MSVC and restart this example'];
    warning(['Example %s is configured to use either GCC, Clang,'...
        ' or MSVC to compile the generated code. %s.'], mfilename,recMsg);
end

**Set MATLAB Coder options**

Set up the configuration object and define the function input types.

cfg = coder.config('lib','ecoder',true);
cfg.GenerateReport = false;
cfg.LaunchReport = false;
cfg.VerificationMode = 'SIL';
cfg.CodeExecutionProfiling = true;

len = 400000;
args = {coder.typeof(single(0),[len,1]), ...
    coder.typeof(single(0))};
global g1;
g1 = single(zeros([len,1]));

**Generate code using the SIMD Examples Code Replacement Library**

To see the code replacement table definition file, look here.
RTW.TargetRegistry.getInstance('reset');

mcode_da16 = 'biased_sum_of_square_differences_da16';
cfg.CodeReplacementLibrary = 'SIMD Examples';
codegen('-config',cfg, mcode_da16,'-args',args,'-global',{'g1',g1});

Inspect the MATLAB Coder Generated Code

After compiling, explore the generated source code.

Performance Gain from Data Alignment

Compare performance of normal ANSI code against the earlier generated code that used SIMD intrinsics.

% Generate ansi code
mcode_noda = 'biased_sum_of_square_differences';
cfg.CodeReplacementLibrary = 'None';
codegen('-config',cfg, mcode_noda,'-args',args,'-global',{'g1',g1});

% Run SIMD executable and collect execution profile information
coder.runTest('run_biased_ssd_da16',[mcode_da16,'_sil.',mexext])
pause(120);
clear([mcode_da16,'_sil']); % stop simulation
executionProfile_simd = getCoderExecutionProfile(mcode_da16);
idx_section = find(strcmp(mcode_da16,{executionProfile_simd.Sections.Name}),1);
avg_selftime_simd = executionProfile_simd.Sections(idx_section)...
    .TotalSelfTimeInTicks/executionProfile_simd.Sections(idx_section).NumCalls;

% Run ANSI executable and collect execution profile information
coder.runTest('run_biased_ssd',[mcode_noda,'_sil.',mexext])
pause(120);
clear([mcode_noda,'_sil']); % stop simulation
executionProfile_ansi = getCoderExecutionProfile(mcode_noda);
idx_section = find(strcmp(mcode_noda,{executionProfile_ansi.Sections.Name}),1);
avg_selftime_ansi = executionProfile_ansi.Sections(idx_section)...
    .TotalSelfTimeInTicks/executionProfile_ansi.Sections(idx_section).NumCalls;

% Compare execution profile results
barObj = bar([avg_selftime_ansi; ...
    avg_selftime_simd]);
axesObj = barObj.Parent;
figObj = axesObj.Parent;
axesObj.XTickLabel = {'ANSI SSD', 'SIMD SSD'};
axesObj.YLabel.String = 'Average Execution Time (Timer Ticks)';
axesObj.YLim = [min([0, avg_selftime_ansi, avg_selftime_simd]), ...
    max(avg_selftime_ansi, avg_selftime_simd)*1.3];

percent_perf_gain = ...
    100 * (avg_selftime_ansi-avg_selftime_simd)/avg_selftime_ansi;
annotation(figObj, 'textbox', axesObj.Position, ...
    'String',sprintf(...
    'Execution speed increased by %d%% on average',percent_perf_gain), ...
    'FontWeight', 'bold', 'FontSize', 12, 'HorizontalAlignment', 'center', ...
    'FitBoxToText','On');

### Starting SIL execution for 'biased_sum_of_square_differences_da16'
To terminate execution: clear biased_sum_of_square_differences_da16_sil
Execution profiling data is available for viewing. Open <a href="matlab:Simulink.sdi.view;">Simulation Data Inspector.</a>
Execution profiling report available after termination.

### Stopping SIL execution for 'biased_sum_of_square_differences_da16'
Execution profiling report: report(getCoderExecutionProfile('biased_sum_of_square_differences_da16'))

### Starting SIL execution for 'biased_sum_of_square_differences'

• “Develop a Code Replacement Library” on page 64-27
Array Layout and Code Replacement

To improve the performance of algorithms or simplify integration with external code or data, you can define code replacement mappings that apply a specific layout for storing array elements in memory. By default, the code generator stores array elements in a column-major layout. To change the layout to row-major, change the value of the entry parameter `ArrayLayout` to `ROW_MAJOR`.

The following table definition file for a sum operation uses the row-major array layout.

1. Create a table definition file that contains a function definition. For example:
   ```
   function hTable = crl_table_rowmajor_matrix
   ```
2. Within the function body, create the table by calling the function `RTW.TflTable`.
   ```
   hTable = RTW.TflTable;
   ```
3. Create an entry for the operator mapping with a call to the `RTW.TflCOperationEntry` function.
   ```
   % Create operation entry
   hEnt = RTW.TflCOperationEntry;
   ```
4. Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. In the function call, set the parameter `ArrayLayout` to `ROW_MAJOR`.
   ```
   setTflCOperationEntryParameters(hEnt, ...
     'Key',                      'RTW_OP_ADD', ...
     'Priority',                 100, ...
     'ArrayLayout',              'ROW_MAJOR', ...
     'ImplementationName',        'MyMul_ROW', ...
     'ImplementationHeaderFile', 'MyMul_ROW.h', ...
     'ImplementationSourceFile', 'MyMul_ROW.c');
   ```
5. Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `RTW.TflArgMatrix` and `addConceptualArg` functions to create and add the arguments.
   ```
   arg = RTW.TflArgMatrix('y1', 'RTW_IO_OUTPUT', 'double');
   arg.DimRange = [2 2; 50 50];
   hEnt.addConceptualArg(arg);
   ```
   ```
   arg = RTW.TflArgMatrix('u1', 'RTW_IO_INPUT', 'double');
   arg.DimRange = [2 3; 2 3];
   ```
Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `getTflArgFromString` function to create the arguments. When defining the implementation function return argument, create a void output argument. When defining the implementation function argument for the conceptual output argument (`y1`), set the operator output argument as an additional input argument. Mark its IOType as output. Make its type a pointer type. The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument and adds the argument to the entry’s array of implementation arguments.

% Implementation Args
arg = hEnt.getTflArgFromString('unused','void');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);

arg = hEnt.getTflArgFromString('u1','double*');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u2','double*');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('y1','double*');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u3','uint32',2);
arg.Type.ReadOnly = true;
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u4','uint32',3);
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u5','uint32',3);
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u6','uint32',4);
hEnt.Implementation.addArgument(arg);

Add the entry to a code replacement table with a call to the `addEntry` function.
addEntry(hTable, hEnt);

8  Save the table definition file. To name the file, use the name of the table definition function. Then, generate code and a code generation report and review the code replacements.

• “Define Code Replacement Mappings” on page 64-43
Allow Shape Agnostic Match

Code replacement shape-agnostic match allows matrix inputs for certain operations to be matched based on the number of elements as opposed to matrix shape. For example, a 6x1 matrix matches a 2x3 matrix in shape-agnostic match because both have a total of 6 elements. Such matches can only be made if the output and inputs are contiguously allocated in memory and if the replacement function can be performed element-wise. Shape-agnostic matrix match increases replacement rate so it is advantageous for replacement that does not require matrix shape to be considered.

Shape-agnostic code replacement entries can be created either with the user interface of the Code Replacement Tool or programmatically.

User Interface Method- Code Replacement Tool

This example shows how to set up shape-agnostic matrix replacement for an addition code replacement table entry.

1. Open the Code Replacement Tool. From the MATLAB command line, enter crtool.
2. Create a code replacement table. Go to File > New Table.
3. Create a table entry. Shape-agnostic matrix replacement only supports Math Operation table entries. Either right-click on your table or go to File > New Entry and select Math Operation. Mapping information appears. From the Operation drop-down menu, select addition.
4. Create conceptual arguments. The Conceptual operation section defines each of your conceptual arguments. To enable shape-agnostic replacement set the Argument type: to matrix to open the Matrix entry properties menu.
5. Set entry parameters. In the Matrix entry properties menu, select the Allow shape-agnostic match check box to enable shape-agnostic replacement.
6. Validate your table entry. Either click the validate entry button or right-click the entry and select Validate entries.
7. Click save.

This display shows the Code Replacement Tool settings for this example.
Programmatic Method

This example shows how to set up a shape-agnostic matrix replacement for an addition code replacement table entry.

1. Create the code replacement table. Create a function definition with the table name 'ShapeAgnosticTable'. Call RTW.TflTable to create the table.

   ```matlab
def function hLib = ShapeAgnosticTable
       hLib = RTW.TflTable;
   end
```

2. Create a table entry for code replacement. Shape-agnostic replacement only supports operation entries, as specified with a call to RTW.TflCOperationEntry.
hEnt = RTW.TflCOperationEntry;

3 Set entry parameters to customize input processing. You can enable shape-agnostic matrix replacement by setting the entry parameter 'AllowShapeAgnosticMatch' to true.

hEnt.setTflCOperationEntryParameters( ... 'Key', 'RTW_OP_ADD', ... 'Priority', 100, ... 'AllowShapeAgnosticMatch', true, ... 'ImplementationName', 'MyAdd_Matrix', ... 'SideEffects', true);

4 Create conceptual arguments. For this example, create conceptual arguments y1, u1, and u2 with calls to the create function, RTW.TflArgMatrix, and add function, addConceptualArg.

arg = RTW.TflArgMatrix('y1', 'RTW_IO_OUTPUT', 'double');
arg.DimRange = [2 2; 50 50];
hEnt.addConceptualArg(arg);

arg = RTW.TflArgMatrix('u1', 'RTW_IO_INPUT', 'double');
arg.DimRange = [2 3; 2 3];
hEnt.addConceptualArg(arg);

arg = RTW.TflArgMatrix('u2', 'RTW_IO_INPUT', 'double');
arg.DimRange = [2 3; 2 3];
hEnt.addConceptualArg(arg);

5 Create implementation arguments. For this example, call the function getTflArgFromString to create the arguments. Define the implementation return argument as a void output argument. Define the conceptual output argument, y1, as a pointer with the IOType as output.

arg = hEnt.getTflArgFromString('unused','void');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);

arg = hEnt.getTflArgFromString('u1','double*');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u2','double*');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('y1','double*');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('numElements','uint32',6);
hEnt.Implementation.addArgument(arg);

6  Add this entry to a code replacement table with the function addEntry.

    hLib.addEntry( hEnt );

7  Save the table as its function name. For this example, ShapeAgnosticTable.

8  Validate your entry at the MATLAB command line. Invoke the table definition file with the following command.

    hTbl = ShapeAgnosticTable

Example Model

An example of this code replacement table entry is demonstrated through the following model. Even though the matrix shape in this model does not match the entry, the operation can be performed element-wise and the entry enables shape-agnostic match, so code replacement is observed in the generated code.
MyAdd_Matrix(Demo_U.In1, Demo_U.In2, Demo_Y.Out1, 6U);

Limitations

• If you enable shape-agnostic match for an operation that is inherently not computed element-wise, a regular match is performed.

• When shape-agnostic match is enabled, code replacement does not honor the setting for 'DimRange'. Instead, it computes the number of elements and uses that value to match.

• If you are working with customized code replacement entries, adjust the 'do_match' function to accept the total number of elements as opposed to matrix dimensions. For more information, see “Customize Match and Replacement Process” on page 64-159.

Replace MATLAB Functions with Custom Code Using `coder.replace`

The `coder.replace` function provides the ability to replace a specified MATLAB function with a code replacement function in generated code. Use `coder.replace` in MATLAB code from which you want to generate C code using:

- MATLAB Coder
- MATLAB code in a Simulink MATLAB Function block

You can replace MATLAB functions that have:

- Single or multiple inputs
- Single or multiple outputs
- Scalar and matrix inputs and outputs

Supported types include:

- `single`, `double` (complex and noncomplex)
- `int8`, `uint8` (complex and noncomplex)
- `int16`, `uint16` (complex and noncomplex)
- `int32`, `uint32` (complex and noncomplex)
- Fixed-point integers
- Mixed types (different type on each input)

Replace coder.ceval Calls to External Functions

The coder.ceval function calls external C/C++ functions from code generated from MATLAB code. The code replacement software supports replacement of the function that you specify in a call to coder.ceval. An application of this code replacement scenario is to write generic MATLAB code that you can customize for different platforms with code replacements. A code replacement library can define hardware-specific code replacements for the function call. Use coder.ceval in MATLAB code from which you want to generate C code using:

- MATLAB Coder
- MATLAB code in a Simulink MATLAB Function block

Example Files

For the examples in “Interactive External Function Call Replacement Specification with Code Replacement Tool” on page 65-112 and “Programmatic External Function Call Replacement Specification” on page 65-114 you must have set up the following:

- Custom C function my_add.c.
  
  /* my_add.c */

  #include "my_add.h"

  double my_add(double in1, double in2)
  {
    return in1 + in2;
  }

- Custom C header file my_add.h.
  
  /* my_add.h */

  double my_add(double in1, double in2);

- MATLAB function call_my_add.m, which uses coder.ceval to invoke my_add.c.

  function y = call_my_add(in1, in2)  %#codegen
  
  y=0.0;

  if ~coder.target('Rtw')
% Executing in MATLAB, call MATLAB equivalent of C function my_add
    y = in1+in2;
else
% Executing in generated code, call C function my_add
    y = coder.ceval('my_add', in1, in2);
end

• MATLAB test function call_my_add_test.m, which calls call_my_add.m.
    in1=10;
in2=20;
y = call_my_add(in1, in2);

    disp('Output')
disp('y =')
disp(y);

• Replacement C function my_add_replacement.c.

    /* my_add_replacement.c */

    #include "my_add_replacement.h"

double my_add_replacement(double in1, double in2)
{
    return in1 + in2;
}

• Replacement C header file my_add_replacement.h.

    /* my_add_replacement.h */

double my_add_replacement(double in1, double in2);

Interactive External Function Call Replacement Specification with Code Replacement Tool

This example shows how to define a code replacement table entry for a MATLAB function that calls coder.ceval to invoke an external C function. The example shows how to define the entry interactively with the Code Replacement Tool.

1 Identify or create the C/C++ code and relevant header files, the MATLAB function that calls coder.ceval, a MATLAB test function, and the source and header files for
your replacement code. To follow along with this example, set up the files identified in “Example Files” on page 65-111.

2 In the Code Replacement Tool, add a table, select that table, and add a function entry. For more information, see “Define Code Replacement Mappings” on page 65-29.

3 On the **Mapping Information** tab, select Custom for the **Function** parameter.

4 In the **function-name** text box, type the custom function name. For this example, type the name **my_add**.

5 Under the **Conceptual arguments** list box, click + to add three arguments. By default, the tool creates an output argument **y1** and input arguments **u1** and **u2** of type **double**.

6 In the **Replacement function > Function prototype** section, type the name **my_add_replacement** in the **Name** text box.

7 Under the **Function arguments** list box, click + to add three function implementation arguments. By default, the tool creates an output argument **y1** and input arguments **u1** and **u2** of type **double**. Use the default settings.

8 In the **Function signature preview** box, if you see the expected function signature, click **Apply**. The function signature for this example, appears as:

   double my_add_replacement(double u1, double u2);

9 On the **Build Information** tab, specify **my_add_replacement.h** for the **Implementation header file** parameter and **my_add_replacement.c** for the **Implementation source file**.

10 Click **Validate entry**.

11 Save the code replacement table in the same folder as **my_add_replacement.c**. Name the file **crl_table_my_add.m**.

To test the example:

1 Register the table that contains the entry in a code replacement library.

2 Configure the code generator to use the code replacement library and to include the Code Replacements Report in the code generation report.

3 Generate code and the report.

4 Review the code replacements.
Programmatic External Function Call Replacement Specification

This example shows how to define a code replacement table entry for a MATLAB function that calls `coder.ceval` to invoke an external C function. The example shows how to define the entry programmatically.

1. Identify or create the C/C++ code and relevant header files, the MATLAB function that calls `coder.ceval` to invoke the C/C++ function, a MATLAB test function, and the source and header files for your replacement code. To follow along with this example, set up the files identified in “Example Files” on page 65-111.

2. Create a table definition file that contains a function definition. For example:

   ```matlab
   function hLib = crl_table_my_add
   ```

3. Within the function body, create the table by calling the function `RTW.TflTable`.

4. Create an entry for the function mapping with a call to the `RTW.TflCFunctionEntry` function.

   ```matlab
   hEnt = RTW.TflCFunctionEntry;
   ```

5. Set function entry parameters with a call to the `setTflCFunctionEntryParameters` function.

   ```matlab
   hEnt.setTflCFunctionEntryParameters( ...
       'Key', 'my_add', ...
       'Priority', 100, ...
       'ImplementationName', 'my_add_replacement', ...
       'ImplementationHeaderFile', 'my_add_replacement.h', ...
       'ImplementationSourceFile', 'my_add_replacement.c');
   ```

6. Create conceptual arguments y1, u1, and u2. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create and add the arguments.

   ```matlab
   arg = hEnt.getTflArgFromString('y1','double');
   arg.IOType = 'RTW_IO_OUTPUT';
   hEnt.addConceptualArg(arg);
   arg = hEnt.getTflArgFromString('u1','double');
   hEnt.addConceptualArg(arg);
   arg = hEnt.getTflArgFromString('u2','double');
   hEnt.addConceptualArg(arg);
   ```
Create the implementation arguments and add them to the entry. This example uses calls to the `getTflArgFromString` function to create implementation arguments. These functions map to arguments in the replacement function prototype: output argument `y1` and input arguments `u1` and `u2`. For each argument, the example uses the convenience method `setReturn` or `addArgument` to specify whether an argument is a return value or argument. For each argument, this example adds the argument to the entry array of implementation arguments.

```matlab
arg = hEnt.getTflArgFromString('y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);

arg = hEnt.getTflArgFromString('u1','double');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u2','double');
hEnt.Implementation.addArgument(arg);
```

Add the entry to a code replacement table with a call to the `addEntry` function.

```matlab
hLib.addEntry(hEnt);
```

Save the table definition file. Use the name of the table definition function to name the file.

To test the example:

1. Register the table that contains the entry in a code replacement library.
2. Configure the code generator to use the code replacement library and to include the Code Replacements Report in the code generation report.
3. Generate code and the report.
4. Review the code replacements.

- “Develop a Code Replacement Library” on page 65-15
Reserved Identifiers and Code Replacement

The code generator and C programming language use, internally, reserved keywords for code generation. Do not use reserved keywords as identifiers or function names. Reserved keywords for code generation include many code replacement library identifiers, the majority of which are function names, such as `acos`.

To view a list of reserved identifiers for the code replacement library that you use to generate code, specify the name of the library in a call to the function `RTW.TargetRegistry.getInstance.getTflReservedIdentifiers`. For example:

```matlab
crl_ids = RTW.TargetRegistry.getInstance.getTflReservedIdentifiers('GNU99 (GNU)')
```

In a code replacement table, the code generator registers each function implementation name defined by a table entry as a reserved identifier. You can register additional reserved identifiers for the table on a per-header-file basis. Providing additional reserved identifiers can help prevent duplicate symbols and other identifier-related compile and link issues.

To register additional code replacement reserved identifiers, use the `setReservedIdentifiers` function. This function registers specified reserved identifiers to be associated with a code replacement table.

You can register up to four reserved identifier structures in a code replacement table. You can associate one set of reserved identifiers with a code replacement library, while the other three (if present) must be associated with ANSI C. The following example shows a reserved identifier structure that specifies two identifiers and the associated header file.

```matlab
d{1}.LibraryName = 'ANSI C';
d{1}.HeaderInfos{1}.HeaderName = 'math.h';
d{1}.HeaderInfos{1}.ReservedIds = {'y0', 'y1'};
```

The code generator adds the identifiers to the list of reserved identifiers and honors them during the build procedure.

More About

- “Code You Can Replace from MATLAB Code” on page 65-5
• “Customize Match and Replacement Process” on page 65-118
• “Define Code Replacement Mappings” on page 65-29
• “Develop a Code Replacement Library” on page 65-15
Customize Match and Replacement Process

During the build process, the code generator uses:

- Preset match criteria to identify functions and operators for which application-specific implementations replace default implementations.
- Preset replacement function signatures.

It is possible that preset match criteria and preset replacement function signatures do not completely meet your function and operator replacement needs. For example:

- You want to replace an operator with a particular fixed-point implementation function only when fraction lengths are within a particular range.
- When a match occurs, you want to modify your replacement function signature based on compile-time information, such as passing fraction-length values into the function.

To add extra logic into the code replacement match and replacement process, create custom code replacement table entries. With custom entries, you can specify additional match criteria and modify the replacement function signature to meet application needs.

To create a custom code replacement entry:

1. Create a custom code replacement entry class, derived from RTW.TflCFunctionEntryML (for function replacement) or RTW.TflCOperationEntryML (for operator replacement).

2. In your derived class, implement a do_match method with a fixed preset signature as a MATLAB function. In your do_match method, provide either or both of the following customizations that instantiate the class:
   - Add match criteria that the base class does not provide. The base class provides a match based on:
     - Argument number
     - Argument name
     - Signedness
     - Word size
     - Slope (if not specified with wildcards)
     - Bias (if not specified with wildcards)
• Math modes, such as saturation and rounding
• Operator or function key
• Modify the implementation signature by adding additional arguments or setting constant input argument values. You can inject a constant value, such as an input scaling value, as an additional argument to the replacement function.

3 Create code replacement entries that instantiate the custom entry class.
4 Register a library containing the code replacement table that includes your entries.

During code generation, the code replacement match process tries to match function or operator call sites with the base class of your derived entry class. If the process finds a match, the software calls your do_match method to execute your additional match logic (if any) and your replacement function customizations (if any).

**Customize Match and Replacement Process for Operators**

This example shows how to create custom code replacement entries that add logic to the code match and replacement process for a scalar operation. Custom entries specify additional match criteria or modify the replacement function signature to meet application needs.

For example:

• When fraction lengths are within a specific range, replace an operator with a fixed-point implementation function.
• When a match occurs, modify the replacement function signature based on compile-time information, such as passing fraction-length values into the function.

This example modifies a fixed-point addition replacement such that the implementation function passes in the fraction lengths of the input and output data types as arguments.

To create custom code replacement entries that add logic to the code replacement match and replacement process:

1 Create a class, for example TflCustomOperationEntry, that is derived from the base class RTW.TflCOperationEntryML. The derived class defines a do_match method with the following signature:

```
function ent = do_match(hThis, ...
    hCS0, ...
    targetBitPerChar, ...
```
In the `do_match` signature:

- `ent` is the return handle, which is returned as empty (indicating that the match failed) or as a `TflCOperationEntry` handle.
- `hThis` is the handle to the class instance.
- `hCSO` is a handle to an object that the code generator creates for querying the library for a replacement.
- Remaining arguments are the number of bits for various data types of the current target.

The `do_match` method adds match criteria that the base class does not provide. The method makes modifications to the implementation signature. In this case, the `do_match` method relies on the base class for checking word size and signedness. `do_match` must match only the number of conceptual arguments to the value 3 (two inputs and one output) and the bias for each argument to value 0. If the code generator finds a match, `do_match`:

- Sets the return handle.
- Removes slope and bias wild cards from the conceptual arguments (the match is for specific slope and bias values).
- Writes fraction-length values for the inputs and output into replacement function arguments 3, 4, and 5.

You can create and add three additional implementation function arguments for passing fraction lengths in the class definition or in each code replacement entry definition that instantiates this class. This example creates the arguments, adds them to a code replacement table definition file, and sets them to specific values in the class definition code.

classdef TflCustomOperationEntry < RTW.TflCOperationEntryML
methods
    function ent = do_match(hThis, ...
    hCSO, ... ok
    targetBitPerChar, ... ok
    targetBitPerShort, ... ok
    targetBitPerInt, ... ok
    targetBitPerLong, ... ok
    targetBitPerLongLong) ok
% DO_MATCH - Create a custom match function. The base class
% checks the types of the arguments prior to calling this
% method. This class will check additional data and can
% modify the implementation function.

% The base class checks word size and signedness. Slopes and biases
% have been wildcarded, so the only additional checking to do is
% to check that the biases are zero and that there are only three
% conceptual arguments (one output, two inputs)

ent = []; % default the return to empty, indicating the match failed

if length(hCSO.ConceptualArgs) == 3 && ...
    hCSO.ConceptualArgs(1).Type.Bias == 0 && ...
    hCSO.ConceptualArgs(2).Type.Bias == 0 && ...
    hCSO.ConceptualArgs(3).Type.Bias == 0
% Modify the default implementation. Since this is a
% generator entry, a concrete entry is created using this entry
% as a template. The type of entry being created is a standard
% TflCOperationEntry. Using the standard operation entry
% provides required information, and you do not need
% a custom match function.
ent = RTW.TflCOperationEntry(hThis);

% Since this entry is modifying the implementation for specific
% fraction-length values (arguments 3, 4, and 5), the conceptual argument
% wild cards must be removed (the wildcards were inherited from the
% generator when it was used as a template for the concrete entry).
% This concrete entry is now for a specific slope and bias.
% hCSO holds the slope and bias values (created by the code generator).
for idx=1:3
    ent.ConceptualArgs(idx).CheckSlope = true;
    ent.ConceptualArgs(idx).CheckBias = true;

    % Set the specific Slope and Biases
    ent.ConceptualArgs(idx).Type.Slope = hCSO.ConceptualArgs(idx).Type.Slope;
    ent.ConceptualArgs(idx).Type.Bias = 0;
end

% Set the fraction-length values in the implementation function.
ent.Implementation.Arguments(3).Value = ...
    -1.0*hCSO.ConceptualArgs(2).Type.FixedExponent;
ent.Implementation.Arguments(4).Value = ...
    -1.0*hCSO.ConceptualArgs(3).Type.FixedExponent;
ent.Implementation.Arguments(5).Value = ...
    -1.0*hCSO.ConceptualArgs(1).Type.FixedExponent;
end

end

Exit the class folder and return to the previous working folder.
Create and save the following code replacement table definition file, `crl_table_custom_sinfcn_double.m`. This file defines a code replacement table that contains a single operator entry, an entry generator for unsigned 32-bit fixed-point addition operations, with arbitrary fraction-length values on the inputs and the output. The table entry:

- Instantiates the derived class `TflCustomOperationEntry` from the previous step. If you want to replace word sizes and signedness attributes, you can use the same derived class, but not the same entry, because you cannot use a wild card with the `WordLength` and `IsSigned` arguments. For example, to support `uint8`, `int8`, `uint16`, `int16`, and `int32`, add five other distinct entries. To use different implementation functions for saturation and rounding modes other than overflow and round to floor, add entries for those match permutations.
- Sets operator entry parameters with the call to the `setTflCOperationEntryParameters` function.
- Calls the `createAndAddConceptualArg` function to create conceptual arguments `y1`, `u1`, and `u2`.
- Calls `createAndSetCImplementationReturn` and `createAndAddImplementationArg` to define the signature for the replacement function. Three of the calls to `createAndAddImplementationArg` create implementation arguments to hold the fraction-length values for the inputs and output. Alternatively, the entry can omit those argument definitions. Instead, the `do_match` method of the derived class `TflCustomOperationEntry` can create and add the three implementation arguments. When the number of additional implementation arguments required can vary based on compile-time information, use the alternative approach.
- Calls `addEntry` to add the entry to a code replacement table.

```matlab
function hTable = crl_table_custom_add_ufix32

hTable = RTW.TflTable;

%% Add TflCustomOperationEntry
op_entry = TflCustomOperationEntry;

setTflCOperationEntryParameters(op_entry, ...
   'Key', 'RTW_OP_ADD', ...
   'Priority', 30, ...
   'SaturationMode', 'RTW_SATURATE_ON_OVERFLOW', ...
   'RoundingModes', {'RTW_ROUND_FLOOR'}, ...
   'ImplementationName', 'myFixptAdd', ...);```
'ImplementationHeaderFile', 'myFixptAdd.h', ...
'ImplementationSourceFile', 'myFixptAdd.c');

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
'Name', 'y1', ...
'IOType', 'RTW_IO_OUTPUT', ...
'CheckSlope', false, ...
'CheckBias', false, ...
'DataType', 'Fixed', ...
'Scaling', 'BinaryPoint', ...
'IsSigned', false, ...
'WordLength', 32);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
'Name', 'u1', ...
'IOType', 'RTW_IO_INPUT', ...
'CheckSlope', false, ...
'CheckBias', false, ...
'DataType', 'Fixed', ...
'Scaling', 'BinaryPoint', ...
'IsSigned', false, ...
'WordLength', 32);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
'Name', 'u2', ...
'IOType', 'RTW_IO_INPUT', ...
'CheckSlope', false, ...
'CheckBias', false, ...
'DataType', 'Fixed', ...
'Scaling', 'BinaryPoint', ...
'IsSigned', false, ...
'WordLength', 32);

% Specify replacement function signature
createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...
'Name', 'y1', ...
'IOType', 'RTW_IO_OUTPUT', ...
'IsSigned', false, ...
'WordLength', 32, ...
'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric', ...
'Name', 'u1', ...
'IOType', 'RTW_IO_INPUT', ...
Create and add implementation args for the operator entry:

```matlab
createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',
                           'Name', 'u2',
                           'IOType', 'RTW_IO_INPUT',
                           'IsSigned', false,
                           'WordLength', 32,
                           'FractionLength', 0);
```

% Add 3 fraction-length args. Actual values are set during code generation.
```matlab
createAndAddImplementationArg(op_entry, 'RTW.TflArgNumericConstant',
                           'Name', 'fl_in1',
                           'IOType', 'RTW_IO_INPUT',
                           'IsSigned', false,
                           'WordLength', 32,
                           'FractionLength', 0,
                           'Value', 0);
```
```matlab
createAndAddImplementationArg(op_entry, 'RTW.TflArgNumericConstant',
                           'Name', 'fl_in2',
                           'IOType', 'RTW_IO_INPUT',
                           'IsSigned', false,
                           'WordLength', 32,
                           'FractionLength', 0,
                           'Value', 0);
```
```matlab
createAndAddImplementationArg(op_entry, 'RTW.TflArgNumericConstant',
                           'Name', 'fl_out',
                           'IOType', 'RTW_IO_INPUT',
                           'IsSigned', false,
                           'WordLength', 32,
                           'FractionLength', 0,
                           'Value', 0);
```
```

Add entry to the table:

```matlab
addEntry(hTable, op_entry);
```

3 Check the validity of the operator entry.

- At the command prompt, invoke the table definition file.

  ```matlab
tbl = crl_table_custom_sinfcn_double
  ```
- In the Code Replacement Viewer, view the table definition file.
crviewer(crl_table_custom_sinfcn_double)

Scalar Operator Code Replacement

This example shows how to define a code replacement mapping for a scalar operator. The example defines a mapping for the + (addition) operator programmatically. Alternatively, you can use the **Code Replacement Tool** to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```matlab
   function hTable = crl_table_add_uint8
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```matlab
   hTable = RTW.TflTable;
   ```

3. Create an entry for the operator mapping with a call to the `RTW.TflCOperationEntry` function.

   ```matlab
   % Create operation entry
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set function entry parameters with a call to the `setTflCOperationEntryParameters` function.

   ```matlab
   % Define addition operation of built-in uint8 data type
   % Saturation on, Rounding unspecified
   setTflCOperationEntryParameters(op_entry, ...
     'Key',                      'RTW_OP_ADD', ...,
     'Priority',                 90, ...,
     'SaturationMode',           'RTW_SATURATE_ON_OVERFLOW', ...,
     'RoundingModes',            {'RTW_ROUND_UNSPECIFIED'}, ...,
     'ImplementationName',       'u8_add_u8_u8', ...,
     'ImplementationHeaderFile', 'u8_add_u8_u8.h', ...,
     'ImplementationSourceFile', 'u8_add_u8_u8.c' );
   ```

5. Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create and add the arguments.

   ```matlab
   arg = getTflArgFromString(hTable, 'y1', 'uint8');
   arg.IOType = 'RTW_IO_OUTPUT';
   addConceptualArg(op_entry, arg);
   arg = getTflArgFromString(hTable, 'u1', 'uint8');
   addConceptualArg(op_entry, arg);
   arg = getTflArgFromString(hTable, 'u2', 'uint8');
   addConceptualArg(op_entry, arg);
   ```

6. Copy the conceptual arguments to the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses a call to the
copyConceptualArgsToImplementation function to create and add implementation arguments to the entry by copying matching conceptual arguments.

copyConceptualArgsToImplementation(op_entry);

7 Add the entry to a code replacement table with a call to the addEntry function.

addEntry(hTable, op_entry);

8 Save the table definition file. Use the name of the table definition function to name the file.

Addition and Subtraction Operator Code Replacement

Consider the following when defining mappings for addition and subtraction operator code replacements.

Algorithm Options

When creating a code replacement table entry for an addition or subtraction operator, first determine the type of algorithm that your library function implements.

- Cast-before-operation (CBO), default — Prior to performing the addition or subtraction operation, the algorithm type casts input values to the output type. If the output data type cannot exactly represent the input values, losses can occur as a result of the cast to the output type. Additional loss can occur when the result of the operation is cast to the final output type.

- Cast-after-operation (CAO) — The algorithm computes the ideal result of the addition or subtraction operation of the two inputs. The algorithm then type casts the result to the output data type. Loss occurs during the type cast. This algorithm behaves similarly to the C language except when the signedness of the operands does not match. For example, when you add a signed long operand to an unsigned long operand, standard C language rules convert the signed long operand to an unsigned long operand. The result is a value that is not ideal.

Interactive Specification with Code Replacement Tool

When you use the Code Replacement Tool to create a code replacement table entry for an addition or subtraction operation, the tool displays an Algorithm menu. Use that menu to specify the Cast before operation or Cast after operation algorithm for that entry.
Programmatic Specification

Create a code replacement table file, as a MATLAB function, that describes the addition or subtraction code replacement table entry. In the call to `setTflCOperationEntryParameters`, set at least these parameters:

- **Key** to `RTW_OP_ADD` or `RTW_OP_MINUS`
- **ImplementationName** to the name of your replacement function
- **EntryInfoAlgorithm** to `RTW_CAST_BFORE_OP` (cast-before-operation) or `RTW_CAST_AFTER_OP` (cast-after-operation)

This example sets parameters for a code replacement operator entry for a cast-after-operation implementation of a `uint8` addition.

```matlab
op_entry = RTW.TflCOperationEntry;
setTflCOperationEntryParameters(op_entry, ...
    'Key',                      'RTW_OP_ADD', ...
    'EntryInfoAlgorithm',       'RTW_CAST_AFTER_OP', ...
    'ImplementationName',       'u8_add_u8_u8');
```

For more information, see `setTflCOperationEntryParameters`.

Algorithm Classification

During code generation, the code generator examines addition and subtraction operations, including adjacent type cast operations, to determine the type of algorithm to compute the expression result. Based on the data types in the expression and the type of the accumulator (type used to hold the result of the addition or subtraction operation), the code generator uses these rules.

- Floating-point types only

<table>

</thead>
</table>
| CBO       | At least one of the following is true:  
  - Accumulator type equals output type (Tacc == Tout).  
  - Output type is a superset of input types (Tacc >= {Tin1, Tin2}) and accumulator type is a superset of output type (Tacc >= Tout).  
  - Operation does not incur range or precision loss. |
Algorith | Conditions
--- | ---
CAO | Net bias is zero and the data types in the expression have equal slope adjustment factors. For more information on net bias, see “Addition” or “Subtraction” in “Fixed-Point Operator Code Replacement” on page 65-154 (for MATLAB code) or “Fixed-Point Operator Code Replacement” on page 64-204 (for Simulink models).

In many cases, the numerical result of a CBO operation is equal to that of a CAO operation. For example, if the input and output types are such that the operation produces the ideal result, as in the case of int8 + int8 → int16. To maximize the probability of code replacement occurring in such cases, set the algorithm to cast-after-operation.

**Limitations**

- The code generator does not replace operations with nonzero net bias.
- When classifying an operation as a CAO operation, the code generator includes the adjacent casts in the expression when the expression involves only fixed-point types. Otherwise, the code generator classifies and replaces only the immediate addition or subtraction operation. Casts that the code generator excludes from the classification appear in the generated code.
- To enable the code generator to include multiple cast operations, which follow an addition or subtraction of fixed-point data, in the classification of an expression, the rounding mode must be simplest or floor. Consider the expression y=(cast A) (cast B)(u1+u2). If the rounding mode of (cast A), (cast B), and the addition operator (+) are set to simplest or floor, the code generator takes into account (cast A) and (cast B) when classifying the expression and performing the replacement only.

• “Develop a Code Replacement Library” on page 65-15
This example shows how to define code replacement mappings that replace non-scalar small matrix operations with processor-specific intrinsic functions. The example defines a table containing two matrix operator replacement entries for the + (addition) operator and the double data type. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```matlab
   function hTable = crl_table_matrix_add_double
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```matlab
   hTable = RTW.TflTable;
   ```

3. Create the entry for the first operator mapping with a call to the `RTW.TflCOperationEntry` function.

   ```matlab
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The code generator ignores saturation and rounding modes for floating-point non-scalar addition and subtraction. For code replacement entries for non-scalar addition and subtraction operations that do not involve fixed-point data, in the call to `setTflCOperationEntryParameters`, specify 'RTW_SATURATE_UNSPECIFIED' for the SaturationMode property and {'RTW_ROUND_UNSPECIFIED'} for RoundingModes.

   ```matlab
   setTflCOperationEntryParameters(op_entry, ...
      'Key',                      'RTW_OP_ADD', ...
      'Priority',                 30, ...
      'SaturationMode',           'RTW_WRAP_ON_OVERFLOW', ...
      'ImplementationName',       'matrix_sum_2x2_double', ...
      'ImplementationHeaderFile', 'MatrixMath.h', ...
      'ImplementationSourceFile', 'MatrixMath.c', ...
      'ImplementationHeaderPath', LibPath, ...
      'ImplementationSourcePath', LibPath, ...
      'AdditionalIncludePaths',   {LibPath}, ...
      'GenCallback',              'RTW.copyFileToBuildDir', ...
      'SideEffects',              true);
   ```

5. Create conceptual arguments y1, u1, and u2. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. To specify a matrix argument in the function call, use the argument class `RTW.TflArgMatrix`. Specify the base type and the dimensions for which the
argument is valid. The first table entry specifies \([2 \ 2]\) and the second table entry specifies \([3 \ 3]\).

```matlab
% Specify operands and result
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
    'Name',         'y1', ...
    'IOType',       'RTW_IO_OUTPUT', ...
    'BaseType',     'double', ...
    'DimRange',     [2 2]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix',...
    'Name',         'u1', ...
    'BaseType',     'double', ...
    'DimRange',     [2 2]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix',...
    'Name',         'u2', ...
    'BaseType',     'double', ...
    'DimRange',     [2 2]);
```

6  Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `getTflArgFromString` to create the arguments. The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument and adds the argument to the entry's array of implementation arguments.

```matlab
arg = getTflArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);
arg = getTflArgFromString(hTable, 'u1', ['double' '*']);
op_entry.Implementation.addArgument(arg);
arg = getTflArgFromString(hTable, 'u2', ['double' '*']);
op_entry.Implementation.addArgument(arg);
arg = getTflArgFromString(hTable, 'y1', ['double' '*']);
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.addArgument(arg);
```

7  Add the entry to a code replacement table with a call to the `addEntry` function.

```matlab
addEntry(hTable, op_entry);
```

8  Create the entry for the second operator mapping.

```matlab
% Create table entry for matrix_sum_3x3_double
op_entry = RTW.TflCOperationEntry;
setTflCOperationEntryParameters(op_entry, ...
    'Key',                      'RTW_OP_ADD', ...
    'Priority',                 30, ...
    'SaturationMode',           'RTW_WRAP_ON_OVERFLOW', ...
    'ImplementationName',       'matrix_sum_3x3_double', ...
    'ImplementationHeaderFile', 'MatrixMath.h', ...
```

65-134
'ImplementationSourceFile', 'MatrixMath.c', ...
'ImplementationHeaderPath', LibPath, ...
'ImplementationSourcePath', LibPath, ...
'AdditionalIncludePaths', {LibPath}, ...
'GenCallback', 'RTW.copyFileToBuildDir', ...
'SideEffects', true);

% Specify operands and result
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
'Name', 'y1', ...
'IOType', 'RTW_IO_OUTPUT', ...
'BaseType', 'double', ...
'DimRange', [3 3]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
'Name', 'u1', ...
'BaseType', 'double', ...
'DimRange', [3 3]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
'Name', 'u2', ...
'BaseType', 'double', ...
'DimRange', [3 3]);

% Specify replacement function signature
arg = getTflArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);
arg = getTflArgFromString(hTable, 'u1', ['double' '*']);
op_entry.Implementation.addArgument(arg);
arg = getTflArgFromString(hTable, 'u2', ['double' '*']);
op_entry.Implementation.addArgument(arg);
arg = getTflArgFromString(hTable, 'y1', ['double' '*']);
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.addArgument(arg);

addEntry(hTable, op_entry);

Save the table definition file. Use the name of the table definition function to name the file.

Matrix Multiplication Operation to MathWorks BLAS Code Replacement

This example shows how to define code replacement mappings that replace nonscalar multiplication operations with Basic Linear Algebra Subroutine (BLAS) multiplication functions \( \text{xgemm} \) and \( \text{xgenv} \). The example defines code replacement entries that map floating-point matrix/matrix and matrix/vector multiplication operations to MathWorks BLAS library multiplication functions \( \text{dgemm} \) and \( \text{dgemv} \). The example defines the function mappings programmatically. Alternatively, you can use the Code Replacement Tool to define the same mappings.

BLAS libraries support matrix/matrix multiplication in the form of
\[ C = a(\text{op}(A) \times \text{op}(B)) + bC \]
where \( \text{op}(X) \) means \( X \), transposition of \( X \), or Hermitian transposition of \( X \). However, code replacement libraries support only the limited case of
\[ C = \text{op}(A) \times \text{op}(B) \] \( (a = 1.0, b = 0.0) \).
Correspondingly, although BLAS libraries support matrix/vector multiplication in the form of
\[ y = a(\text{op}(A) \times x) + by \]
code replacement libraries support only the limited case of
\[ y = \text{op}(A) \times x \] \( (a = 1.0, b = 0.0) \).

1. Create a table definition file that contains a function definition. For example:

   ```matlab
   function hTable = crl_table_tmwblas_mmult_double
   
   2  Within the function body, create the table by calling the function RTW.TflTable.

   hTable = RTW.TflTable;
   ```

3. Define the path for the BLAS function library. If your replacement functions are on the MATLAB search path or are in your working folder, you can skip this step.

   ```matlab
   % Define library path for Windows or UNIX
   arch = computer('arch');
   if ~ispc
     LibPath = fullfile('$(MATLAB_ROOT)', 'bin', arch);
   else
     % Use Stateflow to get the compiler info
     compilerInfo = sf('Private','compilerman','get_compiler_info');
     compilerName = compilerInfo.compilerName;
     if strcmp(compilerName, 'msvc90') || ...
       strcmp(compilerName, 'msvc80') || ...
       strcmp(compilerName, 'msvc71') || ...
       strcmp(compilerName, 'msvc60'), ...
     compilerName = 'microsoft';
   end
   ```
65

Code Replacement Customization for MATLAB Code

LibPath = fullfile('$(MATLAB_ROOT)', 'extern', 'lib', arch, compilerName);
end

4

Create an entry for the first mapping with a call to the
RTW.TflBlasEntryGenerator function.
% Create table entry for dgemm32
op_entry = RTW.TflBlasEntryGenerator;

5

Set operator entry parameters with a call to the
setTflCFunctionEntryParameters function. The function call sets matrix
multiplication operator entry properties. The code generator ignores saturation and
rounding modes for floating-point nonscalar addition and subtraction. For code
replacement entries for nonscalar addition and subtraction operations that do not
involve fixed-point data, in the call to setTflCFunctionEntryParameters, specify
'RTW_SATURATE_UNSPECIFIED' for the SaturationMode property and
{'RTW_ROUND_UNSPECIFIED'} for RoundingModes.
if ispc
libExt = 'lib';
elseif ismac
libExt = 'dylib';
else
libExt = 'so';
end
setTflCOperationEntryParameters(op_entry, ...
'Key',
'RTW_OP_MUL', ...
'Priority',
100, ...
'ImplementationName',
'dgemm32', ...
'ImplementationHeaderFile', 'blascompat32_crl.h', ...
'ImplementationHeaderPath', fullfile('$(MATLAB_ROOT)','extern','include'), ...
'AdditionalLinkObjs',
{['libmwblascompat32.' libExt]}, ...
'AdditionalLinkObjsPaths', {LibPath}, ...
'SideEffects',
true);

6

65-138

Create conceptual arguments y1, u1, and u2. There are multiple ways to set up the
conceptual arguments. This example uses calls to the
createAndAddConceptualArg function to create and add an argument with one
function call. To specify a matrix argument in the function call, use the argument
class RTW.TflArgMatrix and specify the base type and the dimensions for which
the argument is valid. This type of table entry supports a range of dimensions
specified in the format [Dim1Min Dim2Min ... DimNMin; Dim1Max
Dim2Max ... DimNMax]. For example, [2 2; inf inf] means a two-dimensional
matrix of size 2x2 or larger. The conceptual output argument for the dgemm32 entry
for matrix/matrix multiplication replacement specifies dimensions [2 2; inf inf],
while the conceptual output argument for the dgemv32 entry for matrix/vector
multiplication replacement specifies dimensions [2 1; inf 1].


% Specify operands and result
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
    'Name', 'y1', ...
    'IOType', 'RTW_IO_OUTPUT', ...
    'BaseType', 'double', ...
    'DimRange', [2 2; inf inf]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
    'Name', 'u1', ...
    'BaseType', 'double', ...
    'DimRange', [2 2; inf inf]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
    'Name', 'u2', ...
    'BaseType', 'double', ...
    'DimRange', [1 1; inf inf]);

Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `getTflArgFromString` and `RTW.TflArgCharConstant` functions to create the arguments. The example code configures special implementation arguments that are required for `dgemm` and `dgemv` function replacements. The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument and adds the argument to the entry’s array of implementation arguments.

% Using RTW.TflBlasEntryGenerator for xgemm requires the following
% implementation signature:
% void f(char* TRANSA, char* TRANSB, int* M, int* N, int* K,
%       type* ALPHA, type* u1, int* LDA, type* u2, int* LDB,
%       type* BETA, type* y, int* LDC)
% When a match occurs, the code generator computes the
% values for M, N, K, LDA, LDB, and LDC and inserts them into the
% generated code. TRANSA and TRANSB are set to 'N'.

% Specify replacement function signature
arg = getTflArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);
arg = RTW.TflArgCharConstant('TRANSA');
% Possible values for PassByType property are
% RTW_PASSBY_AUTO, RTW_PASSBY_POINTER,
% RTW_PASSBY_VOID_POINTER, RTW_PASSBY_BASE_POINTER
arg.PassByType = 'RTW_PASSBY_POINTER';
op_entry.Implementation.addArgument(arg);
arg = RTW.TflArgCharConstant('TRANSB');
arg.PassByType = 'RTW_PASSBY_POINTER';
op_entry.Implementation.addArgument(arg);
arg = getTflArgFromString(hTable, 'M', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);
arg = getTflArgFromString(hTable, 'N', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'K', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'ALPHA', 'double', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u1', ['double' '*']);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

Matrix Multiplication Operation to ANSI/ISO C BLAS Code Replacement

This example shows how to define code replacement mappings that replace nonscalar multiplication operations with ANSI/ISO C BLAS multiplication functions \texttt{xgemm} and \texttt{xgemv}. The example defines code replacement entries that map floating-point matrix/matrix and matrix/vector multiplication operations to ANSI/ISO C BLAS library multiplication functions \texttt{dgemm} and \texttt{dgemv}. The example defines the function mappings programmatically. Alternatively, you can use the Code Replacement Tool to define the same mappings.

BLAS libraries support matrix/matrix multiplication in the form of
\[ C = a(\text{op}(A) \times \text{op}(B)) + bC \] . \texttt{op}(X) means \( X \), transposition of \( X \), or Hermitian transposition of \( X \). However, code replacement libraries support only the limited case of
\[ C = \text{op}(A) \times \text{op}(B) \ (a = 1.0, \ b = 0.0) \] . Correspondingly, although BLAS libraries support matrix/vector multiplication in the form of \( y = a(\text{op}(A) \times x) + by \), code replacement libraries support only the limited case of \( y = \text{op}(A) \times x \ (a = 1.0, \ b = 0.0) \).

1. Create a table definition file that contains a function definition. For example:
   ```matlab
   function hTable = crl_table_cblas_mmult_double
   ```
2. Within the function body, create the table by calling the function \texttt{RTW.TflTable}.
   ```matlab
   hTable = RTW.TflTable;
   ```
3. Define the path for the CBLAS function library. For example:
   ```matlab
   LibPath = fullfile(matlabroot, 'toolbox', 'rtw', 'rtwdemos', 'crl_demo');
   ```
4. Create an entry for the first mapping with a call to the \texttt{RTW.TflBlasEntryGenerator} function.
   ```matlab
   setTflCOperationEntryParameters(op_entry, ... 
   'Key', 'RTW_OP_MUL', ... 
   )
   ```
5. Set operator entry parameters with a call to the \texttt{setTflCOperationEntryParameters} function. The function call sets matrix multiplication operator entry properties. The code generator ignores saturation and rounding modes for floating-point nonscalar addition and subtraction.
   ```matlab
   setTflCOperationEntryParameters(op_entry, ... 
   'Key', 'RTW_OP_MUL', ... 
   )
   ```
Create conceptual arguments $y_1$, $u_1$, and $u_2$. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. To specify a matrix argument in the function call, use the argument class `RTW.TflArgMatrix` and specify the base type and the dimensions for which the argument is valid. This type of table entry supports a range of dimensions specified in the format $[\text{Dim1Min} \ \text{Dim2Min} \ \ldots \ \text{DimNMin}; \ \text{Dim1Max} \ \text{Dim2Max} \ \ldots \ \text{DimNMax}]$. For example, $[2 \ 2; \ \text{inf} \ \text{inf}]$ means a two-dimensional matrix of size $2 \times 2$ or larger. The conceptual output argument for the $\text{dgemm32}$ entry for matrix/matrix multiplication replacement specifies dimensions $[2 \ 2; \ \text{inf} \ \text{inf}]$. The conceptual output argument for the $\text{dgemv32}$ entry for matrix/vector multiplication replacement specifies dimensions $[2 \ 1; \ \text{inf} \ 1]$.

% Specify operands and result
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
'Name', 'y1', ...
'IOType', 'RTW.IO_OUTPUT', ...
'BaseType', 'double', ...
'DimRange', [2 2; inf inf]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
'Name', 'u1', ...
'BaseType', 'double', ...
'DimRange', [2 2; inf inf]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
'Name', 'u2', ...
'BaseType', 'double', ...
'DimRange', [1 1; inf inf]);

Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `getTflArgFromString` function to create the arguments. The example code configures special implementation arguments that are required for $\text{dgemm}$ and $\text{dgemv}$ function replacements. The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument and adds the argument to the entry’s array of implementation arguments.

% Using RTW.TflCBlasEntryGenerator for xgemm requires the following
% implementation signature:
% % void f(enum ORDER, enum TRANSNA, enum TRANSNB, int M, int N, int K,
% %       type ALPHA, type* u1, int LDA, type* u2, int LDB,
% %       type BETA, type* y, int LDC)
% Since CRLs do not have the ability to specify enums, you must
% use integer. (This will cause problems with C++ code generation,
% so for C++, use a wrapper function to cast each int to the
% corresponding enumeration type.)
%
% When a match occurs, the code generator computes the
% values for M, N, K, LDA, LDB, and LDC and insert them into the
% generated code.

% Specify replacement function signature

arg = getTflArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);

arg = getTflArgFromString(hTable, 'ORDER', 'integer', 102);
% arg.Type.ReadOnly=true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'TRANSA', 'integer', 111);
% arg.Type.ReadOnly=true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'TRANSB', 'integer', 111);
% arg.Type.ReadOnly=true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'M', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'N', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'K', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'ALPHA', 'double', 1);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u1', ['double' '*']);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDA', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u2', ['double' '*']);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDB', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'BETA', 'double', 0);
op_entry.Implementation.addArgument(arg);
arg = getTflArgFromString(hTable, 'y1', ['double' '*']);
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDC', 'integer', 0);
op_entry.Implementation.addArgument(arg);

Add the entry to a code replacement table with a call to the addEntry function.

addEntry(hTable, op_entry);

Create the entry for the second mapping.

% Create table entry for cblas_dgemv
op_entry = RTW.TflCBlasEntryGenerator;
setTflCOperationEntryParameters(op_entry, ...
    'Key',                      'RTW_OP_MUL', ...

arg = getTflArgFromString(hTable, 'LDA', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u2', ['double' '*']);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'INCX', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'BETA', 'double', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'y1', ['double' '*']);
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'INCY', 'integer', 0);
op_entry.Implementation.addArgument(arg);

addEntry(hTable, op_entry);

10  Save the table definition file. Use the name of the table definition function to name the file.

To test this example, create a model that uses two Product blocks. For example:

1  Create a model that includes two Product blocks, such as the following:
2 Configure the model with the following settings:
   • On the **Solver** pane, select a fixed-step, discrete solver with a fixed-step size such as 0.1.
   • On the **Code Generation** pane, select an ERT-based system target file.
   • On the **Code Generation > Interface** pane, select the code replacement library that contains your addition operation entry.
3 For each Product block, set the block parameter **Multiplication** to the value **Matrix(*)**.
4 In the Model Explorer, configure the **Signal Attributes** for the In1, In2, and In3 source blocks. For In1 and In2, set **Port dimensions** to [3 3] and set the **Data type** to double. For In3, set **Port dimensions** to [3 1] and set the **Data type** to double.
5 Generate code and a code generation report.
6 Review the code replacements.

Remap Operator Output to Function Input

If your generated code must meet a specific coding pattern or you want more flexibility, for example, to further improve performance, you can remap operator outputs to input positions in an implementation function argument list.

**Note** Remapping outputs to implementation function inputs is supported only for operator replacement.

For example, for a sum operation, the code generator produces code similar to:

```matlab
add8_Y.Out1 = u8_add_u8_u8(add8_U.In1, add8_U.In2);
```

If you remap the output to the first input, the code generator produces code similar to:

```matlab
u8_add_u8_u8(&add8_Y.Out1;, add8_U.In1, add8_U.In2);
```

The following table definition file for a sum operation remaps operator output y1 as the first function input argument.

1. Create a table definition file that contains a function definition. For example:

   ```matlab
   function hTable = crl_table_add_uint8
   
   2. Within the function body, create the table by calling the function RTW.TflTable.

   ```matlab
   hTable = RTW.TflTable;
   
   3. Create an entry for the operator mapping with a call to the RTW.TflCOperationEntry function.

   ```matlab
   % Create operation entry
   op_entry = RTW.TflCOperationEntry;
   
   4. Set operator entry parameters with a call to the setTflCOperationEntryParameters function. In the function call, set the property SideEffects to true.

   ```matlab
   setTflCOperationEntryParameters(op_entry, ...
   'Key', 'RTW_OP_ADD', ...
   'Priority', 90, ...
   'ImplementationName', 'u8_add_u8_u8', ...
   'ImplementationHeaderFile', 'u8_add_u8_u8.h', ...
   'ImplementationSourceFile', 'u8_add_u8_u8.c', ...
   'SideEffects', true );
   ```
Create conceptual arguments \( y_1, u_1, \) and \( u_2 \). There are multiple ways to set up the conceptual arguments. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create and add the arguments.

```matlab
arg = getTflArgFromString(hTable, 'y1', 'uint8');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(op_entry, arg);

arg = getTflArgFromString(hTable, 'u1', 'uint8');
addConceptualArg(op_entry, arg);

arg = getTflArgFromString(hTable, 'u2', 'uint8');
addConceptualArg(op_entry, arg);
```

Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `getTflArgFromString` function to create the arguments. When defining the implementation function return argument, create a new void output argument, for example, \( y_2 \). When defining the implementation function argument for the conceptual output argument (\( y_1 \)), set the operator output argument as an additional input argument. Mark its IOType as output. Make its type a pointer type. The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument and adds the argument to the entry's array of implementation arguments.

```matlab
% Create new void output \( y_2 \)
arg = getTflArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);

% Set \( y_1 \) as first input arg, mark IOType as output, and use pointer type
arg=getTflArgFromString(hTable, 'y1', 'uint8*');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.addArgument(arg);

arg=getTflArgFromString(hTable, 'u1', 'uint8');
op_entry.Implementation.addArgument(arg);

arg=getTflArgFromString(hTable, 'u2', 'uint8');
op_entry.Implementation.addArgument(arg);
```

Add the entry to a code replacement table with a call to the `addEntry` function.

```matlab
addEntry(hTable, op_entry);
```

Save the table definition file. Use the name of the table definition function to name the file.

To test this example, create a model that uses an Add block. For example:

Create a model that includes an Add block, such as the following:
Configure the model with the following settings:

- On the Solver pane, select a fixed-step solver.
- On the Code Generation pane, select an ERT-based system target file.
- On the Code Generation > Interface pane, select the code replacement library that contains your addition operation entry.
- Set the Optimize global data access parameter to Use global to hold temporary results. This reduces data copies in the generated code.

Generate code and a code generation report.

Review the code replacements.

Fixed-Point Operator Code Replacement

If you have a Fixed-Point Designer license, you can define fixed-point operator code replacement entries to match:

- A binary-point-only scaling combination on the operator inputs and output.
- A slope bias scaling combination on the operator inputs and output.
- Relative scaling or net slope between multiplication or division operator inputs and output. Use one of these methods to map a range of slope and bias values to a replacement function for multiplication or division.
- Equal slope and zero net bias across addition or subtraction operator inputs and output. Use this method to disregard specific slope and bias values and map relative slope and bias values to a replacement function for addition or subtraction.

Common Ways to Match Fixed-Point Operator Entries

The following table maps common ways to match fixed-point operator code replacement entries with the associated fixed-point parameters that you specify in a code replacement table definition file.

<table>
<thead>
<tr>
<th>Match</th>
<th>Create entry</th>
<th>Minimally specify parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>A specific binary-point-only scaling combination on the operator inputs and output.</td>

Fixed-Point Numbers and Arithmetic

Fixed-point numbers use integers and integer arithmetic to represent real numbers and arithmetic with the following encoding scheme:

\[ V = \tilde{V} = SQ + B \]

- \( V \) is an arbitrarily precise real-world value.
- \( \tilde{V} \) is the approximate real-world value that results from fixed-point representation.
- \( Q \) is an integer that encodes \( \tilde{V} \), referred to as the quantized integer.
- \( S \) is a coefficient of \( Q \), referred to as the slope.
- \( B \) is an additive correction, referred to as the bias.

The general equation for an operation between fixed-point operands is:

\[ (S_0Q_0 + B_0) = (S_1Q_1 + B_1) < op > (S_2Q_2 + B_2) \]

The objective of fixed-point operator replacement is to replace an operator that accepts and returns fixed-point or integer inputs and output with a function that accepts and returns built-in C numeric data types. The following sections provide additional programming information for each supported operator.

Addition

The operation \( V_0 = V_1 + V_2 \) implies that

\[ Q_0 = \left( \frac{S_1}{S_0} \right) Q_1 + \left( \frac{S_2}{S_0} \right) Q_2 + \left( \frac{B_1 + B_2 - B_0}{S_0} \right) \]

If an addition replacement function is defined such that the scaling on the operands and sum are equal and the net bias
is zero (for example, a function `s8_add_s8_s8` that adds two signed 8-bit values and produces a signed 8-bit result), then the operator entry must set the operator entry parameters `SlopesMustBeTheSame` and `MustHaveZeroNetBias` to true. To match for replacement, the slopes must be the same for all addition conceptual arguments. (For parameter descriptions, see the reference page for the function `setTflCOperationEntryParameters`.)

**Subtraction**

The operation \( V_0 = V_1 - V_2 \) implies that

\[
Q_0 = \left( \frac{S_1}{S_0} \right) Q_1 - \left( \frac{S_2}{S_0} \right) Q_2 + \left( \frac{B_1 - B_2 - B_0}{S_0} \right)
\]

If a subtraction replacement function is defined such that the scaling on the operands and difference are equal and the net bias

\[
\left( \frac{B_1 - B_2 - B_0}{S_0} \right)
\]

is zero (for example, a function `s8_sub_s8_s8` that subtracts two signed 8-bit values and produces a signed 8-bit result), then the operator entry must set the operator entry parameters `SlopesMustBeTheSame` and `MustHaveZeroNetBias` to true. To match for replacement, the slopes must be the same for all subtraction conceptual arguments. (For parameter descriptions, see the reference page for the function `setTflCOperationEntryParameters`.)

**Multiplication**

There are different ways to specify multiplication replacements. The most direct way is to specify an exact match of the input and output types. This is feasible if a model contains only a few known slope and bias combinations. Use the `TflCOperationEntry` class and specify the exact values of slope and bias on each argument. For scenarios where there

\[
\left( \frac{B_1 + B_2 - B_0}{S_0} \right)
\]
are numerous slope/bias combinations, it is not feasible to specify each value with a
different entry. Use a net slope entry or create a custom entry.

The operation $V_0 = V_1 \times V_2$ implies, for binary-point-only scaling, that

$$S_0Q_0 = (S_1Q_1) (S_2Q_2)$$

$$Q_0 = \left( \frac{S_1S_2}{S_0} \right) Q_1Q_2$$

$$Q_0 = S_nQ_1Q_2$$

where $S_n$ is the net slope.

It is common to replace all multiplication operations that have a net slope of 1.0 with a
function that performs C-style multiplication. For example, to replace all signed 8-bit
multiplications that have a net scaling of 1.0 with the s8_mul_s8_u8_ replacement
function, the operator entry must define a net slope factor, $F2^E$. You specify the values for
$F$ and $E$ using operator entry parameters NetSlopeAdjustmentFactor and
NetFixedExponent. For the s8_mul_s8_u8 function, set
NetSlopeAdjustmentFactor to 1 and NetFixedExponent to 0.0. Also, set the
operator entry parameter SlopesMustBeTheSame to false and the parameter
MustHaveZeroNetBias to true. To match for replacement, the biases must be zero for
all multiplication conceptual arguments. (For parameter descriptions, see the reference
page for the function setTflCOperationEntryParameters.)

**Note** When an operator entry specifies NetSlopeAdjustmentFactor and
NetFixedExponent, matching entries must have arguments with zero bias.

### Division

There are different ways to specify division replacements. The most direct way is to
specify an exact match of the input and output types. This is feasible if a model contains
only a few known slope and bias combinations. Use the TflCOperationEntry class and
specify the exact values of slope and bias on each argument. For scenarios where there
are numerous slope/bias combinations, it is not feasible to specify each value with a
different entry. Use a net slope entry or create a custom entry (see “Customize Match and
Replacement Process” on page 64-159).
The operation \( V_0 = (V_1 / V_2) \) implies, for binary-point-only scaling, that

\[
S_0 Q_0 = \left( \frac{S_1 Q_1}{S_2 Q_2} \right)
\]

\[
Q_0 = S_n \left( \frac{Q_1}{Q_2} \right)
\]

where \( S_n \) is the net slope.

It is common to replace all division operations that have a net slope of 1.0 with a function that performs C-style division. For example, to replace all signed 8-bit divisions that have a net scaling of 1.0 with the `s8_mul_s8_u8_` replacement function, the operator entry must define a net slope factor, \( F_2^E \). You specify the values for \( F \) and \( E \) using operator entry parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`. For the `s16_netslope0p5_div_s16_s16` function, you would set `NetSlopeAdjustmentFactor` to 1 and `NetFixedExponent` to 0.0. Also, set the operator entry parameter `SlopesMustBeTheSame` to false and the parameter `MustHaveZeroNetBias` to true. To match for replacement, the biases must be zero for all division conceptual arguments. (For parameter descriptions, see the reference page for the function `setTflCOperationEntryParameters`.)

**Note** When an operator entry specifies `NetSlopeAdjustmentFactor` and `NetFixedExponent`, matching entries must have arguments with zero bias.

### Data Type Conversion (Cast)

The data type conversion operation \( V_0 = V_1 \) implies, for binary-point-only scaling, that

\[
Q_0 = \left( \frac{S_1}{S_0} \right) Q_1
\]

\[
Q_0 = S_n Q_1
\]

where \( S_n \) is the net slope. Set the operator entry parameter `SlopesMustBeTheSame` to false and the parameter `MustHaveZeroNetBias` to true. To match for replacement,
the biases must be zero for all cast conceptual arguments. (For parameter descriptions, see the reference page for the function `setTflCOperationEntryParameters`.)

**Shift**

The shift left or shift right operation \( V_0 = (V_1 / 2^n) \) implies, for binary-point-only scaling, that

\[
S_0Q_0 = \left( \frac{S_1Q_1}{2^n} \right)
\]

\[
Q_0 = \left( \frac{S_1}{S_0} \right) \left( \frac{Q_1}{2^n} \right)
\]

\[
Q_0 = S_n \left( \frac{Q_1}{2^n} \right)
\]

where \( S_n \) is the net slope. Set the operator entry parameter `SlopesMustBeTheSame` to false and the parameter `MustHaveZeroNetBias` to true. To match for replacement, the biases must be zero for all shift conceptual arguments. (For parameter descriptions, see the reference page for the function `setTflCOperationEntryParameters`.)

Binary-Point-Only Scaling Code Replacement

You can define code replacement entries for operations on fixed-point data types such that they match a binary-point-only scaling combination on operator inputs and output. These binary-point-only scaling entries can map the specified binary-point-scaling combination to a replacement function for addition, subtraction, multiplication, or division.

This example creates a code replacement entry for multiplication of fixed-point data types. You specify arguments using binary-point-only scaling. The example defines the function mapping programatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:
   
   ```
   function hTable = crl_table_fixed_binptscale
   ```

2. Within the function body, create the table by calling the function RTW.TflTable.
   
   ```
   hTable = RTW.TflTable;
   ```

3. Create the entry for the operator mapping with a call to the RTW.TflCOperationEntry function.
   
   ```
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set operator entry parameters with a call to the setTflCOperationEntryParameters function. The parameters specify the type of operation as multiplication, the saturation mode as saturate on integer overflow, rounding modes as unspecified, and the name of the replacement function as s32mul_s16_s16_binarypoint.
   
   ```
   setTflCOperationEntryParameters(op_entry, ...
   'Key',                      'RTW_OP_MUL', ...
   'Priority',                 90, ... 
   'SaturationMode',           'RTW_SATURATE_ON_OVERFLOW', ... 
   'RoundingModes',            {'RTW_ROUND_UNSPECIFIED'}, ... 
   'ImplementationName',      's32_mul_s16_s16_binarypoint', ... 
   'ImplementationHeaderFile', 's32_mul_s16_s16_binarypoint.h', ... 
   'ImplementationSourceFile', 's32_mul_s16_s16_binarypoint.c');
   ```

5. Create conceptual arguments y1, u1, and u2. There are multiple ways to set up the conceptual arguments. This example uses calls to the createAndAddConceptualArg function to create and add an argument with one function call. Each argument specifies that the data type is fixed-point, the mode is binary-point-only scaling, and its derived slope and bias values must exactly match the call-site slope and bias values. The output argument is 32 bits, signed, with a
fraction length of 28. The input arguments are 16 bits, signed, with fraction lengths of 15 and 13.

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...  
'Name',           'y1', ...  
'IOType',         'RTW_IO_OUTPUT', ...  
'CheckSlope',     true, ...  
'CheckBias',      true, ...  
'DataTypeMode',   'Fixed-point: binary point scaling', ...  
'IsSigned',       true, ...  
'WordLength',     32, ...  
'FractionLength', 28);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...  
'Name',           'u1', ...  
'IOType',         'RTW_IO_INPUT', ...  
'CheckSlope',     true, ...  
'CheckBias',      true, ...  
'DataTypeMode',   'Fixed-point: binary point scaling', ...  
'IsSigned',       true, ...  
'WordLength',     16, ...  
'FractionLength', 15);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...  
'Name',           'u2', ...  
'IOType',         'RTW_IO_INPUT', ...  
'CheckSlope',     true, ...  
'CheckBias',      true, ...  
'DataTypeMode',   'Fixed-point: binary point scaling', ...  
'IsSigned',       true, ...  
'WordLength',     16, ...  
'FractionLength', 13);

Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the createAndSetCImplementationReturn and createAndAddImplementationArg functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). In this case, the output argument is 32 bits and signed (int32). The input arguments are 16 bits and signed (int16).

createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...  
'Name',           'y1', ...  
'IOType',         'RTW_IO_OUTPUT', ...  
'IsSigned',       true, ...  
'WordLength',     32, ...  
'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric', ...  
'Name',           'u1', ...  
'IOType',         'RTW_IO_INPUT', ...  
'IsSigned',       true, ...  
'WordLength',     16, ...
'FractionLength', 0);
createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',
   'Name',       'u2', ...
   'IOType',     'RTW_IO_INPUT', ...
   'IsSigned',   true, ...
   'WordLength', 16, ...
   'FractionLength', 0);

7  Add the entry to a code replacement table with a call to the `addEntry` function.
addEntry(hTable, op_entry);
8  Save the table definition file. Use the name of the table definition function to name
    the file.

Slope Bias Scaling Code Replacement

You can define code replacement for operations on fixed-point data types as matching a slope bias scaling combination on the operator inputs and output. The slope bias scaling entries can map the specified slope bias combination to a replacement function for addition, subtraction, multiplication, or division.

This example creates a code replacement entry for division of fixed-point data types. You specify arguments using slope bias scaling. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```matlab
   function hTable = crl_table_fixed_s16divslopebias
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```matlab
   hTable = RTW.TflTable;
   ```

3. Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntry` function.

   ```matlab
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as division, the saturation mode as saturate on integer overflow, rounding modes as round to ceiling, and the name of the replacement function as `s16_div_s16_s16_slopebias`.

   ```matlab
   setTflCOperationEntryParameters(op_entry, ...
   'Key',                      'RTW_OP_DIV', ...
   'Priority',                 90, ...
   'SaturationMode',           'RTW_SATURATE_ON_OVERFLOW', ...
   'RoundingModes',            {'RTW_ROUND_CEILING'}, ...
   'ImplementationName',       's16_div_s16_s16_slopebias', ...
   'ImplementationHeaderFile', 's16_div_s16_s16_slopebias.h', ...
   'ImplementationSourceFile', 's16_div_s16_s16_slopebias.c');
   ```

5. Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Each argument specifies that the data type is fixed-point, the mode is slope bias scaling, and its specified slope and bias values must exactly match the call-site slope and bias values. The output argument and input arguments are 16 bits, signed, each with specific slope bias specifications.
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
'Name',    'y1', ...
'IOType',    'RTW_IO_OUTPUT', ...
'CheckSlope', true, ...
'CheckBias', true, ...
'DataTypeMode', 'Fixed-point: slope and bias scaling', ...
'IsSigned', true, ...
'WordLength', 16, ...
'Slope',    15, ...
'Bias',    2);
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
'Name',    'u1', ...
'IOType',    'RTW_IO_INPUT', ...
'CheckSlope', true, ...
'CheckBias', true, ...
'DataTypeMode', 'Fixed-point: slope and bias scaling', ...
'IsSigned', true, ...
'WordLength', 16, ...
'Slope',    15, ...
'Bias',    2);
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
'Name',    'u2', ...
'IOType',    'RTW_IO_INPUT', ...
'CheckSlope', true, ...
'CheckBias', true, ...
'DataTypeMode', 'Fixed-point: slope and bias scaling', ...
'IsSigned', true, ...
'WordLength', 16, ...
'Slope',    13, ...
'Bias',    5);

6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the createAndSetCImplementationReturn and createAndAddImplementationArg functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). In this case, the output and input arguments are 16 bits and signed (int16).

createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...
'Name',    'y1', ...
'IOType',    'RTW_IO_OUTPUT', ...
'IsSigned', true, ...
'WordLength', 16, ...
'FractionLength', 0);
createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric', ...
'Name',    'u1', ...
'IOType',    'RTW_IO_INPUT', ...
'IsSigned', true, ...
'WordLength', 16, ...
'FractionLength', 0);

65-167
createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',
    'Name', 'u2', ...
    'IOType', 'RTW_IO_INPUT', ...
    'Signed', true, ...
    'WordLength', 16, ...
    'FractionLength', 0);

7 Add the entry to a code replacement table with a call to the `addEntry` function.
   
   addEntry(hTable, op_entry);

8 Save the table definition file. Use the name of the table definition function to name the file.

Net Slope Scaling Code Replacement

Multiplication and Division with Saturation

You can define code replacement entries for operations on fixed-point data types as matching net slope between operator inputs and output. The net slope entries can map a range of slope and bias values to a replacement function for multiplication or division.

This example creates a code replacement entry for division of fixed-point data types, using wrap on overflow saturation mode and a net slope. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```matlab
   function hTable = crl_table_fixed_netslopesaturate
   
   function hTable = getDivOpEntry(hTable, ...
   fixdt(1,wv(iy)),fixdt(1,wv(inum)),fixdt(1,wv(iden)));
   end
   end
   
   function hTable = getDivOpEntry(hTable,dty,dtnum,dtden)
   %---------------------------------------------------------
   % Create an entry for division of fixed-point data types where
   % arguments are specified using Slope and Bias scaling
   % Saturation on, Rounding unspecified
   funcStr = sprintf('user_div_%s_%s_%s',...
                    typeStrFunc(dty),...
                    typeStrFunc(dtnum),...
                    typeStrFunc(dtden));
   ```
op_entry = RTW.TflCOperationEntryGenerator_NetSlope;

Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as division, the saturation mode as wrap on overflow, rounding modes as unspecified, and the name of the replacement function as `user_div_*`. `NetSlopeAdjustmentFactor` and `NetFixedExponent` specify the $F$ and $E$ parts of the net slope $F^{2^E}$.

```matlab
def setTflCOperationEntryParameters(op_entry, ...
    'Key',                      'RTW_OP_DIV', ...
    'Priority',                 90, ... 
    'SaturationMode',           'RTW_WRAP_ON_OVERFLOW',... 
    'RoundingModes',            {'RTW_ROUND_UNSPECIFIED'},...
    'NetSlopeAdjustmentFactor', 1.0, ... 
    'NetFixedExponent',         0.0, ... 
    'ImplementationName',       funcStr, ... 
    'ImplementationHeaderFile', [funcStr,'.h'], ..., 
    'ImplementationSourceFile', [funcStr,'.c']);
```

Create conceptual arguments $y_1$, $u_1$, and $u_2$. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Specify each argument as fixed-point and signed. Also, for each argument, specify that code replacement request processing does not check for an exact match to the call-site slope and bias values.

```matlab
def createAndAddConceptualArg(op_entry, ...
    'RTW.TflArgNumeric', ...
    'Name',           'y1',...
    'IOType',         'RTW_IO_OUTPUT',...
    'CheckSlope',     false,... 
    'CheckBias',      false,... 
    'DataTypeMode',   'Fixed-point: slope and bias scaling',...
    'IsSigned',       dty.Signed,... 
    'WordLength',     dty.WordLength,... 
    'Bias',           0);

def createAndAddConceptualArg(op_entry, ...
    'RTW.TflArgNumeric',...
    'Name',           'u1',...
    'IOType',         'RTW_IO_INPUT',...
    'CheckSlope',     false,... 
    'CheckBias',      false,... 
    'DataTypeMode',   'Fixed-point: slope and bias scaling',...
    'IsSigned',       dtnum.Signed,... 
    'WordLength',     dtnum.WordLength,... 
    'Bias',           0);

def createAndAddConceptualArg(op_entry, ...
    'RTW.TflArgNumeric',...
    'Name',           'u2',...
Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `getTflArgFromString` function to create the arguments. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument. These methods add the argument to the entry array of implementation arguments.

```matlab
arg = getTflArgFromString(hTable, 'y1', typeStrBase(dty));
op_entry.Implementation.setReturn(arg);
arg = getTflArgFromString(hTable, 'u1', typeStrBase(dtnum));
op_entry.Implementation.addArgument(arg);
arg = getTflArgFromString(hTable, 'u2', typeStrBase(dtden));
op_entry.Implementation.addArgument(arg);
```

Add the entry to a code replacement table with a call to the `addEntry` function.

```matlab
addEntry(hTable, op_entry);
```

Define functions that determine the data type word length.

```matlab
function str = typeStrFunc(dt)
if dt.Signed
    sstr = 's';
else
    sstr = 'u';
end
str = sprintf('%s%d',sstr,dt.WordLength);
end
```

```matlab
function str = typeStrBase(dt)
if dt.Signed
    sstr = ;
else
    sstr = 'u';
end
str = sprintf('%sint%d',sstr,dt.WordLength);
end
```
9 Save the table definition file. Use the name of the table definition function to name the file.

**Multiplication and Division with Rounding Mode and Additional Implementation Arguments**

You can define code replacement entries for multiplication and division operations on fixed-point data types such that they match the net slope between operator inputs and output. The net slope entries can map a range of slope and bias values to a replacement function for multiplication or division.

This example creates a code replacement entry for division of fixed-point data types, using the ceiling rounding mode and a net slope scaling factor. The example defines the function mapping programatically. Alternatively, you can use the **Code Replacement Tool** to define the same mapping.

1 Create a table definition file that contains a function definition. For example:

```matlab
function hTable = crl_table_fixed_netsloperound
```

2 Within the function body, create the table by calling the function `RTW.TflTable`.

```matlab
hTable = RTW.TflTable;
```

3 Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntryGenerator_Netslope` function, which provides access to the fixed-point parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`.

```matlab
op_entry = RTW.TflCOperationEntryGenerator_NetSlope;
```

4 Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as division, the saturation mode as saturation off, rounding modes as round to ceiling, and the name of the replacement function as `s16_div_s16_s16`. `NetSlopeAdjustmentFactor` and `NetFixedExponent` specify the $F$ and $E$ parts of the relative scaling factor $F2^E$.

```matlab
setTflCOperationEntryParameters(op_entry, ...
    'Key',                      'RTW_OP_DIV', ...
    'Priority',                 90, ...
    'SaturationMode',           'RTW_WRAP_ON OVERFLOW', ...
    'RoundingModes',            {'RTW_ROUND_CEILING'}, ...
    'NetSlopeAdjustmentFactor',   1.0, ...
    'NetFixedExponent',           0.0, ...
```
Create conceptual arguments y1, u1, and u2. There are multiple ways to set up the conceptual arguments. This example uses calls to the createAndAddConceptualArg function to create and add an argument with one function call. Specify each argument as fixed-point, 16 bits, and signed. Also, for each argument, specify that code replacement request processing does not check for an exact match to the call-site slope and bias values.

```matlab
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...'
  'Name', 'y1', ...'
  'IOType', 'RTW_IO_OUTPUT', ...'
  'CheckSlope', false, ...'
  'CheckBias', false, ...'
  'DataType', 'Fixed', ...'
  'IsSigned', true, ...'
  'WordLength', 16);
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...'
  'Name', 'u1', ...'
  'IOType', 'RTW_IO_INPUT', ...'
  'CheckSlope', false, ...'
  'CheckBias', false, ...'
  'DataType', 'Fixed', ...'
  'IsSigned', true, ...'
  'WordLength', 16);
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...'
  'Name', 'u2', ...'
  'IOType', 'RTW_IO_INPUT', ...'
  'CheckSlope', false, ...'
  'CheckBias', false, ...'
  'DataType', 'Fixed', ...'
  'IsSigned', true, ...'
  'WordLength', 16);
```

Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the createAndSetCImplementationReturn and createAndAddImplementationArg functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). In this case, the output and input arguments are 16 bits and signed (int16).

```matlab
createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...'
  'Name', 'y1', ...'
  'IOType', 'RTW_IO_OUTPUT', ...'
  'IsSigned', true, ...'
  'WordLength', 16, ...'
  'FractionLength', 0);
```
createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',...  
  'Name',       'u1',  ...  
  'IOType',     'RTW_IO_INPUT', ...  
  'IsSigned',   true,  ...  
  'WordLength', 16,  ...  
  'FractionLength', 0);
createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',...  
  'Name',       'u2',  ...  
  'IOType',     'RTW_IO_INPUT', ...  
  'IsSigned',   true,  ...  
  'WordLength', 16,  ...  
  'FractionLength', 0);

7 Add the entry to a code replacement table with a call to the addEntry function.

addEntry(hTable, op_entry);

8 Save the table definition file. Use the name of the table definition function to name the file.

### Equal Slope and Zero Net Bias Code Replacement

You can define code replacement entries for addition or subtraction of fixed-point data types such that they match the relative slope and bias values (equal slope and zero net bias) across operator inputs and output. These entries allow you to disregard slope and bias values when mapping relative slope and bias values to a replacement function for addition or subtraction.

This example creates a code replacement entry for the addition of fixed-point data types. Slopes must be equal and net bias must be zero across the operator inputs and output. The example defines the function mapping programmatically. Alternatively, you can also use the [Code Replacement Tool](#) to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```matlab
   function hTable = crl_table_fixed_slopeseq_netbiaszero
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```matlab
   hTable = RTW.TflTable;
   ```

3. Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntryGenerator` function, which provides access to the fixed-point parameters `SlopesMustBeTheSame` and `MustHaveZeroNetBias`.

   ```matlab
   op_entry = RTW.TflCOperationEntryGenerator;
   ```

4. Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as addition, the saturation mode as saturation off, rounding modes as unspecified, and the name of the replacement function as `u16_add_SameSlopeZeroBias`. The parameters `SlopesMustBeTheSame` and `MustHaveZeroNetBias` must be set to true to indicate that slopes must be equal and net bias must be zero across the addition (or subtraction) of inputs and output.

   ```matlab
   setTflCOperationEntryParameters(op_entry, ...
       'Key',                     'RTW_OP_ADD', ...
       'Priority',                 90, ...
       'SaturationMode',          'RTW_WRAP_ON_OVERFLOW', ...
       'RoundingModes',           {'RTW_ROUND_UNSPECIFIED'}, ...
       'SlopesMustBeTheSame',      true, ...
       'MustHaveZeroNetBias',      true, ...
       'ImplementationName',      'u16_add_SameSlopeZeroBias', ...
       'ImplementationHeaderFile', 'u16_add_SameSlopeZeroBias.h', ...
       'ImplementationSourceFile', 'u16_add_SameSlopeZeroBias.c');
   ```

5. Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the
createAndAddConceptualArg function to create and add an argument with one function call. Each argument is specified as 16 bits and unsigned. Each argument specifies that code replacement request processing does not check for an exact match to the call-site slope and bias values.

```matlab
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name', 'y1', ...
    'IOType', 'RTW_IO_OUTPUT', ...
    'CheckSlope', false, ...
    'CheckBias', false, ...
    'IsSigned', false, ...
    'WordLength', 16);
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name', 'u1', ...
    'IOType', 'RTW_IO_INPUT', ...
    'CheckSlope', false, ...
    'CheckBias', false, ...
    'IsSigned', false, ...
    'WordLength', 16);
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name', 'u2', ...
    'IOType', 'RTW_IO_INPUT', ...
    'CheckSlope', false, ...
    'CheckBias', false, ...
    'IsSigned', false, ...
    'WordLength', 16);
```

6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the createAndSetCImplementationReturn and createAndAddImplementationArg functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). In this case, the output and input arguments are 16 bits and unsigned (uint16).

```matlab
createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...
    'Name', 'y1', ...
    'IOType', 'RTW_IO_OUTPUT', ...
    'IsSigned', false, ...
    'WordLength', 16, ...
    'FractionLength', 0);
createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',...
    'Name', 'u1', ...
    'IOType', 'RTW_IO_INPUT', ...
    'IsSigned', false, ...
    'WordLength', 16, ...
    'FractionLength', 0);
createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',...
```

65-176
7 Add the entry to a code replacement table with a call to the `addEntry` function.

```matlab
addEntry(hTable, op_entry);
```

8 Save the table definition file. Use the name of the table definition function to name the file.

Data Type Conversions (Casts) and Operator Code Replacement

You can use code replacement entries to replace code that the code generator produces for data type conversion (cast) operations.

This example creates a code replacement entry that replaces int32 to int16 data type conversion (cast) operations. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_cast_int32_to_int16
   ```

2. Within the function body, create the table by calling the function RTW.TflTable.

   ```
   hTable = RTW.TflTable;
   ```

3. Create the entry for the operator mapping with a call to the RTW.TflCOperationEntry function.

   ```
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set operator entry parameters with a call to the setTflCOperationEntryParameters function. The parameters specify the type of operation as cast, the saturation mode as saturate on integer overflow, rounding modes as toward negative infinity, and the name of the replacement function as my_sat_cast.

   ```
   setTflCOperationEntryParameters(op_entry, ...
   'Key',                      'RTW_OP_CAST', ...
   'Priority',                 50, ...
   'ImplementationName',       'my_sat_cast', ...
   'SaturationMode',           'RTW_SATURATE_ON_OVERFLOW', ...
   'RoundingModes',            {'RTW_ROUND_FLOOR'}, ...
   'ImplementationHeaderFile', 'some_hdr.h', ..., 
   'ImplementationSourceFile', 'some_hdr.c');
   ```

5. Create the int16 argument as conceptual argument y1 and the implementation return value. There are multiple ways to set up the conceptual and implementation arguments. This example uses calls to the getTflArgFromString and addConceptualArg functions to create the conceptual argument and add it to the entry. Convenience method setReturn specifies the argument as the implementation return value.
6 Create the int32 argument as conceptual and implementation argument \texttt{u1}. This example uses calls to the \texttt{getTflArgFromString} and \texttt{addConceptualArg} functions to create the conceptual argument and add it to the entry. Convenience method \texttt{addArgument} specifies the argument as implementation input argument.

\begin{verbatim}
arg = getTflArgFromString(hTable, 'u1', 'int32');
addConceptualArg(op_entry, arg);
op_entry.Implementation.addArgument(arg);
\end{verbatim}

7 Add the entry to a code replacement table with a call to the \texttt{addEntry} function.

\begin{verbatim}
addEntry(hLib, hEnt);
\end{verbatim}

8 Save the table definition file. Use the name of the table definition function to name the file.

You can use code replacement entries to replace code that the code generator produces for data type conversion (cast) operations.

This example creates a code replacement entry to replace data type conversions (casts) of fixed-point data types by using a net slope. The example defines the function mapping programmatically. Alternatively, you can use the \textbf{Code Replacement Tool} to define the same mapping.

1 Create a table definition file that contains a function definition. For example:

\begin{verbatim}
function hTable = crl_table_cast_fixpt_net_slope
\end{verbatim}

2 Within the function body, create the table by calling the function \texttt{RTW.TflTable}.

\begin{verbatim}
hTable = RTW.TflTable;
\end{verbatim}

3 Create the entry for the operator mapping with a call to the \texttt{RTW.TflCOperationEntryGenerator_Netslope} function, which provides access to the fixed-point parameters \texttt{NetSlopeAdjustmentFactor} and \texttt{NetFixedExponent}.

\begin{verbatim}
op_entry = RTW.TflCOperationEntryGenerator_NetSlope;
\end{verbatim}

4 Set operator entry parameters with a call to the \texttt{setTflCOperationEntryParameters} function. The parameters specify the type of operation as cast, the saturation mode as saturate on integer overflow, rounding modes as toward negative infinity, and the name of the replacement function as
my_fxp_cast.NetSlopeAdjustmentFactor and NetFixedExponent specify the F and E parts of the net slope $F2^E$.

\[ \text{InFL} = 2; \]
\[ \text{InWL} = 16; \]
\[ \text{InSgn} = \text{true}; \]
\[ \text{OutFL} = 4; \]
\[ \text{OutWL} = 32; \]
\[ \text{OutSgn} = \text{true}; \]
\[ \text{setTflCOperationEntryParameters}(\text{op\_entry}, ... \]
\[ '\text{Key}', \quad '\text{RTW\_OP\_CAST}', ... \]
\[ '\text{Priority}', \quad 50, ... \]
\[ '\text{SaturationMode}', \quad '\text{RTW\_SATURATE\_ON\_OVERFLOW}', ... \]
\[ '\text{RoundingModes}', \quad \{'\text{RTW\_ROUND\_FLOOR}'\}, ... \]
\[ '\text{NetSlopeAdjustmentFactor}', \quad 1.0, ... \]
\[ '\text{NetFixedExponent}', \quad (\text{OutFL} - \text{InFL}), ... \]
\[ '\text{ImplementationName}', \quad 'my\_fxp\_cast', ... \]
\[ '\text{ImplementationHeaderFile}', \quad 'some\_hdr.h', ... \]
\[ '\text{ImplementationSourceFile}', \quad 'some\_hdr.c'); \]

5 Create conceptual arguments $y_1$ and $u_1$. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Each argument is specified as fixed-point and signed. Each argument specifies that code replacement request processing does not check for an exact match to the call-site slope and bias values.

createAndAddConceptualArg(\text{op\_entry}, 'RTW.TflArgNumeric', ... \]
\[ '\text{Name}', \quad 'y1', .... \]
\[ '\text{IOType}', \quad 'RTW\_IO\_OUTPUT', ... \]
\[ '\text{CheckSlope}', \quad \text{false}, ... \]
\[ '\text{CheckBias}', \quad \text{false}, ... \]
\[ '\text{DataTypeMode}', \quad 'Fixed-point: binary point scaling', ... \]
\[ '\text{IsSigned}', \quad \text{OutSgn}, ... \]
\[ '\text{WordLength}', \quad \text{OutWL}, ... \]
\[ '\text{FractionLength}',\text{OutFL}); \]

createAndAddConceptualArg(\text{op\_entry}, 'RTW.TflArgNumeric', ... \]
\[ '\text{Name}', \quad 'u1', .... \]
\[ '\text{IOType}', \quad 'RTW\_IO\_INPUT', ... \]
\[ '\text{CheckSlope}', \quad \text{false}, ... \]
\[ '\text{CheckBias}', \quad \text{false}, ... \]
\[ '\text{DataTypeMode}', \quad 'Fixed-point: binary point scaling', ... \]
\[ '\text{IsSigned}', \quad \text{InSgn}, ... \]
\[ '\text{WordLength}', \quad \text{InWL}, ... \]
\[ '\text{FractionLength}',\text{InFL}); \]

6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `createAndSetCImplementationReturn` and `createAndAddImplementationArg` functions to create and add implementation
arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types).

createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...
  'Name',       'y1', ...
  'IOType',     'RTW_IO_OUTPUT', ...
  'IsSigned',   OutSgn, ...
  'WordLength', OutWL, ...
  'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',...
  'Name',       'u1', ...
  'IOType',     'RTW_IO_INPUT', ...
  'IsSigned',   InSgn, ...
  'WordLength', InWL, ...
  'FractionLength', 0);

7  Add the entry to a code replacement table with a call to the addEntry function.

    addEntry(hTable, op_entry);

8  Save the table definition file. Use the name of the table definition function to name the file.

Shift Left Operations and Code Replacement

You can use code replacement entries to replace code that the code generator produces for shift (<<) operations.

This example creates a code replacement entry to replace shift left operations for int16 data. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_shift_left_int16
   ```

2. Within the function body, create the table by calling the function RTW.TflTable.

   ```
   hTable = RTW.TflTable;
   ```

3. Create the entry for the operator mapping with a call to the RTW.TflCOperationEntry function.

   ```
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set operator entry parameters with a call to the setTflCOperationEntryParameters function. The parameters specify the type of operation as shift left and the name of the replacement function as my_shift_left.

   ```
   setTflCOperationEntryParameters(op_entry, ...
   'Key',                      'RTW_OP_SL', ...
   'Priority',                 50, ...
   'ImplementationName',       'my_shift_left', ...
   'ImplementationHeaderFile', 'some_hdr.h', ...
   'ImplementationSourceFile', 'some_hdr.c');
   ```

5. Create the int16 argument as conceptual argument y1 and the implementation return value. There are multiple ways to set up the conceptual and implementation arguments. This example uses calls to the getTflArgFromString and addConceptualArg functions to create the conceptual argument and add it to the entry. Convenience method setReturn specifies the argument as the implementation return value.

   ```
   arg = getTflArgFromString(hTable, 'y1', 'int16');
   arg.IOType = 'RTW_IO_OUTPUT';
   addConceptualArg(op_entry, arg);
   op_entry.Implementation.setReturn(arg);
   ```

6. Create the int16 argument as conceptual and implementation argument u1. This example uses calls to the getTflArgFromString and addConceptualArg functions to create the conceptual argument and add it to the entry. Convenience method addArgument specifies the argument as an implementation input argument.
7 Create the int8 argument as conceptual and implementation argument u2. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create the conceptual argument and add it to the entry. This argument specifies the number of bits to shift the previous input argument. Because the argument type is not relevant, the example disables type checking by setting the `CheckType` property to `false`. Convenience method `addArgument` specifies the argument as implementation input argument.

```matlab
arg = getTflArgFromString(hTable, 'u2', 'int8');
arg.CheckType = false;
addConceptualArg(op_entry, arg);
op_entry.Implementation.addArgument(arg);
```

- The function `getTflArgFromString` is called to create an int8 input argument. This argument is added to the operator entry both as the third conceptual argument and the second implementation input argument.
- Add the entry to a code replacement table with a call to the `addEntry` function.

```matlab
addEntry(hTable, op_entry);
```
- Save the table definition file. Use the name of the table definition function to name the file.

You can use code replacement entries to replace code that the code generator produces for shift (<<) operations.

This example creates a code replacement entry to replace shift left operations for fixed-point data using a net slope. The example defines the function mapping programmatically. Alternatively, you can use the **Code Replacement Tool** to define the same mapping.

1 Create a table definition file that contains a function definition. For example:

```matlab
function hTable = crl_table_shift_left_fixpt_net_slope
```

2 Within the function body, create the table by calling the function `RTW.TflTable`.

```matlab
hTable = RTW.TflTable;
```

3 Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntryGenerator_Netslope` function. This function provides access to the fixed-point parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`. 

65-183
4 Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as shift left, the saturation mode as saturate on integer overflow, rounding modes as toward negative infinity, and the name of the replacement function as `my_fxp_shift_left`. `NetSlopeAdjustmentFactor` and `NetFixedExponent` specify the F and E parts of the net slope $F2^E$.

```
InFL = 2;
InWL = 16;
InSgn = true;
OutFL = 4;
OutWL = 32;
OutSgn = true;
setTflCOperationEntryParameters(op_entry, ...
   'Key',                       'RTW_OP_SL', ...
   'Priority',                  50, ...
   'SaturationMode',            'RTW_SATURATE_ON_OVERFLOW', ...
   'RoundingModes',             {'RTW_ROUND_FLOOR'}, ...
   'NetSlopeAdjustmentFactor',  1.0, ...
   'NetFixedExponent',          (OutFL - InFL),...
   'ImplementationName',        'my_fxp_shift_left', ...
   'ImplementationHeaderFile',  'some_hdr.h', ...
   'ImplementationSourceFile',  'some_hdr.c');
```

5 Create conceptual arguments $y_1$ and $u_1$. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Each argument is specified as fixed-point and signed. Each argument specifies that code replacement request processing does not check for an exact match to the call-site slope and bias values.

```
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
   'Name',         'y1', ...
   'IOType',       'RTW_IO_OUTPUT', ...
   'CheckSlope',   false, ...
   'CheckBias',    false, ...
   'DataTypeMode', 'Fixed-point: binary point scaling', ...
   'IsSigned',     OutSgn, ...
   'WordLength',   OutWL, ...
   'FractionLength',OutFL);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
   'Name',         'u1', ...
   'IOType',       'RTW_IO_INPUT', ...
   'CheckSlope',   false, ...
   'CheckBias',    false, ...
   'DataTypeMode', 'Fixed-point: binary point scaling', ...
   'IsSigned',     InSgn, ...
   'WordLength',   InWL, ...
   'FractionLength',InFL);
```
Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `createAndSetCImplementationReturn` and `createAndAddImplementationArg` functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types).

```matlab
createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'y1', ... 'IOType',         'RTW_IO_OUTPUT', ... 'IsSigned', OutSgn, ... 'WordLength', OutWL, ... 'FractionLength', 0);
createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'u1', ... 'IOType',         'RTW_IO_INPUT', ... 'IsSigned', InSgn, ... 'WordLength', InWL, ... 'FractionLength', 0);
```

Create the `int8` argument as conceptual and implementation argument `u2`. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create the conceptual argument and add it to the entry. This argument specifies the number of bits to shift the previous input argument. Because the argument type is not relevant, type checking is disabled by setting the `CheckType` property to false. Convenience method `addArgument` specifies the argument as implementation input argument.

```matlab
arg = getTflArgFromString(hTable, 'u2', 'uint8');
arg.CheckType = false;
addConceptualArg(op_entry, arg);
op_entry.Implementation.addArgument(arg);
```

Add the entry to a code replacement table with a call to the `addEntry` function.

```matlab
addEntry(hTable, op_entry);
```

Save the table definition file. Use the name of the table definition function to name the file.

Optimize Generated Code By Developing and Using Code Replacement Libraries - MATLAB®

Develop and use code replacement libraries to replace function and operators in generated code. Code replacement is a technique to change the code that the code generator produces for functions and operators to meet application code requirements. For example, you can replace generated code to meet requirements such as:

- Optimization for a specific run-time environment, including, but not limited to, specific target hardware
- Integration with existing application code
- Compliance with a standard, such as AUTOSAR
- Modification of code behavior, such as enabling or disabling nonfinite or inline support
- Application- or project-specific code requirements, such as use of BLAS or elimination of `math.h`, system header files, or calls to `memcpy` or `memset`.

You can configure the code generator to use a code replacement library that MathWorks® provides. If you have an Embedded Coder® license, you can develop your own code replacement library interactively with the Code Replacement Tool or programmatically.

This example provides MATLAB® code that shows a variety of ways you can define code replacement mappings. With each example MATLAB® function, the example provides MATLAB® files that illustrate how to develop function and operator code replacements programmatically.

**Additional Requirements:**

- MATLAB Coder
- Embedded Coder
- Fixed-Point Designer

**Create a New Folder and Copy Relevant Files**

The following code creates a folder in your current working folder (pwd). The new folder contains files that are relevant for this example. If you do not want to affect the current folder (or if you cannot generate files in this folder), change your working folder.
coderdemo_setup('coderdemo_crl');

Steps for Developing a Code Replacement Library

1. Identify your code replacement requirements with respect to function or operating mappings, build information, and registration information.
2. Prepare for code replacement library development (for example, identify or develop models to test your library).
3. Define code replacement mappings.
4. Specify build information for replacement code.
5. Register code replacement mappings.
7. Deploy the library.

For more information, see “Develop a Code Replacement Library” on page 65-15.

Math Function Replacement

This example defines and registers code replacement mappings for math functions. You can define code replacement mappings for a variety of functions. For details, see “Code You Can Replace from MATLAB Code” on page 65-5.

1. Open and explore the MATLAB® file for this example.
   edit(fullfile(matlabroot,'toolbox','coder','codegendemos','coderdemo_crl','replace_math_fcns.m'))
2. Configure the code generator to use the code replacement library Function Replacement Examples.
   RTW.TargetRegistry.getInstance('reset');
   cfg = coder.config('lib','ecoder',true);
   cfg.CodeReplacementLibrary = 'Function Replacement Examples';
   cfg.GenerateReport = false;
   cfg.LaunchReport = false;
3. Set up the configuration parameters to build and define the function input type.
   t = single(2);
4. Explore the code replacement table definition file.
   edit(fullfile(matlabroot,'toolbox','coder','codegendemos','coderdemo_crl','crl_table_functions.m'))
5. Compile the MATLAB® program into a C source file by using the configuration parameters that point to the code replacement library and the example input class defined in step 3 as input parameters to the codegen command.

codegen -config cfg replace_math_fcns -args {t, t};

6. Open the file replace_math_fcns.c and explore the generated source code.

open(fullfile('codegen','lib','replace_math_fcns','replace_math_fcns.c'))

7. Close replace_math_fcns.m.

For more information on math function replacement, see “Math Function Code Replacement” on page 65-79. For more information on embeddable C code generation using MATLAB® Coder™, see “Register Code Replacement Mappings” on page 65-56 and “C/C++ Code Generation” (MATLAB Coder).

**Addition and Subtraction Operator Replacement**

This example shows how to define and register code replacement mappings for addition (+) and subtraction (-) operations. When defining entries for addition and subtraction operations, you can specify which of the following algorithms (EntryInfoAlgorithm) your library functions implement:

- Cast-before-operation (CBO) (RTW_CAST_BEFORE_OP), the default
- Cast-after-operation (CAO) (RTW_CAST_AFTER_OP)

1. Open and explore the MATLAB® file for this example.

edit(fullfile(matlabroot,'toolbox','coder','codegendemos','coderdemo_crl','addsub_two_int16.m'))

% CBO, the default algorithm, is assumed.

2. Configure the code generator to use a code replacement library **Addition & Subtraction Examples**.

RTW.TargetRegistry.getInstance('reset');
cfg = coder.config('lib','ecoder',true);
cfg.CodeReplacementLibrary = 'Addition & Subtraction Examples';
cfg.GenerateReport = false;
cfg.LaunchReport = false;

3. Set up the configuration parameters to build and define the operation input type.
t = int16(2);

4. Explore the code replacement table definition file.

edit(fullfile(matlabroot,'toolbox','coder','codegendemos','coderdemo_crl','crl_table_addsub.m'))

5. Compile the MATLAB® program into a C source file by using the configuration parameters that point to the desired code replacement library and the example input class defined in step 3 as input parameters to the codegen command.

codegen -config cfg addsub_two_int16 -args {t, t};

6. Open the file addsub_two_int16.c and explore the generated source code.

open(fullfile('codegen','lib','addsub_two_int16','addsub_two_int16.c'))

7. Close addsub_two_int16.m.

**Matrix Operator Replacement**

This example defines and registers code replacement mappings for matrix operations: addition, subtraction, multiplication, transposition, conjugate, and Hermitian.

Supported types include:

- single, double
- int8, uint8
- int16, uint16
- int32, uint32
- csingle, cdouble
- cint8, cuint8
- cint16, cuint16
- cint32, cuint32
- fixed-point integers
• mixed types (different type on each input)

1. Open and explore the MATLAB® file for this example:

```matlab
edit(fullfile(matlabroot,'toolbox','coder','codegendemos','coderdemo_crl','replace_matrix_ops.m'))
```

2. Configure the code generator to use a code replacement library **Matrix Op Replacement Examples**.

```matlab
RTW.TargetRegistry.getInstance('reset');
cfg = coder.config('lib','ecoder',true);
cfg.CodeReplacementLibrary = 'Matrix Op Replacement Examples';
cfg.GenerateReport = false;
cfg.LaunchReport = false;
```

3. Set up the configuration parameters to build and define the operation input type.

```matlab
t = [1.0 2.0; 3.0, 4.0];
```

4. Explore the code replacement table definition file.

```matlab
edit(fullfile(matlabroot,'toolbox','coder','codegendemos','coderdemo_crl','crl_table_matops.m'))
```

5. Compile the MATLAB® program using the configuration parameters that point to the desired code replacement library and the example input class defined in step 3 as input parameters to the codegen command.

```matlab
codegen -config cfg replace_matrix_ops -args {t, t};
```

6. Open the file replace_matrix_ops.c and explore the generated source code.

```matlab
open(fullfile('codegen','lib','replace_matrix_ops','replace_matrix_ops.c'))
```

7. Close replace_matrix_ops.m.

For more information on matrix operator replacement, see “Small Matrix Operation to Processor Code Replacement” on page 65-133.

**Matrix Multiplication Replacement for BLAS**

This example defines and registers code replacement mappings for Basic Linear Algebra Subroutines (BLAS) subroutines xGEMM and xGEMV. You can map the following operations to a BLAS subroutine:
• Matrix multiplication
• Matrix multiplication with transpose on single or both inputs
• Matrix multiplication with Hermitian operation on single or both inputs

1. Open and explore the MATLAB® file for this example.
   ```matlab
edit(fullfile(matlabroot,'toolbox','coder','codegendemos','coderdemo_crl','replace_matrix_ops_blas.m'))
```

2. Configure the code generator to use a code replacement library **BLAS Replacement Examples**.
   ```matlab
   RTW.TargetRegistry.getInstance('reset');
cfg = coder.config('lib','ecoder',true);
cfg.CodeReplacementLibrary = 'BLAS Replacement Examples';
cfg.GenerateReport = false;
cfg.LaunchReport = false;
```

3. Set up the configuration parameters to build and define the function input type.
   ```matlab
t = [1.0 2.0 3.0; 4.0 5.0 6.0; 7.0 8.0 9.0];
```

4. Explore the code replacement table definition file.
   ```matlab
eedit(fullfile(matlabroot,'toolbox','coder','codegendemos','coderdemo_crl','crl_table_blas.m'))
```

5. Compile the MATLAB® program using the configuration parameters that point to the desired code replacement library and the example input class defined in step 3 as input parameters to the `codegen` command.
   ```matlab
codegen -config cfg replace_matrix_ops_blas -args {t, t};
```

6. Open the file `replace_matrix_ops_blas.c` and explore the generated source code.
   ```matlab
open(fullfile('codegen','lib','replace_matrix_ops_blas','replace_matrix_ops_blas.c'))
```

7. Close `replace_matrix_ops_blas.m`.

For more information on matrix multiplication replacement for BLAS, see “Matrix Multiplication Operation to MathWorks BLAS Code Replacement” on page 65-137.

**MATLAB Function Replacement Using Coder.Replace**

Code replacement libraries support the replacement of MATLAB® functions with scalar and matrix inputs and outputs for built-in, complex, and fixed-point data types.
1. Open and explore the MATLAB® file for this example.

```matlab
edit(fullfile(matlabroot,'toolbox','coder','codegendemos','coderdemo_crl','coder_replace_fcn.m'))
```

2. Configure the code generator to use a code replacement library **Coder Replace Examples**.

```matlab
RTW.TargetRegistry.getInstance('reset');
cfg = coder.config('lib','ecoder',true);
cfg.CodeReplacementLibrary = 'Coder Replace Examples';
cfg.GenerateReport = false;
cfg.LaunchReport = false;
```

3. Set up the configuration parameters to build and define the function input type.

```matlab
t = [1 2; 3 4];
```

4. Explore the code replacement table definition file.

```matlab
edit(fullfile(matlabroot,'toolbox','coder','codegendemos','coderdemo_crl','crl_table_coder_replace.m'))
```

5. Compile the MATLAB® program using the configuration parameters that point to the desired code replacement library and the example input class defined in step 3 as input parameters to the `codegen` command.

```matlab
codegen -config cfg coder_replace_fcn -args {t, t};
```

6. Open the file `coder_replace_fcn.c` and explore the generated source code.

```matlab
open(fullfile('codegen','lib','coder_replace_fcn','coder_replace_fcn.c'))
```

7. Close `coder_replace_fcn.m`.

For more information, see “Replace MATLAB Functions with Custom Code Using coder.replace” on page 65-110.

**Build Information**

For each entry in a code replacement table, you can specify build information such as the following, for replacement functions:

- Header file dependencies
- Source file dependencies
• Additional include paths
• Additional source paths
• Additional link flags

Additionally, you can specify `RTW.copyFileToBuildDir` to copy header, source, or object files, which are required to generate replacement code, to the build folder before code generation. You can specify `RTW.copyFileToBuildDir` by setting it as the value of:

• Property `GenCallback` in a call to `setTflCFunctionEntryParameters`, `setTflCOperationEntryParameters`, or `setTflCSemaphoreEntryParameters`.
• Argument `genCallback` in a call to `registerCFunctionEntry`, `registerCOperationEntry`, or `registerCSemaphoreEntry`.

**Note:** Models in this example are configured for code generation only because the implementations for the replacement functions are not provided.

For more information on specifying build information for replacement code, see “Specify Build Information for Replacement Code” on page 65-47.

**Cleanup**

Remove files and return to original folder

```matlab
RTW.TargetRegistry.getInstance('reset');
clear coderdemo_crl
cd ..;
```

| “Minimize Memory Requirements During Code Generation” on page 66-4
| “Generate Only Code” on page 66-5
| “No Creation of a Code Generation Report” on page 66-5

The amount of time it takes to generate code for a model depends on the size and configuration settings of the model. For instance, if you are working with a large model, it can take awhile to generate code. To decrease the amount of time for code generation of a model, try one or more of the following methods:

- Build a model in increments
- Build large model reference hierarchies in parallel
- Minimize memory requirements during code generation
- Generate only code
- Disable the creation of a code generation report

Build a Model in Increments

You can use the \texttt{rtwbuild} command to build a model and generate code. By default, when rebuilding a model, \texttt{rtwbuild} provides an incremental model build, which only rebuilds a model or submodels that have changed since the most recent model build. Incremental model build saves code generation time. Use the \texttt{Rebuild} parameter on the \texttt{Model Referencing} pane to change the method that Simulink uses to determine when to rebuild code for referenced models. For more information on the \texttt{Rebuild} parameter, see “Rebuild” (Simulink).

Build Large Model Reference Hierarchies in Parallel

In a parallel computing environment, whenever conditions allow, you can increase the speed of code generation and compilation by building models containing large model reference hierarchies in parallel. For example, if you have Parallel Computing Toolbox software, you can distribute code generation and compilation for each referenced model.
across the cores of a multicore host computer. If you have MATLAB Distributed Computing Server software, you can distribute code generation and compilation for each referenced model across remote workers in your MATLAB Distributed Computing Server configuration.

The performance gain realized by using parallel builds for referenced models depends on several factors, including:

- How many models can be built in parallel for a given model referencing hierarchy
- The size of the referenced models
- Parallel computing resources such as the number of local and remote workers available
- The hardware attributes of the local and remote machines (amount of RAM, number of cores, and so on)

For more information, see “Reduce Build Time for Referenced Models” (Simulink Coder).

**Minimize Memory Requirements During Code Generation**

Models that have large amounts of parameter and constant data (such as lookup tables) can tax memory resources and slow code generation. The code generator copies this data to the `model.rtw` file. The `model.rtw` file is a partial representation of the model that the Target Language Compiler parses to transform block computations, parameters, signals, and constant data into a high-level language (for example, C). The Target Language Compiler (TLC) is an integral part of the code generator. The code generator copies parameters and data into `model.rtw`, whether they originate in the model or come from variables or objects in a workspace.

You can improve code generation speed by specifying the maximum number of elements that data vectors can have for the code generator to copy this data to `model.rtw`. When a data vector exceeds the specified size, the code generator places a reference key in `model.rtw`. The TLC uses this key to access the data from Simulink and format it into the generated code. Reference keys result in maintaining only one copy of large data vectors in memory.

The default value above which the code generator uses reference keys in place of actual data values is 10 elements. You can verify this value. In the Command Window, type the following command:

```
get_param(0, 'RTWDataReferencesMinSize')
```

66-4
To set the threshold to a different value, in the Command Window, type the following `set_param` function:

```matlab
set_param(0, 'RTWDataReferencesMinSize', <size>)
```

Provide an integer value for `size` that specifies the number of data elements above which the code generator uses reference keys in place of actual data values.

**Generate Only Code**

You can increase code generation speed by specifying that the build process generate code and a makefile, but not invoke the make command. When the code generator invokes the make command, the build process takes longer because the code generator generates code, compiles code, and creates an executable file.

On the **Code Generation** pane in the Model Configuration Parameters dialog box, you can specify that the build process generate only code by selecting the **Generate code only** parameter. You can specify that the code generation process build a makefile by selecting the **Configuration Parameters > Code Generation > Build process > Makefile configuration > Generate makefile** parameter.

**No Creation of a Code Generation Report**

You can speed up code generation by not generating a code generation report as a part of the build process. To disable the creation of a code generation report, on the **Code Generation > Report** pane, clear the **Create code generation report** parameter. After the build process, you can generate a code generation report by doing this procedure, “Generate Code Generation Report After Build Process” (Simulink Coder).

Control Compiler Optimizations

To control compiler optimizations for a makefile build at the GUI level, use the Compiler optimization level parameter. The Compiler optimization level parameter provides

- Target-independent values Optimizations on (faster runs) and Optimizations off (faster builds), which allow you to easily toggle compiler optimizations on and off during code development
- The value Custom for entering custom compiler optimization flags at the Simulink GUI level, rather than editing compiler flags into template makefiles (TMFs) or supplying compiler flags to build process make commands

The default setting is Optimizations off (faster builds). Selecting the value Custom enables the Custom compiler optimization flags field, in which you can enter custom compiler optimization flags (for example, -O2).

Note If you specify compiler options for your makefile build using OPT_OPTS, MEX_OPTS (except MEX_OPTS="-v"), or MEX_OPT_FILE, the value of Compiler optimization level is ignored and a warning is issued about the ignored parameter.

For more information about the Compiler optimization level parameter and its values, see “Compiler optimization level” (Simulink Coder) and “Custom compiler optimization flags” (Simulink Coder).

Use the Model Advisor to Optimize a Model for Code Generation

You can use the Model Advisor to analyze a model for code generation and identify aspects of your model that impede production deployment or limit code efficiency. You can select from a set of checks to run on a model's current configuration. The Model Advisor analyzes the model and generates check results providing suggestions for improvements in each area. Most Model Advisor diagnostics do not require the model to be in a compiled state; those that do are noted.

Before running the Model Advisor, select the target you plan to use for code generation. The Model Advisor works most effectively with ERT and ERT-based system target files.

Use the following examples to investigate optimizing models for code generation using the Model Advisor:

- rtwdemo_advisor1
- rtwdemo_advisor2
- rtwdemo_advisor3

**Note** Example models rtwdemo_advisor2 and rtwdemo_advisor3 require Stateflow and Fixed-Point Designer software.

For more information on using the Model Advisor, see “Run Model Checks” (Simulink). For more information about the checks, see “Simulink Coder Checks” (Simulink Coder).

**Design Tips for Optimizing Generated Code for Stateflow Objects**

**Do Not Access Machine-Parented Data In a Graphical Function**

This restriction prevents long parameter lists from appearing in the code generated for a graphical function. You can access local data that resides in the same chart as the graphical function. For more information, see “Reuse Logic Patterns by Defining Graphical Functions” (Stateflow).
Be Explicit About the Inline Option of a Graphical Function

When you use a graphical function in a Stateflow chart, select Inline or Function for the property Function Inline Option. Otherwise, the code generated for a graphical function may not appear as you want. For more information, see “Specify Graphical Function Properties” (Stateflow).

Avoid Using Multiple Edge-Triggered Events in Stateflow Charts

When you use a bus object, you reduce the number of parameters in the parameter list of a generated function. This guideline also applies to output signals of a chart. For more information, see “Define Stateflow Structures” (Stateflow).

Combine Input Signals of a Chart Into a Single Bus Object

When you use a bus object, you reduce the number of parameters in the parameter list of a generated function. This guideline also applies to output signals of a chart. For more information, see “Define Stateflow Structures” (Stateflow).

Use Charts with Discrete Sample Times

The code generated for discrete charts that are not inside a triggered or enabled subsystem uses integer counters to track time instead of Simulink provided time. This allows for more efficient code generation in terms of overhead and memory, as well as enabling this code for use in Software-in-the-Loop (SIL) and Processor-in-the-Loop (PIL) simulation modes.

Additional Optimization Techniques

You can apply the following techniques to optimize a model for code generation:

- For Embedded Coder users, if your application uses only integer arithmetic, clear the Support floating-point numbers parameter in the Software environment section of the Interface pane so that the generated code contains no floating-point data or operations. When this parameter is cleared, an error is raised if noninteger data or expressions are encountered during code generation. The error message reports the offending blocks and parameters.
- Disable the Configuration Parameters > Code Generation > Interface > Advanced parameters > MAT-file logging parameter. Deselecting this parameter eliminates extra code and memory usage for initializing, updating, and cleaning-up
logging variables. In addition, the code generated to support MAT-file logging invokes `malloc`, which can be undesirable for your application.

- Use the Upgrade Advisor to upgrade older models (saved by prior versions or the current version) to use current features. For details, see “Model Upgrades” (Simulink).
- Before building, set optimization flags for the compiler (for example, `-O2` for `gcc`, `-Ot` for the Microsoft Visual C++ compiler).
- Directly inline C/C++ S-functions into the generated code by writing a TLC file for the S-function. For more information, see “Accelerate Simulation, Reuse Code, or Protect Intellectual Property by Using S-Function Target” (Simulink Coder) and see “Inline C MEX S-Functions” (Simulink Coder).
- Use a Simulink data type other than `double` when possible. The available data types are `Boolean`, signed and unsigned 8-, 16-, and 32-bit integers, and 32- and 64-bit floats (a `double` is a 64-bit float). For more information, see “About Data Types in Simulink” (Simulink). For a block-by-block summary, click `showblockdatatypetable` or type the command in the Command Window.
- For tunable block parameters that you configure to store in memory in the generated code, you can match parameter data types with signal data types to eliminate unnecessary typecasts and C shifts. Where possible, store parameter values in small integer data types. See “Parameter Data Types in the Generated Code” on page 31-157.
- Remove repeated values in lookup table data.
- Use the Merge block to merge the output of signals wherever possible. This block is particularly helpful when you need to control the execution of function-call subsystems with a Stateflow chart. The following model shows an example of how to use the Merge block.
When more than one signal connected to a Merge block has a non-Auto storage class, all non-Auto signals connected to that block must be identically labeled and have the same storage class. When Merge blocks connect directly to one another, these rules apply to the signals connected to any of the Merge blocks in the group.

Control Memory Allocation for Time Counters

The Application lifespan (days) parameter lets you control the allocation of memory for absolute and elapsed time counters. Such counters exist in the code for blocks that use absolute or elapsed time. For a list of such blocks, see “Absolute Time Limitations” (Simulink Coder).

The size of the time counters in generated code is 8, 16, 32, or 64 bits. The size is set automatically to the minimum that can accommodate the duration value specified by Application lifespan (days) given the step size specified in the Configuration Parameters Solver pane. To minimize the amount of RAM used by time counters, specify the smallest lifespan possible and the largest step size possible.

An application runs to its specified lifespan. It may be able to run longer. For example, running a model with a step size of one millisecond (0.001 seconds) for one day requires a 32-bit timer, which could continue running without overflow for 49 days more.

To maximize application lifespan, specify Application lifespan (days) as inf. This value allocates 64 bits (two uint32 words) for each timer. Using 64 bits to store timing data would allow a model with a step size of 0.001 microsecond (10E-09 seconds) to run for more than 500 years, which would rarely be required. 64-bit counters do not violate the usual code generator length limitation of 32 bits because the value of a time counter does not provide the value of a signal, state, or parameter.

Execution Profiling for Generated Code

Use code execution profiling to:

• Determine whether the generated code meets execution time requirements for real-time deployment on your target hardware.
• Identify code sections that require performance improvements.

The following tasks represent a general workflow that uses code execution profiling:

1  With the Simulink model, design and optimize your algorithm.
2  Configure the model for code execution profiling, and generate code.
3  Execute generated code on target. For example, you can:
   • Run a software-in-the-loop (SIL) simulation on your development computer.
   • Run a processor-in-the-loop (PIL) simulation using a target support package or custom PIL target.
   • Perform real-time execution with Simulink Real-Time or a target support package.
4  Analyze performance through code execution profiling plots and reports. For example, check that the algorithm code satisfies execution time requirements for real-time deployment:
   • If the algorithm code easily meets the requirements, consider enhancing your algorithm to exploit available processing power.
   • If the code cannot be executed in real time, look for ways to reduce execution time.

Identify the tasks that require the most time. For these tasks, investigate whether trade-offs between functionality and speed are possible.

If your target is a multicore processor, distribute the execution of algorithm code across available cores.

5  If required, refine the model and return to step 2.

To find information about code execution profiling with Simulink products, use the following table.

Optimize Generated Code by Combining Multiple for Constructs

This example shows how the code generator combines for loops. The generated code uses for constructs to represent a variety of modeling patterns, such as a matrix signal or Iterator blocks. Using data dependency analysis, the code generator combines for constructs to reduce static code size and runtime branching.

The benefits of optimizing for loops are:

- Reducing ROM and RAM consumption.
- Increasing execution speed.

for Loop Modeling Patterns

In the model, rtwdemo_forloop, the Switch block and MATLAB Function block represent for constructs. In the In1 Block Parameters dialog box, the Port dimensions parameter is set to 10.
Generate Code

In the model, there are no data dependencies across the for loop iterations. Therefore, the code generator combines all for loops into one loop. Build the model and view the generated code.

### Starting build procedure for model: rtwdemo_forloop
### Successful completion of build procedure for model: rtwdemo_forloop

The generated file, rtwdemo_forloop.c, contains the code for the single for loop.

```c
/* Model step function */
void rtwdemo_forloop_step(void)
{
    int32_T k;

    /* MATLAB Function: '<Root>/Accum' */
```
/ * MATLAB Function 'Accum': '<S1>:1' */
/* '<S1>:1:3' */
/* '<S1>:1:4' */
rtwdemo_forloop_Y.Out1 = 0.0;

/* '<S1>:1:5' */
for (k = 0; k < 10; k++) {
    /* Switch: '<Root>/Switch' incorporates:
       * Gain: '<Root>/G1'
       * Gain: '<Root>/G3'
       * Inport: '<Root>/In1'
       * Sum: '<Root>/Sum1'
       * Sum: '<Root>/Sum2'
       * UnitDelay: '<Root>/Delay'
    */
    if (3.0 * rtwdemo_forloop_U.In1[k] >= 0.0) {
        rtwdemo_forloop_DW.Delay_DSTATE[k] = rtwdemo_forloop_U.In1[k] -
        rtwdemo_forloop_DW.Delay_DSTATE[k];
    } else {
        rtwdemo_forloop_DW.Delay_DSTATE[k] = (rtwdemo_forloop_DW.Delay_DSTATE[k] -
        rtwdemo_forloop_U.In1[k]) * 5.0;
    }
    /* End of Switch: '<Root>/Switch' */

    /* MATLAB Function: '<Root>/Accum' */
    /* '<S1>:1:5' */
    /* '<S1>:1:6' */
    rtwdemo_forloop_Y.Out1 += (1.0 + (real_T)k) +
    rtwdemo_forloop_DW.Delay_DSTATE[k];
}

Close the model.

Subnormal Number Performance

Subnormal numbers, formerly known as denormal numbers in floating-point literature, fill the underflow gap around zero in floating-point arithmetic. Subnormal values are a special category of floating-point values that are too close to 0.0 to be represented as a normalized value. The leading significand (mantissa) of a subnormal number is zero. When adding and subtracting floating-point numbers, subnormal numbers prevent underflow.

Using subnormal numbers provides precision beyond the normal representation by using leading zeros in the significand to represent smaller values after the representation reaches the minimum exponent. As the value approaches 0.0, you trade off precision for extended range. Subnormal numbers are useful if your application requires extra range.

However, in a real-time system, using subnormal numbers can dramatically increase execution latency, resulting in excessive design margins and real-time overruns. If the simulation or generated code performs calculations that produce or consume subnormal numbers, the execution of these calculations can be up to 50 times slower than similar calculations on normal numbers. The actual simulation or code execution time for subnormal number calculations depends on your computer operating environment. Typically, for desktop processors, the execution time for subnormal number calculations is five times slower than similar calculations on normal numbers.

To minimize the possibility of execution slowdowns or overruns due to subnormal number calculation latency, do one of the following:

- In your model, manually flush to zero any incoming or computed subnormal values at inputs and key operations, such as washouts and filters. For an example, see “Flush Subnormal Numbers to Zero” on page 66-20.

To detect a subnormal value for a single precision, 32-bit floating-point number:

1 Find the smallest normalized number on a MATLAB host. In the Command Window, type:

   \[
   \text{>> SmallestNormalSingle = realmin('single')}
   \]

   In the C language, \text{FLT_MIN}, defined in \text{float.h}, is equivalent to \text{realmin('single')}.

2 Look for values in range:

   \[
   0 < \text{fabsf(x)} < \text{SmallestNormalSingle}
   \]
To detect a subnormal value for a double precision, 64-bit floating-point number:

1. Find the smallest normalized number on a MATLAB host. In the Command Window, type:

   `>> SmallestNormalDouble = realmin('double')`

   In the C language, `DBL_MIN`, defined in `float.h`, is equivalent to `realmin('double')`.

2. To detect a subnormal value, look for values in this range:

   \[ 0 < \text{fabs}(x) < \text{SmallestNormalDouble} \]

   • On your processor, set flush-to-zero mode or, with your compiler, specify an option to disable subnormal numbers. Flush-to-zero modes treat a subnormal number as 0 when it is an input to a floating-point operation. Underflow exceptions do not occur in flush-to-zero mode.

   For example, in Intel® processors, the flush-to-zero (FTZ) and denormals-are-zero (DAZ) flags in the MXCSR register control floating-point calculations. For the gcc compiler on Linux, `-ffast-math` sets abrupt underflow (FTZ), flush-to-zero, while `-O3 -ffast-math` reverts to gradual underflow, using subnormal numbers.

   For more information, see the IEEE Standard 754, *IEEE Standard for Floating-Point Arithmetic*.

**Simulation Time With and Without Subnormal Numbers**

This model shows how using subnormal numbers increases simulation time by \( \sim 5 \) times.

Open the model `ex_subnormal`. The Gain is set to subnormal value `realmin('double')/2`. 
To run a simulation, in the Command Window, type

```matlab
for k=1:5, tic;
sim('ex_subnormal'); toc,end
```

Observe the elapsed times for simulation using subnormals, similar to the following:

```matlab
Elapsed time is 9.909326 seconds.
Elapsed time is 9.617966 seconds.
Elapsed time is 9.797183 seconds.
Elapsed time is 9.702397 seconds.
Elapsed time is 9.893946 seconds.
```

Set the Gain to a number, 2, that is not a subnormal value:

```matlab
set_param('ex_subnormal/Gain', 'Gain', '2');
```

To run a simulation, in the Command Window, type

```matlab
for k=1:5, tic;
sim('ex_subnormal'); toc,end
```

Observe elapsed times for simulations that do not use subnormal values, similar to the following:

```matlab
Elapsed time is 2.045123 seconds.
Elapsed time is 1.796598 seconds.
Elapsed time is 1.758458 seconds.
Elapsed time is 1.721721 seconds.
Elapsed time is 1.780569 seconds.
```

**Flush Subnormal Numbers to Zero**

This example shows how to flush single precision subnormal numbers to zero.

1. Open the model `ex_flush_to_zero`: 

```matlab
```
• **Repeating Sequence Stair** generates a sequence of numbers from two raised to the power of 0 through two raised to the power of -165. The sequence approaches zero.

• **ConditionRealScalar** flushes subnormal single precision values that are less than `realmin('single')` to zero.

• MATLAB function block `log2` generates the base 2 logarithm of the **Repeating Sequence Stair** output. Specifically, `log2` generates the numbers 0 through -165.

2. On the **Simulation > Stepping Options** pane:
   • Select **Enable stepping back**.
3 In the model window, run the simulation. The simulation pauses at $T=121$. The displayed values:

- ConditionRealScalar output approaches zero.
- Repeating Sequence Stair output approaches zero.

4 Step the simulation forward to $T=127$. ConditionRealScalar flushes the subnormal value output from Repeating Sequence Stair to zero.

5 Continue stepping the simulation forward. ConditionRealScalar flushes the subnormal single precision values output from Repeating Sequence Stair to zero. When $T=150$, the output of Repeating Sequence Stair is itself zero.

Remove Code From Floating-Point to Integer Conversions That Wraps Out-of-Range Values

This example shows how to remove code for out-of-range floating-point to integer conversions. Without this code, there might be a mismatch between simulation and code generation results. Standard C does not define the behavior of out-of-range floating-point to integer conversions, while these conversions are well-defined during simulation. In Standard C and during simulation, floating-point to integer conversions are well-defined for input values in the range of the output type.

If the input values in your application are in the range of the output type, remove code for out-of-range floating-point to integer conversions. Removing this code reduces the size and increases the speed of the generated code.

Example Model

In this model, a Data Type Conversion block converts an input signal from a double to a uint8. A uint8 can support values from 0 to 255. If the input signal has a value outside of this range, an out-of-range conversion occurs. In this example, the model is named conversion_ex.

1 Use Inport, Outport, and Data Type Conversion blocks to create the example model.
2 Open the Inport Block Parameters dialog box and select the Signal Attributes tab. For the Data Type parameter, select double.
Open the Data Type Conversion dialog box. For the **Output data type** parameter, select `uint8`.

For the signal feeding into the Data Type Conversion block, open the Signal Properties dialog box. Enter the name `U`. On the **Code Generation** tab, for the **Storage Class** parameter, select `ImportedExtern`.

For the signal leaving the Data Type Conversion block, open the Signal Properties dialog box. Enter the name `Y`. On the **Code Generation** tab, for the **Storage Class** parameter, select `ImportedExtern`.

### Generate Code Without Optimization

1. Open the Model Configuration Parameters dialog box. On the **Solver** pane, for the **Type** parameter, select `Fixed step`.
2. On the **Code Generation > Report** pane, select **Create code generation report**.
3. On the **Code Generation** pane, select **Generate code only**, and then, in the model window, press `Ctrl+B`. When code generation is complete, an HTML code generation report opens.
4. In the Code Generation report, select the `conversion_ex.c` file and view the model step function. The code generator applies the `fmod` function to handle out-of-range results.

```c
/* Model step function */
void conversion_ex_step(void)
{
    real_T tmp;

    /* DataTypeConversion:
       '<Root>/Data Type Conversion' incorporates:
       Inport: '<>/In1'
    */
    tmp = floor(U);
    if (rtIsNaN(tmp) || rtIsInf(tmp)) {
        tmp = 0.0;
    } else {
        tmp = fmod(tmp, 256.0);
    }

    Y = (uint8_T)
        (tmp < 0.0 ?
            (int32_T)
Generate Code with Optimization

1 Open the Configuration Parameters dialog box. On the Optimization pane, select Remove code from floating-point to integer conversions that wraps out-of-range values. Generate code.

2 In the code generation report, select the conversion_ex.c file and view the model step function. The generated code does not contain code that protects against out-of-range values.

```c
/* Model step function */
void conversion_ex_step(void)
{
  /* DataTypeConversion: '<Root>/Data Type Conversion' incorporates:
   * Inport: '<Root>/In1'
   */
  Y = (uint8_T)U;
}
```

The generated code is more efficient without this protective code, but it is possible that the execution of generated code does not produce the same results as simulation for values not in the range of 0 to 255.

Remove Code That Maps NaN to Integer Zero

This example shows how to remove code that maps NaN to integer zero. For floating-point to integer conversions involving saturation, Simulink converts NaN to integer zero during simulation. If your model contains an input value of NaN, you can specify that the code generator produce code that maps NaN to zero. Without this code, there is a mismatch between simulation and code generation results because in Standard C, every condition involving NaN evaluates to false.

If there are no input values of NaN in your application, you can remove code that maps NaN to integer zero. Removing this code reduces the size and increases the speed of the generated code.

Example Model

In this model, a Data Type Conversion block converts an input signal from a double to a uint8. In this example, the model is named conversion_ex.

1 Use Inport, Outport, and Data Type Conversion blocks to create the example model.
2 Open the Inport Block Parameters dialog box and click the Signal Attributes tab. For the Data Type parameter, select double.
3 Open the Data Type Conversion dialog box. For the Output data type parameter, select uint8.
4 Select **Saturate on integer overflow**. Selecting this parameter specifies that an out-of-range signal value equals either the minimum or maximum value that the data type can represent.

5 For the signal feeding into the Data Type Conversion block, open the Signal Properties dialog box. Enter a name of U. On the **Code Generation** tab, for the **Storage Class** parameter, select **ImportedExtern**.

6 For the signal leaving the Data Type Conversion block, open the Signal Properties dialog box. Enter a name of Y. On the **Code Generation** tab, for the **Storage Class** parameter, select **ImportedExtern**.

**Generate Code**

1 Set the **Configuration Parameters > Solver > Solver options > Type** parameter to **Fixed-step**.

2 Disable the **Configuration Parameters > Optimization > Advanced parameters > Remove code from floating-point to integer conversions with saturation that maps NaN to zero** parameter.

3 Enable the **Configuration Parameters > Code Generation > Report > Create code generation report** parameter.

4 Enable the **Configuration Parameters > Code Generation > Build process > Generate code only** parameter. Then, in the model window, press **Ctrl+B**. When code generation is complete, an HTML code generation report opens.

5 In the Code Generation report, select the **nan_int_ex.c** file and view the model step function. For an input value of NaN, there is agreement between the generated code and simulation because NaN maps to integer zero.

```c
/* Model step function */
void nan_int_ex_step(void)
{
    /* DataTypeConversion: '<Root>/Data Type Conversion' incorporates:
     *  Inport: '<Root>/In1'
     */
    if (U < 256.0) {
        if (U >= 0.0) {
            Y = (uint8_T)U;
        } else {
            Y = 0U;
        }
    } else if (U >= 256.0) {
```
Y = MAX_uint8_T;
} else {
    Y = 0U;
}

Generate Code with Optimization

1 Enable the Configuration Parameters > Optimization > Code generation > Integer and fixed-point > Remove code from floating-point to integer conversions that wraps out-of-range values parameter. Generate code.

2 In the Code Generation report, select the nan_int_ex.c section and view the model step function. The generated code maps NaN to 255 and not integer zero. The generated code is more efficient without the extra code that maps NaN to integer zero, but the execution of the generated code does not produce the same results as simulation for NaN values.

/* Model step function */
void nan_int_ex_step(void)
{
    /* DataTypeConversion: '<Root>/Data Type Conversion' incorporates:
     *  Inport: '<Root>/In1'
     */
    if (U < 256.0) {
        if (U >= 0.0) {
            Y = (uint8_T)U;
        } else {
            Y = 0U;
        }
    } else {
        Y = MAX_uint8_T;
    }

    /* End of DataTypeConversion: '<Root>/Data Type Conversion' */

Disable Nonfinite Checks or Inlining for Math Functions

When the code generator produces code for math functions:

- If the model option **Support non-finite numbers** is selected, nonfinite number checking is generated uniformly for math functions, without the ability to specify that nonfinite number checking should be generated for some functions, but not for others.
- By default, inlining is applied uniformly for math functions, without the ability to specify that inlining should be generated for some functions, while invocations should be generated for others.

You can use code replacement library (CRL) customization entries to:

- Selectively disable nonfinite checks for math functions. This can improve the execution speed of the generated code.
- Selectively disable inlining of math functions. This can increase code readability and decrease code size.

The functions for which these customizations are supported include the following:

- Floating-point only: atan2, copysign, fix, hypot, log, log10, round, sincos, and sqrt
- Floating-point and integer: abs, max, min, mod, rem, saturate, and sign

The general workflow for disabling nonfinite number checking and/or inlining is as follows:

1. If you can disable nonfinite number checking for a particular math function, or if you want to disable inlining for a particular math function and instead generate a function invocation, you can copy the following MATLAB function code into a MATLAB file with an .m file name extension, for example, `crl_table_customization.m`.

   ```matlab
   function hTable = crl_table_customization
     % Create an instance of the Code Replacement Library table for controlling
     % function intrinsic inlining and nonfinite support
     hTable = RTW.TflTable;
     % Inline - true (if function needs to be inline)
     % false (if function should not be inlined)
     % SNF (support nonfinite) - ENABLE (if non-finite checking should be performed)
     % DISABLE (if non-finite checking should NOT be performed)
   ```
% UNSPECIFIED (Default behavior)

registerCustomizationEntry(hTable, ... 100, 1, 'sqrt', 'single', 'single', true, 'UNSPECIFIED');

2 To reduce the size of the file, you can delete the registerCustomizationEntry lines for functions for which the default nonfinite number checking and inlining behavior is acceptable.

3 For each remaining entry,
   - Set the Inline argument to true if the function should be inlined or false if it should not be inlined.
   - Set the SNF argument to ENABLE if nonfinite checking should be generated, DISABLE if nonfinite checking should not be generated, or UNSPECIFIED to accept the default behavior based on the model option settings.

Save the file.

4 Optionally, perform a quick check of the syntactic validity of the customization table entries by invoking the table definition file at the MATLAB command line (>> tbl = crl_table_customization). Fix syntax errors that are flagged.

5 Optionally, view the customization table entries in the Code Replacement Viewer (>> crviewer(crl_table_customization)). For more information about viewing code replacement tables, see “Choose a Code Replacement Library” (Simulink Coder).

6 To register these changes and make them appear in the Code replacement library drop-down list located on the Code Generation > Interface pane of the Configuration Parameters dialog box, first copy the following MATLAB function code into an instance of the file rtwTargetInfo.m.

Note For the example below, specify the argument 'RTW' if a GRT target is selected for your model, otherwise omit the argument.
function rtwTargetInfo(cm)
    % rtwTargetInfo function to register a code replacement library (CRL)
    cm.registerTargetInfo(@locCrlRegFcn);
end % End of RTWTARGETINFO

function thisCrl = locCrlRegFcn
    % Instantiate a CRL registry entry - specify 'RTW' for GRT
    thisCrl = RTW.TflRegistry('RTW');
    % Define the CRL properties
    thisCrl.Name = 'CRL Customization Example';
    thisCrl.Description = 'Example of CRL Customization';
    thisCrl.TableList = {'crl_table_customization'};
    thisCrl.TargetHWDeviceType = {'*'};
end % End of LOCCRLREGFCN

You can edit the Name field to specify the library name that appears in the Code replacement library drop-down list. Also, the file name in the TableList field must match the name of the file you created in step 1.

To register your changes, with both of the MATLAB files you created present in the MATLAB path, enter the following command at the MATLAB command line:

    sl_refresh_customizations

7 Create or open a model that generates function code corresponding to one of the math functions for which you specified a change in nonfinite number checking or inlining behavior.

8 Open the Configuration Parameters dialog box, go to the Code Generation > Interface pane, and use the Code replacement library drop-down list to select the code replacement entry you registered in step 6, for example, CRL Customization Example.

9 Generate code for the model and examine the generated code to verify that the math functions are generated as expected.
Fold Expressions

Expression folding optimizes code to minimize the computation of intermediate results at block outputs and the storage of such results in temporary buffers or variables. When expression folding is on, the code generator collapses (folds) block computations into a single expression, instead of generating separate code statements and storage declarations for each block in a model. Most Simulink blocks support expression folding.

Expression folding improves the efficiency of generated code, frequently achieving results that compare favorably to hand-optimized code. In many cases, entire groups of model computations fold into a single, highly optimized line of code.

Example Model

```matlab
model = 'rtwdemo_slexprfold';
open_system(model);
```
Generate Code

Expression folding is available only when the **Signal storage reuse** parameter is set to on because expression folding operates only on expressions involving local variables. The **Signal storage reuse** and **Eliminate superfluous local variables (expression folding)** parameters are on by default. Clear the **Eliminate superfluous local variables (expression folding)** parameter or enter the following command in the MATLAB Command Window to turn the parameter off:

```
set_param(model, 'ExpressionFolding','off');
```

Create a temporary folder for the build and inspection process.
currentDir = pwd;
[~,cgDir] = rtwdemodir();

Build the model.

rtwbuild(model)

### Starting build procedure for model: rtwdemo_slexprfold
### Successful completion of build procedure for model: rtwdemo_slexprfold

With expression folding off, in the rtwdemo_slexprfold.c file, there are separate code statements before and in the Switch block operation.

cfile = fullfile(cgDir,'rtwdemo_slexprfold_grt_rtw','rtwdemo_slexprfold.c');
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);

/* Model step function */
void rtwdemo_slexprfold_step(void)
{
    boolean_T rtb_LogicalOperator;
    boolean_T rtb_RelationalOperator;
    real_T rtb_Gain;

    /* RelationalOperator: '<Root>/Relational Operator1' incorporates:
     *  Constant: '<Root>/Constant'
     *  Inport: '<Root>/In2'
     */
    rtb_LogicalOperator = (rtwdemo_slexprfold_P.UPPER >= rtwdemo_slexprfold_U.In2);

    /* RelationalOperator: '<Root>/Relational Operator' incorporates:
     *  Constant: '<Root>/Constant1'
     *  Inport: '<Root>/In2'
     */
    rtb_RelationalOperator = (rtwdemo_slexprfold_U.In2 <= rtwdemo_slexprfold_P.LOWER);

    /* Logic: '<Root>/Logical Operator' */
    rtb_LogicalOperator = (rtb_LogicalOperator || rtb_RelationalOperator);

    /* Switch: '<Root>/Switch' */
    if (rtb_LogicalOperator) {
        /* Gain: '<Root>/Gain' incorporates:
         *  Inport: '<Root>/In1'
        */
    }
rtb_Gain = 2.0 * rtwdemo_slexprfold_U.In1;

/* Lookup n-D: '<Root>/Look-Up Table' */
rtwdemo_slexprfold_Y.Out1 = look1_binlx(rtb_Gain,
    rtwdemo_slexprfold_P.T1Break, rtwdemo_slexprfold_P.T1Data, 10U);
} else {
    /* Lookup n-D: '<Root>/Look-Up Table (2-D)' incorporates:
        * Inport: '<Root>/In3'
        * Inport: '<Root>/In4'
    */
    rtwdemo_slexprfold_Y.Out1 = look2_binlx(rtwdemo_slexprfold_U.In3,
        rtwdemo_slexprfold_U.In4, rtwdemo_slexprfold_P.T2Break,
        rtwdemo_slexprfold_P.T2Break, rtwdemo_slexprfold_P.T2Data,
        rtCP_LookUpTable2D_maxIndex, 3U);
}

/* End of Switch: '<Root>/Switch' */

**Generate Code with Optimization**

Enter the following command to turn expression folding on:

```
set_param(model, 'ExpressionFolding','on');
```

Build the model.

```
rtwbuild(model);
```

The following is a portion of rtwdemo_slexprfold.c. In the optimized code, the code generator folds all computations into the Switch block operation.

```
rtwdemodbtype(cfile,/* Model step', /* Model initialize', 1, 0);

/* Model step function */
void rtwdemo_slexprfold_step(void)
{
    /* Switch: '<Root>/Switch' incorporates:
        * Constant: '<Root>/Constant'
        * Constant: '<Root>/Constant1'
        * Inport: '<Root>/In2'
```
if ((rtwdemo_slexprfold_P.UPPER >= rtwdemo_slexprfold_U.In2) ||
   (rtwdemo_slexprfold_U.In2 <= rtwdemo_slexprfold_P.LOWER)) {
    /* Outport: '<Root>/Out1' incorporates:
       * Gain: '<Root>/Gain'
       * Inport: '<Root>/In1'
       * Lookup_n-D: '<Root>/Look-Up Table'
    */
    rtwdemo_slexprfold_Y.Out1 = look1_binlx(2.0 * rtwdemo_slexprfold_U.In1,
                                           rtwdemo_slexprfold_P.T1Break, rtwdemo_slexprfold_P.T1Data, 10U);
  } else {
    /* Outport: '<Root>/Out1' incorporates:
       * Inport: '<Root>/In3'
       * Inport: '<Root>/In4'
       * Lookup_n-D: '<Root>/Look-Up Table (2-D)'
    */
    rtwdemo_slexprfold_Y.Out1 = look2_binlx(rtwdemo_slexprfold_U.In3,
                                           rtwdemo_slexprfold_U.In4, rtwdemo_slexprfold_P.T2Break,
                                           rtwdemo_slexprfold_P.T2Break, rtwdemo_slexprfold_P.T2Data,
                                           rtCP_LookUpTable2D_maxIndex, 3U);
  }

  /* End of Switch: '<Root>/Switch' */
}

Close the model and code generation report.

bdclose(model)
rtwdemoclean;
cd(currentDir)

For an example in which code expressions are expression folded between Simulink and Stateflow, open this model rtwdemo_sfexprfold.
Minimize Computations and Storage for Intermediate Results at Block Outputs

Expression Folding

Expression folding optimizes code to minimize the computation of intermediate results at block outputs and the storage of such results in temporary buffers or variables. When expression folding is on, the code generator collapses (folds) block computations into a single expression, instead of generating separate code statements and storage declarations for each block in the model. Most Simulink blocks support expression folding.

Expression folding improves the efficiency of generated code, frequently achieving results that compare favorably to hand-optimized code. In many cases, entire groups of model computations fold into a single, highly optimized line of code.

You can use expression folding in your own inlined S-function blocks. For more information, see “S-Functions That Support Expression Folding” (Simulink Coder).

Example Model
Generate Code

With expression folding off, in the explfld.c file, the code generator generates this code.

```c
/* Model step function */
void exprfld_step(void)
{
    /* Gain: '<Root>/Gain' incorporates:
     *  Inport: '<Root>/In1'
    */
    exprfld_B.S1 = exprfld_P.Gain_Gain * exprfld_U.i1;

    /* Gain: '<Root>/Gain1' incorporates:
     *  Inport: '<Root>/In2'
    */
    exprfld_B.S2 = exprfld_P.Gain1_Gain * exprfld_U.i2;

    /* Outport: '<Root>/Out1' incorporates:
     *  Product: '<Root>/Product'
    */
    exprfld_Y.Out1 = exprfld_B.S1 * exprfld_B.S2;
}
```

There are separate code statements for both Gain blocks. Before final output, these code statements compute temporary results for the Gain blocks.

Enable Optimization

Expression folding is on by default. To see if expression folding is on for an existing model:

1. Expression folding is available only when the Configuration Parameters > Signal storage reuse parameter is selected because expression folding operates only on expressions involving local variables. Enable the Signal storage reuse parameter.

2. When you select Signal storage reuse, the Enable local block outputs, Reuse local block outputs, and Eliminate superfluous local variables (expression folding) parameters are all on by default.
Generate Code with Optimization

With expression folding, the code generator generates a single-line output computation, as shown in the expfld.c file. The generated comments document the block parameters that appear in the expression.

```c
/* Model step function */
void exprfld_step(void)
{
    /* Outport: '<Root>/Out1' incorporates:
       * Gain: '<Root>/Gain'
       * Gain: '<Root>/Gain1'
       * Inport: '<Root>/In1'
       * Inport: '<Root>/In2'
       * Product: '<Root>/Product'
    */

    exprfld_Y.Out1 =
        exprfld_P.Gain_Gain *
        exprfld_U.i1 *
        (exprfld_P.Gain1_Gain * exprfld_U.i2);
}
```

For an example of expression folding in the context of a more complex model, click rtwdemo_slexprfold, or at the command prompt, type:

```matlab
rtwdemo_slexprfold
```

For more information, see “Enable and Reuse Local Block Outputs in Generated Code” (Simulink Coder)

**Inline Invariant Signals**

You can optimize the generated code by selecting *Inline invariant signals* on the *Optimization* pane. The generated code uses the numerical values of the invariant signals instead of their symbolic names.

An invariant signal is a block output signal that does not change during Simulink simulation. For example, the signal `S3` is an invariant signal. An *invariant signal* is not the same as an *invariant constant*. The two constants (1 and 2) and the gain value of 3 are invariant constants. To inline invariant constants, set *Default parameter behavior* to *Inlined*.

---

### Optimize Generated Code Using Inline Invariant Signals

This example shows how to use inline invariant signals to optimize the generated code. This optimization transforms symbolic names of invariant signals into constant values.

The InlineInvariantSignals optimization:

- Reduces ROM and RAM consumption.
- Improves execution speed.

**Example Model**

Consider the model `matlab:rtwdemo_inline_invariant_signals`.

```matlab
model = 'rtwdemo_inline_invariant_signals';
open_system(model);
```
Generate Code

Create a temporary folder (in your system temporary folder) for the build and inspection process.

currentDir = pwd;
[~,cgDir] = rtwdemodir();

Build the model using Simulink Coder.

rtwbuild(model)

### Starting build procedure for model: rtwdemoInlineInvariantSignals
### Successful completion of build procedure for model: rtwdemoInlineInvariantSignals

View the generated code without the optimization. These lines of code are in rtwdemoInlineInvariantSignals.c.

cfile = fullfile(cgDir,'rtwdemo_inline_invariant_signals_grt_rtw',...
  'rtwdemo_inline_invariant_signals.c');
rtwdemodbtype(cfile,'/* Output and update for atomic system',...  
  '/* Model output', 1, 0);

/* Output and update for atomic system: '<Root>/InlinedConstFcn' */
void rtwdemoInline__InlinedConstFcn(int32_T rtu_In1,
  B_InlinedConstFcn rtwdemo_inl_T *localB, const ConstB_InlinedConstFcn rtwdem_T
  *localC)
{
  /* Product: '<S1>/Product' */
  localB->Product = rtu_In1 * localC->Sum_p;
}
Enable Optimization

1. Open the Configuration Parameters dialog box.
2. On the Optimization pane, select Inline Invariant Signals.

Alternatively, you can use the command-line API to enable the optimization:

```matlab
set_param(model, 'InlineInvariantSignals', 'on');
```

Generate Code with Optimization

The generated code uses the numerical values of the folded constants instead of creating an additional structure (rtwdemo_inline_invariant(ConstB)).

Build the model using Simulink Coder.

```matlab
rtwbuild(model)
```

### Starting build procedure for model: rtwdemo_inline_invariant_signals
### Successful completion of build procedure for model: rtwdemo_inline_invariant_signals

View the generated code with the optimization. These lines of code are in rtwdemo_minmax.c.

```c
rtwdemodbtype(cfile,...
    /* Output and update for atomic system', /* Model output', 1, 0);

/* Output and update for atomic system: '<Root>/InlinedConstFcn' */
void rtwdemo_inline__InlinedConstFcn(int32_T rtu_In1,
    B_InlinedConstFcn_rtwdemo_inl_T *localB)
{
    /* Product: '<S1>/Product' */
    localB->Product = rtu_In1 << 5;
}
```

Close the model and code generation report.
bdclose(model)
rtwdemoclean;
cd(currentDir)

Related Examples
• “Optimization Tools and Techniques” on page 66-7
• “Inline Numeric Values of Block Parameters” on page 66-48
Inline Numeric Values of Block Parameters

This example shows how to optimize the generated code by inlining the numeric values of block parameters. *Block parameters* include the **Gain** parameter of a Gain block and the table data and breakpoint sets of an n-D Lookup Table block.

This optimization determines whether numeric block parameters occupy global memory in the generated code. The optimization can:

- Improve execution speed.
- Reduce RAM and ROM consumption.

**Explore Example Model**

Open the example model `rtwdemo_paraminline` and configure it to show the generated names of blocks.

```matlab
load_system('rtwdemo_paraminline')
set_param('rtwdemo_paraminline','HideAutomaticNames','off')
open_system('rtwdemo_paraminline')
```
The model contains blocks that have these numeric parameters:

- The **Gain** parameters of the Gain blocks
- The **Constant value** parameters of the Constant blocks
- The table data and breakpoint sets of the n-D Lookup Table blocks

The output of the block G2, and the outputs of blocks upstream of G2, change only if you tune the values of the block parameters during simulation or during code execution. When you update the model diagram, these blocks and signal lines appear magenta in color.

Several blocks use `Simulink.Parameter` objects in the base workspace to set the values of their parameters. The parameter objects all use the storage class `Auto`, which means that you can configure the generated code to inline the parameter values.

**Generate Code Without Optimization**

Create a temporary folder for the build and inspection process.

```matlab
currentDir = pwd; [~,cgDir] = rtwdemodir();
```

Disable the optimization by setting `Configuration Parameters > Default parameter behavior` to `Tunable`.

```matlab
set_param('rtwdemo_paraminline','DefaultParameterBehavior','Tunable')
```

Generate code from the model.

```matlab
rtwbuild('rtwdemo_paraminline')
```

### Starting build procedure for model: rtwdemo_paraminline
### Successful completion of build procedure for model: rtwdemo_paraminline

In the code generation report, view the source file `rtwdemo_paraminline_data.c`. The code defines a global structure that contains the block parameter values. Each block parameter in the model, such as a lookup table array, breakpoint set, or gain, appears as a field of the structure.

```matlab
cfile = fullfile(...
    cgDir,'rtwdemo_paraminline_grt_rtw','rtwdemo_paraminline_data.c');
rtwdemodbtype(cfile,'/* Block parameters (default storage) */', '}', 1, 1);
```
/* Block parameters (default storage) */
P_rtwdemo_paraminline_T rtwdemo_paraminline_P = {
    /* Variable: MAX_LIFT */
    * Referenced by: '<Root>/Constant'
    */
    10.0,

    /* Variable: SLIDER_POS */
    * Referenced by: '<Root>/Constant1'
    */
    0.0,

    /* Variable: T1Break */
    * Referenced by: '<Root>/1D Lookup'
    */
    { -5.0, -4.0, -3.0, -2.0, -1.0, 0.0, 1.0, 2.0, 3.0, 4.0, 5.0 },

    /* Variable: T1Data */
    * Referenced by: '<Root>/1D Lookup'
    */
    { -1.0, -0.99, -0.98, -0.96, -0.76, 0.0, 0.76, 0.96, 0.98, 0.99, 1.0 },

    /* Variable: T2Break */
    * Referenced by: '<Root>/2D Lookup'
    */
    { 1.0, 2.0, 3.0 },

    /* Variable: T2Data */
    * Referenced by: '<Root>/2D Lookup'
    */
    { 4.0, 16.0, 10.0, 5.0, 19.0, 18.0, 6.0, 20.0, 23.0 },

    /* Expression: 2 */
    * Referenced by: '<Root>/G1'
    */
    2.0,

    /* Expression: -2 */
    * Referenced by: '<Root>/G2'
    */
    -2.0,

    /* Computed Parameter: uDLookup_maxIndex */
You can tune the structure fields during code execution because they occupy global memory. However, at each step of the generated algorithm, the code must calculate the output of each block, including the outputs of the block G2 and the upstream blocks. View the algorithm in the model step function in the file rtwdemo_paraminline.c.

cfile = fullfile(cgDir,'rtwdemo_paraminline_grt_rtw','rtwdemo_paraminline.c');
rtwdemodbtype(...
    cfile,'/* Model step function */','/* Model initialize function */',1,0);

/* Model step function */
void rtwdemo_paraminline_step(void)
{
    /* Outport: '<Root>/Out1' incorporates:
    *  Constant: '<Root>/Constant'
    *  Constant: '<Root>/Constant1'
    *  Gain: '<Root>/G1'
    *  Gain: '<Root>/G2'
    *  Inport: '<Root>/In1'
    *  Lookup_n-D: '<Root>/1D Lookup'
    *  Lookup_n-D: '<Root>/2D Lookup'
    *  Sum: '<Root>/Sum'
    */
    rtwdemo_paraminline_Y.Out1 = rtwdemo_paraminline_P.G1_Gain * rtwdemo_paraminline_U.In1 + rtwdemo_paraminline_P.G2_Gain * look2_binlx (rtwdemo_paraminline_P.MAX_LIFT, look1_binlx (rtwdemo_paraminline_P.SLIDER_POS, rtwdemo_paraminline_P.T1Break, rtwdemo_paraminline_P.T1Data, 10U), rtwdemo_paraminline_P.T2Break, rtwdemo_paraminline_P.T2Break, rtwdemo_paraminline_P.T2Data, rtwdemo_paraminline_P.uDLookup_maxIndex, 3U);
}

**Generate Code with Optimization**

Set **Default parameter behavior** to Inlined.

set_param('rtwdemo_paraminline','DefaultParameterBehavior','Inlined')

Generate code from the model.
### Starting build procedure for model: rtwdemo_paraminline
### Successful completion of build procedure for model: rtwdemo_paraminline

In the code generation report, view the algorithm in the file `rtwdemo_paraminline.c`.

```c
rtwdemodbtype(...
    cfile,'/* Model step function */','/* Model initialize function */',1,0);

/* Model step function */
void rtwdemo_paraminline_step(void)
{
    /* Outport: '<Root>/Out1' incorporates:
       * Gain: '<Root>/G1'
       * Inport: '<Root>/In1'
       * Sum: '<Root>/Sum'
    */
    rtwdemo_paraminline_Y.Out1 = 2.0 * rtwdemo_paraminline_U.In1 + 150.0;
}
```

The code does not allocate memory for block parameters or for parameter objects that use the storage class `Auto`. Instead, the code generator uses the parameter values from the model, and from the parameter objects, to calculate and inline the constant output of the block G2, `150.0`. The generator also inlines the value of the `Gain` parameter of the Gain block G1, `2.0`.

With the optimization, the generated code leaves out computationally expensive algorithmic code for blocks such as the lookup tables. The optimized code calculates the output of a block only if the output can change during execution. For this model, only the outputs of the Inport block In1, the Gain block G1, and the Sum block can change.

Close the model and the code generation report.

```c
bdclose('rtwdemo_paraminline')
rtwdemoclean;
cd(currentDir)
```

**Preserve Block Parameter Tunability**

When you set Default parameter behavior to Inlined, you can preserve block parameter tunability by creating `Simulink.Parameter` objects for individual parameters. You can configure each object to appear in the code as a tunable field of the...
global parameter structure or as an individual global variable. You can change parameter values during code execution and interface the generated code with your own handwritten code. For more information, see “Create Tunable Calibration Parameter in the Generated Code” (Simulink Coder).

**Inline Invariant Signals**

You can select the **Inline invariant signals** code generation option (which also places constant values in the generated code) only when you set **Default parameter behavior** to **Inlined**. See “Inline Invariant Signals” (Simulink Coder).

**See Also**

“Default parameter behavior” (Simulink Coder)

**Related Examples**

- “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 31-50
Configure Loop Unrolling Threshold

The **Loop unrolling threshold** parameter on the **Optimization** pane determines when a wide signal or parameter should be wrapped into a for loop and when it should be generated as a separate statement for each element of the signal. The default threshold value is 5.

For example, consider the model below:

![Model Diagram](image)

The gain parameter of the Gain block is the vector `myGainVec`.

Assume that the loop unrolling threshold value is set to the default, 5.

If `myGainVec` is declared as

```
myGainVec = [1:10];
```

an array of 10 elements, `myGainVec_P.Gain_Gain[]`, is declared within the `Parameters_model` data structure. The size of the gain array exceeds the loop unrolling threshold. Therefore, the code generated for the Gain block iterates over the array in a for loop, as shown in the following code:
{  
    int32_T i1;

    /* Gain: '<Root>/Gain' */
    for(i1=0; i1<10; i1++) {
        myGainVec_B.Gain_f[i1] = rtb_foo * myGainVec_P.Gain_Gain[i1];
    }
}

If myGainVec is declared as

myGainVec = [1:3];

an array of three elements, myGainVec_P.Gain_Gain[], is declared within the Parameters data structure. The size of the gain array is below the loop unrolling threshold. The generated code consists of inline references to each element of the array, as in the code below.

/* Gain: '<Root>/Gain' */
myGainVec_B.Gain_f[0] = rtb_foo * myGainVec_P.Gain_Gain[0];
myGainVec_B.Gain_f[1] = rtb_foo * myGainVec_P.Gain_Gain[1];

See “Explore Variable Names and Loop Rolling” (Simulink Coder) for more information on loop rolling.

**Note** When a model includes Stateflow charts or MATLAB Function blocks, you can apply a set of Stateflow optimizations on the Optimization pane. The settings you select for the Stateflow options also apply to MATLAB Function blocks in the model. This is because the MATLAB Function blocks and Stateflow charts are built on top of the same technology and share a code base. You do not need a Stateflow license to use MATLAB Function blocks.

Use memcpy Function to Optimize Generated Code for Vector Assignments

In this section...

“Example Model” on page 66-58
“Generate Code” on page 66-59
“Generate Code with Optimization” on page 66-59

You can use the **Use memcpy for vector assignment** parameter to optimize generated code for vector assignments by replacing for loops with memcpy function calls. The memcpy function is more efficient than for-loop controlled element assignment for large data sets. This optimization improves execution speed.

Selecting the **Use memcpy for vector assignment** parameter enables the associated parameter **Memcpy threshold (bytes)**, which allows you to specify the minimum array size in bytes for which memcpy function calls should replace for loops in the generated code. For more information, see “Use memcpy for vector assignment” (Simulink Coder) and “Memcpy threshold (bytes)” (Simulink Coder). In considering whether to use this optimization,

- Verify that your target supports the memcpy function.
- Determine whether your model uses signal vector assignments (such as \( Y=\text{expression} \)) to move large amounts of data, for example, using the Selector block.

To apply this optimization,

1. Consider first generating code without this optimization and measuring its execution speed, to establish a baseline for evaluating the optimized assignment.
2. Select **Use memcpy for vector assignment** and examine the setting of **Memcpy threshold (bytes)**, which by default specifies 64 bytes as the minimum array size for which memcpy function calls replace for loops. Based on the array sizes used in your application's signal vector assignments, and target environment considerations that might bear on the threshold selection, accept the default or specify another array size.
3. Generate code, and measure its execution speed against your baseline or previous iterations. Iterate on steps 2 and 3 until you achieve an optimal result.
**Note** The `memcpy` optimization may not occur under certain conditions, including when other optimizations have a higher precedence than the `memcpy` optimization, or when the generated code is originating from Target Language Compiler (TLC) code, such as a TLC file associated with an S-function block.

**Note** If you are licensed for Embedded Coder software, you can use a code replacement library (CRL) to provide your own custom implementation of the `memcpy` function to be used in generated model code. For more information, see “Memory Function Code Replacement” on page 64-99.

**Example Model**

To examine the result of using the **Use memcpy for vector assignment** parameter on the generated vector assignment code, create a model that generates signal vector assignments. For example,

1. Use In, Out, and Selector blocks to create the following model.

2. Open Model Explorer and configure the **Signal Attributes** for the In1 and In2 source blocks. For each, set **Port dimensions** to `[1, 100]`, and set **Data type** to `int32`. Apply the changes and save the model. In this example, the model has the name `vectorassign`. 
For each Selector block, set the **Index** parameter to 1:50. Set the **Input port size** parameter to 100.

**Generate Code**

1. The **Use memcpy for vector assignment** parameter is on by default. To turn off the parameter, go to the **Optimization** pane and clear the **Use memcpy for vector assignment** parameter.

2. Go to the **Code Generation > Report** pane of the Configuration Parameters dialog box and select the **Create code generation report**. Then go to the **Code Generation** pane, select the **Generate code only** option, and generate code for the model. When code generation completes, the HTML code generation report is displayed.

3. In the HTML code generation report, click the **vectorassign.c** section and inspect the model step function. Notice that the vector assignments are implemented using for loops.

   ```c
   /* Model step function */
   void vectorassign_step(void)
   {
   int32_T i;
   for (i = 0; i < 50; i++) {
      /* Outport: '<Root>/Out1' incorporates:
         *  Inport: '<Root>/In1'
         */
      vectorassign_Y.Out1[i] = vectorassign_U.In1[i];

      /* Outport: '<Root>/Out2' incorporates:
         *  Inport: '<Root>/In2'
         */
      vectorassign_Y.Out2[i] = vectorassign_U.In2[i];
   }
   }
   ```

**Generate Code with Optimization**

1. Go to the **Optimization** pane of the Configuration Parameters dialog box and select the **Use memcpy for vector assignment** option. Leave the **Memcpy threshold (bytes)** option at its default setting of 64. Apply the changes and regenerate code for the model. When code generation completes, the HTML code generation report again is displayed.

2. In the HTML code generation report, click the **vectorassign.c** section and inspect the model output function. Notice that the vector assignments now are implemented using memcpy function calls.
/* Model step function */
void vectorassign_step(void)
{
    /* Outport: '<Root>/Out1' incorporates:
     *  Inport: '<Root>/In1'
     */
    memcpy(&vectorassign_Y.Out1[0], &vectorassign_U.In1[0], 50U * sizeof(real_T));

    /* Outport: '<Root>/Out2' incorporates:
     *  Inport: '<Root>/In2'
     */
    memcpy(&vectorassign_Y.Out2[0], &vectorassign_U.In2[0], 50U * sizeof(real_T));
}

Generate Target Optimizations Within Algorithm Code

Some application components are hardware-specific and cannot simulate on a host system. For example, consider a component that includes pragmas and assembly code for enabling hardware instructions for saturate on add operations or a Fast Fourier Transform (FFT) function.

The following table lists integration options to customize generated algorithm code with target-specific optimizations.

**Note** Solutions marked with *EC only* require an Embedded Coder license.

<table>
<thead>
<tr>
<th>If...</th>
<th>Then...</th>
<th>For More Information, See</th>
</tr>
</thead>
<tbody>
<tr>
<td>You want to optimize the execution speed and memory of the model code by replacing default math functions and operators with target-specific code</td>
<td><em>EC only</em>—Implement function and operator replacements by using the <strong>Code Replacement Tool</strong>, code replacement library (CRL) API, and <strong>Code Replacement Viewer</strong> to create, examine, validate, and register hardware-specific replacement tables</td>
<td>“Optimize Generated Code By Developing and Using Code Replacement Libraries - Simulink®”</td>
</tr>
<tr>
<td>You want to control how code generation technology declares, stores, and represents signals, tunable parameters, block states, and data objects in generated code</td>
<td><em>EC only</em>—Design (create) and apply custom storage classes</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <code>rtwdemo_cscpredef</code></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <code>rtwdemo_importstruct</code></td>
</tr>
<tr>
<td></td>

<td></td>
<td>• “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 35-28</td>
</tr>
</tbody>
</table>
**Note** To simulate an algorithm that includes target-specific elements in a host environment, you must create code that is equivalent to the target code and can run in the host environment.
Remove Code for Blocks That Have No Effect on Computational Results

This example shows how the code generator optimizes generated code by removing code that has no effect on computational results. This optimization:

- Increases execution speed.
- Reduces ROM consumption.

Example

In the model `rtwdemo_blockreduction`, a Gain block of value 1.0 is in between Inport and Outport blocks.

```matlab
model = 'rtwdemo_blockreduction';
open_system(model);
```

Generate Code

Create a temporary folder for the build and inspection process.

```matlab
currentDir=pwd;
[~,cgDir]=rtwdemodir();

Build the model.

set_param(model,'BlockReduction','off');
rtwbuild(model)
```

### Starting build procedure for model: rtwdemo_blockreduction
### Successful completion of build procedure for model: rtwdemo_blockreduction
Here is the code from `rtwdemo_blockreduction.c`.

```c
void rtwdemo_blockreduction_step(void)
{
    rtwdemo_blockreduction_Y.Out1 = 1.0 * rtwdemo_blockreduction_U.In1;
}
```

### Enable Optimization

1. Open the Configuration Parameters dialog box.

2. Select **Block reduction**. This optimization is on by default.

Alternately, use the command-line API to enable the optimization.

```c
set_param(model,'BlockReduction','on');
```

### Generate Code with Optimization

```c
rtwbuild(model)
```

---

Here is the optimized code from `rtwdemo_blockreduction.c`.

```c
void rtwdemo_blockreduction_step(void)
{
    rtwdemo_blockreduction_Y.Out1 = 1.0 * rtwdemo_blockreduction_U.In1;
}
```
rtwdemo_blockreduction_Y.Out1 = rtwdemo_blockreduction_U.In1;
}

Because multiplying the input signal by a value of 1.0 does not impact computational results, the code generator excludes the Gain block from the generated code. Close the model and clean up.

bdclose(model)
rtwdemoclean;
cd(currentDir)

**See Also**

“Block reduction” (Simulink)

Eliminate Dead Code Paths in Generated Code

This example shows how the code generator eliminates dead (that is, unused) code paths from generated code. This optimization increases execution speed and conserves ROM and RAM consumption.

**Example**

In the model `rtwdemo_deadpathElim`, the signal leaving the Sum block divides into two separate code paths. The top path is not a dead code path. If the user disables the Assertion block, the bottom path becomes a dead code path.

```matlab
model = 'rtwdemo_deadpathElim';
open_system(model);
```

### Generate Code with an Enabled Assertion Block

1. For the Assertion block, open the block parameters dialog box.
2. Select the **Enable assertion** box. Alternatively, use the command-line API to enable the Assertion block.

```matlab
set_param([model '/Assert1'], 'Enabled', 'on');
```

Create a temporary folder for the build and inspection process.

```matlab
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```matlab
rtwbuild(model)
```
Because the Assertion block is enabled, these lines of `rtwdemo_deadpathElim.c` include code for the Gain and Assertion blocks.

```c
void rtwdemo_deadpathElim_step(void)
{
    /* Sum: '<Root>/Sum1' incorporates:
    *  Constant: '<Root>/Constant1'
    *  Inport: '<Root>/In1'
    */
    rtwdemo_deadpathElim_Y.Out1 = rtwdemo_deadpathElim_U.In1 + 1.0;

    /* Assertion: '<Root>/Assert1' incorporates:
    *  Gain: '<Root>/G1'
    */
    utAssert(2.0 * rtwdemo_deadpathElim_Y.Out1 != 0.0);
}
```

**Generate Code with a Disabled Assertion Block**

Disable the Assertion block to generate a dead code path. The code generator detects the dead code path and eliminates it from the generated code.

1. For the Assertion block, open the Block Parameters dialog box.
2. Deselect the **Enable assertion** box.

Alternatively, use the command-line API to disable the Assertion block.

```matlab
set_param([model '/Assert1'], 'Enabled', 'off');
```

Build the model.

```bash
rtwbuild(model)
```

Because the Assertion block is disabled, these lines of `rtwdemo_deadpathElim.c` do not include code for the Gain and Assertion blocks.

```c
void rtwdemo_deadpathElim_step(void)
{
    /* Sum: '<Root>/Sum1' incorporates:
    *  Constant: '<Root>/Constant1'
    *  Inport: '<Root>/In1'
    */
    rtwdemo_deadpathElim_Y.Out1 = rtwdemo_deadpathElim_U.In1 + 1.0;

    /* Assertion: '<Root>/Assert1' incorporates:
    *  Gain: '<Root>/G1'
    */
    utAssert(2.0 * rtwdemo_deadpathElim_Y.Out1 != 0.0);
}
```
void rtwdemo_deadpathElim_step(void)
{
    /* Outport: '<Root>/Out1' incorporates:
       * Constant: '<Root>/Constant1'
       * Inport: '<Root>/In1'
       * Sum: '<Root>/Sum1'
    */
    rtwdemo_deadpathElim_Y.Out1 = rtwdemo_deadpathElim_U.In1 + 1.0;
}

Close the model and clean-up.

bdclose(model)
rtwdemoclean;
cd(currentDir)

For another example of how the code generator eliminates dead code paths in the generated code, see rtwdemo_deadpath.

Floating-Point Multiplication to Handle a Net Slope Correction

This example shows how to use floating-point multiplication to handle a net slope correction. When converting floating-point data types to fixed-point data types in the generated code, a net slope correction is one method of scaling fixed-point data types. Scaling the fixed-point data types avoids overflow conditions and minimizes quantization errors.

For processors that support efficient multiplication, using floating-point multiplication to handle a net slope correction improves code efficiency. If the net slope correction has a value that is not a power of two, using division improves precision.

**Note:** This example requires a Fixed-Point Designer™ license.

**Example**

In the model `rtwdemo_float_mul_for_net_slope_correction`, a Convert block converts an input signal from a floating-point data type to a fixed-point data type. The net slope correction has a value of 3.

```matlab
model = 'rtwdemo_float_mul_for_net_slope_correction';
open_system(model);
```

Generate Code

Create a temporary folder for the build and inspection process.

```matlab
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.
rtwbuild(model)
### Starting build procedure for model: rtwdemo_float_mul_for_net_slope_correction
### Successful completion of build procedure for model: rtwdemo_float_mul_for_net_slope_correction

In these lines of `rtwdemo_float_mul_for_net_slope_correction.c` code, the code generator divides the input signal by `3.0F`.

cfile = fullfile(cgDir,'rtwdemo_float_mul_for_net_slope_correction_ert_rtw',...
    'rtwdemo_float_mul_for_net_slope_correction.c');
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);

/* Model step function */
void rtwdemo_float_mul_for_net_slope_correction_step(void)
{
    /* Outport: '<Root>/Output' incorporates:
     *  DataTypeConversion: '<Root>/Data Type Conversion'
     *  Inport: '<Root>/Input'
     */
    rtY.Output = (int16_T)(real32_T)floor((real_T)(rtU.Input / 3.0F));
}

Enable Optimization

1. Open the Configuration Parameters dialog box.
2. On the Math and Data Types pane, select Use floating-point multiplication to handle net slope corrections. This optimization is on by default.

Alternatively, you can use the command-line API to enable the optimization.

set_param(model, 'UseFloatMulNetSlope', 'on');

Generate Code with Optimization

rtwbuild(model)
### Starting build procedure for model: rtwdemo_float_mul_for_net_slope_correction
### Successful completion of build procedure for model: rtwdemo_float_mul_for_net_slope_correction

In the optimized code, the code generator multiplies the input signal by the reciprocal of `3.0F`, that is `0.333333343F`.

rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);
/* Model step function */
void rtwdemo_float_mul_for_net_slope_correction_step(void)
{
    /* Outport: '<Root>/Output' incorporates:
    *  DataTypeConversion: '<Root>/Data Type Conversion'
    *  Inport: '<Root>/Input'
    */
    rtY.Output = (int16_T)(real32_T)floor((real_T)(rtU.Input * 0.333333343F));
}

Close the model and the code generation report.

bdclose(model)
rtwdemoclean;
cd(currentDir)

Use Conditional Input Branch Execution

This example shows how to optimize the generated code for a model that contains Switch and Multiport Switch blocks. When you select the model configuration parameter **Conditional input branch execution**, Simulink executes only blocks that compute the control input and data input that the control input selects. This optimization improves execution speed.

**Example Model**

In this example, switch paths are conditionally executed. If Switch1 control input is true, Switch1 executes blocks grouped in the Switch1:Path1 branch. If Switch1 control input is false, Switch1 executes blocks grouped in the Switch1:Path2 branch. If Switch1 executes blocks in the Switch1:Path2 branch and Switch2 control input is true, Switch2 executes blocks in the Switch2:Path1 branch. If Switch2 control input is false, Switch2 executes blocks in the Switch2:Path2 branch. The pseudo code shows this logic.

```matlab
model='rtwdemo_condinput';
open_system(model);
```
This model shows conditional input branch execution performed by Simulink and Simulink Coder. Conditional input branch execution improves simulation and code generation execution performance. In this example, switch paths are conditionally executed. That is, if Switch1’s control input is true, Switch1 executes blocks grouped in the "Switch1:Path1" branch. Otherwise, it executes blocks grouped in the "Switch1:Path2" branch. If blocks in "Switch1:Path2" are executed, Switch2 executes the "Switch2:Path1" branch if its control input is true. Otherwise, it executes the "Switch2:Path2" branch. This logic is illustrated by the pseudo code above.

```
if Switch1 true
  execute "Switch1:Path1"
else
  execute "Switch1:Path2"
if Switch2 true
  execute "Switch2:Path1"
else
  execute "Switch2:Path2"
end
end
```
**Generate Code**

The **Conditional input branch execution** parameter is on by default. Enter the following command-line API to turn off the parameter.

```matlab
set_param(model, 'ConditionallyExecuteInputs', 'off');
```

Create a temporary folder for the build and inspection process.

```matlab
currentDir=pwd;
[~,cgDir]=rtwdemodir();
```

Build the model.

```matlab
rtwbuild(model)
```

### Starting build procedure for model: rtwdemo_condinput
### Successful completion of build procedure for model: rtwdemo_condinput

View the generated code without the optimization. These lines of code are in the `rtwdemo_condinput.c` file.

```matlab
cfile = fullfile(cgDir,'rtwdemo_condinput_grt_rtw','rtwdemo_condinput.c');
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);
```

```c
/* Model step function */
void rtwdemo_condinput_step(void)
{
    /* Switch: '<Root>/ Switch2' incorporates:
    *  Constant: '<Root>/ C_10'
    *  Constant: '<Root>/C_5'
    *  Gain: '<Root>/ G3'
    *  Inport: '<Root>/input'
    *  RelationalOperator: '<Root>/Relational Operator'
    *  Sum: '<Root>/ Sum'
    */
    if (rtwdemo_condinput_U.input >= -5.0) {
        rtwdemo_condinput_Y.output = 3.0 * rtwdemo_condinput_U.input;
    } else {
        rtwdemo_condinput_Y.output = rtwdemo_condinput_U.input + -10.0;
    }

    /* End of Switch: '<Root>/ Switch2' */
```
The generated code contains an if-else statement for the Switch1 block and an if statement for the Switch2 block. Therefore, the generated code for Switch1:Path2 executes even if the if statement for Switch1:Path1 evaluates to true.

**Enable Optimization**

1. Open the Configuration Parameters dialog box.
2. Select the Conditional input branch execution parameter. Alternatively, you can use the command-line API to enable the optimization.

```matlab
set_param(model, 'ConditionallyExecuteInputs','on');
```

**Generate Code with Optimization**

```matlab
rtwbuild(model)
cfile = fullfile(cgDir,'rtwdemo_condinput_grt_rtw','rtwdemo_condinput.c');
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);
```

```c
/* Model step function */
void rtwdemo_condinput_step(void)
{
  /* Switch: '<Root>/Switch1' incorporates:
   * Constant: '<Root>/C5'
   * Inport: '<Root>/input'
   * RelationalOperator: '<Root>/Relational Operator1'
   */
  if (rtwdemo_condinput_U.input >= 5.0) {
    /* Outport: '<Root>/output' incorporates:
     * Constant: '<Root>/C10'
     * Sum: '<Root>/Sum1'
     */
    rtwdemo_condinput_Y.output = rtwdemo_condinput_U.input + 10.0;
  }
  /* End of Switch: '<Root>/Switch1' */
}
```
if (rtwdemo_condinput_U.input >= 5.0) {
    rtwdemo_condinput_Y.output = rtwdemo_condinput_U.input + 10.0;
} else if (rtwdemo_condinput_U.input >= -5.0) {
    rtwdemo_condinput_Y.output = 3.0 * rtwdemo_condinput_U.input;
} else {
    rtwdemo_condinput_Y.output = rtwdemo_condinput_U.input + -10.0;
}

The generated code contains one if statement. The generated code for Switch1:Path2 only executes if the if statement evaluates to false.

Optimize Generated Code for Complex Signals

This example shows how Simulink Coder handles complex signals efficiently. To view the data types of the signals, update the model using **Simulation > Update Diagram**. Complex signals are represented as structures in generated code. Simulink Coder performs various optimizations on these structures. For example:

- Expression Folding: Gain and Sum operations on the complex signal are folded into a single expression.
- For-loop fusion: Two separate for-loops, one for the complex signal and one for noncomplex signal, are combined into a single for-loop.
- Inlined block parameters: The value of Gain block "pi" is inlined in the expression of the complex Gain-Sum.

Because of optimizations such as these, the code generated for complex and noncomplex signals is equally efficient.

**Example Model**

```matlab
model='rtwdemo_complex';
open_system(model);
```
This model shows how Simulink Coder handles complex signals efficiently. To view the data types of the signals, update the model using Simulation > Update Diagram. Complex signals are represented as structures in generated code. Simulink Coder performs various optimizations on these structures. For example,

- Expression folding: Gain and Sum operations on the complex signal are folded into a single expression.
- For-loop fusion: Two separate for-loops, one for the complex signal and one for the noncomplex signal, are combined into a single for-loop.
- Inlined block parameters: The value of Gain block "pi" is inlined in the expression of the complex Gain-Sum.

Because of optimizations such as these, the code generated for complex and noncomplex signals is equally efficient.

Speed Up Linear Algebra in Code Generated from a MATLAB Function Block

To improve the execution speed of code generated for certain linear algebra functions in a MATLAB Function block, specify that the code generator produce LAPACK calls. LAPACK is a software library for numerical linear algebra. The code generator uses the LAPACKE C interface to LAPACK. If you specify that you want to generate LAPACK calls, and the input arrays for the linear algebra functions meet certain criteria, the code generator produces the LAPACK calls. Otherwise, the code generator produces code for the linear algebra functions.

The code generator uses the LAPACK library that you specify. Specify a LAPACK library that is optimized for your execution environment. See www.netlib.org/lapack/faq.html#_what_and_where_are_the_lapack_vendors_implementations.

Specify LAPACK Library

To generate LAPACK calls, you must have access to a LAPACK callback class. A LAPACK callback class specifies the LAPACK library and LAPACKE header file for the LAPACK calls. To indicate that you want to generate LAPACK calls and that you want to use a specific LAPACK library, specify the name of the LAPACK callback class. In the Configuration Parameters dialog box, set Custom LAPACK library callback to the name of the callback class, for example, useMyLAPACK.

Write LAPACK Callback Class

To specify the locations of a particular LAPACK library and LAPACKE header file, write a LAPACK callback class. Share the callback class with others who want to use this LAPACK library for LAPACK calls in generated code.

The callback class must derive from the abstract class coder.LAPACKCallback. Use this example callback class as a template.

```matlab
classdef useMyLAPACK < coder.LAPACKCallback
    methods (Static)
        function hn = getHeaderFilename()
            hn = 'mylapacke_custom.h';
        end
        function updateBuildInfo(buildInfo, buildctx)
end
```
buildInfo.addIncludePaths(fullfile(pwd,'include'));
libName = 'mylapack';
libPath = fullfile(pwd,'lib');
[~,linkLibExt] = buildctx.getStdLibInfo();
builtInfo.addLinkObjects([libName linkLibExt], libPath, ...
    '', true, true);
builtInfo.addDefines('HAVE_LAPACK_CONFIG_H');
builtInfo.addDefines('LAPACK_COMPLEX_STRUCTURE');
end
end
end

You must provide the getHeaderFilename and updateBuildInfo methods. The getHeaderFilename method returns the LAPACKE header file name. In the example callback class, replace mylapacke_custom.h with the name of your LAPACKE header file. The updateBuildInfo method provides the information required for the build process to link to the LAPACK library. Use code like the code in the template to specify the location of header files and the full path name of the LAPACK library. In the example callback class, replace mylapack with the name of your LAPACK library.

If your compiler supports only complex data types that are represented as structures, include these lines in the updateBuildInfo method.

buildInfo.addDefines('HAVE_LAPACK_CONFIG_H');
builtInfo.addDefines('LAPACK_COMPLEX_STRUCTURE');

**Generate LAPACK Calls by Specifying a LAPACK Callback Class**

This example shows how to generate code that calls LAPACK functions in a specific LAPACK library. For this example, assume that the LAPACK callback class useMyLAPACK specifies the LAPACK library that you want.

1. Create a Simulink model.
2. Add a MATLAB Function block to the model.
3. In the MATLAB Function block, add code that calls a linear algebra function. For example, add the function mysvd that calls the MATLAB function svd.

```matlab
function s = mysvd(A)
    %#codegen
    s = svd(A);
end
```
4. Add a Constant block to the left of the MATLAB Function block. Set the value to zeros(500).
5 Add an Outport block to the right of the MATLAB Function block.
6 Connect the blocks.

![Diagram](image.png)

7 Set the **Configuration Parameters > Code Generation > Advanced parameters > Custom LAPACK library callback** parameter to useMyLAPACK.

The callback class must be on the MATLAB path.

8 Build the model.

If the input to *mysvd* is large enough, the code generator produces a LAPACK call for *svd*. An example of a call to the LAPACK library function for *svd* is:

```c
info_t = LAPACKE_dgesvd( ... 
    LAPACK_COL_MAJOR, 'N', 'N', (lapack_int)500, ... 
    (lapack_int)500, &A[0], (lapack_int)500, &S[0], ... 
    NULL, (lapack_int)1, NULL,(lapack_int)1, &superb[0]);
```

**Locate LAPACK Library in Execution Environment**

The LAPACK library must be available in your execution environment. If your LAPACK library is shared, use environment variables or linker options to specify the location of the LAPACK library.

- On a Windows platform, modify the PATH environment variable.
- On a Linux platform, modify the LD_LIBRARY_PATH environment variable or use the rpath linker option.
- On a macOS platform, modify the DYLD_LIBRARY_PATH environment variable or use the rpath linker option.

To specify the rpath linker option, you can use the build information `addLinkFlags` method in the `updateBuildInfo` method of your `coder.LAPACKCallback` class. For example, for a GCC compiler:

```c
buildInfo.addLinkFlags(sprintf('-Wl,-rpath,"%s"',libPath));
```

• “LAPACK Calls for Linear Algebra in a MATLAB Function Block” (Simulink)

External Websites
• www.netlib.org/lapack
• www.netlib.org/lapack/
  faq.html#_what_and_where_are_the_lapack_vendors_implementations
To improve the execution speed of code generated for certain low-level vector and matrix operations (such as matrix multiplication) in a MATLAB Function block, specify that you want the code generator to produce BLAS calls. BLAS is a software library for low-level vector and matrix computations that has several highly optimized machine-specific implementations. The code generator uses the CBLAS C interface to BLAS. If you specify that you want to generate BLAS calls, and the input arrays for the matrix functions meet certain criteria, the code generator produces the BLAS calls. Otherwise, the code generator produces code for the matrix functions.

The code generator uses the BLAS library that you specify. Specify a BLAS library that is optimized for your execution environment.

**Specify BLAS Library**

To produce BLAS calls in generated code, you must have access to a BLAS callback class. A BLAS callback class specifies the BLAS library, the CBLAS header file, certain C data types the particular CBLAS interface uses and the compiler and linker options for the build process.

To indicate that you want to generate BLAS calls and use a specific BLAS library, specify the name of the BLAS callback class. In the Configuration Parameters dialog box, set Custom BLAS library callback to the name of the callback class.

**Write BLAS Callback Class**

To generate calls to a specific BLAS library in the generated code, write a BLAS callback class. Share the callback class with others who want to use this BLAS library for BLAS calls in standalone code.

The callback class must derive from the abstract class coder.BLASCallback. This example is an implementation of the callback class mklcallback for integration with the Intel MKL BLAS library on a Windows platform.

```matlab
classdef mklcallback < coder.BLASCallback
    methods (Static)
        function updateBuildInfo(buildInfo, ~)
```
libPath = fullfile(pwd,'mkl','WIN','lib','intel64');
libPriority = '';
libPreCompiled = true;
libLinkOnly = true;
libs = {'mkl_intel_ilp64.lib' 'mkl_intel_thread.lib' 'mkl_core.lib'};
buildInfo.addLinkObjects(libs, libPath, libPriority, libPreCompiled, libLinkOnly);
buildInfo.addLinkObjects('libiomp5md.lib',fullfile(matlabroot,'bin','win64'), ... 
    libPriority, libPreCompiled, libLinkOnly);
buildInfo.addIncludePaths(fullfile(pwd,'mkl','WIN','include'));
buildInfo.addDefines('-DMKL_ILP64');
end

function headerName = getHeaderFilename()
    headerName = 'mkl_cblas.h';
end

function intTypeName = getBLASIntTypeName()
    intTypeName = 'MKL_INT';
end
end

You must provide the getHeaderFilename, getBLASIntTypeName, and updateBuildInfo methods. The getHeaderFilename method returns the CBLAS header file name. If you are using a different BLAS library, replace mkl_cblas.h with the name of your CBLAS header file. The getBLASIntTypeName method returns the name of the integer data type that your CBLAS interface uses. If you are using a different BLAS library, replace MKL_INT with the name of the integer data type specific to your CBLAS interface. The updateBuildInfo method provides the information required for the build process to link to the BLAS library. Use code that is like the code in the example callback class to specify the location of header file, the full path name of the BLAS library, and the compiler and linker options. If you use the Intel MKL BLAS library, use the link line advisor to see which libraries and compiler options are recommended for your use case.

There are three other methods that are already implemented in coder.BLASCallback. These methods are getBLASDoubleComplexTypeName, getBLASSingleComplexTypeName, and useEnumNameRatherThanTypedef. By default, your callback class inherits these implementations from coder.BLASCallback. In certain situations, you must override these methods with your own definitions when you define your callback class.

The getBLASDoubleComplexTypeName method returns the type used for double-precision complex variables in the generated code. If your BLAS library takes a type other than double* and void* for double-precision complex array arguments, include this method in your callback class definition.
function doubleComplexTypeName = getBLASDoubleComplexTypeName()
doubleComplexTypeName = 'my_double_complex_type';
end

Replace `my_double_complex_type` with the type that your BLAS library takes for double-precision complex array arguments.

The `getBLASSingleComplexTypeName` method returns the type used for single-precision complex variables in the generated code. If your BLAS library takes a type other than `float*` and `void*` for single-precision complex array arguments, include this method in your callback class definition.

function singleComplexTypeName = getBLASSingleComplexTypeName()
doubleComplexTypeName = 'my_single_complex_type';
end

Replace `my_single_complex_type` with the type that your BLAS library takes for single-precision complex array arguments.

The `useEnumNameRatherThanTypedef` method returns `false` by default. If types for enumerations in your BLAS library include the `enum` keyword, redefine this method to return `true` in your callback class definition.

function p = useEnumNameRatherThanTypedef()
p = true;
end

An excerpt from generated C source code that includes the `enum` keyword is:

```c
enum CBLAS_SIDE t;
enum CBLAS_UPLO b_t;
double temp;
enum CBLAS_TRANPOSE c_t;
enum CBLAS_DIAG d_t;
```

**Generate BLAS Calls by Specifying a BLAS Callback Class**

This example shows how to generate code that calls BLAS functions in a specific BLAS library. The BLAS callback class `useMyBLAS` specifies the BLAS library that you want to use in this example.

1. Create a Simulink model.
2. Add a MATLAB Function block to the model.
In the MATLAB Function block, add code that calls a function for a basic matrix operation. For example, add the function `myMultiply` that multiplies two matrices `A` and `B`.

```matlab
function C = myMultiply(A,B) %#codegen
C = A*B;
end
```

Add two Constant blocks to the left of the MATLAB Function block. Set their values to `zeros(1000)`.

Add an Outport block to the right of the MATLAB Function block.

Connect the blocks.

In the Configuration Parameters dialog box, set **Custom BLAS library callback** to the name of the callback class `useMyBLAS`.

The callback class must be on the MATLAB path.

Build the model.

If `A` and `B` are large enough, the code generator produces a BLAS call for the matrix multiplication function.

## Locate BLAS Library in Execution Environment

The BLAS library must be available in your execution environment. If your BLAS library is shared, use environment variables or linker options to specify the location of the BLAS library.

- On a Windows platform, modify the `PATH` environment variable.
- On a Linux platform, modify the `LD_LIBRARY_PATH` environment variable or use the `rpath` linker option.
- On a macOS platform, modify the `DYLD_LIBRARY_PATH` environment variable or use the `rpath` linker option.
To specify the rpath linker option, use the build information addLinkFlags method in the updateBuildInfo method of your BLAS callback class. For example, for a GCC compiler:

```cpp
buildInfo.addLinkFlags(sprintf('-Wl,-rpath,"%s"',libPath));
```

## Usage Notes and Limitations for OpenBLAS Library

If you generate code that includes calls to the OpenBLAS library functions, follow these guidelines and restrictions:

- If you generate C++ code that includes calls to OpenBLAS library functions, compiling it with the -pedantic option produces warnings. To disable the -pedantic compiler option, include these lines in the updateBuildInfo method:

  ```cpp
  if ctx.getTargetLang() == 'C++'
      buildInfo.addCompileFlags('-Wno-pedantic');
  end
  ```

- OpenBLAS does not support the C89/C90 standard.

Speed Up Fast Fourier Transforms in Code Generated from a MATLAB Function Block

This example shows how to generate calls to a specific installed FFTW library. For more information about FFTW, see www.fftw.org.

When you simulate a model that includes a MATLAB Function block that calls MATLAB fast Fourier transform (FFT) functions, the simulation software uses the library that MATLAB uses for FFT algorithms. If you generate C/C++ code for this model, by default, the code generator produces code for the FFT algorithms instead of producing FFT library calls. To increase the speed of fast Fourier transforms in generated code, specify that the code generator produce calls to a specific installed FFTW library.

The code generator produces FFTW library calls when all of these conditions are true:

- A MATLAB Function block calls one of these MATLAB functions: `fft`, `fft2`, `fftn`, `ifft`, `ifft2`, or `ifftn`.
- You generate C/C++ code from a model that includes the MATLAB Function block.
- You have access to an FFTW library installation, version 3.2 or later.
- You specify the FFTW library installation in an FFT library callback class that derives from `coder.fftw.StandaloneFFTW3Interface`.
- You set the **Custom FFT library callback** configuration parameter to the name of the callback class.

**Install an FFTW Library**

If you do not have access to an installed FFTW library, version 3.2 or later, then you must install one.

For a Linux platform or a Mac platform, consider using a package manager to install the FFTW library.

For a Windows platform, in addition to .dll files, you must have .lib import libraries, as described in the Windows installation notes on the FFTW website.

See the installation instructions for your platform on the FFTW website.
Write FFT Callback Class

To specify your installation of the FFTW library, write an FFT callback class. Share the callback class with others who want to use this FFTW library for FFTW calls.

The callback class must derive from the abstract class `coder.fftw.StandaloneFFTW3Interface`. Use this example callback class as a template.

```matlab
% copyright 2017 The MathWorks, Inc.

classdef useMyFFTW < coder.fftw.StandaloneFFTW3Interface

    methods (Static)
        function th = getNumThreads
            coder.inline('always');
            th = int32(coder.const(1));
        end

        function updateBuildInfo(buildInfo, ctx)
            fftwLocation = '/usr/lib/fftw';
            includePath = fullfile(fftwLocation, 'include');
            buildInfo.addIncludePaths(includePath);
            libPath = fullfile(fftwLocation, 'lib');

            %Double
            libName1 = 'libfftw3-3';
            [~, libExt] = ctx.getStdLibInfo();
            libName1 = [libName1 libExt];
            addLinkObjects(buildInfo, libName1, libPath, 1000, true, true);

            %Single
            libName2 = 'libfftw3f-3';
            [~, libExt] = ctx.getStdLibInfo();
            libName2 = [libName2 libExt];
            addLinkObjects(buildInfo, libName2, libPath, 1000, true, true);
        end
    end
end
```

Implement the `updateBuildInfo` and `getNumThreads` methods. In the `updateBuildInfo` method, set `fftwLocation` to the full path for your installation of the library. Set `includePath` to the full path of the folder that contains `fftw3.h`. Set `libPath` to the full path of the folder that contains the library files. If your FFTW installation uses multiple threads, modify the `getNumThreads` method to return the number of threads that you want to use.

Optionally, you can implement these methods:
• `getPlanMethod` to specify the FFTW planning method. See `coder.fftw.StandaloneFFTW3Interface`.

• `lock` and `unlock` to synchronize multithreaded access to the FFTW planning process. See “Synchronize Multithreaded FFTW Planning in Code Generated from a MATLAB Function Block” (Simulink Coder).

**Generate FFTW Calls by Specifying an FFT Callback Class**

1. Create a Simulink model.
2. Add a MATLAB Function block to the model.
3. In the MATLAB Function block, add code that calls a MATLAB FFT function. For example, add the function `myfft` that calls the MATLAB function `fft`.

   ```matlab
   function y = myfft()
   t = 0:1/50:10-1/50;
   x = sin(2*pi*15*t) + sin(2*pi*20*t);
   y = fft(x);
   end
   ```

4. Connect the blocks.

5. Indicate that the code generator produce calls to the FFTW library specified in the FFT library callback class `useMyFFTW`. In the Configuration Parameters dialog box, set **Custom FFT library callback** to `useMyFFTW`.

   The callback class must be on the MATLAB path.

6. Build the model.

**Locate FFTW Library in Execution Environment**

The FFTW library must be available in your execution environment. If the FFTW library is shared, use environment variables or linker options to specify the location of the library.

• On a Windows platform, modify the PATH environment variable.
• On a Linux platform, modify the `LD_LIBRARY_PATH` environment variable or use the `rpath` linker option.
• On a macOS platform, modify the DYLD_LIBRARY_PATH environment variable or use the rpath linker option.

To specify the rpath linker option, you can use the build information addLinkFlags method in the updateBuildInfo method of your coder.fftw.StandaloneFFTW3Interface class. For example, for a GCC compiler:

```c
buildInfo.addLinkFlags(sprintf('-Wl,-rpath,%s',libPath));
```

Synchronize Multithreaded FFTW Planning in Code Generated from a MATLAB Function Block

This example shows how to generate code that synchronizes multithreaded access to the FFTW planning process for FFTW library calls in code generated from a MATLAB Function block.

The code generator produces FFTW library calls when all of these conditions are true:

- A MATLAB Function block calls one of these functions: `fft`, `fft2`, `fftn`, `ifft`, `ifft2`, or `ifftn`.
- You generate C/C++ code for a model that includes the MATLAB Function block.
- You have access to an FFTW library installation, version 3.2 or later.
- You specify the FFTW library installation in an FFT library callback class that derives from `coder.fftw.StandaloneFFTW3Interface`.
- You set the **Custom FFT library callback** configuration parameter to the name of the callback class.

If you integrate the code that contains the FFTW calls with external code that runs on multiple threads, then you must prevent concurrent access to the FFTW planning process. In your FFT library callback class, implement the `lock` and `unlock` methods. You must also provide C code that manages a lock or mutex. Many libraries, such as OpenMP, pthreads, and the C++ standard library (C++ 11 and later), provide locks. This example shows how to implement the `lock` and `unlock` methods and provide supporting C code. To manage a lock, this example uses the OpenMP library.

**Prerequisites**

Before you start, for the basic workflow for generating FFTW library calls for fast Fourier transforms in a MATLAB Function block, see “Speed Up Fast Fourier Transforms in Code Generated from a MATLAB Function Block” (Simulink Coder).

You must have:

- Access to an installed FFTW library.
- A compiler that supports the OpenMP library. To use a different library, such as pthreads, modify the supporting C code accordingly.
Create a Model with a MATLAB Function Block That Calls an FFT Function

1. Create a Simulink model and add a MATLAB Function block to it.
2. Add this code to the MATLAB Function block.

   ```matlab
   function y = mycustomfft()
   t = 0:1/50:10-1/50;
   x = sin(2*pi*15*t) + sin(2*pi*20*t);
   y = fft(x);
   for k = 1:100
       y = y + ifft(x+k);
   end
   ``

3. Add an `outport` block and connect it to the MATLAB Function block.

Write Supporting C Code

Write C functions that initialize, set, and unset a lock. This example uses the OpenMP library to manage the lock. For a different library, modify the code accordingly.

- Create a file `mylock.c` that contains this C code:

```c
#include "mylock.h"
#include "omp.h"

static omp_nest_lock_t lockVar;

void mylock_initialize(void)
{
    omp_init_nest_lock(&lockVar);
}

void mylock(void)
```

```
{  
    omp_set_nest_lock(&lockVar);
}

void myunlock(void)
{
    omp_unset_nest_lock(&lockVar);
}

• Create a header file mylock.h that contains:

```c
#ifndef MYLOCK_H
#define MYLOCK_H

void mylock_initialize(void);
void mylock(void);
void myunlock(void);

#endif
```

Create an FFT Library Callback Class

Write an FFT callback class myfftcb that:

• Specifies the FFTW library.
• Implements lock and unlock methods that call the supporting C code to control access to the FFTW planning.

Use this class as a template. Replace `fftwLocation` with the location of your FFTW library installation.

```matlab
classdef myfftcb < coder.fftw.StandaloneFFTW3Interface

    methods (Static)
        function th = getNumThreads
            coder.inline('always');
            th = int32(coder.const(1));
        end

        function lock()
            coder.cinclude('mylock.h', 'InAllSourceFiles', true);
            coder.inline('always');
            coder.ceval('mylock');
        end
```
function unlock()
    coder.cinclude('mylock.h', 'InAllSourceFiles', true);
    coder.inline('always');
    coder.ceval('myunlock');
end

function updateBuildInfo(buildInfo, ctx)
    fftwLocation = '\usr\lib\fftw';
    includePath = fullfile(fftwLocation, 'include');
    buildInfo.addIncludePaths(includePath);
    libPath = fullfile(fftwLocation, 'lib');
    
    %Double
    libName1 = 'libfftw3-3';
    [~, libExt] = ctx.getStdLibInfo();
    libName1 = [libName1 libExt];
    addLinkObjects(buildInfo, libName1, libPath, 1000, true, true);
    
    %Single
    libName2 = 'libfftw3f-3';
    [~, libExt] = ctx.getStdLibInfo();
    libName2 = [libName2 libExt];
    addLinkObjects(buildInfo, libName2, libPath, 1000, true, true);
end
end

**Configure Code Generation Parameters and Build the Model**

1. Configure code generation to use the FFTW callback class and the C code called by the lock and unlock methods. Configure code generation to generate a call to mylock_initialize in the initialization code.

In the Configuration Parameters dialog box:

- Set **Custom FFT library callback** to myfftcb.
- In **Code Generation > Custom Code**, under **Additional build information**, set **Source files** to mylock.c.
- In **Code Generation > Custom Code**, under **Insert custom C code in generated**, set **Initialize function** to mylock_initialize();.
2 Build the model.

Control Memory Allocation for Variable-Size Arrays in a MATLAB Function Block

Dynamic memory allocation allocates memory on the heap as needed at run time, instead of allocating memory statically on the stack. You can use dynamic memory allocation for arrays inside a MATLAB Function block.

You cannot use dynamic memory allocation for:

- Input and output signals. Variable-size input and output signals must have an upper bound.
- Parameters or global variables. Parameters and global variables must be fixed-size.
- Fields of bus arrays. Bus arrays cannot have variable-size fields.
- Discrete state properties of System objects associated with a MATLAB System block.

Dynamic memory allocation is beneficial when:

- You do not know the upper bound of an array.
- You do not want to allocate memory on the stack for large arrays.

Dynamic memory allocation and the freeing of this memory can result in slower execution of the generated code. To control the use of dynamic memory allocation for variable-size arrays in a MATLAB Function block, you can:

- Provide upper bounds for variable-size arrays on page 66-99.
- Disable dynamic memory allocation for MATLAB Function blocks on page 66-100.
- Modify the dynamic memory allocation threshold on page 66-100.

Provide Upper Bounds for Variable-Size Arrays

For an unbounded variable-size array, the code generator allocates memory dynamically on the heap. For a bounded variable-size array, if the size, in bytes, is less than the dynamic memory allocation threshold, the code generator allocates memory statically on the stack. To avoid dynamic memory allocation, provide upper bounds for the array dimensions so that the size of the array, in bytes, is less than the dynamic memory allocation threshold. See “Specify Upper Bounds for Variable-Size Arrays” (Simulink).
Disable Dynamic Memory Allocation for MATLAB Function Blocks

By default, dynamic memory allocation for MATLAB Function blocks is enabled for GRT-based targets and disabled for ERT-based targets. To change the setting, in the Configuration Parameters dialog box, clear or select Dynamic memory allocation in MATLAB Function blocks.

If you disable dynamic memory allocation, you must provide upper bounds for variable-size arrays.

Modify the Dynamic Memory Allocation Threshold

Instead of disabling dynamic memory allocation for all variable-size arrays, you can use the dynamic memory allocation threshold to specify when the code generator uses dynamic memory allocation.

Use the dynamic memory allocation threshold to:

- Disable dynamic memory allocation for smaller arrays. For smaller arrays, static memory allocation can speed up generated code. However, static memory allocation can lead to unused storage space. You can decide that the unused storage space is not a significant consideration for smaller arrays.
- Enable dynamic memory allocation for larger arrays. For larger arrays, when you use dynamic memory allocation, you can significantly reduce storage requirements.

The default value of the dynamic memory allocation threshold is 64 kilobytes. To change the threshold, in the Configuration Parameters dialog box, set the Dynamic memory allocation threshold in MATLAB Function blocks parameter.

To use dynamic memory allocation for all variable-size arrays, set the threshold to 0.

Optimize Memory Usage for Time Counters

This example shows how to optimize the amount of memory that the code generator allocates for time counters. The example optimizes the memory that stores elapsed time, the interval of time between two events.

The code generator represents time counters as unsigned integers. The word size of time counters is based on the setting of the model configuration parameter `Application lifespan (days)`, which specifies the expected maximum duration of time the application runs. You can use this parameter to prevent time counter overflows. The default size is 64 bits.

The number of bits that a time counter uses depends on the setting of the `Application lifespan (days)` parameter. For example, if a time counter increments at a rate of 1 kHz, to avoid an overflow, the counter has the following number of bits:

- Lifespan < 0.25 sec: 8 bits
- Lifespan < 1 min: 16 bits
- Lifespan < 49 days: 32 bits
- Lifespan > 50 days: 64 bits

A 64-bit time counter does not overflow for 590 million years.

**Open Example Model**

Open the example model `rtwdemo_abstime`. 
The model consists of three subsystems SS1, SS2, and SS3. On the **Math and Data Types** pane, the **Application lifespan (days)** parameter is set to the default, which is inf.
The three subsystems contain a discrete-time integrator that requires elapsed time as input to compute its output value. The subsystems vary as follows:

- **SS1** - Clocked at 1 kHz. Does not require a time counter. **Sample time type** parameter for trigger port is set to periodic. Elapsed time is inlined as 0.001.
- **SS2** - Clocked at 100 Hz. Requires a time counter. Based on a lifespan of 1 day, a 32-bit counter stores the elapsed time.
- **SS3** - Clocked at 0.5 Hz. Requires a time counter. Based on a lifespan of 1 day, a 16-bit counter stores the elapsed time.

**Simulate the Model**

Simulate the model. By default, the model is configured to show sample times in different colors. Discrete sample times for the three subsystems appear red, green, and blue. Triggered subsystems are blue-green.

**Generate Code and Report**

1. Create a temporary folder for the build and inspection process.

2. Configure the model for the code generator to use the GRT system target file and a lifespan of inf days.

3. Build the model.

```plaintext
### Starting build procedure for model: rtwdemo_abstime
### Successful completion of build procedure for model: rtwdemo_abstime
```

**Review Generated Code**

Open the generated source file `rtwdemo_abstime.c`.

```c
struct tag_RTM_rtwdemo_abstime_T {
    const char_T *errorStatus;

    /*
    * Timing:
    * The following substructure contains information regarding
    * the timing information for the model.
    */
    struct {
        uint32_T clockTick1;
```
uint32_T clockTickH1;
uint32_T clockTick2;
uint32_T clockTickH2;
struct {
    uint16_T TID[3];
    uint16_T cLimit[3];
} TaskCounters;
} Timing;
};

/* Block states (default storage) */
extern DW_rtwdemo_abstime_T rtwdemo_abstime_DW;

/* External inputs (root inport signals with default storage) */
extern ExtU_rtwdemo_abstime_T rtwdemo_abstime_U;

/* External outputs (root outports fed by signals with default storage) */
extern ExtY_rtwdemo_abstime_T rtwdemo_abstime_Y;

/* Model entry point functions */
extern void rtwdemo_abstime_initialize(void);
extern void rtwdemo_abstime_step(int_T tid);
extern void rtwdemo_abstime_terminate(void);

/* Real-time Model object */
extern RT_MODEL_rtwdemo_abstime_T *const rtwdemo_abstime_M;

/* The generated code includes comments that allow you to trace directly
back to the appropriate location in the model. The basic format
is <system>/block_name, where system is the system number (uniquely
assigned by Simulink) and block_name is the name of the block.
* Use the MATLAB hilite_system command to trace the generated code back
to the model. For example,
* hilite_system('<S3>') - opens system 3
* hilite_system('<S3>/Kp') - opens and selects block Kp which resides in S3
* Here is the system hierarchy for this model
* '<Root>' : 'rtwdemo_abstime'
* '<S1>' : 'rtwdemo_abstime/SS1'
* '<S2>' : 'rtwdemo_abstime/SS2'
Four 32-bit unsigned integers, `clockTick1`, `clockTickH1`, `clockTick2`, and `clockTickH2` are counters for storing the elapsed time of subsystems SS2 and SS3.

**Enable Optimization and Regenerate Code**

1. Reconfigure the model to set the lifespan to 1 day.

2. Build the model.

```plaintext
### Starting build procedure for model: rtwdemo_abstime
### Successful completion of build procedure for model: rtwdemo_abstime
```

**Review the Regenerated Code**

```c
struct tag_RTM_rtwdemo_abstime_T {
    const char_T *errorStatus;

    /*
    * Timing:
    * The following substructure contains information regarding
    * the timing information for the model.
    */
    struct {
        uint32_T clockTick1;
        uint16_T clockTick2;
        struct {
            uint16_T TID[3];
            uint16_T cLimit[3];
        } TaskCounters;
    } Timing;

    /* Block states (default storage) */
    extern DW_rtwdemo_abstime_T rtwdemo_abstime_DW;

    /* External inputs (root inport signals with default storage) */
    extern ExtU_rtwdemo_abstime_T rtwdemo_abstime_U;

    /* External outputs (root outports fed by signals with default storage) */
    extern ExtY_rtwdemo_abstime_T rtwdemo_abstime_Y;
}
```
The new setting for the **Application lifespan (days)** parameter instructs the code generator to set aside less memory for the time counters. The regenerated code includes:

- 32-bit unsigned integer, `clockTick1`, for storing the elapsed time of the task for SS2
- 16-bit unsigned integer, `clockTick2`, for storing the elapsed time of the task for SS3

Optimize generated code by storing logical signals as Boolean data. When you select the model configuration parameter **Implement logic signals as Boolean data (vs. double)**, blocks that generate logic signals output Boolean signals.

The optimization:

- Reduces the ROM and RAM consumption.
- Improves execution speed.

**Example Model**

Consider the model `rtwdemo_logicalAsBoolean`. The outputs of the Relational Operator, Logical Operator and HitCrossing blocks are double, even though they represent logical data.

```plaintext
model = 'rtwdemo_logicalAsBoolean';
open_system(model);
```

Copyright 1994-2012 The MathWorks, Inc.
**Generate Code**

Create a temporary folder (in your system temporary folder) for the build and inspection process.

```matlab
currentDir = pwd;
[~,cgDir] = rtwdemodir();

Build the model.
rtwbuild(model)
```

### Starting build procedure for model: rtwdemo_logicalAsBoolean
### Successful completion of build procedure for model: rtwdemo_logicalAsBoolean

View the generated code without the optimization. These lines of code are in `rtwdemo_logicalAsBoolean.h`.

```matlab
hfile = fullfile(cgDir,'rtwdemo_logicalAsBoolean_ert_rtw', ...
    'rtwdemo_logicalAsBoolean.h');
rtwdemodbtype(hfile,'/* External outputs','/* Parameters (default storage) */',1,0);

/* External outputs (root outports fed by signals with default storage) */
typedef struct {
    real_T Out1;       /* '<Root>/Out1' */
    real_T Out2;       /* '<Root>/Out2' */
    real_T Out3;       /* '<Root>/Out3' */
} ExtY_rtwdemo_logicalAsBoolean_T;
```

**Enable Optimization**

1. Open the Configuration Parameters dialog box.
2. Select the **Implement logic signals as Boolean data (vs. double)** parameter.

Alternatively, you can use the command-line API to enable the optimization:

```matlab
set_param(model,'BooleanDataType','on');
```

**Generate Code with Optimization**

The generated code stores the logical signal output as Boolean data.

Build the model.
rtwbuild(model)

### Starting build procedure for model: rtwdemo_logicalAsBoolean
### Successful completion of build procedure for model: rtwdemo_logicalAsBoolean

View the generated code with the optimization. These lines of code are in `rtwdemo_logicalAsBoolean.h`.

```c
rtwdemodbtype(hfile,'/* External outputs','/* Parameters (default storage) */',1,0);

typedef struct {
    boolean_T Out1; /* '<Root>/Out1' */
    boolean_T Out2; /* '<Root>/Out2' */
    boolean_T Out3; /* '<Root>/Out3' */
} ExtY_rtwdemo_logicalAsBoolean_T;
```

Close the model and code generation report.

```c
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

Reduce Memory Usage for Boolean and State Configuration Variables

1. Open the Model Configuration Parameters dialog box.
2. In the Model Configuration Parameters dialog box, select the **Optimization** pane.
3. Choose from these options:

   - **Use bitsets for storing state configuration** — Reduces the amount of memory that stores state configuration variables. However, it can increase the amount of memory that stores target code if the target processor does not include instructions for manipulating bitsets.
   - **Use bitsets for storing Boolean data** — Reduces the amount of memory that stores Boolean variables. However, it can increase the amount of memory that stores target code if the target processor does not include instructions for manipulating bitsets.

**Note** You cannot use bitsets when you generate code for these cases:

- An external mode simulation
- A target that specifies an explicit structure alignment

**See Also**

Customize Stack Space Allocation

Your application might be constrained by limited memory. Controlling the maximum allowable size for the stack is one way to modify whether data is defined as local or global in the generated code. You can limit the use of stack space by specifying a positive integer value for the “Maximum stack size (bytes)” (Simulink Coder) parameter, on the Optimization pane of the Configuration parameter dialog box. Specifying the maximum allowable stack size provides control over the number of local and global variables in the generated code. Specifically, lowering the maximum stack size might generate more variables into global structures. The number of local and global variables help determine the required amount of stack space for execution of the generated code.

The default setting for “Maximum stack size (bytes)” (Simulink Coder) is Inherit from target. In this case, the value of the maximum stack size is the smaller value of the following: the default value set by the code generator (200,000 bytes) or the value of the TLC variable MaxStackSize found in the system target file (ert.tlc).

To specify a smaller stack size for your application, select the Specify a value option of the Maximum stack size (bytes) parameter and enter a positive integer value. To specify a smaller stack size at the command line, use:

```plaintext
set_param(model_name, 'MaxStackSize', 65000);
```

**Note** For overall executable stack usage metrics, you might want to do a target-specific measurement, such as using runtime (empirical) analysis or static (code path) analysis with object code.

It is recommended that you use the Maximum stack size (bytes) parameter to control stack space allocation instead of modifying the TLC variable, MaxStackSize, in the system target file. However, a target author might want to set the TLC variable, MaxStackSize, for a target. To set MaxStackSize, use assign statements in the system target file (ert.tlc), as in the following example.

```plaintext
%assign MaxStackSize = 4096
```

Write your %assign statements in the Configure RTW code generation settings section of the system target file. The %assign statement is described in “Target Language Compiler” (Simulink Coder).

Optimize Generated Code Using memset Function

This example shows how to optimize the generated code by using the memset function to clear the internal storage. When you select the model configuration parameter **Use memset to initialize floats and doubles to 0.0**, the memset function clears internal storage, regardless of type, to the integer bit pattern 0 (that is, all bits are off).

If your compiler and target CPU both represent floating-point zero with the integer bit pattern 0, consider setting this parameter to gain execution and ROM efficiency.

**NOTE:** The command-line values are the reverse of the settings values. 'on' in the command line corresponds to clearing the setting. 'off' in the command line corresponds to selecting the setting.

This optimization:

- Reduces ROM consumption.
- Improves execution speed.

**Example Model**

Consider the model `matlab:rtwdemo_memset`.

```matlab
text = 'rtwdemo_memset';
open_system(text);
```

This optimization:

- Reduces ROM consumption.
- Improves execution speed.

**Generate Code**

The code generator uses a loop to initialize the Constant block values.

Create a temporary folder (in your system temporary folder) for the build and inspection process.
currentDir = pwd;
 [~,cgDir] = rtwdemodir();

Build the model.

rtwbuild(model)

### Starting build procedure for model: rtwdemo_memset
### Successful completion of build procedure for model: rtwdemo_memset

View the generated code without the optimization. These lines of code are in rtwdemo_memset.c.

cfile = fullfile(cgDir,'rtwdemo_memset_grt_rtw','rtwdemo_memset.c');
rtwdemodbtype(cfile,'/* Model initialize function */','/* Model terminate function */',1,0);

/* Model initialize function */
void rtwdemo_memset_initialize(void)
{
    /* Registration code */

    /* initialize error status */
    rtmSetErrorStatus(rtwdemo_memset_M, (NULL));

    /* external outputs */
    {
        int32_T i;
        for (i = 0; i < 50; i++) {
            rtwdemo_memset_Y.Out1[i] = 0.0;
        }
    }

    {
        int32_T i;
        /* ConstCode for Outport: '<Root>/Out1' */
        for (i = 0; i < 50; i++) {
            rtwdemo_memset_Y.Out1[i] = 56.0;
        }
    }

    /* End of ConstCode for Outport: '<Root>/Out1' */
}

Enable Optimization

1. Open the Configuration Parameters dialog box.
2. Clear the **Use memset to initialize floats and doubles to 0.0** parameter. Alternatively, you can use the command-line API to enable the optimization:

   ```matlab
   set_param(model,'InitFltsAndDblsToZero','off');
   ```

Generate Code with Optimization

The code generator uses the **memset** function to initialize the **Constant** block values.

Build the model.

```matlab
rtwbuild(model)
```

### Starting build procedure for model: rtwdemo_memset
### Successful completion of build procedure for model: rtwdemo_memset

View the generated code with the optimization. These lines of code are in `rtwdemo_memset.c`.

```c
rtwdemodbtype(cfile,'/* Model initialize function */',...  
    /* Model terminate function */',1,0);

/* Model initialize function */
void rtwdemo_memset_initialize(void)
{
    /* Registration code */

    /* initialize error status */
    rtmSetErrorStatus(rtwdemo_memset_M, (NULL));

    /* external outputs */
    (void) memset(&rtwdemo_memset_Y.Out1[0], 0,  
                  50U*sizeof(real_T));

    {
        int32_T i;

        /* ConstCode for Outport: '<Root>/Out1' */
        for (i = 0; i < 50; i++) {
            rtwdemo_memset_Y.Out1[i] = 56.0;
        }
    }
```

Optimize Generated Code Using **memset** Function

Vector Operation Optimization

This example shows how Simulink® Coder™ optimizes generated code by setting block output that generates vectors to scalars, for blocks such as the Mux, Sum, Gain, and Bus. This optimization reduces stack memory by replacing temporary local arrays with local variables.

Example Model

In the model, rtwdemo_VectorOptimization, the output of Gain blocks G1 and G2 are the vector signals tmp1 and tmp2. These vectors have a width of 10.

```matlab
model = 'rtwdemo_VectorOptimization';
open_system(model);
set_param(model, 'SimulationCommand', 'update')
```

Generate Code

Create a temporary folder (in your system temporary folder) for the build and inspection process.

```matlab
currentDir = pwd;
[~,cgDir] = rtwdemodir();

Build the model.

rtwbuild(model)
```
### Starting build procedure for model: rtwdemo_VectorOptimization
### Successful completion of build procedure for model: rtwdemo_VectorOptimization

The optimized code is in rtwdemo_VectorOptimization.c. The signals tmp1 and tmp2 are the local variables rtb_tmp1 and rtb_tmp2.

cfile = fullfile(cgDir,'rtwdemo_VectorOptimization_grt_rtw',...  
  'rtwdemo_VectorOptimization.c');
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);

/* Model step function */
void rtwdemo_VectorOptimization_step(void)
{
  int32_T i;
  real_T rtb_tmp2;
  real_T rtb_tmp1;
  real_T rtb_Sum3;
  for (i = 0; i < 10; i++) {
    /* Gain: '<Root>/G2' incorporates:
     *  UnitDelay: '<Root>/X2'
     */
    rtb_tmp2 = 0.3 * rtwdemo_VectorOptimization_DW.X2_DSTATE[i];

    /* Gain: '<Root>/G1' incorporates:
     *  UnitDelay: '<Root>/X1'
     */
    rtb_tmp1 = 0.2 * rtwdemo_VectorOptimization_DW.X1_DSTATE[i];

    /* Sum: '<Root>/Sum3' incorporates:
     *  Gain: '<Root>/G3'
     *  Inport: '<Root>/In2'
     *  Sum: '<Root>/Sum1'
     *  Sum: '<Root>/Sum2'
     *  UnitDelay: '<Root>/X3'
     */
    rtb_Sum3 = ((rtwdemo_VectorOptimization_U.In2[i] - 0.4 * rtwdemo_VectorOptimization_DW.X3_DSTATE[i]) - rtb_tmp2) - rtb_tmp1;

    /* Outport: '<Root>/Out2' */
    rtwdemo_VectorOptimization_Y.Out2[i] = rtb_Sum3;

    /* Update for UnitDelay: '<Root>/X3' */
    rtwdemo_VectorOptimization_DW.X3_DSTATE[i] = rtb_tmp2;
/* Update for UnitDelay: '<Root>/X2' */
rtwdemo_VectorOptimization_DW.X2_DSTATE[i] = rtb_tmp1;

/* Update for UnitDelay: '<Root>/X1' */
rtwdemo_VectorOptimization_DW.X1_DSTATE[i] = rtb_Sum3;
}

Close the model and code generation report.

bdclose(model)
rtwdemoclean;
cd(currentDir)

Enable and Reuse Local Block Outputs in Generated Code

In this section...

“Example Model” on page 66-122
“Generate Code Without Optimization” on page 66-123
“Enable Local Block Outputs and Generate Code” on page 66-123
“Reuse Local Block Outputs and Generate Code” on page 66-124

This example shows how to specify block output as local variables. The code generator can potentially reuse these local variables in the generated code. Declaring block output as local variables conserves ROM consumption. Reusing local variables conserves RAM consumption, reduces data copies, and increases execution speed.

Example Model

1 Use Inport, Outport, Gain, and Switch blocks to create the following model. In this example, the model is named local_variable_ex.

2 For G2, open the Gain Block Parameters dialog box. Enter a value of 2.
3 For G1, enter a value of 3.
4 For the Switch block, open the Block Parameters dialog box. For the Criteria for passing first input parameter, select u2>=Threshold.
Generate Code Without Optimization

1. Open the Model Configuration Parameters dialog box. Select the Solver pane. For the Type parameter, select Fixed-step.

2. Clear the Configuration Parameters > Signal storage reuse parameter.

4. Select the Code Generation pane. Select Generate code only, and then, in the model window, press Ctrl+B. When code generation is complete, an HTML code generation report appears.

5. In the code generation report, select the local_variable_ex.c section and view the model step function. The Gain block outputs are the global variables local_variable_ex_B.G2 and local_variable_ex_B.G1.

```c
/* Model step function */
void local_variable_ex_step(void)
{
    /* Switch: '<Root>/Switch' incorporates:
     * Inport: '<Root>/In1'
     */
    if (local_variable_ex_U.In1 >= 0.0) {
        /* Gain: '<Root>/G2' */
        local_variable_ex_B.G2 = 2.0 * local_variable_ex_U.In1;

        /* Outport: '<Root>/Out1' */
        local_variable_ex_Y.Out1 = local_variable_ex_B.G2;
    } else {
        /* Gain: '<Root>/G1' */
        local_variable_ex_B.G1 = 3.0 * local_variable_ex_U.In1;

        /* Outport: '<Root>/Out1' */
        local_variable_ex_Y.Out1 = local_variable_ex_B.G1;
    }

    /* End of Switch: '<Root>/Switch' */
}
```

Enable Local Block Outputs and Generate Code

1. Select the Configuration Parameters > Signal Storage Reuse parameter. The Signal Storage Reuse enables the following optimization parameters:
• Enable local block outputs
• Reuse local block outputs
• Eliminate superfluous local variables (expression folding)

2 Clear Reuse local block outputs and Eliminate superfluous local variables (expression folding).

3 Generate code and view the model step function. There are three local variables in the model step function because you selected the optimization parameter Enable Local Block Outputs. The local variables rtb_G2 and rtb_G1 hold the outputs of the Gain blocks. The local variable rtb_Switch holds the output of the Switch block.

```c
/* Model step function */
void local_variable_ex_step(void)
{
    real_T rtb_Switch;
    real_T rtb_G2;
    real_T rtb_G1;

    /* Switch: '<Root>/Switch' incorporates:
     * Inport: '<Root>/In1'
    */
    if (local_variable_ex_U.In1 >= 0.0) {
        /* Gain: '<Root>/G2' */
        rtb_G2 = 2.0 * local_variable_ex_U.In1;
        rtb_Switch = rtb_G2;
    } else {
        /* Gain: '<Root>/G1' */
        rtb_G1 = 3.0 * local_variable_ex_U.In1;
        rtb_Switch = rtb_G1;
    }

    /* End of Switch: '<Root>/Switch' */

    /* Outport: '<Root>/Out1' */
    local_variable_ex_Y.Out1 = rtb_Switch;
}
```

**Reuse Local Block Outputs and Generate Code**

1 Select the Configuration Parameters > Reuse local block outputs parameter.

2 Generate code. In the local_variable_ex.c section, view the model step function. There is one local variable, rtb_G2, that the code generator uses three times.
/* Model step function */
void local_variable_ex_step(void)
{
    real_T rtb_G2;

    /* Switch: '<Root>/Switch' incorporates:
    *  Inport: '<Root>/In1'
    */
    if (local_variable_ex_U.In1 >= 0.0) {
        /* Gain: '<Root>/G2' */
        rtb_G2 = 2.0 * local_variable_ex_U.In1;
    } else {
        /* Gain: '<Root>/G1' */
        rtb_G2 = 3.0 * local_variable_ex_U.In1;
    }

    /* End of Switch: '<Root>/Switch' */

    /* Outport: '<Root>/Out1' */
    local_variable_ex_Y.Out1 = rtb_G2;
}

The extra temporary variable rtb_Switch and the associated data copy is not in the
generated code.

Configuration in Embedded Coder
Set Hardware Implementation Parameters

Specification of target hardware device characteristics (such as word sizes for char, short, int, and long data types, or desired rounding behaviors in integer operations) for generated code can be critical in embedded systems development. The **Hardware Implementation** category of parameters in a configuration set provides a way to control such characteristics in simulation and code generation.

By configuring the **Hardware Implementation** parameters of the active configuration set for a model to match the behaviors of your compiler and hardware, you can generate more efficient code. For example, if you specify the **Byte ordering** parameter, you can avoid generation of extra code that tests the byte ordering of the target CPU.

Before generating and deploying code, get familiar with the **Hardware Implementation** pane of the Configuration Parameters dialog box. By default, target hardware microprocessor device details are hidden. To view the details, click the **Device details** arrow. See “Hardware Implementation Pane” (Simulink) and “Configure Run-Time Environment Options” (Simulink Coder) for more information.

You can use the example “Configure Target Hardware Characteristics” on page 52-13 to determine characteristics of your C or C++ compiler and target hardware. By using the example model with your target development system and debugger, you can observe the behavior of the code as it executes on the target hardware. You can then use the information to refine hardware target device parameters for your model.

Optimize Global Variable Usage

To tune your application and choose tradeoffs for execution speed and memory usage, you can choose a global variable reference optimization for the generated code.

On the Configuration Parameters dialog box, in the **Optimize global data access** drop-down list, three parameter options control global variable usage optimizations.

- **None.** Use default optimizations. This choice works well for most models. The code generator balances the use of local and global variables. It generates code which balances RAM and ROM consumption and execution speed.

- **Use global to hold temporary results.** Reusing global variables improves code efficiency and readability. This optimization reuses global variables, which results in the code generator defining fewer variables. It reduces RAM and ROM consumption and data copies.

- **Minimize global data access.** Using local variables to cache global data reduces ROM consumption by reducing code size. This optimization improves execution speed because the code uses fewer instructions for local variable references than for global variable references.

Minimizing the use of global variables by using local variables interacts with stack usage control. For example, stack size can determine the number of local and global variables that the code generator can allocate in the generated code. For more information, see “Customize Stack Space Allocation” (Simulink Coder).

**Use Global to Hold Temporary Results**

The code generator uses global and local variables when you select **None** versus when you select **Use global to hold temporary results**.

**Example Model**

In the model matlab:rtwdemo_optimize_global_ebf, an Assignment block assigns values coming from the Inport and Constant blocks to an output signal. The output signal feeds into a Gain block.
model = 'rtwdemo_optimize_global_ebf';
load_system('rtwdemo_optimize_global_ebf')

**Generate Code without Optimization**

1. In the Configuration Parameters dialog box, verify that the *Signal storage reuse* parameter is selected.

2. In the Configuration Parameters dialog box, for the *Optimize global access parameter*, select *None* or enter the following command in the MATLAB Command Window:

```matlab
set_param('rtwdemo_optimize_global_ebf','GlobalVariableUsage','None');
```

In your system's temporary folder, create a folder for the build and inspection process:

```matlab
currentDir = pwd;
 [~,cgDir] = rtwdemodir();
```

Build the model.

```matlab
rtwbuild(model);
```

### Starting build procedure for model: rtwdemo_optimize_global_ebf
### Successful completion of build procedure for model: rtwdemo_optimize_global_ebf

View the generated code without the optimization. Here is a portion of rtwdemo_optimize_global_ebf.c.

```c
cfile = fullfile(cgDir,'rtwdemo_optimize_global_ebf_ert_rtw','rtwdemo_optimize_global_ebf.c');
rtwdemodbtype(cfile,'/* Model step','/* Model initialize',1, 0);
/* Model step function */
void rtwdemo_optimize_global_ebf_step(void) {
```
The code assigns values to the local vector `rtb_Assignment`. The last statement copies the values in the local vector `rtb_Assignment` to the global vector `rtY.Out1`. Fewer global variable references result in improved execution speed. The code uses more instructions for global variable references than for local variable references.

In the Static Code Metrics Report, examine the Global Variables section.

1. In the Code Generation Report window, select **Static Code Metrics Report**.
2. Scroll down to the **Global Variables** section.
3. Select the `[+]` sign before each variable to expand it.
The total number of reads and writes for global variables is 2.

**Generate Code with Optimization**

In the Configuration Parameters dialog box, for the Optimize global access parameter, select Use global to hold temporary results, or enter the following command in the MATLAB Command Window:

```matlab
set_param('rtwdemo_optimize_global_ebf',...
    'GlobalVariableUsage','Use global to hold temporary results');
```

Build the model.

```matlab
rtwbuild(model);
```

**View the generated code with the optimization. Here is a portion of**

```c
rtwdemo_optimize_global_ebf.c
```

```c
void rtwdemo_optimize_global_ebf_step(void)
{
    int32_T i;
```

<table>
<thead>
<tr>
<th>Global Variable</th>

</tr>
</tbody>
</table>

* The global variable is not directly used in any function.
The code assigns values to the global vector `rtY.Out1` without using a local variable. This assignment improves ROM and RAM consumption and reduces data copies. The code places the value in the destination variable for each assignment instead of copying the value at the end. In the Static Code Metrics Report, examine the Global Variables section.

<table>
<thead>
<tr>
<th>Global Variable</th>
<th>Size (bytes)</th>
<th>Reads / Writes</th>
<th>Reads / Writes in a Function</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</tbody>
</table>

* The global variable is not directly used in any function.
As a result of using global variables to hold local results, the total number of reads and writes for global variables has increased from 2 to 5. This optimization reduces data copies by reusing global variables.

Close the code generation report.

rtwdemoclean;
cd(currentDir)

**Minimize Global Data Access**

Generate optimized code that reads from and writes to global variables less frequently.

**Example Model**

In the model matlab:rtwdemo_optimize_global, five signals feed into a Multiport Switch block.

model = 'rtwdemo_optimize_global';
load_system('rtwdemo_optimize_global')
Generate Code without Optimization

1. In the Configuration Parameters dialog box, verify that the **Signal storage reuse** parameter is selected.

2. In the Configuration Parameters dialog box, for the **Optimize global access** parameter, select **None** or enter the following command in the MATLAB Command Window:

   ```matlab
   set_param('rtwdemo_optimize_global','GlobalVariableUsage','None');
   ```

   In your system's temporary folder, create a folder for the build and inspection process.

   ```
   currentDir = pwd;
   [~,cgDir] = rtwdemodir();
   ```

   Build the model.
rtwbuild(model);

### Starting build procedure for model: rtwdemo_optimize_global
### Successful completion of build procedure for model: rtwdemo_optimize_global

View the generated code without the optimization. Here is a portion of `rtwdemo_optimize_global.c`.

cfile = fullfile(cgDir,'rtwdemo_optimize_global_ert_rtw', ...
  'rtwdemo_optimize_global.c');
rtwdemodbtype(cfile,'/* Model step','/* Model initialize',1, 0);

/* Model step function */
void rtwdemo_optimize_global_step(void)
{
  /* MultiPortSwitch: '<Root>/Multiport Switch' incorporates:
   * Inport: '<Root>/In1'
   */
  switch ((int32_T)rtU.In1) {
    case 1:
      /* Outport: '<Root>/Out1' incorporates:
       * Constant: '<Root>/Constant'
       */
      rtY.Out1 = 1.0;
      break;
    case 2:
      /* Outport: '<Root>/Out1' incorporates:
       * Constant: '<Root>/Constant1'
       */
      rtY.Out1 = 2.0;
      break;
    case 3:
      /* Outport: '<Root>/Out1' incorporates:
       * Constant: '<Root>/Constant2'
       */
      rtY.Out1 = 3.0;
      break;
    default:
      /* Outport: '<Root>/Out1' incorporates:
       * Constant: '<Root>/Constant3'
       */
      rtY.Out1 = 4.0;
break;
}

/* End of MultiPortSwitch: '<Root>/Multiport Switch' */
}

In the Static Code Metrics Report, examine the Global Variables section.

2. Scroll down to the Global Variables section.
3. Select the [+] sign before each variable to expand it.

The total number of reads and writes for global variables is 5.

**Enable Optimization and Generate Code**

In the Configuration Parameters dialog box, for the Optimize global data access parameter, select Minimize global data access or enter the following command in the MATLAB Command Window:

```matlab
set_param('rtwdemo_optimize_global',...
    'GlobalVariableUsage','Minimize global data access');
```

Build the model.

```matlab
rtwbuild(model);
```
View the generated code with the optimization. Here is a portion of `rtwdemo_optimize_global.c`.

cfile = fullfile(cgDir,'rtwdemo_optimize_global_ert_rtw',...
    'rtwdemo_optimize_global.c');
rtwdemodbtype(cfile,'/* Model step','/* Model initialize',1, 0);

/* Model step function */
void rtwdemo_optimize_global_step(void)
{
    real_T tmp_Out1;

    /* MultiPortSwitch: '<Root>/Multiport Switch' incorporates:
     *  Inport: '<Root>/In1'
     */
    switch ((int32_T)rtU.In1) {
    case 1:
        /* Outport: '<Root>/Out1' incorporates:
         *  Constant: '<Root>/Constant'
         */
        tmp_Out1 = 1.0;
        break;

    case 2:
        /* Outport: '<Root>/Out1' incorporates:
         *  Constant: '<Root>/Constant1'
         */
        tmp_Out1 = 2.0;
        break;

    case 3:
        /* Outport: '<Root>/Out1' incorporates:
         *  Constant: '<Root>/Constant2'
         */
        tmp_Out1 = 3.0;
        break;

    default:
        /* Outport: '<Root>/Out1' incorporates:
         *  Constant: '<Root>/Constant3'
         */
        tmp_Out1 = 4.0;
In `rtwdemo_optimize_global.c`, the code assigns a constant value to the local variable `tmp_Out1` in each case statement. The last statement in the code copies the value of `tmp_Out1` to the global variable `rtY.Out1`. Fewer global variable references result in fewer instructions and improved execution speed.

In the **Static Code Metrics Report**, examine the **Global Variables** section. As a result of minimizing global data accesses, the total number of reads and writes for global variables has decreased from 5 to 2.

Close the code generation report.

```
rtwdemoclean;
```

```
cd(currentDir)
```

Reuse Global Block Outputs in the Generated Code

Reduce ROM and RAM consumption and data copies and increase execution speed of generated code. Configure the code generator to reuse global variables by selecting the model configuration parameter **Reuse global block outputs**.

**Example**

In the Command Window, type `rtwdemo_reuse_global`.

![Diagram of a simple model](image)

### Generate Code without Optimization

1. On the Configuration Parameters dialog box, verify that **Signal storage reuse** is selected.
2. Clear **Reuse global block outputs** and click **Apply**.
3. On the **Code Generation > Report** pane, select **Static code metrics**.
4. In your system's temporary folder, create a folder for the build and inspection process.

Press **Ctrl+B** to generate code.

```plaintext
### Starting build procedure for model: rtwdemo_reuse_global
### Successful completion of build procedure for model: rtwdemo_reuse_global
```
View the generated code without the optimization. Here is a portion of rtwdemo_reuse_global.c.

```c
/* Model step function */
void rtwdemo_reuse_global_step(void)
{
    /* Sum: '<Root>/Sum' incorporates:
     *  Delay: '<Root>/Delay'
     *  Inport: '<Root>/In1'
    */
    rtDW.Delay_DSTATE += rtU.In1;

    /* Outport: '<Root>/Out1' incorporates:
     *  Delay: '<Root>/Delay'
    */
    rtY.Out1 = rtDW.Delay_DSTATE;
}
```

The generated code contains a data copy to the global variable `rtDW.Delay_DSTATE`. Open the Static Code Metrics Report. The total number of reads and writes for global variables is 8. The total size is 32 bytes.

**Enable Optimization and Generate Code**

1. On the Configuration Parameters dialog box, select **Reuse global block outputs** and click **Apply**.
2. Generate code.
3. View the generated code with the optimization. Here is a portion of rtwdemo_reuse_global.c.

```c
### Starting build procedure for model: rtwdemo_reuse_global
### Successful completion of build procedure for model: rtwdemo_reuse_global

/* Model step function */
void rtwdemo_reuse_global_step(void)
{
    /* Sum: '<Root>/Sum' incorporates:
     *  Delay: '<Root>/Delay'
     *  Inport: '<Root>/In1'
    */
    rtY.Out1 += rtU.In1;
}
```
The code generator eliminates a data copy, reduces two statements to one statement and three global variables to two global variables.

Open the Static Code Metrics Report. For global variables, this optimization reduces the total number of reads and writes for global variables from 8 to 5 and the total size from 32 bytes to 24 bytes.

Virtualized Output Ports Optimization

The virtualized output ports optimization lets you store the signal entering the root output port as a global variable. Clearing the MAT-file logging option and setting the TLC variable FullRootOutputVector to 0, both defaults for Embedded Coder, eliminate code and data storage associated with root output ports.

Consider the model in the following block diagram. The signal exportedSig has exportedGlobal storage class.

In the default case, the output of the Gain block is written to the signal storage location, exportedSig. The code generator does not generate code or data for the Out1 block, which has become a virtual block.

/* Gain Block: <Root>/Gain */
 exportedSig = rtb_PulseGen * VirtOutPortLogOFF_P.Gain_Gain;

In cases where you enable MAT-file logging or set FullRootOutputVector = 1, the generated code represents root output ports as members of an external outputs vector.

The following code fragment was generated with MAT-file logging enabled. The output port is represented as a member of the external outputs vector VirtOutPortLogON_Y. The Gain block output value is copied to exportedSig and to the external outputs vector.

/* Gain Block: <Root>/Gain */
 exportedSig = rtb_PulseGen * VirtOutPortLogON_P.Gain_Gain;

/* Outport Block: <Root>/Out1 */
 VirtOutPortLogON_Y.Out1 = exportedSig;

Data maintenance in the external outputs vector can be significant for smaller models that perform benchmarks.

You can force root output ports to be stored in the external outputs vector (regardless of the setting of MAT-file logging) by setting the TLC variable FullRootOutputVector to 1. Add the statement
to the Embedded Coder system target file. Alternatively, you can enter the assignment from the MATLAB command line using the `set_param` command, the model parameter `TLCOptions`, and the TLC option `-a`. For more information, see “Specify TLC for Code Generation” (Simulink Coder) and “Configure TLC” (Simulink Coder).

For more information on how to control signal storage in generated code, see “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 31-50 and “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 31-82.

Specify Buffer Reuse by Using Simulink.Signal Objects

If your model has the optimal parameter settings for removing data copies, you might be able to remove additional data copies by using Simulink.Signal objects to specify buffer reuse. After studying the generated code and the Static Code Metrics Report and identifying areas where you think buffer reuse is possible, you specify signal objects on signal lines.

You can specify buffer reuse on signals that include a pair of root inport and outport signals. You can also specify buffer reuse on just a pair of root inport and outport signals. This optimization reduces ROM and RAM consumption because there are less global variables and data copies in the generated code. Code execution speed also increases.

Example Model

The model rtwdemo_reusable_csc contains the nonreusable subsystem DeltaSubsystem and the MATLAB Function block Downsample. DeltaSubsystem contains the MATLAB Function blocks DeltaX and DeltaY.

```matlab
model = 'rtwdemo_reusable_csc';
open_system(model);
```

Specify a Simulink Signal Object for Reuse

1. In the model, open the Model Data Editor (View > Model Data Editor).
2. In the Model Data Editor, on the Signals tab, from the Change view drop-down list, select Code.
3. Click the Show/refresh additional information button. Now, the Model Data Editor shows information about variables and objects in workspaces such as the base workspace.
4. Next to the Filter contents box, activate the Filter using selection button.
In the model, select the RCSC_REAL signal line. The Model Data Editor shows two rows: One that represents the signal line and one that represents a Simulink.Signal object in the base workspace.

For the row that represents the signal line, inspect the Resolve column. The check box is selected, which means the signal line resolves to the Simulink.Signal object, acquiring code generation settings from that object.

For the row that represents the signal object, inspect the Storage Class column. The signal object uses the storage class Reusable, which means the object appears in the generated code as a global variable named RCSC_REAL.

In the model, navigate into the DeltaSubsystem subsystem.

Select the RCSC_REAL signal line in this subsystem. This signal also resolves to the signal object in the base workspace.

With the Reusable storage class, the generated code can store the output of the Complex to Real-Imag block (at the root level of the model) and the output of the DeltaX block (in the subsystem) in the RCSC_REAL global variable.

**Generate Code**

Build the model.

```matlab
currentState = pwd;
[~, cgDir] = rtwdemodir();
rtwbuild(model);

### Starting build procedure for model: rtwdemo_reusable_csc
### Successful completion of build procedure for model: rtwdemo_reusable_csc

For buffer reuse, the rtwdemo_reusable_csc.c file contains these global variables:

- static real_T RCSC_IMAG[1048576];
- static real_T RCSC_IMAG2[262144];
- static real_T RCSC_REAL[1048576];
- static real_T RCSC_REAL2[262144];

The rtwdemo_reusable_csc.c file contains this code:

```c
""cfile = fullfile(cgDir,...
    'rtwdemo_reusable_csc_ert_rtw','rtwdemo_reusable_csc.c');
rtwdemodbtype(cfile,...
    '/* Output and update for atomic system: '<Root>/DeltaSubsystem' */','...""c
```
/* Output and update for atomic system: '<Root>/Downsample' */
rtwdemodbtype(cfile,...
'/* Model step function */'','/* Model initialize function */',1,0);

/* Output and update for atomic system: '<Root>/DeltaSubsystem' */
static void DeltaSubsystem(void)
{
    /* MATLAB Function: '<S1>/DeltaX' */
    DeltaX((&(RCSC_REAL2[0])), (&(RCSC_IMAG2[0])), rtDWork.z2, rtDWork.z1);
    /* SignalConversion: '<S1>/TmpSignal ConversionAtDeltaXOutport1' */
    memcpy((&(RCSC_REAL[0])), &rtDWork.z2[0], 261632U * sizeof(real_T));
    /* SignalConversion: '<S1>/TmpSignal ConversionAtDeltaXOutport2' */
    memcpy((&(RCSC_IMAG[0])), &rtDWork.z1[0], 261632U * sizeof(real_T));
    /* MATLAB Function: '<S1>/DeltaY' */
    DeltaY((&(RCSC_REAL[0])), (&(RCSC_IMAG[0])), &rtDWork.z1[0], &rtDWork.z2[0]);
    /* SignalConversion: '<S1>/TmpSignal ConversionAtDeltaYOutport1' */
    memcpy(&RCSC_REAL2_0[0], &rtDWork.z1[0], 261121U * sizeof(real_T));
    /* SignalConversion: '<S1>/TmpSignal ConversionAtDeltaYOutport2' */
    memcpy(&RCSC_IMAG2_0[0], &rtDWork.z2[0], 261121U * sizeof(real_T));
}

/* Model step function */
void rtwdemo_reusable_csc_step(void)
{
    int32_T i;
    /* ComplexToRealImag: '<Root>/Complex to Real-Imag' incorporates:
     * Inport: '<Root>/ComplexData'
     */
    for (i = 0; i < 1048576; i++) {
        RCSC_REAL[i] = rtU.ComplexData[i].re;
        RCSC_IMAG[i] = rtU.ComplexData[i].im;
    }
    /* End of ComplexToRealImag: '<Root>/Complex to Real-Imag' */

    /* SignalConversion: '<Root>/TmpSignal ConversionAtDownsampleOutport2' incorporates:
     * MATLAB Function: '<Root>/Downsample'
     * SignalConversion: '<Root>/TmpSignal ConversionAtDownsampleOutport1'
     */

    /* Model step function */
The variables RCSC_REAL and RCSC_IMAG hold the outputs of the Complex to Real-Image block and DeltaX. These variables hold the inputs to the DeltaY block. The variables RCSC_REAL2 and RCSC_IMAG2 hold the outputs of Downsample and DeltaY. These variables hold the inputs to the DeltaX block. By interleaving buffers in this way, you eliminate global variables in the generated code.

To remove the signal objects from the signal lines and regenerate code, in the MATLAB Command Window, enter these commands:

```matlab
portHandles = get_param(...
    'rtwdemo_reusable_csc/Complex to Real-Imag','portHandles');
set_param(portHandles.Outport(1),'MustResolveToSignalObject','off');
set_param(portHandles.Outport(2),'MustResolveToSignalObject','off');

portHandles = get_param(...
    'rtwdemo_reusable_csc/Downsample','portHandles');
set_param(portHandles.Outport(1),'MustResolveToSignalObject','off');
set_param(portHandles.Outport(2),'MustResolveToSignalObject','off');

portHandles = get_param(...
    'rtwdemo_reusable_csc/DeltaSubsystem/DeltaX','portHandles');
set_param(portHandles.Outport(1),'MustResolveToSignalObject','off');
set_param(portHandles.Outport(2),'MustResolveToSignalObject','off');
```
portHandles = get_param(...
    'rtwdemo_reusable_csc/DeltaSubsystem/DeltaY','portHandles');
set_param(portHandles.Outport(1),'MustResolveToSignalObject','off');
set_param(portHandles.Outport(2),'MustResolveToSignalObject','off');

rtwbuild(model);

### Starting build procedure for model: rtwdemo_reusable_csc
### Successful completion of build procedure for model: rtwdemo_reusable_csc

The rtwdemo_reusable_csc.c file now contains this code.

cfile = fullfile(cgDir,...
    'rtwdemo_reusable_csc_ert_rtw','rtwdemo_reusable_csc.c');
rtwdemodbtype(cfile,...
    '/* Output and update for atomic system: '<Root>/DeltaSubsystem'' */,...
    '/* Output and update for atomic system: '<Root>/Downsample'' */',1,0);
rtwdemodbtype(cfile,...
    '/* Model step function */','/* Model initialize function */',1,0);

/* Output and update for atomic system: '<Root>/DeltaSubsystem' */
static void DeltaSubsystem(void)
{
    /* MATLAB Function: '<S1>/DeltaX' */
    DeltaX(rtDWork.z2, rtDWork.z1, rtDWork.z1_m, rtDWork.z2_c);

    /* MATLAB Function: '<S1>/DeltaY' */
    DeltaY(rtDWork.z1_m, rtDWork.z2_c, &rtDWork.z1[0], &rtDWork.z2[0]);
}

/* Model step function */
void rtwdemo_reusable_csc_step(void)
{
    int32_T i;

    /* ComplexToRealImag: '<Root>/Complex to Real-Imag' incorporates:
     * Inport: '<Root>/ComplexData'
     */
    for (i = 0; i < 1048576; i++) {
        rtDWork.RCSC_REAL[i] = rtU.ComplexData[i].re;
        rtDWork.RCSC_IMAG[i] = rtU.ComplexData[i].im;
    }

    /* End of ComplexToRealImag: '<Root>/Complex to Real-Imag' */
/* MATLAB Function: '<Root>/Downsample' */
Downsample(rtDWork.RCSC_REAL, rtDWork.RCSC_IMAG, rtDWork.z2, rtDWork.z1);

/* Outputs for Atomic SubSystem: '<Root>/DeltaSubsystem' */
DeltaSubsystem();

/* End of Outputs for SubSystem: '<Root>/DeltaSubsystem' */

/* Outport: '<Root>/Out1' incorporates:
*  RealImagToComplex: '<Root>/Real-Imag to Complex'
*/
for (i = 0; i < 261121; i++) {
    rtY.Out1[i].re = rtDWork.z1[i];
    rtY.Out1[i].im = rtDWork.z2[i];
}

/* End of Outport: '<Root>/Out1' */

The generated code contains two additional global variables for holding block inputs and outputs.

Note: You can specify buffer reuse on signals that the code generator cannot implement. For those cases, use two new diagnostics to specify the message type that the model displays. In the Configuration Parameters dialog box, these diagnostics are Detect non-reused custom storage classes and Detect ambiguous custom storage class final values.

bdclose(model)
rtwdemoclean;
cd(currentDir)

**Buffer Reuse for Unit Delay and Delay Blocks**

To reuse the signal of a Unit Delay or Delay block:

1. Use the same reusable custom storage class specification for a pair of input and state arguments or a pair of output and state arguments of a Unit Delay block or a Delay block.

2. In the Model Data Editor, select the States tab and from the Change view drop-down list, select Code.
3 Use the Name column to set the name of the target Unit Delay or Delay block states. Specify the name of the signal object that you want to reuse.

4 For each state, check the box in the Resolve column.

For Delay blocks, you must set the Delay length parameter to 1 and Initial condition > Source to Dialog. To access these parameters, in the model, open the Property Inspector (View > Property Inspector) and click the block in the model.

Limitations for Root Inport and Outport Signals

These limitations apply to a model in which you specify buffer reuse for a pair of root inport and outport signals:

- The output ports cannot be conditional.
- If the code generator cannot reuse the same buffer in a top model, the generated code contains additional buffers. If the top model is a reference model, the code generator reports an error. To resolve the error, remove the Simulink.signal specification from the signal that connects to the outport port.
- When you run the executable that the code generator produces, and you reuse a pair of root inport and outport signals, when the root input value is zero, the root output value must also be zero. If the output value is nonzero and you reuse the signals, then the results from the simulation can differ from the results that the executable produces.

Limitations for the Model

These limitations apply to a model in which you specify buffer reuse for signals:

- Signals that you specify for reuse must have the same data types and sampling rates.
- For user-specified buffer reuse, blocks that modify a signal specified for reuse must execute before blocks that use the original signal value. Sometimes the code generator has to change the block operation order so that buffer reuse can occur. For models in which the code generator is unable to reorder block operations, buffer reuse does not occur.
- For models in which the code generator reorders block operations so that Simulink.Signal reuse can occur, you can observe the difference in the sorted order. In the model window, select Display > Blocks > Sorted Execution Order. To display the sorted execution order during simulation, select Simulation > Update.
Diagram. To display the execution order in the generated code, select Code > C/C++ Code > Build Model.

Specify Buffer Reuse for MATLAB Function Blocks in a Path

You can specify buffer reuse across MATLAB Function blocks by using the same variable name for the input and output arguments. The code generator tries to reuse the output of one MATLAB Function block as the input to the next MATLAB Function block. This optimization conserves RAM and ROM consumption and reduces data copies.

**Example Model**

1. Use Inport, Outport, and MATLAB Function blocks to create the model `mf_inplace`.

```
function y = fcn(y)
    %#codegen
    y = y + 4;
```

2. Open each MATLAB Function block and copy the following code:

```
function y = fcn(y)
    %#codegen
    y = y + 4;
```

3. Open the Configuration Parameters dialog box. On the Code Generation tab, change the System target file to `ert.tlc`.

4. On the Solver tab, change the Type parameter to Fixed-step.

**Generate Code with Optimization**

Generate code for the model. The `mf_inplace.c` file contains this code:
void mf_inplace_MATLABFunction(real_T *rty_y)
{
    *rty_y += 4.0;
}

void mf_inplace_step(void)
{
    real_T rtb_y_p5;
    rtb_y_p5 = mf_inplace_U.In1;
    mf_inplace_MATLABFunction(&rtb_y_p5);
    mf_inplace_MATLABFunction(&rtb_y_p5);
    mf_inplace_MATLABFunction(&rtb_y_p5);
    mf_inplace_Y.Out1 = rtb_y_p5;
    mf_inplace_MATLABFunction(&mf_inplace_Y.Out1);
}

The code generator reuses the variable rtb_y_p5 for the input and output arguments of each MATLAB Function block.

**Note** On the **Code Generation** tab in the Subsystem Block Parameters dialog box, if the **Function packaging** parameter is set to **Nonreusable function** and the **Function interface** parameter is set to **Allow arguments**, the code generator cannot reuse the input and output arguments.

Remove Data Copies by Reordering Block Operations in
the Generated Code

This example show how to remove data copies by changing the Optimize block order in
the generated code parameter from off to Improved Execution Speed. Changing
this setting indicates to the code generator to reorder block operations where possible to
remove data copies. This parameter is in the Configuration Parameters dialog box. This
optimization conserves RAM and ROM consumption.

Example Model

In the model ex_optimizeblockorder, the signal that leaves the Sum block enters a
Subtract block and a Concatenate block. The signal that leaves the Subtract block enters
a Product block and a Sum of Elements block.
Generate Code without Optimization

The image shows the model `ex_optimizeblockorder` after a model build. The red numbers indicate the default block order in the generated code. The Subtract block executes before the Concatenate block. The Product block executes before the Sum of Elements block.

View the generated code without the optimization. Here is the `ex_optimizeblockorder_step` function.

```c
/* Model step function */
void ex_optimizeblockorder_step(void)
{
    real_T rtb_Sum2x3[6];
    int32_T i;
    real_T rtb_Sum2x3_d;
    real_T rtb_Subtract;

    /* Sum: '<Root>/SumOfElements' */
    rtY.Out2 = -0.0;
```
for (i = 0; i < 6; i++) {
    /* Sum: '<Root>/Sum2x3' incorporates:
     * Inport: '<Root>/In1'
     * Inport: '<Root>/In2'
    */
    rtb_Sum2x3_d = rtU.In1[i] + rtU.In2;

    /* Sum: '<Root>/Subtract' incorporates:
     * Inport: '<Root>/In3'
    */
    rtb_Subtract = rtb_Sum2x3_d - rtU.In3;

    /* Outport: '<Root>/Out1' incorporates:
     * Inport: '<Root>/In4'
     * Product: '<Root>/Product'
    */
    rtY.Out1[i] = rtU.In4[i] * rtb_Subtract;

    /* Sum: '<Root>/Sum2x3' */
    rtb_Sum2x3[i] = rtb_Sum2x3_d;

    /* Sum: '<Root>/SumOfElements' */
    rtY.Out2 += rtb_Subtract;
}

/* Concatenate: '<Root>/MatrixConcat ' */
for (i = 0; i < 3; i++) {
    /* Outport: '<Root>/Out3' incorporates:
     * Inport: '<Root>/In5'
    */
    rtY.Out3[i << 2] = rtb_Sum2x3[i << 1];
    rtY.Out3[2 + (i << 2)] = rtU.In5[i << 1];
    rtY.Out3[1 + (i << 2)] = rtb_Sum2x3[(i << 1) + 1];
    rtY.Out3[3 + (i << 2)] = rtU.In5[(i << 1) + 1];
}

/* End of Concatenate: '<Root>/MatrixConcat ' */
}

With the default order, the generated code contains three buffers, rtb_Sum2x3[6], rtb_Sum2x3_d, and rtb_Subtract. The generated code contains these temporary variables and associated data copies because the Matrix Concatenate block must use the output from the Sum block and the Sum of Elements block must use the output from the Subtract block.
Generate Code with Optimization

The image shows the ex_optimizeblockorder model after setting the Optimize block order in the generated code parameter to Improved Execution Speed and building the model. The Subtract block executes after the Concatenate block. The Product block executes after the Sum of Elements block.

In the optimized code, the three buffers rtb_Sum2x3[6], rtb_Sum2x3_d, and rtb_Subtract and their associated data copies are gone. The generated code does not require these temporary variables to hold the outputs of the Sum and Subtract blocks because the Subtract block executes after the Concatenate block and the Product block executes after the Sum of Elements block.

```c
/* Model step function */
void ex_optimizeblockorder_step(void)
{
    int32_T i;

    /* Sum: '<Root>/Sum2x3' incorporates:
```
To implement buffer reuse, the code generator does not violate user-specified block priorities.

• “Data Copy Reduction”
Data Copy Reduction for Data Store Read and Data Store Write Blocks

This example shows how the code generator removes temporary buffers for Data Store Read and Data Store Write blocks. This optimization improves execution speed and reduces RAM consumption.

Example Model

The model `rtwdemo_optimizeddatastorebuffers` contains the Function caller `UpdateFunc`, which calls the Simulink Function `DefineUpdateFunc`. The Data Store Read block `DSR` reads from `mem`. The Data Store Write block `DSW` writes to `mem`.

```matlab
model='rtwdemo_optimizeddatastorebuffers';
open_system(model);
```

Generate Code without Optimization

In the Configuration Parameters dialog box, deselect the **Reuse buffers for Data Store Read and Data Store Write blocks** parameter or at the MATLAB command prompt, enter this command:
set_param(model,'OptimizeDataStoreBuffers','off');

Build the model.

currentDir = pwd;
 [~, cgDir] = rtwdemodir();
rtwbuild(model)

### Starting build procedure for model: rtwdemo_optimizedatastorebuffers
### Successful completion of build procedure for model: rtwdemo_optimizedatastorebuffers

View the generated code without the optimization. This code is in rtwdemo_optimizedatastorebuffers.c.

cfile = fullfile(cgDir,'rtwdemo_optimizedatastorebuffers_ert_rtw',...
   'rtwdemo_optimizedatastorebuffers.c');
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);

/* Model step function */
void rtwdemo_optimizedatastorebuffers_step(void)
{
    real_T rtb_DSR_last;
    real_T rtb_SimFuncCall_o1;
    real_T rtb_Sum_p;

    /* DataStoreRead: '<Root>/DSR' */
    rtb_DSR_last = mem.last;

    /* Switch: '<Root>/Switch' incorporates:
     * Constant: '<Root>/Constant'
     * DataStoreRead: '<Root>/DSR'
     * Inport: '<Root>/Clear'
     */
    if (rtU.Clear) {
        rtb_SimFuncCall_o1 = 0.0;
    } else {
        rtb_SimFuncCall_o1 = mem.max;
    }

    /* End of Switch: '<Root>/Switch' */

    /* FunctionCaller: '<Root>/SimFuncCall' incorporates:
    * Inport: '<Root>/DataNew'
    */
}
The generated code contains data copies for the Data Store Read and Data Store Write blocks, respectively.

**Generate Code with Optimization**

In the Configuration Parameters dialog box, clear the **Reuse buffers for Data Store Read and Data Store Write blocks** parameter or at the MATLAB command prompt, enter this command:

```
set_param(model,'OptimizeDataStoreBuffers','on');
```

Build the model.

```
rtwbuild(model)
```

### Starting build procedure for model: rtwdemo_optimizedatastorebuffers
### Successful completion of build procedure for model: rtwdemo_optimizedatastorebuffers

View the generated code with the optimization. This code is in `rtwdemo_optimizedatastorebuffers.c`.

```
cfile = fullfile(cgDir,'rtwdemo_optimizedatastorebuffers_ert_rtw','rtwdemo_optimizedatastorebuffers.c');
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);
```

```
/* Model step function */
void rtwdemo_optimizedatastorebuffers_step(void)
{
    real_T rtb_DSR_last;
    real_T tmp;
```
/* DataStoreRead: '<Root>/DSR' */
rtb_DSR_last = mem.last;

/* Switch: '<Root>/Switch' incorporates:
 *  Constant: '<Root>/Constant'
 *  DataStoreRead: '<Root>/DSR'
 *  Inport: '<Root>/Clear'
 */
if (rtU.Clear) {
  tmp = 0.0;
} else {
  tmp = mem.max;
}
/* End of Switch: '<Root>/Switch' */

/* FunctionCaller: '<Root>/SimFuncCall' incorporates:
 *  DataStoreWrite: '<Root>/DSW'
 *  Inport: '<Root>/DataNew'
 */
UpdateFunc(tmp, rtU.DataNew, &mem.last, &mem.max);

/* Outport: '<Root>/Delta' incorporates:
 *  Inport: '<Root>/DataNew'
 *  Sum: '<Root>/Sum'
 */
rtY.Delta = rtU.DataNew - rtb_DSR_last;
}

The data copy for the Data Store Write block is not in the generated code. The code contains the data copy for the Data Store Read block because the Sum block executes after the Data Store Write block. The generated code contains the variable rtb_DSR_last to hold the output of the Sum block. Therefore, the Sum block gets the values that SimFuncCall calculates at the start of the time step rather than those values at the next time step. If the priority of the Sum block is lower than SimFuncCall, the code generator can remove the data copy for the Data Store Read block. Some other cases in which the code generator might not eliminate data copies are:

- A Simulink Function internally writes to the Data Store Memory block.
- The Data Store Read or Data Store Write blocks select elements of an array from the Data Store Memory block.
- The Data Store Memory block has a custom storage class.
The Data Store Read and Data Store Write blocks occur on the same block unless that block is a Bus Assignment block or an Assignment block.

Close the model and clean up.

bdclose(model)
rtwdemoclean;
cd(currentDir)

- “Reuse Local Block Outputs and Generate Code” (Simulink Coder)
Reduce Data Copies for Bus Assignment Blocks

For models containing a Bus Assignment block, if possible, the code generator uses the same variable for the block input and output. Reusing these variables reduces data copies, conserves RAM consumption and increases code execution speed.

Example Model

For example, in bus_assignoptim, a bus signal containing six elements feeds into a Bus Assignment block and a Bus Selector block. The Bus Assignment block assigns new values to the bus element a1_real_array. This bus signal feeds into Out1.

Generate Code Without Optimization

Generate code without the optimization by setting the Perform inplace updates for Bus Assignment blocks parameter to on. Without the optimization the bus_assignoptim_step function contains this code:

```c
void bus_assignoptim_step(void)
{
    real_T rtb_Assignment[36];
    int32_T i;

    /* Assignment: '<Root>/Assignment' incorporates:
       * Inport: '<Root>/In1'
       * Inport: '<Root>/In2'
       * Product: '<Root>/Product'
       * Selector: '<Root>/Selector'
       * Sum: '<Root>/Sum1'
    */
    for (i = 0; i < 36; i++) {
        rtb_Assignment[i] = bus_assignoptim_U.In1.a1_real_array[i];
    }
```
for (i = 0; i < 2; i++) {
    rtb_Assignment[(int32_T)(i + 22)] = (bus_assignoptim_U.In1.al_real_array[(int32_T)(i + 22)] + bus_assignoptim_U.In1.al_num) * bus_assignoptim_U.In2;
}

/* End of Assignment: '<Root>/Assignment' */

/* Outport: '<Root>/Out' incorporates:
 *  BusAssignment: '<Root>/Bus Assignment'
 *  Inport: '<Root>/In1'
 */
bus_assignoptim_Y.Out = bus_assignoptim_U.In1;

/* BusAssignment: '<Root>/Bus Assignment' incorporates:
 *  Outport: '<Root>/Out'
 */
for (i = 0; i < 36; i++) {
    bus_assignoptim_Y.Out.al_real_array[i] = rtb_Assignment[i];
}

The generated code contains the temporary array rtb_Assignment for holding data before this data is assigned to bus_assignoptim_Y.Out.al_real_array.

**Generate Code with Optimization**

Generate code with the optimization by setting the **Perform inplace updates for Bus Assignment blocks** parameter to off. With the optimization, the bus_assignoptim_step function contains this code:

/* Model step function */
void bus_assignoptim_step(void)
{
    int32_T i;

    /* Outport: '<Root>/Out' incorporates:
     *  Inport: '<Root>/In1'
     *  SignalConversion: '<Root>/TmpBusAssignmentBufferAtBus AssignmentInport1'
     */
    bus_assignoptim_Y.Out = bus_assignoptim_U.In1;
for (i = 0; i < 36; i++) {
    bus_assignoptim_Y.Out.a1_real_array[i] =
    bus_assignoptim_U.In1.a1_real_array[i];
}

for (i = 0; i < 2; i++) {
    bus_assignoptim_Y.Out.a1_real_array[(int32_T)(i + 22)] =
    (bus_assignoptim_U.In1.a1_real_array[(int32_T)(i + 22)] +
    bus_assignoptim_U.In1.a1_num) * bus_assignoptim_U.In2;
}

The generated code does not contain the temporary array rtb_Assignment1 for holding data. The generated code directly assigns this data to bus_assignoptim_Y.Out.a1_real_array.

- “Data Copy Reduction”
Optimize Generated Code by Using Signal Labels to Guide Buffer Reuse

If your model has the optimal parameter settings for removing data copies, you might be able to remove additional data copies by using signal labels. After studying the generated code and the Static Code Metrics Report and identifying areas where you think buffer reuse is possible, you can add labels to signal lines. If possible, the code generator reorders block operations to implement the reuse specification.

Specifying buffer reuse improves execution speed and may reduce RAM consumption.

Example Model

The model `rtwdemo_label_guided_reuse` demonstrates how you can use signal labels to request buffer reuse for block input and output signals. For this model, the code generator can use the same variable for the Atomic Subsystem and either the Gain or Saturation block outputs. The generated code uses the same variable for the Saturation and Atomic Subsystem block outputs because those signals contain the same label and the **Use Signal Labels to Guide Buffer Reuse** parameter is selected.

Generate Code Without Optimization

1. Open the model.

```matlab
model='rtwdemo_label_guided_reuse';
open_system(model);
```
In the Configuration Parameters dialog box, clear the **Use Signal Labels to Guide Buffer Reuse** parameter.

Build the model. The `rtwdemo_label_guided_reuse_step` function contains this code:

```c
void rtwdemo_label_guided_reuse_step(void)
{
    real_T rtb_Saturation[4];
    real_T rtb_Bias[4];
    int32_T i;
    AtomicSubsystem(rtU.In1, rtb_Bias);
    for (i = 0; i < 4; i++) {
        if (rtb_Bias[i] > 10.0) {
            rtb_Saturation[i] = 10.0;
        } else if (rtb_Bias[i] < -10.0) {
            rtb_Saturation[i] = -10.0;
        } else {
            rtb_Saturation[i] = rtb_Bias[i];
        }
        rtb_Bias[i] *= 3.0;
    }
    AtomicSubsystem1(rtb_Saturation, rtb_Bias, rtY.Out1);
}
```

By default, within the `for` loop, the Gain block executes after the Saturation block. The generated code uses the same variable for the output of the Atomic Subsystem and the Gain blocks. As a result, the generated code contains two local variables `rtb_Saturation` and `rtb_Bias` for holding intermediate results.

**Generate Code with Optimization**

In the Configuration Parameters dialog box, select the **Use Signal Labels to Guide Buffer Reuse** parameter and build the model. The `rtwdemo_label_guided_reuse_step` function contains this code:

```c
void rtwdemo_label_guided_reuse_step(void)
{
    real_T rtb_Gain1[4];
    int32_T i;
    AtomicSubsystem(rtU.In1, rtY.Out1);
    for (i = 0; i < 4; i++) {
```
rtb_Gain1[i] = 3.0 * rtY.Out1[i];
if (rtY.Out1[i] > 10.0) {
    rtY.Out1[i] = 10.0;
} else {
    if (rtY.Out1[i] < -10.0) {
        rtY.Out1[i] = -10.0;
    }
}

AtomicSubsystem1(rtY.Out1, rtb_Gain1, rtY.Out1);

The code generator changed the block execution order so that within the for loop, the Saturation block executes after the Gain block. The generated code contains one local variable rtb_Gain1 for holding intermediate results.

In addition to requesting which buffers to reuse, another possible use case is to request buffer reuse for block input and output signals that are complex.

Using Label-Based Reuse Versus Reusable Custom Storage Classes

You can also use the same Reusable custom storage class specification on different signal lines to specify which buffers to reuse. As compared to using Reusable custom storage classes, using signal labels to specify reuse has these benefits:

- Signal labels are not observation points in the generated code, so using them does not block other optimizations such as dead code elimination and expression folding.
- The code generator does not force a signal with a label to be a global variable in the generated code. The signal can be a local or global variable.
- Signals with labels can reuse buffers with signals that do not have labels, so reuse among local and global variables is possible.

Using signal labels is a more conservative method of specifying reuse than using Reusable custom storage classes. The code generator does not implement label-based reuse when it can implement reuse by using Reusable custom storage classes in these cases:

- Reuse that can potentially prevent other optimizations from occurring in the generated code.
• Reuse on root inport and outport ports.
• Reuse across model reference or subsystem boundaries.
• Within a subsystem, buffer reuse on an intermediary signal and an input or output port.

Reduce Memory Usage for Signals

The configuration parameter Signal storage reuse reduces the memory requirements of your real-time program by enabling parameters that reuse the memory allocated for signals with an auto storage class. These parameters are the following:

- **Enable local block outputs**
- **Reuse local block outputs**
- **Reuse global block outputs**
- **Optimize global data access**

When the Enable local block outputs parameter is on, where possible the code generator declares block outputs as local variables instead of global variables. Replacing global variables with local variables improves execution speed and reduces RAM/ROM consumption. Creating more local variables can increase stack usage. Some of the global variables that the code generator can localize include:

- Global signals that cross subsystem boundaries
- Global signals across Simulink and Stateflow domains
- Unused global state variables
- Redundant local Data Store Memory block signals

When the Reuse local block outputs parameter is on, wherever possible the code generator reuses local (function) variables for block outputs. When you select Reuse global block outputs, the code generator reuses global (function) variables wherever possible.

The Optimize global data access parameter has these settings:

- None
- Use global to hold temporary results
- Minimize global data access

When you select None, the code generator uses the default optimizations. The setting Use global to hold temporary results maximizes the use of global variables. The setting Minimize global data access minimizes the use of global variables by using local variables to hold intermediate values.
Clearing **Signal storage reuse** makes all block outputs global and unique, which often significantly increases RAM and ROM usage.

The code generator does not localize global variables for MATLAB system objects or AUTOSAR.

Remove Initialization Code

The “Remove root level I/O zero initialization” (Simulink Coder) and “Remove internal data zero initialization” (Simulink Coder) parameters control whether the generated code contains initialization code for internal data (block states and block outputs) and external data (root inports and outports) whose value is zero. If your embedded application initializes RAM to zero at startup, you might not need initialization code. Eliminating this code accelerates model initialization, reduces ROM consumption and increases the execution speed of the generated code.

Remove Zero Initialization Code for Internal Data

This example shows how to eliminate code that initializes internal data to zero. If your embedded application does not require generating initialization code for internal data whose value is zero, you can enable this optimization.

Example Model

Open the model rtwdemo_internal_init. The model contains an enabled subsystem whose initial output is zero. The subsystem contains a Unit Delay block whose initial condition is 0.

---

Generate Code Without Optimization

Build the model using Embedded Coder.

```bash
### Starting build procedure for model: rtwdemo_internal_init
### Successful completion of build procedure for model: rtwdemo_internal_init
```
This code is in the `rtwdemo_internal_init.c` file.

```c
/* Model initialize function */
void rtwdemo_internal_init_initialize(void)
{
    /* Registration code */

    /* initialize error status */
    rtmSetErrorStatus(rtM, (NULL));

    /* states (dwork) */
    (void) memset((void *)&rtDWork, 0,
                  sizeof(D_Work));

    /* SystemInitialize for Enabled SubSystem: '<Root>/Enabled Subsystem' */
    /* InitializeConditions for UnitDelay: '<S1>/Unit Delay' */
    rtDWork.UnitDelay_DSTATE = 0.0;

    /* End of SystemInitialize for SubSystem: '<Root>/Enabled Subsystem' */
}

/* Enable Optimization */
Open the Configuration Parameters dialog box. On the **Optimization** pane, select **Remove internal data zero initialization**.

Alternatively, you can use the command prompt to enable the optimization. To enable the optimization, set the model parameter **ZeroInternalMemoryAtStartup** to 'off'.

```c
set_param(model, 'ZeroInternalMemoryAtStartup', 'off');
```  

**Generate Code with Optimization**

Build the model using Embedded Coder.

```c
### Starting build procedure for model: rtwdemo_internal_init
### Successful completion of build procedure for model: rtwdemo_internal_init
```  

This code is in the `rtwdemo_internal_init.c` file. The generated code does not initialize internal data by assignment to zero.

```c
/* Model initialize function */
```
void rtwdemo_internal_init_initialize(void)
{
    /* (no initialization code required) */
}

/*
If you select the **Remove internal data zero initialization** parameter, be aware that memory might not be in a known state each time the generated code executes. This means that running a model (or a generated S-function) multiple times can result in different answers for each run. This behavior is sometimes desirable. For example, you can select the **Remove internal data zero initialization** parameter if you want to test the behavior of your design during a warm boot (that is, a restart without full system reinitialization). For models in which you select the **Remove internal data zero initialization** parameter but still want to get the same answer on every run from an S-function, you can use either of the following commands before each run:

clear SFcnName

where **SFcnName** is the name of the S-function, or

clear mex

### Remove Initialization Code for Root-Level Inports and Outports Set to Zero

This example shows how to remove initialization code for root-level inports and outports set to zero. If your embedded application does not require generating initialization code for external data whose value is zero, you can enable this optimization.

**Note:** This example requires an Embedded Coder® license.

### Example Model

In the model **rtwdemo_rootlevel_zero_initialization**, all of the input and output signals have a numeric value of zero. Because signals **sig1** and **sig2** have data types int16 and Boolean, respectively, and all of the output signals have data type double, these signals also have initial values of bitwise zero. The signals have an integer bit pattern of 0, meaning that all bits are off. Signals **sig1_b** and **sig2_b** have a fixed-point data type with bias, so their initial value is not bitwise zero.

```matlab
model = 'rtwdemo_rootlevel_zero_initialization';
open_system(model);
```
**Generate Code**

In your system temporary folder, create a temporary folder for the build and inspection process.

```matlab
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```matlab
set_param(model, 'ZeroExternalMemoryAtStartup','on');
rtwbuild(model)
```

### Starting build procedure for model: rtwdemo_rootlevel_zero_initialization
### Successful completion of build procedure for model: rtwdemo_rootlevel_zero_initialization

These lines of `rtwdemo_rootlevel_zero_initialization.c` code show the initialization of root-level inports and outports without the optimization. The four input signals are individually initialized as global variables. The four output signals are members of a global structure that the `memset` function initializes to bitwise zero.

```matlab
cfile = fullfile(cgDir,'rtwdemo_rootlevel_zero_initialization_ert_rtw',... 'rtwdemo_rootlevel_zero_initialization.c');
rtwdemodbtype(cfile, 'rtwdemo_rootlevel_zero_initialization_initialize',... 'trailer for generated code', 1, 0);
```

```c
void rtwdemo_rootlevel_zero_initialization_initialize(void)
{
    /* Registration code */

    /* external inputs */
```
sig1 = 0;
sig1_b = -3;
sig2 = false;
sig2_b = -3;

/* external outputs */
(void) memset((void *)&rtY, 0,
    sizeof(ExternalOutputs));
}

/*
Enable Optimization
*/
1  Open the Configuration Parameters dialog box.
2  On the Optimization pane, select Remove root level I/O zero initialization.

Alternatively, use the command-line API to enable the optimization:

set_param(model, 'ZeroExternalMemoryAtStartup','off');

Generate Code with Optimization

The optimized code does not contain initialization code for the input signals sig1, sig2, and the four output signals, because their initial values are bitwise zero.

Build the model.

rtwbuild(model)

### Starting build procedure for model: rtwdemo_rootlevel_zero_initialization
### Successful completion of build procedure for model: rtwdemo_rootlevel_zero_initialization

Here is the rtwdemo_rootlevel_zero_initialization.c optimized code in the initialization function.

cfile = fullfile(cgDir,'rtwdemo_rootlevel_zero_initialization_ert_rtw',...
    'rtwdemo_rootlevel_zero_initialization.c');
rtwdemodbtype(cfile, 'rtwdemo_rootlevel_zero_initialization_initialize',...
    'trailer for generated code', 1, 0);

void rtwdemo_rootlevel_zero_initialization_initialize(void)
{
    /* Registration code */
/* external inputs */
sig1_b = -3;
sig2_b = -3;
}

/*

Close the model and the code generation report.

bdclose(model)
rtwdemoclean;
cd(currentDir)

Additional Information

• You can use the Use memset to initialize floats and doubles parameter to control
  the representation of zero during initialization. See “Use memset to initialize floats
  and doubles to 0.0” (Simulink Coder).

• The code still initializes data structures whose value is not zero when you select
  Remove internal data zero initialization and Remove root level I/O zero
  initialization.

• The data of ImportedExtern or ImportedExternPointer storage classes are not
  initialized, regardless of the settings of the Remove internal data zero
  initialization and Remove root level I/O zero initialization parameters.

Simplify Multiply Operations in Array Indexing

The generated code might have multiply operations when indexing an element of an array. You can select the optimization parameter “Simplify array indexing” (Simulink Coder) to replace multiply operations in the array index with a temporary variable. This optimization can improve execution speed by reducing the number of times the multiply operation executes.

Example Model

If you have the following model:

The Constant blocks have the following **Constant value**:

- Const1: reshape(1:30, [1 5 3 2])
- Const2: reshape(1:20, [1 5 2 2])
- Const3: reshape(1:90, [1 5 9 2])

The Concatenate block parameter **Mode** is set to **Multidimensional array**. The Constant blocks **Sample time** parameter is set to −1.
Generate Code

Building the model with the **Simplify array indexing** parameter turned off generates the following code:

```c
int32_T i;
int32_T i_0;
int32_T i_1;

for (i = 0; i < 2; i++) {
    for (i_1 = 0; i_1 < 3; i_1++) {
        for (i_0 = 0; i_0 < 5; i_0++) {
            ex_arrayindex_Y.Out[(i_0 + 5 * i_1) + 70 * i] =
            ex_arrayindex_P.Constant1_Value[(5 * i_1 + i_0) + 15 * i];
        }
    }
}

for (i = 0; i < 2; i++) {
    for (i_1 = 0; i_1 < 2; i_1++) {
        for (i_0 = 0; i_0 < 5; i_0++) {
            ex_arrayindex_Y.Out[(i_0 + 5 * (i_1 + 3)) + 70 * i] =
            ex_arrayindex_P.Constant2_Value[(5 * i_1 + i_0) + 10 * i];
        }
    }
}

for (i = 0; i < 2; i++) {
    for (i_1 = 0; i_1 < 9; i_1++) {
        for (i_0 = 0; i_0 < 5; i_0++) {
            ex_arrayindex_Y.Out[(i_0 + 5 * (i_1 + 5)) + 70 * i] =
            ex_arrayindex_P.Constant3_Value[(5 * i_1 + i_0) + 45 * i];
        }
    }
}
```

Generate Code with Optimization

Open the Configuration Parameters dialog box and select the **Simplify array indexing** parameter. Build the model again. In the generated code, \([(i_0 + \text{tmp}_1) + \text{tmp}]\) replaces a multiply operation in the array index, \([(i_0 + 5 \cdot i_1) + 70 \cdot i]\). The generated code is now:
int32_T i;
int32_T i_0;
int32_T i_1;
int32_T tmp;
int32_T tmp_0;
int32_T tmp_1;

tmp = 0;
tmp_0 = 0;
for (i = 0; i < 2; i++) {
    tmp_1 = 0;
    for (i_1 = 0; i_1 < 3; i_1++) {
        for (i_0 = 0; i_0 < 5; i_0++) {
            ex_arrayindex_Y.Out[(i_0 + tmp_1) + tmp] =
                ex_arrayindex_P.Constant1_Value[(i_0 + tmp_1) + tmp_0];
        }
        tmp_1 += 5;
    }
    tmp += 70;
tmp_0 += 15;
}

tmp = 0;
tmp_0 = 0;
for (i = 0; i < 2; i++) {
    tmp_1 = 0;
    for (i_1 = 0; i_1 < 2; i_1++) {
        for (i_0 = 0; i_0 < 5; i_0++) {
            ex_arrayindex_Y.Out[((i_0 + tmp_1) + tmp) + 15] =
                ex_arrayindex_P.Constant2_Value[(i_0 + tmp_1) + tmp_0];
        }
        tmp_1 += 5;
    }
    tmp += 70;
tmp_0 += 10;
}

tmp = 0;
tmp_0 = 0;
for (i = 0; i < 2; i++) {
tmp_1 = 0;
for (i_1 = 0; i_1 < 9; i_1++) {
    for (i_0 = 0; i_0 < 5; i_0++) {
        ex_arrayindex_Y.Out[((i_0 + tmp_1) + tmp) + 25] =
            ex_arrayindex_P.Constant3_Value[(i_0 + tmp_1) + tmp_0];
    }
    tmp_1 += 5;
}

tmp += 70;
tmp_0 += 45;

Replace boolean with Specific Integer Data Type

Depending on the architecture of the processor that your production hardware uses, you can improve the execution speed of the generated code. Select a specific integer data type for the built-in type `boolean`. Using data type replacement, in the generated code you can replace the `boolean` built-in data type with one of these integer types:

- `int8`
- `uint8`
- `intn`

To match the integer word size for the production hardware, replace `n` with 8, 16, or 32.

Example Model

The model `ex_bool` contains two blocks that output `boolean` values and two blocks that take `boolean` values as inputs. This example shows how to replace the data type `boolean` with the integer data type `int32` in the code generated for a 32-bit hardware target.
Generate Code That Contains the Default boolean Data Type

View the generated file `rtwtypes.h`. The `typedef` statements contain the generic type definition of `boolean_T`, which is the code generation name for `boolean`.

```c
/*---------------------------------------------*/
* Generic type definitions: boolean_T, char_T, byte_T, int_T, uint_T,    *
*                              real_T, time_T, ulong_T.
*---------------------------------------------*/
typedef double real_T;
typedef double time_T;
typedef unsigned char boolean_T;
typedef int int_T;
typedef unsigned int uint_T;
typedef unsigned long ulong_T;
```
typedef char char_T;
typedef unsigned char uchar_T;
typedef char_T byte_T;

View the generated file ex_bool.c. The code declares boolean variables by using the type boolean_T.

/* External inputs (root inport signals with auto storage) */
typedef struct {
    real_T In1;                          /* '<Root>/In1' */
    real_T In2;                          /* '<Root>/In2' */
    boolean_T In3;                       /* '<Root>/In3' */
    boolean_T In4;                       /* '<Root>/In4' */
    real_T In5;                          /* '<Root>/In5' */
} ExtU_ex_bool_T;

/* External outputs (root outports fed by signals with auto storage) */
typedef struct {
    boolean_T Out1;                      /* '<Root>/Out1' */
    boolean_T Out2;                      /* '<Root>/Out2' */
    real_T Out3;                         /* '<Root>/Out3' */
} ExtY_ex_bool_T;

**Generate Code That Contains the Target boolean Data Type**

1. Define a Simulink.AliasType object with a base type of int32. Name the object using the replacement name that you want to appear in the generated code.

```c
mybool = Simulink.AliasType;
mybool.BaseType = 'int32';
```

2. In the Configuration Parameters dialog box, specify the Replacement Name field for the data type boolean as mybool.
View the generated file `rtwtypes.h`. The code maps the identifier `mybool` to the native integer type of the target hardware by creating `typedef` statements.

```c
/* Generic type definitions ... */
...
typedef int boolean_T;
.../* Define Simulink Coder replacement data types. */
typedef boolean_T mybool;  /* User defined replacement datatype for boolean_T */
```

View the generated file `ex_bool.c`. The code declares `boolean` variables that use the type `mybool`.

```c
/* External inputs (root inport signals with auto storage) */
typedef struct {
    real_T In1;                        /* '<Root>/In1' */
    real_T In2;                        /* '<Root>/In2' */
    mybool In3;                        /* '<Root>/In3' */
    mybool In4;                        /* '<Root>/In4' */
    real_T In5;                        /* '<Root>/In5' */
} ExtU_ex_bool_T;
/* External outputs (root outports fed by signals with auto storage) */
typedef struct {
    mybool Out1;                      /* '<Root>/Out1' */
    mybool Out2;                      /* '<Root>/Out2' */
    real_T Out3;                      /* '<Root>/Out3' */
} ExtY_ex_bool_T;
```

Replace boolean with Specific Integer Data Type

• “Model Configuration Parameters: Code Generation Data Type Replacement”
Remove Code That Guards Against Division Exceptions for Integers and Fixed-Point Data

Optimize generated code by removing code that protects against division by zero and overflows in division INT_MIN/-1 operations for integers and fixed-point data. If you are sure that these arithmetic exceptions do not occur during program execution, enable this optimization.

This optimization:

- Increases execution speed.
- Reduces ROM consumption.

**NOTE:** If you enable this optimization, it is possible that simulation results and results from generated code are not in bit-for-bit agreement. This example requires an Embedded Coder® license.

**Example Model**

In the model rtwdemo_nzcheck, two signals of type int8 feed into a divide block.

```matlab
model = 'rtwdemo_nzcheck';
open_system(model);
```

![Example Model Diagram]

**Generate Code**

In your system's temporary folder, create a temporary folder for the build and inspection process.
currentDir = pwd;
[~,cgDir] = rtwdemodir();

Build the model.

set_param(model, 'NoFixptDivByZeroProtection', 'off');
rtwbuild(model);

## Starting build procedure for model: rtwdemo_nzcheck
## Successful completion of code generation for model: rtwdemo_nzcheck

View the generated code without the optimization. Here is a portion of rtwdemo_nzcheck.c.

cfile = fullfile(cgDir,'rtwdemo_nzcheck_ert_rtw','rtwdemo_nzcheck.c');
rtwdemodbtype(cfile,'/* Real-time model','/* Model initialize function',1, 1);

/* Real-time model */
RT_MODEL_rtwdemo_nzcheck rtwdemo_nzcheck_M_;
RT_MODEL_rtwdemo_nzcheck *const rtwdemo_nzcheck_M = &rtwdemo_nzcheck_M_;
int32_T div_s32(int32_T numerator, int32_T denominator)
{
    int32_T quotient;
    uint32_T tempAbsQuotient;
    if (denominator == 0) {
        quotient = numerator >= 0 ? MAX_int32_T : MIN_int32_T;

        /* Divide by zero handler */
    } else {
        tempAbsQuotient = (numerator < 0 ? ~(uint32_T)numerator + 1U : (uint32_T)
            numerator) / (denominator < 0 ? ~(uint32_T)denominator + 1U : (uint32_T)denominator);
        quotient = (numerator < 0) != (denominator < 0) ? -(int32_T)tempAbsQuotient :
            (int32_T)tempAbsQuotient;
    }

    return quotient;
}

/* Model step function */
void rtwdemo_nzcheck_step(void)
{
    /* Product: '<Root>/Divide' incorporates:
     *  Inport: '<Root>/In1'
Y = div_s32(U1, U2);

**Enable Optimization**

1. Open the Configuration Parameters dialog box.
2. On the **Optimization** pane, select **Remove code that protects against division arithmetic exceptions**.

Alternatively, you may use the command-line API to enable the optimization:

```matlab
set_param(model, 'NoFixptDivByZeroProtection', 'on');
```

**Generate Code with Optimization**

The optimized code does not contain code that checks for whether or not the divisor has a value of zero.

Build the model.

```bash
rtwbuild(model);
```

### Starting build procedure for model: rtwdemo_nzcheck
### Successful completion of code generation for model: rtwdemo_nzcheck

The following is a portion of `rtwdemo_nzcheck.c`. The code that protects against division arithmetic exceptions is not in the generated code.

```c
rtwdemodbtype(cfile,'/* Real-time model','/* Model initialize function',1, 1);

/* Real-time model */
RT_MODEL_rtwdemo_nzcheck rtwdemo_nzcheck_M_;
RT_MODEL_rtwdemo_nzcheck *const rtwdemo_nzcheck_M = &rtwdemo_nzcheck_M_;

/* Model step function */
void rtwdemo_nzcheck_step(void)
{
    /* Product: '<Root>/Divide' incorporates:
    * Inport: '<Root>/In1'
    * Inport: '<Root>/In2'
    */
```
\[ Y = \frac{U_1}{U_2}; \]

Close the model and code generation report.

\begin{verbatim}
bdclose(model)
rtwdemoclean;
cd(currentDir)
\end{verbatim}

- “Division Arithmetic Exceptions in Generated Code” on page 69-23
Division Arithmetic Exceptions in Generated Code

The **Remove code that protects against division arithmetic exceptions** parameter in the **Optimization** pane of the Configuration Parameters dialog box controls the generation of code that protects against division arithmetic exceptions in integer and fixed-point operations. Division arithmetic exceptions include division by zero and INT_MIN/-1, which results in a quotient that cannot be represented.

When the parameter is selected, the generated code does not contain code that guards against these types of exceptions. This produces smaller, more efficient code, however it can affect numerical results. Select the parameter if you are sure that your model would not encounter these exceptions to optimize the efficiency of the generated code.

When the parameter is not selected, the generated code does not contain code that guards against division arithmetic exceptions. The added protection code checks that there is a numerical match between simulation and code generation for division operations at a cost of code size and performance.

**Division by Zero**

Division by zero is undefined and results in a runtime error in the generated code. When the **Remove code that protects against division arithmetic exceptions** parameter is selected, the code generator does not produce code that protects against division by zero. Select this option only when you are sure that your model will not produce such a division operation.

**INT_MIN/-1**

When you divide the minimum representable value of a signed integer by negative one, the ideal result is equal to the maximum representable value plus one (INT_MAX + 1), which is not representable. This exception may cause the application to unexpectedly halt or crash at run-time. When the **Remove code that protects against division arithmetic exceptions** parameter is selected, the code generator does not produce code that protects against this situation. Select this option only when you are sure that your model will not produce such a division operation.

The following illustrates an example of this type of exception:

```plaintext
a = int32(-2147483648);
b = a/-1
```
The ideal quotient of this operation is 2147483648, but this is not representable in an int32 data type, resulting in an exception at runtime.

### Other Factors Affecting Generated Code of Division Operations

In addition to the Remove code that protects against division arithmetic exceptions parameter, there are several other factors that can affect the appearance of code generated for division operations. The manner in which this parameter controls code generated from blocks containing MATLAB code with integer or fixed-point division operations differs from the built-in Divide block in Simulink. Blocks containing MATLAB code include MATLAB Function blocks and Stateflow charts using MATLAB action language. To balance the efficiency and semantics of fixed-point and integer divisions in these blocks, use fi objects and set the fimath properties to fit your needs. Usage of fi and fimath objects requires a Fixed-Point Designer license.

Rounding and overflow modes also affect the size and efficiency of the generated code. For more information, see “Optimize Generated Code with the Model Advisor” (Fixed-Point Designer).

- “Optimization Tools and Techniques” on page 66-7
Optimize Generated Code by Consolidating Redundant If-Else Statements

This example shows how to optimize generated code by combining if-else statements that share the same condition. This optimization:

- Improves control flow.
- Reduces code size.
- Reduces RAM consumption.
- Increases execution speed.

**Example**

The model rtwdemo_controlflow_opt contains three Switch blocks. The Constant block provides the control input to the Switch blocks. The variable named Cond determines the value of the Constant block.

```matlab
model = 'rtwdemo_controlflow_opt';
open_system(model);
```
Generate Code

Create a temporary folder for the build and inspection process.

```matlab
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```matlab
rtwbuild(model)
```

### Starting build procedure for model: rtwdemo_controlflow_opt
### Successful completion of build procedure for model: rtwdemo_controlflow_opt

These lines of `rtwdemo_controlflow_opt.c` code show that in the generated code, two `if-else` statements and one `else-if` statement represent the three Switch blocks.
cfile = fullfile(cgDir,'rtwdemo_controlflow_opt_ert_rtw',...
     'rtwdemo_controlflow_opt.c');
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);

/* Model step function */
void rtwdemo_controlflow_opt_step(void)
{
    /* Switch: '<Root>/Switch3' incorporates:
        * Constant: '<Root>/Const'
        * Switch: '<Root>/Switch2'
    */
    if (Cond) {
        /* Switch: '<Root>/Switch1' */
        if (Cond) {
            /* Outport: '<Root>/Out1' incorporates:
                * Inport: '<Root>/In1'
            */
            rtY.Out1 = rtU.In1;
        } else {
            /* Outport: '<Root>/Out1' incorporates:
                * Inport: '<Root>/In2'
            */
            rtY.Out1 = rtU.In2;
        }
    } else if (Cond) {
        /* Switch: '<Root>/Switch2' incorporates:
            * Inport: '<Root>/In1'
            * Outport: '<Root>/Out1'
        */
        rtY.Out1 = rtU.In1;
    } else {
        /* Outport: '<Root>/Out1' incorporates:
            * Inport: '<Root>/In2'
        */
        rtY.Out1 = rtU.In2;
    }
}

/* End of Switch: '<Root>/Switch3' */
}
Enable Optimization

1 Open the Configuration Parameters dialog box.
2 On the Code generation -> Code Style pane, clear Preserve condition expression in if statement. This parameter is on by default.

Alternatively, use the command-line API to turn off the parameter:

```matlab
set_param(model, 'PreserveIfCondition', 'off');
```

Generate Code with Optimization

In the optimized code, the code generator consolidates the two if-else statements and one else-if statement into one if-else statement. The code generator consolidates these statements because they all share the same condition. There is no intervening code that affects the outcomes of these statements.

Build the model.

```matlab
rtwbuild(model)
```

```bash
### Starting build procedure for model: rtwdemo_controlflow_opt
### Successful completion of build procedure for model: rtwdemo_controlflow_opt
```

Here is the `rtwdemo_controlflow_opt.c` optimized code.

```c
rtwmoddbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);

/* Model step function */
void rtwdemo_controlflow_opt_step(void)
{
    /* Switch: '<Root>/Switch1' incorporates:
       * Constant: '<Root>/Const'
       * Switch: '<Root>/Switch3'
    */
    if (Cond) {
        /* Outport: '<Root>/Out1' incorporates:
           * Inport: '<Root>/In1'
        */
        rtY.Out1 = rtU.In1;
    } else {
        /* Outport: '<Root>/Out1' incorporates:
           * Inport: '<Root>/In2'
        */
```
rtY.Out1 = rtU.In2;
}

/* End of Switch: '<Root>/Switch1' */
}

Close the model and clean up.

bdclose(model)
rtwdemoclean;
cd(currentDir)

• “Eliminate Dead Code Paths in Generated Code” on page 66-66
Optimize Generated Code for Fixed-Point Data Operations

This example shows how the code generator optimizes fixed-point operations by replacing expensive division operations with highly efficient product operations. This optimization improves execution speed.

Example Model

In the model `rtwdemo_fixptdiv`, two fixed point signals connect to a Divide block. The `Number of inputs` parameter has the value `/*`.

```matlab
model='rtwdemo_fixptdiv';
load_system(model);
set_param(model,'HideAutomaticNames','off','SimulationCommand','Update')
open_system(model);
```
Generate Code

Create a temporary folder for the build and inspection process.

```matlab
currentDir = pwd;
 [~, cgDir] = rtwdemodir();

Build the model.

set_param(model,'GenCodeOnly','on');
rtwbuild(model);
```
### Starting build procedure for model: rtwdemo_fixptdiv
### Successful completion of code generation for model: rtwdemo_fixptdiv

View the generated code. Here is a portion of `rtwdemo_fixptdiv.c`.

cfile = fullfile(cgDir,'rtwdemo_fixptdiv_ert_rtw','rtwdemo_fixptdiv.c');
rtwdemodbtype(cfile,'/* Model step','/* Model initialize', 1, 0);

```c
/* Model step function */
void rtwdemo_fixptdiv_step(void)
{
    /* Outport: '<Root>/Out1' incorporates:
       *  Inport: '<Root>/In1'
       *  Product: '<Root>/Divide'
    */
    rtY.Out1 = (int16_T)(rtU.In1 >> 3);
}
```

The generated code contains a highly efficient right shift operation instead of an expensive division operation. The generated code also contains the precomputed value for the constant input to the Product block.

Note that the resulting operation also includes the adjustment in signal scaling from $2^{-3}$ to $2^{-5}$.

Close the model and code generation report.

```c
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

Optimize Generated Code By Developing and Using Code Replacement Libraries - Simulink®

Develop and use code replacement libraries to replace function and operators in generated code. Code replacement is a technique to change the code that the code generator produces for functions and operators to meet application code requirements. For example, you can replace generated code to meet requirements such as:

- Optimization for a specific run-time environment, including, but not limited to, specific target hardware
- Integration with existing application code
- Compliance with a standard, such as AUTOSAR
- Modification of code behavior, such as enabling or disabling nonfinite or inline support
- Application- or project-specific code requirements, such as use of BLAS or elimination of math.h, system header files, or calls to memcpy or memset.

You can configure a model such that the code generator uses a code replacement library that MathWorks® provides. If you have an Embedded Coder® license, you can develop your own code replacement library interactively with the Code Replacement Tool or programmatically.

This example uses models to show a variety of ways you can define code replacement mappings programmatically. Each model includes buttons that you can use to

- View the code replacement library table definitions from the Code Replacement Viewer
- Open the library table definition file in the editor
- Open the library registration file in the editor
- View the model configuration
- Generate code

For more information, see “Define Code Replacement Mappings” on page 64-43 and “Register Code Replacement Mappings” on page 64-70.

Steps for Developing a Code Replacement Library

1. Identify your code replacement requirements with respect to function or operating mappings, build information, and registration information.
Prepare for code replacement library development (for example, identify or develop models to test your library).

Define code replacement mappings.

Specify build information for replacement code.

Register code replacement mappings.

Verify code replacements.

Deploy the library.

For more information, see “Quick Start Code Replacement Library Development - Simulink®” on page 64-28.

**Math Function Replacement**

This example defines and registers code replacement mappings for math functions. You can define code replacement mappings for a variety of functions (see “Code You Can Replace From Simulink Models” on page 64-7).

Open the model `rtwdemo_crlmath` and use the buttons at the bottom of the model window to explore the files that define and register the code replacement library mappings.

For more information, see “Math Function Code Replacement” on page 64-97.

```matlab
open_system('rtwdemo_crlmath')
```
Optimize Generated Code By Developing and Using Code Replacement Libraries - Simulink®

Set of supported math functions:
- floating point versions of
  sin, cos, tan, asin, acos, atan, sinh, cosh, tanh,
  exp, log, log10, ceil, floor, abs, sqrt, pow/power

Replaced with:
- cos_db1, pow_db1 and log10_sgl

Replaced with:
- asin_db1 and tanh_db1

Replaced with:
- pow_db1

Set of additional supported functions:
memcpy, getNaN, getInf, getMinusInf

Replaced memcpy with memcpy_int

Replaced non-finite support utility functions
getNaN, getInf, getMinusInf
(see rt_InitInfAndNaN)

Generate Code Using Embedded Coder (double-click)

Addition and Subtraction Operator Replacement

This example shows how to define and register code replacement mappings for addition (+) and subtraction (-) operations. When defining entries for addition and subtraction operations, you can specify which of the following algorithms (EntryInfoAlgorithm) your library functions implement:

- Cast-before-operation (CBO) (RTW_CAST_BEFORE_OP), the default
- Cast-after-operation (CAO) (RTW_CAST_AFTER_OP)

1. Open the model rtwdemo_crladdsub. The model shows how to define and register code replacement mappings for scalar addition subtraction (-) operations on two operands with the following pairings of built-in integer data types:

- int8, uint8
- int16, uint16
- int32, uint32

CBO, the default algorithm, is assumed.

open_system('rtwdemo_crladdsub')
Built-in integer operator replacement for scalar addition and subtraction

**Note:**
The default 'EntryInfoAlgorithm' setting for addition/subtraction code replacement library entries is 'RTW_CAST_BEFORE_OP'.
2. Use the buttons at the bottom of the model window to explore the files that define and register the code replacement library mappings.

3. Explore the differences between the CBO and CAO algorithms by opening the model `rtwdemo_crl_cbo_cao`. The model shows two SUM blocks, each demonstrating one of the algorithm settings to match a corresponding code replacement entry.

   • For the `Cast_before_operation_Sub` block, the code generator calculates the subtraction operation in the accumulator data type (`int8`), which is smaller than the input data type (`int16`). This is equivalent to a CBO because the code generator converts the input to the output data type before calculating the result.

   • For the `Cast_after_operation_Sub` block, the code generator calculates the subtraction operation in the accumulator data type (`int32`), which is larger than the input data type (`int16`). This is equivalent to a CAO because the code generator produces the same result by calculating the result without loss of range or precision before converting to the output data type.

\[
\text{open\_system('rtwdemo\_crl\_cbo\_cao')}
\]
4. Use the buttons at the bottom of the model window to explore the files that define and register the code replacement library mappings.

For more information on addition and subtraction operator replacement, see “Addition and Subtraction Operator Code Replacement” on page 64-177. For more information on the addition and subtraction algorithm (EntryInfoAlgorithm) options, see setTflCOperationEntryParameters.
**Multiplication and Division Operator Replacement for Built-In Integers**

This example defines and registers code replacement mappings for scalar multiplication (*) and division (/) operations. The operations take two operands with the following pairings of built-in integer data types:

- `int8`, `uint8`
- `int16`, `uint16`
- `int32`, `uint32`

Open the model `rtwdemo_crlmuldiv` and use the buttons at the bottom of the model window to explore the files that define and register the code replacement library mappings.

```matlab
open_system('rtwdemo_crlmuldiv')
```

Scalar Operator Replacement

This example defines and registers code replacement mappings for scalar operations: addition, subtraction, multiplication, complex conjugate, cast, arithmetic shift right, and arithmetic shift left.

Supported types include:

- single, double
- int8, uint8
- int16, uint16
- int32, uint32
- csingle, cdouble
- cint8, cuint8
- cint16, cuint16
- cint32, cuint32
- fixed-point integers
- mixed types (different type on each input)

Open the model `rtwdemo_crlscalarops` and use the buttons at the bottom of the model window to explore the files that define and register the code replacement library mappings.

CBO, the default algorithm for addition and subtraction operations, is assumed.

```matlab
open_system('rtwdemo_crlscalarops')
```
This example shows how to replace scalar operations with function calls using code replacement libraries.

The supported scalar operations are addition, subtraction, multiplication, complex conjugate, cast, arithmetic shift right and shift left.

NOTE: For replacement of shift right operation of target unsigned integer, an entry for logical shift right must be registered.
Matrix Operator Replacement

This example defines and registers code replacement mappings for matrix operations: addition, subtraction, multiplication, transposition, conjugate, and Hermitian.

Supported types include:

- single, double
- int8, uint8
- int16, uint16
- int32, uint32
- csingle, cdouble
- cint8, cuint8
- cint16, cuint16
- cint32, cuint32
- fixed-point integers
- mixed types (different type on each input)

Open the model `rtwdemo_crlmatops`, which shows some of these replacements. Use the buttons at the bottom of the model window to explore the files that define and register the code replacement library mappings.

For more information on matrix operator replacement, see “Small Matrix Operation to Processor Code Replacement” on page 64-182.

CBO, the default algorithm for addition and subtraction operations, is assumed.

```matlab
open_system('rtwdemo_crlmatops')
```
Optimize Generated Code By Developing and Using Code Replacement Libraries - Simulink®

This example shows how to replace matrix operations with function calls using code replacement libraries.

The supported matrix operations are addition, subtraction, multiplication, division, inverse, transposition, hermitian and complex conjugate.

Generate Code Using Embedded Coder (double-click)

View Interface Configuration (double-click)
Matrix Multiplication Replacement for BLAS

This example defines and registers code replacement mappings for Basic Linear Algebra Subroutines (BLAS) subroutines xGEMM and xGEMV. You can map the following operations to a BLAS subroutine:

• Matrix multiplication
• Matrix multiplication with transpose on single or both inputs
• Matrix multiplication with Hermitian operation on single or both inputs

Open the model rtwdemo_crlblas and use the buttons at the bottom of the model window to explore the files that define and register the code replacement library mappings.

For more information on matrix multiplication replacement for BLAS, see “Matrix Multiplication Operation to MathWorks BLAS Code Replacement” on page 64-186.

open_system('rtwdemo_crlblas')
This example replaces floating point matrix multiplication with either MathWorksBLAS library calls or with ANSI/ISO C BLAS library calls. Double-click the 'Current CRL' button to switch between the BLAS and ANSI/ISO C BLAS code replacement libraries.

Although BLAS supports matrix/matrix multiplication in the form of \( C = a \cdot \text{op}(A) \cdot \text{op}(B) + bC \), code replacement only supports the limited case of \( C = \text{op}(A) \cdot \text{op}(B) \) (\( a = 1.0, b = 0.0 \)).

Likewise, although BLAS supports matrix/vector multiplication in the form of \( y = a \cdot \text{op}(A)x + b \), code replacement only supports the limited case of \( y = \text{op}(A)x \) (\( a = 1.0, b = 0.0 \)).

Here, \( \text{op}(X) = X \) (no Transpose), \( XT \) (Transpose), \( XH \) (Conjugate Transpose)

The BLAS library used by this example is supported on Windows and UNIX platforms.

The C BLAS example does not include BLAS implementations and therefore does not create an executable.
Fixed-Point Operator Replacement for Basic Operators

This example defines and registers code replacement mappings for scalar addition (+), subtraction (-), multiplication (*), and division (/) operations. The operations take two operands with fixed-point data types.

You can define code replacements as matching:

- Slope/bias scaling combination on the inputs and output
- Binary-point scaling combination on the inputs and output
- Relative scaling between the inputs and output
- Same slope value and a zero net bias across the inputs and output.

Open the model `rtwdemo_crlfixpt` and use the buttons at the bottom of the model window to explore the files that define and register the code replacement library mappings.

- By default, for addition and subtraction operator code replacements, the code generator assumes that replacement code implements a cast-before-operation (CBO) algorithm.
- Using fixed-point data types in a model requires a Fixed-Point Designer™ license.

For more information about fixed-point operator code replacement, see “Fixed-Point Operator Code Replacement” on page 64-204.

Match and Replacement Process Customization for Functions

This example defines and registers code replacement mappings for custom entries. You can create your own entry by subclassing from RTW.TflCFunctionEntryML or RTW.TflCOperationEntryML. Your entry class must implement a do_match method that customizes your matching logic or modifies the matched entry. The do_match method must have a fixed preset signature.

Open the model rtwdemo_crlcustomentry. The model shows how to modify the matched entry by injecting constants as additional implementation function arguments. DTC1, Trigonometric Function, and Product show custom entry code replacement for:

- Cast operation that demonstrates how to extract the fraction lengths from types and pass them into the implementation function - Out1 = custom_cast(In1, 2, 4).
- Sine that demonstrates how to pass a constant value to the implementation function - Out2 = custom_sin(In2, 1).
- Multiplication operation that demonstrates how to compute the net slope of an operation and pass that into the implementation function - Out3 = custom_multiply_shift_right(In3, In4, 3).

Use the buttons at the bottom of the model window to explore the files that define and register the code replacement mappings.

For more information on custom entries, see “Customize Match and Replacement Process” on page 64-159.

open_system('rtwdemo_crlcustomentry')
Custom entry replacement for cast operation demonstrates how to extract the fraction-lengths from types and pass them into the implementation function.

\[Out1 = \text{custom\_cast}(\text{In1}, 2, 4)\]

Custom entry replacement for sine demonstrates how to pass a constant value to the implementation function.

\[Out2 = \text{custom\_sin}(\text{In2}, 1)\]

Custom entry replacement for the multiplication operation demonstrates how to compute the net slope of an operation and pass that into the implementation function.

\[Out3 = \text{custom\_multiply\_shift\_right}(\text{In3}, \text{In4}, 3);\]

MATLAB Function Replacement

This example defines and registers code replacement mappings for MATLAB® functions specified in the MATLAB Function block. The function can be opted for replacement by specifying coder.replace within it. This feature supports replacement of MATLAB® functions with the following:

- Single or multiple inputs
- Single or multiple outputs
- Scalar and matrix inputs and outputs

Open the model rtwdemo_crlcoderreplace. The model shows some of these requirements. Supported types include:

- single, double
- int8, uint8
- int16, uint16
- int32, uint32
- csingle, cdouble
- cint8, cuint8
- cint16, cuint16
- cint32, cuint32
- Fixed-point integers
- Mixed types (different type on each input)

Use the buttons at the bottom of the model window to explore the files that define and register the code replacement mappings.

For more information on MATLAB® function replacement, see coder.replace.

open_system('rtwdemo_crlcoderreplace')
Data Alignment for Function Implementations

This example shows how to specify the alignment of matrix operands passed into a replacement function. Some target-specific function implementations require data to be aligned to optimize application performance. To configure data alignment for a function implementation:

- Specify the data alignment requirements in a table entry. You can specify alignment for implementation function arguments individually or collectively.
• Specify the data alignment capabilities and syntax for your compiler. Attach an AlignmentSpecification object to the TargetCharacteristics object of the registry entry specified in your rtwTargetInfo.m file.

Open the model rtwdemo_crlalign. The model shows three data alignment code replacement scenarios:

• Add - Alignment of exported and imported signals. You can specify an exact value for the alignment in the Signal Properties dialog box or allow the code generator to determine the best alignment based on usage by leaving the alignment value set to -1.

• Product - Alignment of virtual and nonvirtual bus types. You can specify an exact value for the alignment for the Alignment property of the Simulink.Bus object or allow the code generator to determine the best alignment based on usage by leaving the Alignment property set to -1.

• EML_MMUL - Alignment of local variables, global variables, and block parameters.

Use the buttons at the bottom of the model window to explore the files that define and register the code replacement mappings. Note that the model is configured to use a GCC, Clang, MSVC, or MinGW compiler.

For more information on specifying data alignment for code replacement, see “Data Alignment for Code Replacement” on page 64-136.

open_system('rtwdemo_crlalign')
Optimize Generated Code By Developing and Using Code Replacement Libraries - Simulink®

Code replacement supports alignment of exported and imported signals. You can specify either an exact value for the alignment in the signal properties dialog box or you can allow the code generator to determine the best alignment based on usage by leaving the alignment value set to -1.

Alignment of imported signals must be specified to allow use of that signal in a replaced function requiring alignment.

3. <B1E1>
4. <B1E1>

Code replacement supports alignment of virtual and non-virtual bus types. You can specify either an exact value for the alignment in the Alignment property of the Simulink.Bus object or you can allow the code generator to determine the best alignment based on usage by leaving the alignment property set to -1.

5. const1

Code replacement supports alignment of local and global variables as well as block parameters.

This example shows how to specify the alignment of matrix operands using code replacement libraries. Alignment requirements are specified on the entry’s arguments. The compiler’s alignment syntax is specified on the registry in the sl_customization.m or the rtwTargetInfo.m file.

Note:
Select “Data Alignment Examples for Non-MinGW” CRL for GCC, Clang, and MSVC. Select “Data Alignment Examples for MinGW” CRL for MinGW.

Performance Gain from Data Alignment

This example shows how code replacement data alignment can accelerate execution of a generated executable by enabling deployment of SIMD operations in generated code.

1. Open model `rtwdemo_crlalignperf`. This model illustrates a basic image processing algorithm, represented by subsystem `Root/Filtering/Process/ALGORITHM`. The algorithm slides a 5x5 template across the image one pixel at a time. The image area covered by the template forms another 5x5 matrix. This matrix is element-wise multiplied by the template matrix. The twenty-five elements in the resultant matrix are summed together to form the new value for that pixel. This element-wise matrix multiplication is performed for all pixels in an image, so its efficiency has a significant impact on the overall algorithm performance.

```matlab
perf = 'rtwdemo_crlalignperf';
open_system(perf)
cc = rtwprivate('getCompilerForModel',perf);
isDaDemoSupported = strcmpi(cc.comp.Manufacturer,'GNU') || ...
    strcmpi(cc.comp.Manufacturer,'Apple') || ...
    strcmpi(cc.comp.Manufacturer,'Microsoft');
if ~isDaDemoSupported
    recMsg = ['Use "mex -setup" to select either GCC, Clang,'...
              'MSVC, or MinGW and restart this example'];
    warning(['The model "%s" is configured to use GCC, Clang,'...
             'MSVC, or MinGW to create a Data Aligned Executable. %s.'],...
             perf,recMsg);
end
```
This example shows how the code replacement data alignment capability can accelerate the execution of the generated program by enabling the deployment of SIMD operations in generated code.

This model example illustrates a basic image processing algorithm, represented by subsystem <Root/Filtering/Process/ALGORITHM>. The algorithm slides a 5x5 template across the image one pixel at a time. The image area covered by the template forms another 5x5 matrix. This matrix is element-wise multiplied by the template matrix.

The twenty-five elements in the resultant matrix are summed together to form the new value for that pixel. This element-wise matrix multiply is performed for all of the pixels in an image, so its efficiency has a significant impact on the overall algorithm performance.

In this example, the model is compiled twice. First, the model is compiled to generate portable, ANSI-C code without data alignment. Next, the model is compiled using a SIMD CRL that does the element-wise matrix multiply using SIMD instructions. The data that the SIMD instructions operate on need to be aligned on a 16-byte boundary.

Double-click the blue button below to execute the example. For both compilations, the generated code is profiled by a profiling hook. After the compilations complete, a figure is displayed that compares the execution time of the subsystem <Root/Filtering/Process/ALGORITHM> with and without data alignment.

For details about how a profile hook works, please refer to example: rtwdemo_profile.

Note:
Select “SIMD Single 5x5 Element-wise Mul for Non-MinGW” CRL for GCC, Clang, and MSVC.
Select “SIMD Single 5x5 Element-wise Mul for MinGW” CRL for MinGW.

Copyright 2011-2012 The MathWorks, Inc.
2. Use the buttons at the bottom of the model window to explore the files that define and register the code replacement mappings.

3. Execute the example by double-clicking Start the Example. Note that the model is configured to use a GCC, Clang, MSVC, or MinGW compiler. This example compiles the model twice. The first compilation produces portable, ANSI-C code without data alignment. The second compilation uses a SIMD code replacement library that does the element-wise matrix multiply using SIMD instructions. The data on which the SIMD instructions operate needs to be aligned on a 16-byte boundary. For both compilations, the generated code is profiled by a profiling hook. After the compilations complete, a figure appears to show a comparison of the execution time of the subsystem Root/Filtering/Process/ALGORITHM with and without data alignment.

4. Generate a baseline by selecting the ANSI® library, building the model, and then running the generated executable ten times. This model uses an element-wise matrix multiplication operation as part of an image processing algorithm. The matrix multiplication is executed numerous times as each pixel in the image is processed. Profiling hooks time the execution of the executable.

```matlab
if (isDaDemoSupported)
    % Create a temporary folder (in your system's temporary folder) for the
    % build and inspection process.
    currentDir = pwd;
    [~,cgDir] = rtwdemodir();

    set_param(perf, 'CodeReplacementLibrary','None'...
              , 'TargetLangStandard','C89/C90 (ANSI)');
    rtwbuild(perf);
    iterations = 10;
    T1 = zeros(iterations, 1);
    for idx = 1:iterations
        evalc(['!', fullfile('.', perf))];
        evalc(['load ', fullfile('.', 'rtwdemo_crlalignperf.mat'))];
        T1(idx) = rt_yout.signals(1).values;
    end
    if exist('rtwdemo_crlalignperf_ANSI', 'dir')
        rmdir('rtwdemo_crlalignperf_ANSI', 's');
    end
    movefile('rtwdemo_crlalignperf_ert_rtw', 'rtwdemo_crlalignperf_ANSI');
else
    warning('Unable to build model "%s". %s.', perf,recMsg);
end
```
5. Generate an optimized, data-aligned executable by selecting a library that maps element-wise matrix multiplication operations to SIMD intrinsic calls, and then building the model. The SIMD intrinsic calls impose an alignment requirement on data passed to the intrinsic. The optimized executable is run ten times. Profiling hooks again capture timing data.

```matlab
if (isDaDemoSupported)
    crl=getCorrectCrlForSelectedCompiler(perf);
    set_param(perf,'CodeReplacementLibrary',crl);
    rtwBuild(perf);
    T2 = zeros(iterations, 1);
    for idx=1:iterations
        evalc(['!', fullfile('.', perf)]);
        evalc(['load ', fullfile('.','rtwdemo_crlalignperf.mat')]);
        T2(idx) = rt_yout.signals(1).values;
    end
    if exist('rtwdemo_crlalignperf_SIMD', 'dir')
        rmdir('rtwdemo_crlalignperf_SIMD','s');
    end
    movefile('rtwdemo_crlalignperf_ert_rtw', 'rtwdemo_crlalignperf_SIMD');
else
    warning(...
        'The Data Aligned Executable for the model "%s" could not be generated. %s.'...
        ,perf,recMsg);
end
```

6. Compare timing results of the baseline and data-aligned executables. The timing data captured from running the baseline and data-aligned executables is displayed in a graph. The graph illustrates that using SIMD operations with data alignment can effectively speed up execution of data-parallel operations.

```matlab
if (isDaDemoSupported)
    T1(T1<0) = NaN;        % The profile counter may overflow.
    T2(T2<0) = NaN;
    t = [min(T1), min(T2)];
    h = figure;
    bar([NaN, t(1), NaN, t(2), NaN]);
```
set(gca, 'XLim', [0.5, 5.5], 'XTickLabel',...
    {'', 'ANSI Multiply', '', 'SIMD Multiply', ''}, ...
    'TickLength', [0 0], 'YLim', [0, max(t) * 1.3], 'YTick', []);
ylabel('Execution Time (CPU Cycles)');

% annotate the plot
annotation('textbox', get(gca, 'Position'), ...
    'String', ['Execution Speed Increased By: ',...
    num2str((1 - t(2)/t(1))*100, '%2.0f'), '%'], ...
    'LineStyle', 'none', 'FitBoxToText', 'off', ...
    'FitHeightToText', 'on', ...
    'FontWeight', 'bold', 'FontSize', 12,...
    'HorizontalAlignment', 'center');

% annotate first bar (simple multiply without alignment)
text('Position', [2, t(1)], 'String', int2str(t(1)),...
    'LineStyle', 'none', ...
    'FontSize', 12, 'HorizontalAlignment', 'center',...
    'VerticalAlignment', 'bottom');

% annotate second bar (SIMD Multiply without alignment)
text('Position', [4, t(2)], 'String', int2str(t(2)),...
    'LineStyle', 'none', ...
    'FontSize', 12, 'HorizontalAlignment', 'center',...
    'VerticalAlignment', 'bottom');

else
    warning(['The Data Alignment Performance Gain example'...
        ' could not be executed. %s.'], recMsg);
end
**Code Replacement Library Exploration and Verification**

This example shows Code Replacement Viewer. You can use the Code Replacement Viewer to:

- Explore which code replacement library to use
- Verify the list of tables in a library and the entries in each table
- Review table entry specifications
- Troubleshoot code replacement misses

The following commands open the Code Replacement Viewer for code replacement table `crl_tablemuldiv`:
crl = crl_table_muldiv;
crviewer(crl);
daRoot = DASTudio.Root;
me = daRoot.find('-isa', 'DASTudio.Explorer');

For more information on the Code Replacement Viewer, see “Verify Code Replacements” on page 64-79.

**Build Information**

For each entry in a code replacement table, you can specify build information such as the following, for replacement functions:

- Header file dependencies
- Source file dependencies
- Additional include paths
- Additional source paths
- Additional link flags

Additionally, you can specify `RTW.copyFileToBuildDir` to copy header, source, or object files, which are required to generate replacement code, to the build folder before code generation. You can specify `RTW.copyFileToBuildDir` by setting it as the value of:

- Property `GenCallback` in a call to `setTflCFunctionEntryParameters`, `setTflCOperationEntryParameters`, or `setTflCSemaphoreEntryParameters`.
- Argument `genCallback` in a call to `registerCFunctionEntry`, `registerCOperationEntry`, or `registerCSemaphoreEntry`.

**Note:** Models in this example are configured for code generation only because the implementations for the replacement functions are not provided.

For more information on specifying build information, see “Specify Build Information for Replacement Code” on page 64-61.

**Reserved Identifiers**

Each function implementation name defined by a code replacement table entry is reserved as a unique identifier. You can specify other identifiers with a table on a per-header-file basis. Providing additional reserved identifiers can help prevent duplicate symbols and other identifier related compile and link issues.
For more information on specifying reserved identifiers, see “Reserved Identifiers and Code Replacement” on page 64-157.

**Remove Example Code Replacement Libraries**

When you finish using the example models, remove the example code replacement libraries and close the example models with these commands:

```matlab
rmpath(fullfile(matlabroot,'toolbox','rtw','rtwdemos','crl_demo'));
sl_refresh_customizations;

close_system('rtwdemo_crladdsub', 0)
close_system('rtwdemo_crl.cbo.cao', 0)

cd(currentDir)
Improve Execution Efficiency by Reordering Block Operations in the Generated Code

To improve execution efficiency, the code generator can change the block execution order. In the Configuration Parameters dialog box, when you set the **Optimize Block Order** parameter to **Improved Execution Speed**, the code generator can change the block operation order to implement these optimizations:

- Eliminate data copies for blocks that perform *inplace* operations (that is, use the same input and output variable) and contain algorithm code with unnecessary data copies.
- Combine more for loops by executing blocks together that have the same size.
- Reuse the same variable for the input, output, and state of a Unit Delay block by executing the Unit Delay block before upstream blocks.

These optimizations improve execution speed and conserve RAM and ROM consumption.

**Example Model**

Open the model `matlab:rtwdemo_optimizeblockorder`. This model contains three subsystems for demonstrating how reordering block operations improves execution efficiency.
**for Loop Fusion**

The subsystem `LoopFusionScheduling` shows how the code generator reorders block operations so that blocks that have the same output size execute together. This
reordering enables for loop fusion. Set the **Optimize block order in the generated code** parameter to **Off**.

In your system's temporary folder, create a folder for the build and inspection process and build the model.

```plaintext
### Starting build procedure for model: rtwdemo_optimizeblockorder
### Successful completion of build procedure for model: rtwdemo_optimizeblockorder
```

View the generated code without the optimization. Code for the `LoopFusionScheduling` subsystem:

```c
/* Output and update for atomic system: '<Root>/LoopFusionScheduling' */
static void LoopFusionScheduling(const real_T rtu_In1[6], const real_T rtu_In2[6],
                                  const real_T rtu_In3[6], const real_T rtu_In4[6],
                                  real_T rty_Out1[6], real_T rty_Out2[9],
                                  real_T rty_Out3[6], real_T rty_Out4[9])
{
    int32_T i;
    int32_T i_0;
    int32_T tmp;
    int32_T tmp_0;
    int32_T tmp_1;

    /* Bias: '<S2>/Bias' incorporates:
     *  Gain: '<S2>/Gain'
     */
    for (i = 0; i < 6; i++) {
        rty_Out1[i] = -0.3 * rtu_In1[i] + 0.5;
    }

    /* End of Bias: '<S2>/Bias' */

    /* Product: '<S2>/Product' */
    for (i = 0; i < 3; i++) {
        for (i_0 = 0; i_0 < 3; i_0++) {
            tmp = i_0 + 3 * i;
            rty_Out2[tmp] = 0.0;
            tmp_0 = i << 1;
            tmp_1 = 3 * i + i_0;
            rty_Out2[tmp] = rty_Out2[tmp_1] + rtu_In2[tmp_0] * rtu_In1[i_0];
            rty_Out2[tmp] = rty_Out2[tmp_0 + 1] * rtu_In1[i_0 + 3] + rty_Out2[tmp_1];
        }
    }
}
```
With the default execution order, the blocks execute from left to right and from top to bottom. As a result, there are separate for loops for the two combinations of Gain and Bias blocks and the Product blocks.

Generate code with the optimization. Set the **Optimize block order in the generated code** parameter to **Improved Execution Speed** and build the model.

### Starting build procedure for model: rtwdemo_optimizeblockorder
### Successful completion of build procedure for model: rtwdemo_optimizeblockorder

View the generated code with the optimization.
int32_T i;
int32_T i_0;
int32_T tmp;
int32_T tmp_0;
int32_T tmp_1;
for (i = 0; i < 3; i++) {
    for (i_0 = 0; i_0 < 3; i_0++) {
        /* Product: '<S2>/Product' incorporates:
         *  Product: '<S2>/Product1'
         */
        tmp = i_0 + 3 * i;
        rty_Out2[tmp] = 0.0;

        /* Product: '<S2>/Product1' */
        rty_Out4[tmp] = 0.0;

        /* Product: '<S2>/Product' incorporates:
         *  Product: '<S2>/Product1'
         */
        tmp_0 = i << 1;
        tmp_1 = 3 * i + i_0;
        rty_Out2[tmp] = rty_Out2[tmp_1] + rtu_In2[tmp_0] * rtu_In1[i_0];

        /* Product: '<S2>/Product1' */
        rty_Out4[tmp] = rty_Out4[tmp_1] + rtu_In4[tmp_0] * rtu_In3[i_0];

        /* Product: '<S2>/Product' incorporates:
         *  Product: '<S2>/Product1'
         */
        tmp_0++;
        rty_Out2[tmp] = rtu_In2[tmp_0] * rtu_In1[i_0 + 3] + rty_Out2[tmp_1];

        /* Product: '<S2>/Product1' */
        rty_Out4[tmp] = rtu_In4[tmp_0] * rtu_In3[i_0 + 3] + rty_Out4[tmp_1];
    }
}
for (i = 0; i < 6; i++) {
    /* Bias: '<S2>/Bias' incorporates:
     *  Gain: '<S2>/Gain'
     */
    rty_Out1[i] = -0.3 * rtu_In1[i] + 0.5;

    /* Bias: '<S2>/Bias1' incorporates:
In the optimized code, blocks with the same output size execute together. The two sets of Gain and Bias blocks have an output dimension size of 6, so they execute together. The Product blocks have an output dimension size of 9, so they execute together. The fusion of for loops enables the code generator to set the value of the expression $3 * i + i_0$ equal to the temporary variable tmp_0. This optimization also improves execution efficiency.

**Buffer Reuse for the Input, Output, and State of Unit Delay Blocks**

The subsystem RegionScheduling shows how the code generator reorders block operations to enable buffer reuse for the input, output, and state of Unit Delay blocks. When computation is part of separate regions that connect only through Delay blocks, the code generator can change the block execution order so that the downstream regions execute before the upstream regions. This execution order enables maximum reuse of Delay block states and input and output variables. Set the **Optimize block order in the generated code** parameter to Off and build the model.

```c
/* Output and update for atomic system: '<Root>/RegionScheduling' */
static void RegionScheduling(const real_T rtu_In1[6], const real_T rtu_In2[6],
   real_T rty_Out1[6], rtDW_RegionScheduling *localDW)
{
  int32_T i;
  real_T rtb_Sum;
  for (i = 0; i < 6; i++) {
    /* Sum: '<S3>/Sum' incorporates:
       * UnitDelay: '<S3>/Delay'
       * UnitDelay: '<S3>/UnitDelay'
    */
    rtb_Sum = localDW->Delay_DSTATE[i] + localDW->UnitDelay_DSTATE[i];
    /* UnitDelay: '<S3>/UnitDelay2' */
```

---

69 Execution Speed in Embedded Coder

---

69-70
rtv_Out1[i] = localDW->UnitDelay2_DSTATE[i];
/* Update for UnitDelay: '<S3>/UnitDelay' incorporates:
  * Gain: '<S3>/Gain'
 */
localDW->UnitDelay_DSTATE[i] = rtu_In2[i] + 3.0;
/* Update for UnitDelay: '<S3>/UnitDelay2' */
localDW->UnitDelay2_DSTATE[i] = rtb_Sum;
}

With the default execution order, the generated code contains the extra, temporary variable rtb_Sum and a data copy.

Generate code with the optimization. Set the **Optimize block order in the generated code** parameter to **Improved Execution Speed** and build the model.

```
### Starting build procedure for model: rtwdemo_optimizeblockorder
### Successful completion of build procedure for model: rtwdemo_optimizeblockorder
```

View the generated code with the optimization.

```
/* Output and update for atomic system: '<Root>/RegionScheduling' */
static void RegionScheduling(const real_T rtu_In1[6], const real_T rtu_In2[6],
    real_T rtv_Out1[6], rtDW_RegionScheduling *localDW)
{
    int32_T i;
    for (i = 0; i < 6; i++) {
        /* UnitDelay: '<S3>/UnitDelay2' */
        rtv_Out1[i] = localDW->UnitDelay2_DSTATE[i];

        /* Sum: '<S3>/Sum' incorporates:
           * UnitDelay: '<S3>/Delay'
           * UnitDelay: '<S3>/UnitDelay'
           * UnitDelay: '<S3>/UnitDelay2'
        */
        localDW->UnitDelay2_DSTATE[i] = localDW->Delay_DSTATE[i] + 
            localDW->UnitDelay_DSTATE[i];
```
In the optimized code, the blocks in Regions 3, 2, and 1 execute in that order. With that execution order, the generated code does not contain the temporary variable `rtb_Sum` and the corresponding data copy.

### Eliminate Data Copies for Blocks That Perform Inplace Operations

The subsystem `InplaceScheduling` shows how the code generator reorders block operations to eliminate data copies for blocks that perform inplace operations. In the Configuration Parameters dialog box, set the **Optimize block order in the generated code** parameter to Off and build the model.

### Starting build procedure for model: rtwdemo_optimizeblockorder

### Successful completion of build procedure for model: rtwdemo_optimizeblockorder

View the generated code without the optimization. Code for the `InplaceScheduling` subsystem:

```c
/* Output and update for atomic system: '<Root>/InplaceScheduling' */
static void InplaceScheduling(void)
{
    int32_T idx1;
    int32_T idx2;
    real_T acc;
    int32_T k;
    real_T rtb_Max[6];
    for (idx1 = 0; idx1 < 6; idx1++) {
        /* Sum: '<S1>/Sum2x3' incorporates:
         *  Inport: '<Root>/In7'
         *  UnitDelay: '<S1>/Unit Delay'
         */
```
rtDWork.UnitDelay_DSTATE[idx1] += rtU.In7[idx1];

/* MinMax: '<S1>/Max' */
if (2.0 > rtDWork.UnitDelay_DSTATE[idx1]) {
    rtb_Max[idx1] = 2.0;
} else {
    rtb_Max[idx1] = rtDWork.UnitDelay_DSTATE[idx1];
}

/* End of MinMax: '<S1>/Max' */

/* S-Function (sdsp2norm2): '<S1>/Normalization' incorporates:
 * Outport: '<Root>/Out7'
 */
idx1 = 0;
idx2 = 0;
acc = 0.0;
for (k = 0; k < 6; k++) {
    acc += rtb_Max[idx1] * rtb_Max[idx1];
    idx1++;
}
acc = 1.0 / (sqrt(acc) + 1.0E-10);
for (k = 0; k < 6; k++) {
    rtY.Out7[idx2] = rtb_Max[idx2] * acc;
    idx2++;
}

/* Outport: '<Root>/Out6' incorporates:
 * Bias: '<S1>/Bias'
 * Inport: '<Root>/In8'
 * Outport: '<Root>/Out7'
 * Product: '<S1>/Product'
 */
rtY.Out6[k] = (rtU.In8 + 1.0) * rtDWork.UnitDelay_DSTATE[k];

/* Switch: '<S1>/Switch' incorporates:
 * Inport: '<Root>/In9'
 * UnitDelay: '<S1>/Unit Delay'
 */
if (rtU.In9[k] > 0.0) {
    rtDWork.UnitDelay_DSTATE[k] = 0.0;
} else {
    rtDWork.UnitDelay_DSTATE[k] = rtb_Max[k];
With the default execution order, the Max block executes before the Product block. To hold the Sum block output, the generated code contains two variables, UnitDelay_DSTATE and rtb_Max.

Generate code with the optimization. Set the **Optimize block order in the generated code** parameter to **Improved Execution Speed** and build the model.

```c
### Starting build procedure for model: rtwdemo_optimizeblockorder
### Successful completion of build procedure for model: rtwdemo_optimizeblockorder

View the generated code with the optimization.

```c
/* Output and update for atomic system: '<Root>/InplaceScheduling' */
static void InplaceScheduling(void)
{
    real_T rtb_Max[6];
    int32_T idx2;
    real_T acc;
    int32_T k;
    int32_T i;
    for (i = 0; i < 6; i++) {
        /* Sum: '<S1>/Sum2x3' incorporates:
           * Inport: '<Root>/In7'
           * UnitDelay: '<S1>/Unit Delay'
        */
        acc = rtU.In7[i] + rtDWork.UnitDelay_DSTATE[i];

        /* Outport: '<Root>/Out6' incorporates:
           * Bias: '<S1>/Bias'
           * Inport: '<Root>/In8'
           * Product: '<S1>/Product'
        */
        rtY.Out6[i] = (rtU.In8 + 1.0) * acc;

        /* MinMax: '<S1>/Max' */
        if (2.0 > acc) {
```
acc = 2.0;
}

/* End of MinMax: '<S1>/Max' */

/* Switch: '<S1>/Switch' incorporates:
  * Inport: '<Root>/In9'
  * UnitDelay: '<S1>/Unit Delay'
 */
if (rtU.In9[i] > 0.0) {
  rtDWork.UnitDelay_DSTATE[i] = 0.0;
} else {
  rtDWork.UnitDelay_DSTATE[i] = acc;
}

/* End of Switch: '<S1>/Switch' */

/* Sum: '<S1>/Sum2x3' */
rtb_Max[i] = acc;

/* S-Function (sdsp2norm2): '<S1>/Normalization' incorporates:
  * Outport: '<Root>/Out7'
 */
i = 0;
idx2 = 0;
acc = 0.0;
for (k = 0; k < 6; k++) {
  acc += rtb_Max[i] * rtb_Max[i];
  i++;
}
acc = 1.0 / (sqrt(acc) + 1.0E-10);
for (k = 0; k < 6; k++) {
  rtY.Out7[idx2] = rtb_Max[idx2] * acc;
  idx2++;
}

/* End of S-Function (sdsp2norm2): '<S1>/Normalization' */

The optimized code does not contain the variable rtb_Max or the data copy. The generated code contains one variable, UnitDelay_DSTATE, for holding the Sum block...
output. The Product block reads from UnitDelay_DSTATE and the Max block reads from and writes to UnitDelay_DSTATE.

To implement buffer reuse, the code generator does not violate user-specified block priorities.

Optimize Generated Code Using Minimum and Maximum Values

To optimize the generated code for your model, you can choose an option to use input range information, also known as design minimum and maximum, that you specify on signals and parameters. These minimum and maximum values usually represent environmental limits, such as temperature, or mechanical and electrical limits, such as output ranges of sensors.

In the Configuration Parameters dialog box, when you select the **Optimize using specified minimum and maximum values** check box, the software uses the minimum and maximum values to derive range information for downstream signals in the model. It then uses this derived range information to determine if it is possible to streamline the generated code by:

- Reducing expressions to constants
- Removing dead branches of conditional statements
- Eliminating unnecessary mathematical operations

This optimization results in:

- Reduced ROM and RAM consumption
- Improved execution speed

Configure Your Model

To make optimization more likely:

- Provide as much design minimum and maximum information as possible. Specify minimum and maximum values for signals and parameters in the model for:
  - Inport and Outport blocks
  - Block outputs
  - Block inputs, for example, for the MATLAB Function and Stateflow Chart blocks
  - `Simulink.Signal` objects
- Before generating code, test the minimum and maximum values for signals and parameters. Otherwise, optimization might result in numerical mismatch with
simulation. You can simulate your model with simulation range checking enabled. If errors or warnings occur, fix these issues before generating code.

**Enable Simulation Range Checking**

1. In your model, select **Simulation > Model Configuration Parameters** to open the Configuration Parameters dialog box.
2. In the Configuration Parameters dialog box, select **Diagnostics > Data Validity**.
3. On the **Data Validity** pane, under **Signals**, set **Simulation range checking** to **warning** or **error**.

- Provide design minimum and maximum information upstream of blocks as close to the inputs of the blocks as possible. If you specify minimum and maximum values for a block output, these values are most likely to affect the outputs of the blocks immediately downstream.

**Optimize Generated Code Using Specified Minimum and Maximum Values**

This example shows how the minimum and maximum values specified on signals and parameters in a model are used to optimize the generated code.

**Overview**

The specified minimum and maximum values usually represent environmental limits, such as temperature, or mechanical and electrical limits, such as output ranges of sensors.

This optimization uses these values to streamline the generated code. For example, it reduces expressions to constants or removes dead branches of conditional statements.

**NOTE:** Make sure the minimum and maximum values that you specify are valid limits. Otherwise, this optimization might result in numerical mismatch with simulation.

The benefits of optimizing the generated code are:

- Reducing the ROM and RAM consumption.
- Improving the execution speed.

**Review Minimum and Maximum Information**

Consider the model rtwdemo_minmax. In this model, there are minimum and maximum values specified on Inports and on the gain parameter of the Gain block.
model = 'rtwdemo_minmax';
open_system(model);

Generate Code Without This Optimization

First, generate code for this model without considering the min and max values.

currentDir = pwd;
 [~,cgDir] = rtwdemodir();
rtwconfiguredemo(model,'ERT')
rtwbuild(model)
## Starting build procedure for model: rtwdemo_minmax

### Successful completion of build procedure for model: rtwdemo_minmax

A portion of `rtwdemo_minmax.c` is listed below.

```c

cfile = fullfile(cgDir,'rtwdemo_minmax_ert_rtw','rtwdemo_minmax.c');
rtwdemodbttype(cfile,/* Model step', '/* Model initialize', 1, 0);

/* Model step function */
void rtwdemo_minmax_step(void)
{
    int32_T tmp;

    /* Sum: '<Root>/Sum' incorporates:
    *  Inport: '<Root>/U1'
    *  Inport: '<Root>/U2'
    *  Sum: '<Root>/Sum2'
    *  Switch: '<Root>/Switch'
    */
    tmp = U1 + U2;

    /* Switch: '<Root>/Switch' incorporates:
    *  Gain: '<Root>/Gain'
    *  Inport: '<Root>/U3'
    *  RelationalOperator: '<Root>/Relational Operator'
    *  Sum: '<Root>/Sum'
    */
    if (tmp <= k * U3) {
        /* Outport: '<Root>/Out1' incorporates:
        *  Sum: '<Root>/Sum2'
        */
        rtY.Out1 = tmp + U3;
    } else {
        /* Outport: '<Root>/Out1' incorporates:
        *  Inport: '<Root>/U1'
        *  Inport: '<Root>/U2'
        *  Product: '<Root>/Product'
        */
        rtY.Out1 = U1 * U2 * U3;
    }
}
```

Optimize Generated Code Using Minimum and Maximum Values
Enable This Optimization

1. Open the Configuration Parameters dialog box.
2. On the Optimization pane, select Optimize using the specified minimum and maximum values.

Alternatively, you can enable this optimization by setting the command-line parameter.

```
set_param(model, 'UseSpecifiedMinMax', 'on');
```

Generate Code With This Optimization

In the model, with the specified minimum and maximum values for U1 and U2, the sum of U1 and U2 has a minimum value of 50. Considering the range of U3 and the specified minimum and maximum values for the Gain block parameter, the maximum value of the Gain block's output is 40.

The output of the Relational Operator block remains false, and the output of the Switch block remains the product of the three inputs.

Configure and build the model using Embedded Coder.

```
rtwconfiguredemo(model,'ERT')
rtwbuild(model)
```
rtY.Out1 = U1 * U2 * U3;
}

Close the model and cleanup.

bdclose(model)
rtwdemoclean;
cd(currentDir)

**Limitations**

- This optimization does not take into account minimum and maximum values for:
  - Merge block inputs. To work around this issue, use a `Simulink.Signal` object on the Merge block output and specify the range on this object.
  - Bus elements.
  - Conditionally-executed subsystem (such as a triggered subsystem) block outputs that are directly connected to an Outport block.

  Outport blocks in conditionally-executed subsystems can have an initial value specified for use only when the system is not triggered. In this case, the optimization cannot use the range of the block output because the range might not cover the initial value of the block.

- If you use Polyspace software to verify code generated using this optimization, it might mark code that was previously green as orange. For example, if your model contains a division where the range of the denominator does not include zero, the generated code does not include protection against division by zero. Polyspace might mark this code orange because it does not have information about the minimum and maximum values for the inputs to the division.

Polyspace Code Prover automatically captures some minimum and maximum values specified in the MATLAB workspace, for example, for `Simulink.Signal` and `Simulink.Parameter` objects. In this example, to provide range information to the Polyspace software, use a `Simulink.Signal` object on the input of the division and specify a range that does not include zero.

Polyspace Code Prover stores these values in a Data Range Specification (DRS) file. However, they do not capture all minimum and maximum values in your Simulink model. To provide additional minimum and maximum information to Polyspace, you can manually define a DRS file.
• If you are using double-precision data types and the **Support non-finite numbers** configuration parameter is selected, this optimization does not occur.

• If your model contains multiple instances of a reusable subsystem and each instance uses input signals with different minimum and maximum values, this optimization might result in different generated code for each subsystem so code reuse does not occur. Without this optimization, code is generated once for the subsystem and shares this code among the multiple instances of the subsystem.

• The Model Advisor check Check safety-related optimization settings generates a warning if this option is selected. For many safety-critical applications, removing dead code automatically is unacceptable because doing so might make code untraceable.

Reduce Global Variables in Nonreusable Subsystem Functions

Global variables can increase memory requirements and reduce execution speed. To reduce global RAM for a nonreusable subsystem, you can generate a function interface that passes data through arguments instead of global variables. The Subsystem block parameter “Function interface” (Simulink) provides this option. To compare the outputs for the Function interface options, first generate a function for a subsystem with a void-void interface, and then generate a function with arguments.

Generate void-void Function

By default, when you configure a Subsystem block as a nonreusable function, it generates a void-void interface.

1. Open the example model rtwdemo_roll.
2. Right-click the subsystem RollAngleReference. From the list select Block Parameter (Subsystem).
3. In the Block Parameters dialog box, confirm that the Treat as atomic unit check box is selected.
4. Click the Code Generation tab and set the Function packaging parameter to Nonreusable function.
5. The Function interface parameter is already set to void_void.
6. Click Apply and OK.
7. Repeat steps 2–6, for the other subsystems HeadingMode and BasicRollMode.
8. Generate code and the static code metrics report for rtwdemo_roll. This model is configured to generate a code generation report and to open the report automatically. For more information, see “Generate Static Code Metrics Report for Simulink Model” on page 48-38.

In the code generation report, in rtwdemo_roll.c, the generated code for subsystem RollAngleReference contains a void-void function definition:
void rtwdemo_roll_RollAngleReference(void)
{
    ...
}

In the static code metrics report, navigate to **Global Variables**. With the `void void` option, the number of bytes for global variables is 55.

2. Global Variables [hide]

Global variables defined in the generated code.

<table>
<thead>
<tr>
<th>Global Variable</th>
<th>Size (bytes)</th>
<th>Reads / Writes</th>
<th>Reads / Writes in a Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>rtwdemo_roll_U</td>
<td>26</td>
<td>14</td>
<td>6</td>
</tr>
<tr>
<td>rtwdemo_roll_DW</td>
<td>9</td>
<td>17</td>
<td>14</td>
</tr>
<tr>
<td>rtwdemo_roll_B</td>
<td>8</td>
<td>17</td>
<td>10</td>
</tr>
<tr>
<td>rtwdemo_roll_M</td>
<td>8</td>
<td>0*</td>
<td>0*</td>
</tr>
<tr>
<td>rtwdemo_roll_Y</td>
<td>4</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td><strong>Total</strong></td>
<td><strong>55</strong></td>
<td><strong>49</strong></td>
<td></td>
</tr>
</tbody>
</table>

* The global variable is not directly used in any function.

Next, generate the same function with the Allow arguments option to compare the results.

**Generate Function with Arguments**

To reduce global RAM, improve ROM usage and execution speed, generate a function that allows arguments:

1. Open the Subsystem Block Parameter dialog box for RollAngleReference.
2. Click the **Code Generation** tab. Set the **Function interface** parameter to Allow arguments.
3. Click **Apply** and **OK**.
4. Repeat steps 2 and 3, for the other subsystems HeadingMode and BasicRollMode.
5. Generate code and the static code metrics report for rtwdemo_roll.
In the code generation report, in `rtwdemo_roll.c`, the generated code for subsystem RollAngleReference now has arguments:

```c
real32_T rtwdemo_roll_RollAngleReference(real32_T rtu_Phi, ...
    boolean_T rtu_AP_Eng, ...
    real32_T rtu_Turn_Knob)
{
    ...
}
```

In the static code metrics report, navigate to **Global Variables**. With the Allow arguments option set, the total number of bytes for global variables is now 47 bytes.

### 2. Global Variables [hide](#)

Optimize Generated Code By Packing Boolean Data Into Bitfields

This example shows how to optimize the generated code by packing Boolean data into bitfields. When you select the model configuration parameter **Pack Boolean data into bitfields**, Embedded Coder® packs the Boolean signals into 1-bit bitfields, reducing RAM consumption. By default, the optimization is enabled. This optimization reduces the RAM consumption. Be aware that this optimization can potentially increase code size and execution speed.

**Example Model**

Consider the model `rtwdemo_pack_boolean`.

```matlab
model = 'rtwdemo_pack_boolean';
open_system(model);
```

**Disable Optimization**

1. Open the Configuration Parameters dialog box.
2 On the **Optimization > Signals and Parameters** pane, clear **Pack Boolean data into bitfields**.

Alternatively, you can use the command-line API to disable the optimization:

```matlab
set_param(model,'BooleansAsBitfields','off');
```

Create a temporary folder (in your system temporary folder) for the build and inspection process.

```matlab
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

**Generate Code Without Optimization**

Build the model using Embedded Coder®.

```matlab
rtwbuild(model)
```

### Starting build procedure for model: rtwdemo_pack_boolean
### Successful completion of build procedure for model: rtwdemo_pack_boolean

View the generated code without the optimization. These lines of code are in `rtwdemo_pack_boolean.h`.

```matlab
hfile = fullfile(cgDir,'rtwdemo_pack_boolean_ert_rtw','rtwdemo_pack_boolean.h');
rtwdemodbtype(hfile,'/* Block signals and states','/* External inputs',1,0);
```

```c
/* Block signals and states (default storage) for system '<Root>' */
typedef struct {
    boolean_T LogicalOp1;     /* '<Root>/Logical Op1' */
    boolean_T LogicalOp2;     /* '<Root>/Logical Op2' */
    boolean_T LogicalOp5;     /* '<Root>/Logical Op5' */
    boolean_T LogicalOp3;     /* '<Root>/Logical Op3' */
    boolean_T LogicalOp4;     /* '<Root>/Logical Op4' */
    boolean_T RelationalOperator;    /* '<Root>/Relational Operator' */
    boolean_T UnitDelay_DSTATE;    /* '<Root>/Unit Delay' */
} DW;
```

**Enable Optimization**

1 Open the Configuration Parameters dialog box.

2 On the **Optimization > Signals and Parameters** pane, select **Pack Boolean data into bitfields**.
Alternatively, you can use the command-line API to enable the optimization:

```matlab
set_param(model,'BooleansAsBitfields','on');
```

**Generate Code with Optimization**

Build the model using Embedded Coder®.

```matlab
rtwbuild(model)
```

### Starting build procedure for model: rtwdemo_pack_boolean
### Successful completion of build procedure for model: rtwdemo_pack_boolean

View the generated code with the optimization. These lines of code are in `rtwdemo_pack_boolean.h`.

```matlab
hfile = fullfile(cgDir,'rtwdemo_pack_boolean_ert_rtw','rtwdemo_pack_boolean.h');
rtwdemodbtype(hfile,'/* Block signals and states','/* External inputs',1,0);
```

```c
/* Block signals and states (default storage) for system '<Root>' */
typedef struct {
    struct {
        uint_T LogicalOp1:1; /* '<Root>/Logical Op1' */
        uint_T LogicalOp2:1; /* '<Root>/Logical Op2' */
        uint_T LogicalOp5:1; /* '<Root>/Logical Op5' */
        uint_T LogicalOp3:1; /* '<Root>/Logical Op3' */
        uint_T LogicalOp4:1; /* '<Root>/Logical Op4' */
        uint_T RelationalOperator:1; /* '<Root>/Relational Operator' */
        uint_T UnitDelay_DSTATE:1; /* '<Root>/Unit Delay' */
    } bitsForTID0;
} DW;
```

Selecting **Pack Boolean data into bitfields** enables model configuration parameter **Bitfield declarator type specifier**. To optimize your code further, select `uchar_t`. However, the optimization benefit of the **Bitfield declarator type specifier** setting depends on your choice of target.

Close the model and code generation report.
bdclose(model)
rtwdemoclean;
cd(currentDir)

Optimize Generated Code By Passing Reusable Subsystem Outputs as Individual Arguments

This example shows how passing reusable subsystem outputs as individual arguments instead of as a pointer to a structure stored in global memory optimizes the generated code. This optimization conserves RAM consumption and increases code execution speed by reducing global memory usage and eliminating data copies from local variables back to global block I/O structures.

Example Model

Consider the model rtwdemo_reusable_sys_outputs. In this model, the reusable subsystem outputs feed the root outputs of the model.

```matlab
model = 'rtwdemo_reusable_sys_outputs';
open_system(model);
```

Generate Code Without This Optimization

Generate code for this model while passing subsystem outputs as a structure reference. Create a temporary folder for the build and inspection process.

```matlab
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```
Build the model.

rtwbuild(model)

### Starting build procedure for model: rtwdemo_reusable_sys_outputs
### Successful completion of build procedure for model: rtwdemo_reusable_sys_outputs

The code snippet shows portions of `rtwdemo_reusable_sys_outputs.c`. Notice the global block I/O structure and in the model step function a data copy from this structure.

cfile = fullfile(cgDir,'rtwdemo_reusable_sys_outputs_ert_rtw',...
'rtwdemo_reusable_sys_outputs.c');
rtwmoddbtype(cfile,'/* Output and update for atomic system',...
'/* Model initialize', 1, 0);

/* Output and update for atomic system: '<Root>/ReusableSubsystem' */
static void ReusableSubsystem(real_T rtu_In1, real_T rtu_In2, real_T rtu_In3,
DW_ReusableSubsystem *localDW)
{
    /* Gain: '<S1>/Gain' */
    localDW->Gain = 5.0 * rtu_In1;

    /* Gain: '<S1>/Gain1' */
    localDW->Gain1 = 6.0 * rtu_In2;

    /* Gain: '<S1>/Gain2' */
    localDW->Gain2 = 7.0 * rtu_In3;
}

/* Model step function */
void rtwdemo_reusable_sys_outputs_step(void)
{
/* Outputs for Atomic SubSystem: '<Root>/ReusableSubsystem' */

/* Inport: '<Root>/In1' incorporates:
 * Inport: '<Root>/In2'
 * Inport: '<Root>/In3'
 */
ReusableSubsystem(rtU.In1, rtU.In2, rtU.In3, &rtDW.ReusableSubsystem_d);

/* End of Outputs for SubSystem: '<Root>/ReusableSubsystem' */

/* Outport: '<Root>/Out1' */
rtY.Out1 = rtDW.ReusableSubsystem_d.Gain;
Enable This Optimization

1. Open the Configuration Parameters dialog box.
2. On the Optimization pane, set Pass reusable subsystem outputs as to Individual arguments.

Alternatively, you can use the command-line API to enable the optimization:

```matlab
set_param(model, 'PassReuseOutputArgsAs', 'Individual arguments');
```

Generate Code With This Optimization

With this optimization, the ReusableSubsystem function has three output arguments, which are direct references to the external outputs. The rtDW global structure no longer exists, and the data copies from this structure to the rtY (external outputs) structure are not in the generated code.

Build the model.

```matlab
rtwbuild(model)
```

### Starting build procedure for model: rtwdemo_reusable_sys_outputs

### Successful completion of build procedure for model: rtwdemo_reusable_sys_outputs

The code snippet below is a portion of rtwdemo_reusable_sys_outputs.c. Observe the optimized code.

```c
rtwmoddbtype(cfile,'/* Output and update for atomic system',...  '/* Model initialize', 1, 0);

/* Output and update for atomic system: '<Root>/ReusableSubsystem' */
static void ReusableSubsystem(real_T rtu_In1, real_T rtu_In2, real_T rtu_In3,
                              real_T *rty_Out1, real_T *rty_Out2, real_T *rty_Out3)
{
    /* Gain: '<S1>/Gain' */
```
*rty_Out1 = 5.0 * rtu_In1;

/* Gain: '<S1>/Gain1' */
*rty_Out2 = 6.0 * rtu_In2;

/* Gain: '<S1>/Gain2' */
*rty_Out3 = 7.0 * rtu_In3;
}

/* Model step function */
void rtwdemo_reusable_sys_outputs_step(void)
{
    /* Outputs for Atomic SubSystem: '<Root>/ReusableSubsystem' */

    /* Inport: '<Root>/In1' incorporates:
    * Inport: '<Root>/In2'
    * Inport: '<Root>/In3'
    * Outport: '<Root>/Out1'
    * Outport: '<Root>/Out2'
    * Outport: '<Root>/Out3'
    */
    ReusableSubsystem(rtU.In1, rtU.In2, rtU.In3, &rtY.Out1, &rtY.Out2, &rtY.Out3);

    /* End of Outputs for SubSystem: '<Root>/ReusableSubsystem' */
}

Close the model and cleanup.

bdclose(model);
rtwdemoclean;
cd(currentDir)

Convert Data Copies to Pointer Assignments

The code generator optimizes generated code for vector signal assignments by trying to replace for loop controlled element assignments and memcpy function calls with pointer assignments. Pointer assignments avoid expensive data copies. Therefore, they use less stack space and offer faster execution speed than for loop controlled element assignments and memcpy function calls. If you assign large data sets to vector signals, this optimization can result in significant improvements to code efficiency.

Configure Model to Optimize Generated Code for Vector Signal Assignments

To apply this optimization:

1. Verify that your target supports the memcpy function.
2. Determine whether your model uses vector signal assignments (such as Y=expression) to move large amounts of data. For example, your model could use a Selector block to select input elements from a vector, matrix, or multidimension signal.
3. On the Optimization pane, the Use memcpy for vector assignment parameter, which is on by default, enables the associated Memcpy threshold (bytes) parameter.
4. Examine the setting of Memcpy threshold (bytes). By default, it specifies 64 bytes as the minimum array size for which memcpy function calls or pointer assignments can replace for loops in the generated code. Based on the array sizes in your application's vector signal assignments, and target environment considerations on the threshold selection, accept the default value or specify another array size.

Example Model

Consider the following model named rtwdemo_pointer_conversion. This model uses a Switch block to assign data to a vector signal. This signal then feeds into a Bus Selector block.
Generate Code without Optimization

1. In the Configuration Parameters dialog box, clear the **Use memcpy for vector assignment** parameter.

2. Create a temporary folder for the build and inspection process.

3. Press **Ctrl+B** to generate code.

```c
/* Model step function */
void rtwdemo_pointer_conversion_step(void)
{
    int16_T rtb_dataX[100];
    int16_T rtb_dataY[100];
    int32_T i;

    /* Switch: '<Root>/Switch' incorporates:
    * Constant: '<Root>/Constant'
    * Constant: '<Root>/Constant1'
    * Constant: '<Root>/Constant2'
    * Constant: '<Root>/Constant3'
```
* Inport: '<Root>/In1'
*/
for (i = 0; i < 100; i++) {
   if (rtU.In1) {
      rtb_dataX[i] = rtCP_Constant_Value[i];
      rtb_dataY[i] = rtCP_Constant1_Value[i];
   } else {
      rtb_dataX[i] = rtCP_Constant2_Value[i];
      rtb_dataY[i] = rtCP_Constant3_Value[i];
   }
}

/* End of Switch: '<Root>/Switch' */

/* S-Function (sfix_look1_dyn): '<Root>/Lookup Table Dynamic' incorporates:
 * Inport: '<Root>/In2'
 * Outport: '<Root>/Out1'
 */
/* Dynamic Look-Up Table Block: '<Root>/Lookup Table Dynamic'
 * Input0 Data Type:  Integer        S16
 * Input1 Data Type:  Integer        S16
 * Input2 Data Type:  Integer        S16
 * Output0 Data Type:  Integer        S16
 * Lookup Method: Linear_Endpoint
 * */
LookUp_S16_S16( &(rtY.Out1), &rtb_dataY[0], rtU.In2, &rtb_dataX[0], 99U);
}

Without the optimization, the generated code contains for loop controlled element assignments.

**Enable Optimization and Generate Code**

1. In the Configuration Parameter dialog box, select the Use memcpy for vector assignment parameter.

2. Generate code.

### Starting build procedure for model: rtwdemo_pointer_conversion
### Successful completion of build procedure for model: rtwdemo_pointer_conversion

View the generated code without the optimization. Here is a portion of rtwdemo_pointer_conversion.c.
/* Model step function */
void rtwdemo_pointer_conversion_step(void)
{
    const int16_T *rtb_dataX_0;
    const int16_T *rtb_dataY_0;

    /* Switch: '<Root>/Switch' incorporates:
     * Inport: '<Root>/In1'
     */
    if (rtU.In1) {
        /* Switch: '<Root>/Switch' incorporates:
         * Constant: '<Root>/Constant'
         * Constant: '<Root>/Constant1'
         */
        rtb_dataX_0 = &rtCP_Constant_Value[0];
        rtb_dataY_0 = &rtCP_Constant1_Value[0];
    } else {
        /* Switch: '<Root>/Switch' incorporates:
         * Constant: '<Root>/Constant2'
         * Constant: '<Root>/Constant3'

     */
    LookUp_S16_S16( &(rtY.Out1), &rtb_dataY_0[0], rtU.In2, &rtb_dataX_0[0], 99U);
}
Because the setting of the **Memcpy threshold (bytes)** parameter is below the array sizes in the generated code, the optimized code contains pointer assignments for the vector signal assignments.

Reuse Buffers of Different Sizes and Dimensions

You can reuse buffers for matrices that have different sizes and shapes. In the Configuration Parameters dialog box, you enable this optimization by selecting **Reuse buffers of different sizes and dimensions**. This optimization conserves RAM and ROM usage and improves code execution speed.

**Example Model**

The model `rtwdemo_differentsizereuse` contains signals of different sizes and dimensions.

```matlab
model = 'rtwdemo_differentsizereuse';
open_system(model);
```

### Generate Code Without Optimization

In the Configuration Parameters dialog box, set **Reuse buffers of different sizes and dimension** parameter to off or in the MATLAB Command Window, enter:

```matlab
set_param('rtwdemo_differentsizereuse','DifferentSizesBufferReuse','off');
```

Create a folder for the build and inspection process.

```matlab
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Turn off comments and build the model.

```matlab
set_param('rtwdemo_differentsizereuse','GenerateComments','off');
rtwbuild('rtwdemo_differentsizereuse');
```

### Starting build procedure for model: rtwdemo_differentsizereuse

{
    int32_T x;
    int32_T y;
    int32_T tmp;
    for (x = 0; x < 63; x++) {
        for (y = 0; y < 64; y++) {
            tmp = (y << 6) + x;
            rty_z[x + 63 * y] = fabs(rtu_u[tmp] - rtu_u[tmp + 1]);
        }
    }
}

static void NoninplaceableSS2(void)
{
    DeltaX(rtDWork.z, &rtDWork.z_e[0]);
    DeltaX(&rtDWork.z_i[0], &rtDWork.z[0]);
}

static void DeltaY(const real_T rtu_u[4032], real_T rty_z[3969])
{
    int32_T x;
    int32_T y;
    for (x = 0; x < 63; x++) {
        for (y = 0; y < 63; y++) {
            rty_z[x + 63 * y] = fabs(rtu_u[63 * y + x] - rtu_u[(y + 1) * 63 + x]);
        }
    }
}

static void NoninplaceableSS3(void)
void rtwdemo_differentsizereuse_step(void)
{
    int32_T i;
    for (i = 0; i < 16384; i++) {
        rtDWork.z_i[i] = rtU.ComplexData[i].re;
        rtDWork.z_e[i] = rtU.ComplexData[i].im;
    }

    NoninplaceableSS1();
    NoninplaceableSS2();
    NoninplaceableSS3();
    for (i = 0; i < 3969; i++) {
        rtY.Out1[i].re = rtDWork.z_i[i];
        rtY.Out1[i].im = rtDWork.z_e[i];
    }
}

The D_work structure now contains three global variables instead of eight global variables for holding the inputs and outputs of Downsample, DeltaX, and DeltaY. The generated code uses these variables to hold the differently-sized inputs and outputs.

Close the model and code generation report.

bdclose(model)
rtwdemoclean;
cd(currentDir)

Limitations

• If you use a Reusable custom storage class to specify reuse on signals that have different sizes and shapes, you must select the Reuse buffers of different sizes and dimensions parameter. Otherwise, the model does not build.

• The code generator does not replace a buffer with a lower priority buffer that has a smaller size.
• The code generator does not reuse buffers that have different sizes and symbolic dimensions.

**See Also**
“Reuse buffers of different sizes and dimensions” (Simulink Coder)

**Related Examples**
• “Specify Buffer Reuse by Using Simulink.Signal Objects” on page 68-19
Remove Reset and Disable Functions from the Generated Code

This example shows how the code generator removes unreachable (dead code) instances of the reset and disable functions from the generated code for ERT-based systems that include model referencing hierarchies. Optimizing the generated code to remove unreachable code is a requirement for safety-critical systems. This optimization also improves execution speed and reduces ROM consumption.

If a model contains blocks with states, the generated code contains reset and disable functions. If the model is not part of a conditionally executed system, such as an enabled subsystem, the code generator can remove the disable function because the generated code does not call it. If the model is not part of a conditionally executed system that can reset states when a control input enables it, the code generator can remove the reset function because the generated code does not call it.

**Example Model**

A referenced model, `rtwdemo_optionalDisableResetFunc_bot`, is in `rtwdemo_optionalDisableResetFunc_top`. The referenced model contains two blocks with states, a Delay block and a Discrete-Time Integrator block.
Generate Code

1. Open the models. In the Command Window, type `rtwdemo_optionalDisableResetFunc_bot` and `rtwdemo_optionalDisableResetFunc_top`.

2. In your system temporary folder, create a temporary folder for the build and inspection process.

3. Build the model.

4. Open the `rtwdemo_optionalDisableResetFunc_top.c` and `rtwdemo_optionalDisableResetFunc_bot.c` files.
The `rtwdemo_optionalDisableResetFunc_bot.c` file contains these reset and disable functions.

```c
/* System reset for referenced model: 'rtwdemo_optionalDisableResetFunc_bot' */
void rtwdemo_optionalDisableResetFunc_bot_Reset(DW_rtwdemo_optionalDisableResetFunc_bot_f_T *localDW)
{
    /* InitializeConditions for Delay: '<Root>/Delay' */
    localDW->Delay_DSTATE = 0.0;

    /* InitializeConditions for DiscreteIntegrator: '<Root>/Discrete-Time Integrator' */
    localDW->DiscreteTimeIntegrator_DSTATE = 3.0;
}

/* Disable for referenced model: 'rtwdemo_optionalDisableResetFunc_bot' */
void rtwdemo_optionalDisableResetFunc_bot_Disable(real_T *rty_Out1,
    DW_rtwdemo_optionalDisableResetFunc_bot_f_T *localDW)
{
    /* Disable for DiscreteIntegrator: '<Root>/Discrete-Time Integrator' */
    localDW->DiscreteTimeIntegrator_DSTATE = *rty_Out1;
}
```

The `rtwdemo_optionalDisableResetFunc_top_step` function does not call the `rtwdemo_optionalDisableResetFunc_bot_Disable` function because the model is not part of a conditionally executed system. The `rtwdemo_optionalDisableResetFunc_top_step` function does not call the `rtwdemo_optionalDisableResetFunc_bot_Reset` function because the model is not part of a conditionally executed system that can reset states when a control input enables it.

### Enable Optimization

1. Open the Model Configuration Parameters dialog box for `rtwdemo_optionalDisableResetFunc_bot`.
2. Select **Remove Disable Function** and **Remove Reset Function**.

Open the `rtwdemo_optionalDisableResetFunc_bot.c` file. The code does not contain the `rtwdemo_optionalDisableResetFunc_bot_Reset` function or the `rtwdemo_optionalDisableResetFunc_bot_Disable` function.

**Code Execution Profiling with SIL and PIL**

You can configure a software-in-the-loop (SIL) or processor-in-the-loop (PIL) on page 77-2 simulation to produce execution-time metrics for tasks and functions in your generated code. The software calculates execution times from data that is obtained through code instrumentation added to the SIL or PIL application or the generated code under test. You can use the execution-time metrics to determine whether the generated code meets the requirements for real-time deployment on your target hardware.

For example, you can perform the following analysis:

1. Identify tasks that require the most time. Tasks are main entry points into the generated code. For example, the step function for a sample rate or the `model_initialize` function.
2. In these tasks, investigate code sections that require the most time.
3. Identify variations in execution time over time steps.

If you are trying to reduce execution times, the analysis results help you to focus on the most critical code sections. To observe performance changes for an updated model, rerun the SIL or PIL simulation and compare the new metrics against previous metrics.

**Note** Execution-time measurements depend greatly on the hardware that you use. For reliable results, collect execution-time metrics using hardware on which you plan to deploy the generated code, that is, run PIL simulations that execute code on your target hardware. SIL simulations, which execute code on your host computer, might not produce representative metrics.

When the SIL or PIL simulation is complete, you can:

- View execution-time metrics through a display window or report.
- Use the Simulation Data Inspector to view and compare the variation of execution times over a simulation.
- Analyze the measurements within the MATLAB environment.

**Configure Code Execution Profiling**

To configure code execution profiling for a SIL or PIL simulation:
1. In your top model, open the Configuration Parameters dialog box, and select the **Code Generation > Verification** pane.

2. Select the **Measure task execution time** check box.

3. For function execution times, from the **Measure function execution times** drop-down list, select one of these options:
   - **Coarse** (referenced models and subsystems only) -- if you want to analyse generated function code for the main model components.
   - **Detailed** (all function call sites) -- if you want to analyse generated function code for all blocks in the model.

4. In the **Workspace variable** field, specify a name. When you run the simulation, the software generates a variable with this name in the MATLAB base workspace. The variable contains the execution-time measurements, and is an object of type `coder.profile.ExecutionTime`.

   If you select the **Data Import/Export > Single simulation output** check box, the software creates the variable in the `Simulink.SimulationOutput` object that you specify.

5. From the **Save options** drop-down list, select one of the following:
   - **Summary data only** — If you want to generate only a report and reduce memory usage, for example, during a long simulation.
   - **All data** — Allows you to generate a report and store execution-time profiles in the base workspace. After the simulation, you can use methods from the `coder.profile.ExecutionTime` and `coder.profile.ExecutionTimeSection` classes to retrieve execution-time measurements for every call to each profiled section of code that occurs during the simulation.

6. Click **OK**.

For a PIL simulation, you must configure a hardware-specific timer. When you set up the connectivity configuration for your target, create a timer object. This action is not required for a SIL simulation.

If you select All data from the **Save options** drop-down list, the metrics display window and generated report display Simulation Data Inspector icons. When you click one of the icons, the software imports simulation results into the Simulation Data Inspector. You can then plot execution times and manage and compare plots from various simulations.
Control Profiling Granularity

You can control the granularity of execution-time profiling, that is, prevent the addition of code instrumentation to specific function-call sites. Through the control of profiling granularity, you can:

• Focus on the performance of model components that require improvement. For example, after an initial run, disable profiling for blocks that require little processing time. This action reduces the number of items displayed by the profiling report.

• Reduce the code instrumentation overhead. For example, for simple functions, the code instrumentation overhead can be greater than the execution time of the function code.

To generate execution-time metrics for tasks only, on the Code Generation > Verification pane of the Configuration Parameters dialog box, select the Measure task execution time check box and set Measure function execution times to Off.

To generate function execution data for referenced models and atomic subsystems in the top model, on the Code Generation > Verification pane, select the Measure task execution time check box and set Measure function execution times to Coarse (referenced models and subsystems only).

The generation of function execution data requires the insertion of measurement probes into the generated code. The software inserts measurement probes for an atomic subsystem only if you set the Function packaging field (on the Code Generation tab of the Function Block Parameters dialog box) to either Nonreusable function or Reusable function. If the field is set to Auto, then the insertion of probes depends on the packaging choice that results from the Auto setting. If the field is set to Inline, the software does not insert probes.

Note In the generated code, the software wraps each function call with measurement probes except when:

• The call site cannot be wrapped because of expression folding (see “Minimize Computations and Storage for Intermediate Results at Block Outputs” (Simulink Coder)).

• The call site is located in the shared utility code (see “Sharing Utility Code” (Simulink Coder)).
To generate function execution times for model reference hierarchies:

1. In the top model, open the Configuration Parameters dialog box, and select the **Code Generation > Verification** pane.
2. Select the **Measure task execution time** check box.
3. For each Model block that you want to profile, specify **Measure function execution times** only at the reference level for which you require function execution times.

For example, consider a top model that has Model block A, which in turn contains Model block B.

![Diagram of model hierarchy](image)

If you want to generate execution times for functions from model B, select **Measure task execution time** for the top model and specify **Measure function execution times** for model B.

These parameters of the top model override the corresponding parameters of referenced models:

- **Measure task execution time**. If you disable this parameter for the top model, you also disable function profiling for referenced models.
- **Workspace variable**
- **Save options**

To control code execution profiling for a block in a model, for example, a subsystem block, use the **CodeProfilingOverride** block parameter:

1. In the Simulink Editor, select the block.
2. In the Command Window, run:
   ```matlab
   set_param(gcf, 'CodeProfilingOverride', 'blockParameterValue')
   ```
Use one of these values for `blockParameterValue`:

- `'off'` -- Disables profiling for the block.
- `'on'` -- Enables profiling for the block if profiling is enabled for the parent model.
- `'inherit'` (default) -- Applies profiling settings of parent block.

Changing the block profiling configuration does not cause the regeneration of production code.

If your top model has a PIL block, the execution profiling settings that apply to the PIL block are the settings from the original model that you used to create the PIL block. See “Simulation with Blocks From Subsystems” on page 77-21. You cannot use `CodeProfilingOverride` to control profiling for a PIL block.

- “View and Analyze Simulation Results” (Simulink)
View and Compare Code Execution Times

During a software-in-the-loop (SIL) or processor-in-the-loop (PIL) simulation, you can use the Simulation Data Inspector to observe streamed execution times. At the end of the simulation, you can:

- View execution-time metrics for a profiled model component.
- Open a report of execution-time metrics for all profiled components.
- Use the Simulation Data Inspector to plot and compare execution times from various simulations.

Consider the `rtwdemo_sil_topmodel` model, which has two subsystems `CounterTypeA` and `CounterTypeB`. To measure code execution times for the subsystems, on the Configuration Parameters > Code Generation > Verification pane:

1. Select **Measure task execution time**, which provides execution-time metrics for the task generated from the top model `rtwdemo_sil_topmodel`.
2. Set **Measure function execution times** to Coarse (referenced models and subsystems only), which provides execution-time metrics for the functions generated from the subsystems `CounterTypeA` and `CounterTypeB`.
3. Specify a **Workspace variable**, for example, `executionProfile`.
4. From the **Save options** drop-down list, select **All data**.

Running a simulation generates the variable `executionProfile` in the MATLAB base workspace.

**Note** If you select the **Data Import/Export > Single simulation output** check box, the simulation creates the variable in your specified `Simulink.SimulationOutput` object.

To view streamed execution times during the simulation, open the Simulation Data Inspector. On the Simulink Editor toolbar, click the Simulation Data Inspector button.

When the simulation is complete, the profiled model components are colored blue. To view execution-time metrics for a profiled component, click the component. For example, subsystem `CounterTypeB`. 

71-7
The display window also has links to:

- The complete profiling report, which provides execution-time metrics for all profiled code sections.
- The profiled code section in the code generation report.
- The Simulation Data Inspector, which allows you to plot and compare execution-time measurements for the profiled code section.

For top-model SIL or PIL simulations, the Simulink Editor background is also colored blue. When you click the background, the display window shows execution-time metrics for top-model tasks.

If you close the model or display window, you can reopen the colored model and display window with this line command:
Code Execution Profiling Report

At the end of the simulation, you can open this report through the metrics display window or with this line command:

```matlab
>> report(executionProfile)
```

Code Execution Profiling Report for rtwdemo_sil_topmodel

The code execution profiling report provides metrics based on data collected from a SIL or PIL execution. Execution times are calculated from data recorded by instrumentation probes added to the SIL or PIL test harness or inside the code generated for each component. See Code Execution Profiling for more information.

1. Summary

</tr>
</tbody>
</table>

The report contains time measurements for:

- The model initialization function `rtwdemo_sil_topmodel_initialize`.
- A task represented by the step function `rtwdemo_sil_topmodel_step [0.1 0]`.
- Functions generated from the subsystems `CounterTypeA` and `CounterTypeB`.

You can go to a profiled code section in the Generated Code view of the Code Generation Report. In the Code Execution Profiling Report, on a code section row, click the icon 

For example, if you click the icon for the `rtwdemo_sil_topmodel_initialize` task, you see the measurement probes around the call site in the SIL application.
If you click the icon for a function, the call site is highlighted.
From the Code Execution Profiling Report, you can trace the model component that produces a set of metrics. For example, in the **Section** column, if you click the **CounterTypeA** hyperlink, the Simulink Editor identifies the subsystem.
By default, the report displays time in nanoseconds ($10^{-9}$ seconds). You can specify the time unit and numeric display format. For example, to display time in microseconds ($10^{-6}$ seconds), use the following command:

```matlab
>>report(executionProfile,'Units', 'Seconds', 'ScaleFactor', '1e-06', 'NumericFormat', '%0.3f')
```

The report displays time in seconds only if the timer is calibrated, that is, the number of timer ticks per second is known. On a Windows machine, the software determines this value for a SIL simulation. On a Linux machine, calibrate the timer manually. For example, if your processor speed is 1 GHz, specify the number of timer ticks per second:

```matlab
>>executionProfile.TimerTicksPerSecond = 1e9;
```

To display measured execution times for a task or function, click the Simulation Data Inspector icon on the corresponding row. Use the Simulation Data Inspector to manage and compare plots from various simulations.

**Note** To observe how code sections are invoked over the execution timeline, use the `timeline` function.

The following table describes the information provided in the code section profiles.

<table>
<thead>

More About

- “Tips and Limitations” on page 71-19
Analyze Code Execution Data

After a SIL or PIL simulation, you can analyze execution-time data using methods from the `coder.profile.ExecutionTime` and `coder.profile.ExecutionTimeSection` classes.

1. Open `rtwdemo_sil_topmodel`.
2. On the **Configuration Parameters > Code Generation > Verification** pane, specify profiling options:
   - Select the **Measure task execution time** check box.
   - Specify a **Workspace variable**, for example, `myExecutionProfile`.
   - From the **Save options** drop-down list, select **All data**.
3. Run a SIL simulation.

The software generates the workspace variable `myExecutionProfile`, an `coder.profile.ExecutionTime` object.

To get the total number of code sections that have profiling data, use the `Sections` method.

```matlab
>> no_of_Sections = myExecutionProfile.Sections
```

```
no_of_Sections =
1×2 ExecutionTimeTaskSection array with properties:
Name    Number    ExecutionTimeInTicks    SelfTimeInTicks    TurnaroundTimeInTicks    TotalExecutionTimeInTicks    TotalSelfTimeInTicks    TotalTurnaroundTimeInTicks    MaximumExecutionTimeInTicks    MaximumSelfTimeInTicks    MaximumTurnaroundTimeInTicks    MaximumExecutionTimeCallNum    MaximumSelfTimeCallNum    MaximumTurnaroundTimeCallNum    NumCalls    ExecutionTimeInSeconds    Time
```

To get the `coder.profile.ExecutionTimeSection` object for a profiled code section, use the method `Sections`.

71-16
FirstSectionProfile = myExecutionProfile.Sections(1)
SecondSectionProfile = myExecutionProfile.Sections(2)

FirstSectionProfile =

ExecutionTimeTaskSection with properties:

    Name: 'rtwdemo_sil_topmodel_initialize'
    Number: 1
    ExecutionTimeInTicks: 1188
    SelfTimeInTicks: 1188
    TurnaroundTimeInTicks: 1188
    TotalExecutionTimeInTicks: 1188
    TotalSelfTimeInTicks: 1188
    TotalTurnaroundTimeInTicks: 1188
    MaximumExecutionTimeInTicks: 1188
    MaximumExecutionTimeCallNum: 1
    MaximumSelfTimeInTicks: 1188
    MaximumSelfTimeCallNum: 1
    MaximumTurnaroundTimeInTicks: 1188
    MaximumTurnaroundTimeCallNum: 1
    NumCalls: 1
    ExecutionTimeInSeconds: 5.4000e-07
    Time: 0

SecondSectionProfile =

ExecutionTimeTaskSection with properties:

    Name: 'rtwdemo_sil_topmodel_step [0.1 0]'
    Number: 2
    ExecutionTimeInTicks: [1×101 uint64]
    SelfTimeInTicks: [1×101 uint64]
    TurnaroundTimeInTicks: [1×101 uint64]
    TotalExecutionTimeInTicks: 70316
    TotalSelfTimeInTicks: 70316
    TotalTurnaroundTimeInTicks: 70316
    MaximumExecutionTimeInTicks: 2448
    MaximumExecutionTimeCallNum: 2
    MaximumSelfTimeInTicks: 2448
    MaximumSelfTimeCallNum: 2
    MaximumTurnaroundTimeInTicks: 2448
    MaximumTurnaroundTimeCallNum: 2
    NumCalls: 101
    ExecutionTimeInSeconds: [1×101 double]
    Time: [101×1 double]

Use coder.profile.ExecutionTimeSection methods to extract profiling information for a particular code section. For example, use Name to obtain the name of a profiled task.

>> name_of_section = SecondSectionProfile.Name
name_of_section =
If the timer is uncalibrated and you know the timer rate, for example 2.2 GHz, you can use the `coder.profile.ExecutionTime` method `TimerTicksPerSecond` to calibrate the timer:

```matlab
>> myExecutionProfile.TimerTicksPerSecond = 2.2e9;
>> SecondSectionProfile = myExecutionProfile.Sections(2);
```

Tips and Limitations

Triggered Model Block

Consider the case where a triggered Model block is configured to run in the SIL or PIL simulation mode. The software generates one execution-time measurement each time the referenced model is triggered to run. If there are multiple triggers in a single time step, the software generates multiple measurements for the triggered Model block. Conversely, if there is no trigger in a given time step, the software generates no time measurements.

Outliers in Execution-Time Profiles

When you run a SIL simulation with execution time profiling enabled, you might see spikes in execution-time measurements.

The spikes are due to process preemption that occurs with a multitasking host operating system. If the operating system preempts the SIL process and runs another process, the
measured execution time includes the time during which the SIL process is suspended. With a PIL simulation, you do not see spikes because code execution on the target is not preempted.

Counter wrapping produces execution-time measurements that are smaller than expected. For SIL, the counter wraps when an execution-time period is greater than $2^{64}$ ticks ($2^{32}$ ticks if the MEX compiler is LCC). For PIL, the wrapping point depends on the timer you specify and can be $2^8$, $2^{16}$, $2^{32}$, or $2^{64}$ ticks.

Consider a PIL example where the timer frequency is 20 MHz. For a 32-bit timer, wrapping occurs when the execution-time period is greater than $1/(20e6)*(2^{32}-1)$, that is, 214.7 s. However, for a 16-bit timer, the point at which wrapping occurs is 0.0033 s.

For a real-time, multi-core application, the software accommodates synchronization discrepancies when recording timer values for different cores, which effectively reduces the timer measurement range.

**Hardware-Specific Timer**

If your target configuration does not already specify a timer, create a timer object that provides details of the hardware-specific timer and associated source files:

- For SIL simulation, the timer word length is 64 bits.
- For PIL simulation, you can specify an 8-, 16-, 32-, or 64-bit timer.

**Task Context Switching Due to Preemption**

Profiling instrumentation is intrusive and affects the quantity that it is meant to measure. Therefore, the design goal is to maximize code understanding with a minimum of instrumentation. For example, with a real-time system, there can be task context switches due to preemption. These context switches are not explicitly instrumented. To record the start and end of each task, the software must infer context switches from instrumentation. As a result, the software reports behavior that is an estimate. The estimate is subject to error because of incomplete instrumentation within the kernel.

In some cases, when the software cannot accurately determine behavior, the software generates a warning:

Warning: Analysis unsuccessful for one or more profiling data points. ...
For example, the software might generate this warning when not all mutex take system calls (associated with rate transitions) are instrumented. In the case of Simulink Real-Time, this situation might arise if you generate code for a model reference hierarchy without enabling function profiling for all referenced models (\texttt{set_param(model, 'CodeProfilingInstrumentation', 'on')}). If a mutex take system call is not instrumented, a task context switch might occur that is not visible to the execution profiling analysis.

In other cases, although the software cannot accurately determine behavior, the software does not generate a warning.

**Subsystem Code Reuse**

You cannot generate execution-time profiles for function call sites within subsystem code that is reused across a model or multiple models. For information about subsystem code reuse, see “Generate Reusable Code from Library Subsystems Shared Across Models” (Simulink Coder).

**Cannot Load Execution-Time Measurements from Previous Release**

You cannot load execution-time measurements saved with a previous release. For example, using R2014a, you save workspace variables to a MAT-file. One of the workspace variables contains execution-time measurements. In R2015b, if you try to load the MAT-file, you see this error:

\texttt{Format of execution profiling data is invalid. This error can occur if you load data from a previous release. Loading data from a previous release is not supported.}
Code Execution Profiling for MATLAB Coder

- “Analyze Execution Time Data” on page 72-7
Execution Time Profiling for SIL and PIL

During a software-in-the-loop (SIL) or processor-in-the-loop (PIL) execution, you can produce a profile of execution times for code generated from entry-point functions. The software calculates execution times from data that is obtained through instrumentation probes added to the SIL or PIL application.

Use the execution time profile to check whether your code runs within the required time on your target hardware:

- If code execution overruns, look for ways to reduce execution time.
- If your code easily meets time requirements, consider enhancing functionality to exploit the unused processing power.

At the end of the SIL or PIL execution, you can:

- View a report of code execution times.
- Use the Simulation Data Inspector to view and compare plots of function execution times.
- Access and analyze execution time profiling data.

**Note** SIL and PIL execution supports multiple entry-point functions. An entry-point function can call another entry-point function as a subfunction. However, the software generates execution time profiles only for functions that are called at the entry-point level. The software does not generate execution time profiles for entry-point functions that are called as subfunctions by other entry-point functions.

Generate Execution Time Profile

Before running a software-in-the-loop (SIL) or processor-in-the-loop (PIL) execution, enable execution time profiling:

1. To open the MATLAB Coder app, on the MATLAB Toolstrip Apps tab, under Code Generation, click the app icon.
2. To open your project, click and then click Open existing project. Select the project.
4. Select the Enable entry point execution profiling for SIL/PIL check box.

Or, from the Command Window, specify the CodeExecutionProfiling property of your coder.EmbeddedCodeConfig object. For example:

```matlab
config.CodeExecutionProfiling = true;
```

More About

- “Execution Time Profiling for SIL and PIL” on page 72-2
View Execution Times

When you run a SIL or PIL execution with execution time profiling enabled, the software generates a message in the Test Output tab. For example:

Current plot held
### Starting SIL execution for 'kalman01'
  To terminate execution: clear kalman01_sil
  Execution profiling data is available for viewing. Open Simulation Data Inspector.
  Execution profiling report available after termination.
Current plot released

To observe streamed execution times while the execution runs, click the Simulation Data Inspector link.

To open the code execution profiling report:

1  Click the Stop SIL Verification link.

   The software terminates the execution process and displays a new link.

   ### Stopping SIL execution for 'kalman01'
   Execution profiling report: report(getCoderExecutionProfile('kalman01'))

2  Click the new link.

**Code Execution Profiling Report for kalman01**

The code execution profiling report provides metrics based on data collected from a SIL or PIL execution. Execution times are calculated from data recorded by instrumentation probes added to the SIL or PIL test harness or inside the code generated for each component. See [Code Execution Profiling](#) for more information.

<td>1</td>
</tr>
</tbody>
</table>

3. Definitions

   - **Execution Time**: Time between start and end of code section.
   - **Self Time**: Execution time, excluding time in child sections.

The report provides:
A summary.

Information about profiled code sections, which includes time measurements for:

- The `entry_point_fn_initialize` function, for example, `kalman01_initialize`.
- The entry-point function, for example, `kalman01`.
- The `entry_point_fn_terminate` function, for example, `kalman01_terminate`.

Definitions for metrics.

By default, the report displays time in nanoseconds ($10^{-9}$ seconds). You can specify the time unit and numeric display format. For example, to display time in microseconds ($10^{-6}$ seconds), use the `report` command:

```matlab
evaluationProfile = getCoderExecutionProfile('kalman01'); % Create workspace
var report(evaluationProfile, ... 
    'Units', 'Seconds', ... 
    'ScaleFactor', '1e-06', ... 
    'NumericFormat', '%0.3f')
```

The report displays time in seconds only if the timer is calibrated, that is, the number of timer ticks per second is established. On a Windows machine, the software determines this value for a SIL simulation. On a Linux machine, you must manually calibrate the timer. For example, if your processor speed is 1 GHz, specify the number of timer ticks per second:

```matlab
evaluationProfile.TimerTicksPerSecond = 1e9;
```

To display measured execution times for a code section, click the Simulation Data Inspector icon on the corresponding row. You can use the Simulation Data Inspector to manage and compare plots from various executions.

The following table lists the information provided in the code section profiles.

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>

Analyze Execution Time Data

After a software-in-the-loop (SIL) or processor-in-the-loop (PIL) execution, you can analyze execution-time data using methods from the `coder.profile.ExecutionTime` and `coder.profile.ExecutionTimeSection` classes.

In the following example, you run a SIL execution and apply supplied methods to execution-time data.

**Extract Execution Time Data for Kalman Estimator Code**

1. **Run SIL execution to generate execution time data**

Copy MATLAB code to your working folder.

```matlab
src_dir = ...
fullfile(docroot,'toolbox','coder','examples','kalman');
copyfile(fullfile(src_dir,'kalman01.m'), '.')
copyfile(fullfile(src_dir,'test01_ui.m'), '.')
copyfile(fullfile(src_dir,'plot_trajectory.m'), '.')
copyfile(fullfile(src_dir,'position.mat'), '.')
```

For a description of the Kalman estimator, see “C Code Generation at the Command Line” (MATLAB Coder).

Create a `coder.EmbeddedCodeConfig` object.

```matlab
config = coder.config('lib');
config.GenerateReport = true; % HTML report
```

Configure the object for SIL and enable execution time profiling.

```matlab
config.VerificationMode = 'SIL';
config.CodeExecutionProfiling = true;
```

Generate library code for the `kalman01` MATLAB function and the SIL interface.

```matlab
codegen('-config', config, '-args', {zeros(2,1)}, 'kalman01');
```

Run the MATLAB test file `test01_ui` with `kalman01_sil`. `kalman01_sil` is the SIL interface for `kalman01`.

```matlab
coder.runTest('test01_ui', ['kalman01_sil.' mexext]);
```
You see the following message.

```matlab
### Starting SIL execution for 'kalman01'
To terminate execution: clear kalman01_sil
Execution profiling data is available for viewing. Go to Simulation Data Inspector.
Execution profiling report available after termination.
Current plot released

Terminate the SIL execution process. Click the link clear kalman01_sil.

### Stopping SIL execution for 'kalman01'
Execution profiling report: report(getCoderExecutionProfile('kalman01'))
```

2. **Create workspace variable that holds execution time data**

Use the `getCoderExecutionProfile` function to create a workspace variable that holds execution time profiling data.

```matlab
executionProfile=getCoderExecutionProfile('kalman01');
```

3. **Extract code sections**

Use the `Sections` method.

```matlab
allSections = executionProfile.Sections
```

The software displays the number of code sections and a list of properties.

```matlab
allSections =
1x3 ExecutionTimeTaskSection array with properties:
    Name
    Number
    ExecutionTimeInTicks
    SelfTimeInTicks
    TurnaroundTimeInTicks
    TotalExecutionTimeInTicks
    TotalSelfTimeInTicks
    TotalTurnaroundTimeInTicks
    MaximumExecutionTimeInTicks
    MaximumExecutionTimeCallNum
    MaximumSelfTimeInTicks
    MaximumSelfTimeCallNum
    MaximumTurnaroundTimeInTicks
    MaximumTurnaroundTimeCallNum
    NumCalls
    ExecutionTimeInSeconds
    Time
```

4. **Extract execution time data from specific code section**

Specify the code section that you want to examine.
secondSectionProfile = executionProfile.Sections(2)

The software displays profile data for the code section.

secondSectionProfile =

   ExecutionTimeTaskSection with properties:
       Name: 'kalman01'
       Number: 2
       ExecutionTimeInTicks: [1x300 uint64]
       SelfTimeInTicks: [1x300 uint64]
       TurnaroundTimeInTicks: [1x300 uint64]
       TotalExecutionTimeInTicks: 6641016
       TotalSelfTimeInTicks: 6641016
       TotalTurnaroundTimeInTicks: 6641016
       MaximumExecutionTimeInTicks: 48864
       MaximumSelfTimeInTicks: 48864
       MaximumTurnaroundTimeInTicks: 48864
       MaximumExecutionTimeCallNum: 158
       MaximumSelfTimeCallNum: 158
       MaximumTurnaroundTimeCallNum: 158
       NumCalls: 300
       ExecutionTimeInSeconds: [1x300 double]
       Time: [300x1 double]

You can extract specific properties, for example, the name of a profiled function.

nameOfSection = secondSectionProfile.Name

The software displays the name.

nameOfSection =

kalman01

The following table lists the information that you can extract from each code section.

<table>
<thead>
<tr>
<th>Property</th>

<tr>
<td>NumCalls</td>
<td>Total number of calls to the code section over the entire execution.</td>
</tr>
</tbody>
</table>
### Property | Description
--- | ---
ExecutionTimeInSeconds | Vector of execution times, measured in seconds. Each element contains the difference between the timer reading at the start and at the end of the code section. Produced only if TimerTicksPerSecond is set.
Time | Vector of execution time measurements for the code section.

Simulation and Code Comparison in Simulink Coder
Simulation and Code Comparison

In this section...

“Configure Signal Data for Logging” on page 73-2
“Log Simulation Data” on page 73-3
“Run Executable and Load Data” on page 73-5
“Visualize and Compare Results” on page 73-6
“Compare States for Simulation and Code Generation” on page 73-8

This example shows how to verify the answers computed by code generated from the slexAircraftExample model. It shows how to capture and compare two sets of output data. Simulating the model produces one set of output data. Executing the generated code produces a second set of output data.

Note To obtain a valid comparison between model output and the generated code, use the same Solver selection and Step size for the simulation run and the build process.

Configure Signal Data for Logging

Configure the model for logging and recording signal data.

1 Make sure that slexAircraftExample is closed. Clear the base workspace to eliminate the results of previous simulation runs. In the Command Window, type:

    clear

    The clear operation clears variables created during previous simulations and all workspace variables, some of which are standard variables that the slexAircraftExample model requires.

2 In the Command Window, enter slexAircraftExample to open the model.

3 In the model window, choose File > Save As, navigate to the working folder, and save a copy of the slexAircraftExample model as myAircraftExample.

4 Set up your model to log signal data for signals: Stick, alpha, rad, and q, rad/sec. For each signal:

   a Right-click the signal. From the context menu, select Properties.
b In the Signal Properties dialog box, select **Log signal data**.

c In the **Logging name** section, from the drop-down list, select **Custom**.

d In the text field, enter the logging name for the corresponding signal.

<table>
<thead>
<tr>
<th>Signal Name</th>
<th>Logging Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stick</td>
<td>Stick_input</td>
</tr>
<tr>
<td>alpha, rad</td>
<td>Alpha</td>
</tr>
<tr>
<td>q, rad/sec</td>
<td>Pitch_rate</td>
</tr>
</tbody>
</table>

e Click **Apply** and **OK**.

For more information, see “Export Signal Data Using Signal Logging” (Simulink).

5 Select **Simulation > Model Configuration Parameters** to open the Configuration Parameters dialog box.

6 Select the **Solver** pane and in the **Solver selection** section, specify the **Type** parameter as **Fixed-step**.

7 On the **Data Import/Export** pane:

   • Specify the **Format** parameter as **Structure with time**.
   • Clear the **States** parameter check box.
   • Select the **Signal logging** parameter.
   • Select the **Record logged workspace data in Simulation Data Inspector** parameter to enable logged signal data to send to the Simulation Data Inspector after the simulation is finished.

8 Save the model.

Proceed to “Log Simulation Data” on page 73-3.

**Log Simulation Data**

Run the simulation, log the signal data, and view the data in the Simulation Data Inspector.

1 Run the model. When the simulation is done, on the Simulink Editor toolbar, the **Simulation Data Inspector** button is highlighted to indicate that new simulation output is available in the Simulation Data Inspector.
2 Click the **Simulation Data Inspector** button to open the Simulation Data Inspector.

3 Group the signals:
   a On the **Visualize** tab, click **Group Signals**.
   b In the Group Signals dialog box, select **Data Hierarchy** from the **Then By** list.
   c Click **OK**.

4 Click the **logout** expander to view the logged signals.

5 Click the **Format** tab.

6 Click the **Subplots** button and select **3x1** to show three subplots.

7 For each signal:
   a Click the top subplot. A blue border indicates the plot selection.
   b Select the check box next to the **Alpha** signal name. The signal data appears in the subplot.
   c Plot the **Pitch_rate** signal in the middle subplot.
   d Plot the **Stick_input** signal in the bottom subplot.
Proceed to “Run Executable and Load Data” on page 73-5.

Run Executable and Load Data

You must rebuild and run the myAircraftExample executable to obtain a valid data file because you have modified the model.

1. Select Simulation > Model Configuration Parameters to open the Configuration Parameters dialog box.
2. Select the Code Generation > Interface pane.
3. Set the MAT-file variable name modifier parameter to `rt_`. `rt_` is prefixed to each variable that you selected for logging in the first part of this example.
4. Click Apply and OK.
5. Save the model.
6. On the Simulink Editor toolbar, click the Build Model button to generate code.
7. When the build is finished, run the standalone program from the Command Window.

`!myAircraftExample`
The executing program writes the following messages to the Command Window.

```
** starting the model **
** created myAircraftExample.mat **
```

8 Load the data file `myAircraftExample.mat`.

```
load myAircraftExample
```

**Tip** For UNIX platforms, run the executable in the Command Window with the syntax `!/executable_name`. If preferred, run the executable from an OS shell with the syntax `./executable_name`. For more information, see “Run External Commands, Scripts, and Programs” (MATLAB).

Proceed to “Visualize and Compare Results” on page 73-6.

**Visualize and Compare Results**

When you follow the example sequence that began in “Configure Signal Data for Logging” on page 73-2, you obtain data from a Simulink run of the model and from a run of the program generated from the model.

1 To view the execution output for `alpha, rad`, import the data into the Simulation Data Inspector.
   a On the Simulation Data Inspector **Visualize** tab, click the **Import** button to open the Import dialog.
   b Specify **Import from** as **Base workspace**.
   c Specify **Import to** as **New run**.
   d To the left of **Signal Name**, click the check mark to clear the check boxes.
   e Select the check box for the `alpha, rad` data where the **Time Series Root** is `rt_yout`.
   f Click **Import**.
The selected data is now under **Run 2: Imported_Data**.

2 View a plot of the executed data.

   a Click the rt_yout expander.
   b Click the top subplot and select the check box next to the alpha, rad signal name. The signal data appears in the top subplot.

   The alpha, rad signal from Run 1 and Run 2 overlap in the subplot because the signals are equivalent.
It is possible to see a very small difference between simulation and code generation results. A slight difference can be caused by many factors, including:

- Different compiler optimizations
- Statement ordering
- Run-time libraries

For example, a function call such as `sin(2.0)` can return a slightly different value depending on which C library you use. Such variations can also cause differences between your results and these results.

**Compare States for Simulation and Code Generation**

The order in which Simulink logs states during simulation is different than the order in which Simulink Coder logs states during code generation. If you want to compare states between simulation and code generation, sort the states by block name.

For example, by default, Simulink exports state data to the MATLAB variable, `xout`. Simulink Coder exports state data to the variable `rt_xout`. To sort the state data for these variables, enter the following commands in the MATLAB Command Window:
```matlab
[~, idx1] = sort({xout.signals.blockName});
xout_sorted = [xout.signals(idx1).values];
[~, idx2] = sort({rt_xout.signals.blockName});
rt_xout_sorted = [rt_xout.signals(idx2).values];
```

You can confirm that the logging order is the same between code generation and simulation by entering the following command in the MATLAB Command Window:

```matlab
isequal(xout_sorted, rt_xout_sorted)
```

</table>

Code tracing (traceability) uses hyperlinks to navigate between a line of generated code and its corresponding elements in a model. To find the lines of code and their corresponding elements, you can also right-click an element or elements in a model. This two-way navigation is bidirectional traceability.

Using code tracing, you can:

- Verify that generated code is as you expect. You can identify which model elements correspond to a line of code. You can track code from different elements that you have or have not reviewed.
- Verify that generated code meets the design requirements. You can link requirements to the model element and use code tracing to verify that the generated code for a model element meets the assigned requirements.

The HTML code generation report includes resources that support code tracing:

- Code element hyperlinks (indicated by underlining when you hover over the code) to trace variables or types in the generated code to their declarations or definitions in the header files.
- Tags in code comments that identify elements in a model from which lines of code are generated.
- Line number hyperlinks that link to the model component from which the line of code was generated.

**Traceable Elements**

Bidirectional traceability is supported for Simulink blocks and these Stateflow elements:
• States
• Transitions
• State transition tables
• MATLAB functions. Traceability is not supported for external code that you call from a MATLAB function.
• Truth table blocks
• Graphical functions
• Simulink functions

Traceability in one direction is supported for these Stateflow elements:

• Events (code-to-model)

  Code-to-model traceability works for explicit events, but not implicit events. Clicking a hyperlink for an explicit event in the generated code highlights that item in the Contents pane of the Model Explorer.

• Junctions (model-to-code)

  Model-to-code traceability works for junctions with at least one outgoing transition. Right-clicking such a junction in the Stateflow Editor highlights the line of code that corresponds to the first outgoing transition for that junction.

For more information, see “Trace Stateflow Elements in Generated Code” on page 74-13.

MATLAB Function blocks that you insert directly into a Simulink model are also traceable. For more information, see “Use Traceability in MATLAB Function Blocks” on page 74-42.

**Traceability in Code Generation Report**

This example shows how to create an HTML code generation report that includes links for tracing between the source code and the Simulink model.

1. Open the model and make sure that it is configured for an ERT target.
2. Select **Create code generation report** if it is not already selected. By default, **Open report automatically**, **Code-to-model**, and **Model-to-code** are selected.
3. If your model contains referenced models and you want to enable traceability for the referenced model's code generation report, repeat step 2 for each referenced model.
4 Press Ctrl+B to generate code for your model. The build process opens the code generation report in a MATLAB web browser.

5 In the left navigation pane, select a source code file. The source code and line numbers in the right pane contain hyperlinks to blocks in the model.

6 Click a comment or line number hyperlink. The Simulink Editor displays and highlights the corresponding block or blocks in the model.

7 To highlight the generated code for a block in your Simulink model, right-click the block and select C/C++ Code > Navigate to C/C++ Code. The generated code for the block is then highlighted in the HTML code generation report. To highlight the generated code for multiple blocks that you select, hold the SHIFT key, select multiple blocks, and then right-click any one block to select C/C++ Code > Navigate to C/C++ Code. The generated code for the blocks is then highlighted in the HTML code generation report.

8 If you have a referenced model in your model, in the left navigation pane, under Reference Models, click the link to a referenced model. The code generation report for the referenced model is now displayed in the MATLAB web browser.

9 In the left navigation pane, you can click the Back button to go back to the previous code generation report.

**Traceability Tags**

A traceability tag appears in a comment above the corresponding line of generated code. The format of the tag is `<system>/block_name`.

- **system** is one of the following:
  - The text Root
  - A unique system number assigned by the Simulink engine

- **block_name** is the name of the source block.

The code generator documents the tags for a model in the comments section of the generated header file `model.h`. For example, this comment appears in the header file for a model, `foo`, that has a subsystem `Outer` and a nested subsystem `Inner`:

```c
/* Here is the system hierarchy for this model. */
*
* <Root> : foo
* <S1>   : foo/Outer
```
This code shows a tag comment above the generated line of code. A Gain block at the root level of a source model generates this code:

```c
/* Gain: '<Root>/UnDeadGain1' */
rtb_UnDeadGain1_h = dead_gain_U.In1 * dead_gain_P.UnDeadGain1_Gain;
```

This code shows a tag comment above the generated line of code. A Gain block within a subsystem one level below the root level of the source model generates this code:

```c
/* Gain: '<S1>/Gain' */
dead_gain_B.temp0 *= (dead_gain_P.s1_Gain_Gain);
```

**Operator Traceability**

The HTML code generation report provides traceability between operators in the generated code and Simulink blocks, Stateflow elements, or MATLAB Function blocks.

To verify the generated code by using operator traceability, in the HTML report window, click an operator hyperlink to highlight the source block in the model.

These operators are supported.

<table>
<thead>

</tr>
<tr>
<td></td>
<td>delete, delete[]</td>
</tr>
</tbody>
</table>

**Traceability Limitations**

These limitations apply to reports generated by Embedded Coder software:

- Under the following conditions, model-to-code traceability is disabled for a block if the block name contains:
  - A single quote (').
  - An asterisk (*) that causes a name-mangling ambiguity relative to other names in the model. This name-mangling ambiguity occurs if in a block name or at the end of a block name, an asterisk precedes or follows a slash (/).
  - The character ų (char(255)).
- If a block name contains a newline character (\n), the generated code comment for the block path hyperlink replaces the newline character with a space for readability.
- You cannot trace blocks representing these types of subsystems to generated code:
  - Virtual subsystems
  - Masked subsystems
  - Nonvirtual subsystems for which code has been removed due to optimization

If you cannot trace a subsystem at subsystem level, you can trace individual blocks within the subsystem.
• If you open a model on a platform that is different from the platform used to generate code, you cannot use model-to-code and code-to-model traceability.

Related Examples
• “Trace Simulink Model Elements in Generated Code” on page 74-8
Trace Simulink Model Elements in Generated Code

To verify the generated code, Embedded Coder provides bidirectional traceability between the Simulink model and the code generation report. You can use either method for traceability:

- **Code-to-model**: The code generation report displays these hyperlinks in comment lines in the generated code:
  - Block/subsystems names
  - Line numbers
  - Operators

  To highlight the corresponding block or subsystem in the Simulink Editor, click the hyperlinks.

- **Model-to-code**: You can select single or multiple blocks of a model in the Simulink Editor and navigate to the corresponding generated code in the code generation report.

**Code-to-Model Traceability**

To use hyperlinks for tracing code-to-model elements:

1. Open the model and make sure that it is configured for an ERT target.
2. On the Code Generation > Report pane, verify that you have selected these parameters:
   - **Create code generation report** (Simulink Coder)
   - **Open report automatically** (Simulink Coder)
   - **Code-to-model** (Simulink Coder)
   - **Model-to-code** (Simulink Coder)
3. Build or generate code for the model. An HTML code generation report is displayed in the MATLAB web browser.
4. In the HTML report window, click hyperlinks to highlight source blocks. For example, generate an HTML report for the model rtwdemo_hyperlinks. In the generated code for the model step function in rtwdemo_hyperlinks.c, click the first UnitDelay: '<Root>/X' block hyperlink.
In the model window, the corresponding UnitDelay block is highlighted.

To use line numbers for tracing code-to-model elements:

1. In the previous model, `rtwdemo_hyperlinks`, click the hyperlink at line number 147. The line numbers can differ from the numbers that appear in your code generation report.

2. In the model window, the Chart subsystem is highlighted and contains the functionality on line 147.
**Model-to-Code Traceability**

To trace model elements to their corresponding generated code:

1. Complete steps 1 and 2 as in “Code-to-Model Traceability” on page 74-8
2. Verify that you have selected the **Model-to-code** parameter. This parameter enables the **Configure** (Simulink Coder) button, which opens a dialog box for loading existing traceability information. For more information, see “Reload Existing Traceability Information” on page 74-34.
3. Build or generate code for the model. An HTML code generation report is displayed in the MATLAB web browser.
4. In the model window, right-click a model element. To select multiple blocks, hold the **SHIFT** key and select additional blocks.
5. From the context menu, select **C/C++ Code > Navigate to C/C++ Code**. In the HTML code generation report, you see the first instance of highlighted code that is generated for the model element. In the left pane of the report, numbers that appear to the right of generated file names indicate the total number of highlighted lines in each file. This figure shows the result of tracing the Unit Delay block in model `rtwdemo_hyperlinks`. 
At the top of the code window, use the navigation bar to move forward and backward through multiple instances of highlighted lines. Use the navigation sidebar to go directly to a line of code.

If you close and reopen a model, the **Navigate to Code** context menu option might not be available because Embedded Coder cannot find a build folder for your model in the current working folder. Do one of the following:

- Reset the current working folder to the parent folder of the existing build folder.
- Select **Model-to-code** and rebuild the model. Rebuilding the model regenerates the build folder into the current working folder.
- Click **Configure**. In the Model-to-code navigation dialog box, reload the existing traceability information by specifying the original build folder.

</tbody>
</table>

To verify the generated code for your Stateflow elements, you can trace Stateflow elements in your model to the code generation report by using these types of navigation:

- **Code-to-model**: Trace generated code from the code generation report back to the model by clicking hyperlinks in the comments or the hyperlinked line numbers, which highlights the corresponding model element in the Simulink Editor.
- **Model-to-code**: Trace the model elements in the Simulink Editor to corresponding lines in generated code by right-clicking the model element and navigating to the generated code.

These examples illustrate how to trace different Stateflow elements.

**Inline Traceability for Stateflow Elements**

Inline traceability refers to the line-level traceability available in the code generation report. You can click the hyper-linked line numbers to trace single or multiple Stateflow elements at the same time.

1. At the command prompt, type `old_sf_car`.
2. Select **Simulation > Model Configuration Parameters**.
3. In the **Code Generation** pane, go to the **Target selection** section and enter `ert.tlc` for the system target file. Click **Apply**.
4. On the **Code Generation > Report** pane, verify that you have selected these parameters:
• **Create code generation report** (Simulink Coder)
• **Open report automatically** (Simulink Coder)
• **Code-to-model** (Simulink Coder)
• **Model-to-code** (Simulink Coder)

5 Go to the **Code Generation > Interface** pane. In the **Software environment** section, select **continuous time**. Click **Apply**. Before generating code, you must perform this step because this model contains a block with a continuous sample time.

6 Press **Ctrl+B**.

After the code generation process is complete, the code generation report appears.

7 In the report, on the left navigation pane, click the **old_sf_car.c** hyperlink.

8 To view the inline traceability hyperlinks, scroll through the code. These line numbers can differ from the numbers that appear in your code generation report.

```c
185 /* Function for Chart: '<Root>/shift_logic' */
186 static void old_sf_car_gear_state(const int32_T *sfEvent)
187 {
188     switch (old_sf_car_DW.is_gear_state) {
189     case old_sf_car_IN_first:
190         old_sf_car_B.gear = 1.0;
191         if (*sfEvent == old_sf_car_event_UP) {
192             old_sf_car_DW.is_gear_state = old_sf_car_IN_second;
193             old_sf_car_B.gear = 2.0;
194         }
195         break;
```

9 Click the hyperlink on line number 190. The corresponding element is highlighted.
Bidirectional Traceability for States and Transitions

1. At the command prompt, type `old_sf_car`.
2. Select Simulation > Model Configuration Parameters.
3. In the Code Generation pane, go to the Target selection section and enter `ert.tlc` for the system target file. Click Apply. Traceability comments appear in generated code only for embedded real-time targets.
4. Verify that you have selected these parameters on the Code Generation > Report pane:
   - Create code generation report
   - Open report automatically
   - Code-to-model
   - Model-to-code
5 Go to the **Code Generation > Comments** pane and select **Stateflow object comments**. This parameter enables the traceability comments for Stateflow elements.

6 Go to the **Code Generation > Interface** pane. In the **Software environment** section, select **continuous time**. Click **Apply**. Before generating code, you must perform this step because this model contains a block with a continuous sample time.

7 Press **Ctrl+B** to generate source code and header files for the **old_sf_car** model that contains the **shift_logic** chart. After the code generation process is complete, the code generation report appears.

8 In the report, click the **old_sf_car.c** hyperlink.

**View Results**

1 To see the traceability comments, scroll through the code. These line numbers can differ from the numbers that appear in your code generation report.

```c
185 /* Function for Chart: '<Root>/shift_logic' */
186 static void old_sf_car_gear_state(const int32_t *sfEvent)
187 {
188     /* During 'gear_state': '<S5>:2' */
189     switch (old_sf_car DW.is_gear_state) {
190         case old_sf_car_IN_first:
191             /* During 'first': '<S5>:6' */
192                 if (*sfEvent == old_sf_car_event_UP) {
193                     /* Transition: '<S5>:12' */
194                     old_sf_car DW.is_gear_state = old_sf_car_IN_second;
195                 
196                 /* Entry 'second': '<S5>:4' */
197                 old_sf_car B.gear = 2.0;
198     }
199 }
200 }
```

2 Click the **<S5>:2** hyperlink in this traceability comment:

```c
/* During 'gear_state': '<S5>:2' */
```

The corresponding state appears highlighted in the chart.

3 Click the **<S5>:12** hyperlink in this traceability comment:

```c
/* Transition: '<S5>:12' */
```

The corresponding transition appears highlighted in the chart. To remove highlighting from an element in the chart, select **Display > Remove Highlighting**.
4 You can also trace elements in the model to lines of generated code. In the chart, right-click the element `gear_state` and select C/C++ Code > Navigate to C/C++ Code.

The code for that state appears highlighted in `old_sf_car.c`.

```c
108 /* Function for Stateflow: '<Root>/shift_logic' */
109 static void old_sf_car_gear_state(void)
110 {*/
111 /* During 'gear_STATE': '<S5>:2' */
112 if (old_sf_car_dWork.is_active_gear_state != 0) {
113     switch (old_sf_car_dWork.is_gear_state) {
114         case old_sf_car_IN_first:
115             /* During 'first': '<S9>:6' */
```

5 In the chart, right-click the transition with the condition `[speed > up_th]` and select C/C++ Code > Navigate to C/C++ Code.

The code for that transition appears highlighted in `old_sf_car.c`.

```c
446 case old_sf_car_IN_steady_state;
447     /* During 'steady_state': '<S5>:9' */
448     if (old_sf_car_d.mph > old_sf_car_d.interp_up) {
449         /* Transition: '<S5>:18' */
450         /* Exit 'steady_state': '<S5>:9' */
```
4 To see the traceability comments, scroll through the code. The line numbers shown can differ from the numbers that appear in your code generation report.

```c
/* Function for State Transition Table: '<Root>/CdPlayerModeManager' */
static void sf_cdplayer_S_enter_internal_ON(void)
{
    /* Entry Internal 'ON': '<S2>:58' */
    switch (sf_cdplayer_STT_DWork.bitsForTID1.was_ON) {
        case sf_cdplayer_STT_IN_AMMode:
            sf_cdplayer_STT_DWork.bitsForTID1.is_ON = sf_cdplayer_STT_IN_AMMode;
            sf_cdplayer_STT_DWork.bitsForTID1.was_ON = sf_cdplayer_STT_IN_AMMode;
        /* Entry 'AMMode': '<S2>:61' */
            sf_cdplayer_STT_B.CurrentRadioMode = AM;
            sf_cdplayer_STT_B.MechCmd = STOP;
        break;
    }
}
```

5 Click the <S2>:58 hyperlink in this traceability comment:

```c
/* Entry Internal 'ON': '<S2>:58' */
```

The corresponding state 'ON' appears highlighted in the state transition table.
6 Right-click the highlighted state and select **View state element**. The state 'ON' also appears highlighted in the underlying state transition diagram.

7 You can trace a state or transition from the state transition table to the generated code. Right-click the state **Standby** and select **C/C++ Code > Navigate to C/C++ Code**.

The entry code for the state **Standby** is highlighted in the generated code.
Bidirectional Traceability for Truth Table Blocks

1. At the command prompt, type `sf_climate_control`
2. Complete steps 2 through 6 in “Bidirectional Traceability for States and Transitions” on page 74-15.
3. To build the model, press **Ctrl+B**.
4. In the code generation report, click the `sf_climate_control.c` hyperlink.
5. To see the traceability comments, scroll through the code. These line numbers can differ from the numbers that appear in your code.

6. Click the `<S1>:1:47` hyperlink in this traceability comment:

   /* Action '3': '<S1>:1:47' */

   In the Truth Table Editor, row 3 of the Action Table appears highlighted.
You can also trace a condition, decision, or action in the table to a line of generated code. For example, right-click a cell in the column D2 and select C/C++ Code > Navigate to C/C++ Code.

The code for that decision appears highlighted in sf_climate_control.c.
Tip To select C/C++ Code > Navigate to C/C++ Code for a condition, decision, or action, right-click a cell in the row or column that corresponds to that truth table element.

### Bidirectional Traceability for Graphical Functions

1. At the command prompt, type `sf_clutch_enabled_subsystems`.
2. Complete steps 2 through 6 in “Bidirectional Traceability for States and Transitions” on page 74-15.
3. In the Model Configuration Parameters dialog box, go to the Solver pane. In the Solver selection section, select Fixed-step in the Type field. Click Apply. Before generating code, you must perform this step because the model does not work with variable-step solvers.
4. To build the model, press Ctrl+B.
5. In the code generation report, click the `sf_clutch_enabled_subsystems.c` hyperlink.
6. To see the traceability comments, scroll through the code. These line numbers can differ from the numbers that appear in your code generation report.
7. Click the `<S1>:3` hyperlink in this traceability comment:

   /* Graphical Function 'getSlipTorque': '<S1>:3' */

   In the chart, the graphical function getSlipTorque appears highlighted.
8. You can trace a graphical function in the chart to a line of generated code. For example, right-click the graphical function detectSlip and select C/C++ Code > Navigate to C/C++ Code.
The code for that graphical function appears highlighted in `sf_clutch_enabled_subsystems.c`.

```
184  case sf_clutch_IN_Locked:
185      /* Graphical Function 'detectSlip': '<S1>:16' */
186      /* Transition: '<S1>:18' */
```

### Code-to-Model Traceability for Events

1. At the command prompt, type `sf_security`.
2. Complete steps 2 through 6 in “Bidirectional Traceability for States and Transitions” on page 74-15.
3. To build the model, press **Ctrl+B**.
4. In the code generation report, click the `sf_security.c` hyperlink.
5. To see this traceability comment, scroll through the code. These numbers can differ from the numbers that appear in your code generation report.

```
236     /* Entry 'Pending': '<S3>:5' */
237     /* Event: '<S3>:56' */
238     sf_security_DW.SoundEventCounter++;
239   }
240   break;
```

6. Click the `<S3>:56` hyperlink in this traceability comment:

   /* Event: '<S3>:56' */

   In the **Contents** pane of the Model Explorer, the event Sound appears highlighted.
Model-to-Code Traceability for Junctions

1. At the command prompt, type `sf_abs`.
2. Complete steps 2 through 6 in “Bidirectional Traceability for States and Transitions” on page 74-15.
3. In the Model Configuration Parameters dialog box, go to the Solver pane. In the Solver selection section, select Fixed-step in the Type field. Click Apply. Before generating code, you must perform this step because the model does not work with variable-step solvers.
4. To build the model, press Ctrl+B.
5 In the code generation report, open the AbsoluteValue chart.
6 Right-click the left junction and select **C/C++ Code > Navigate to C/C++ Code**.

The code for the first outgoing transition of that junction appears highlighted in `sf_abs.c`.

```c
58     /* Entry Internal: AbsoluteValue */
59     /* Transition: '<S1>:5' */
60     if (SinWave1 >= 0.0) {
61     /* Transition: '<S1>:6' */
62     stateChanged = true;
63     sf_abs_DW.is_c1 sf_abs = sf_abs_IN_P;
64     } else {
65     /* Transition: '<S1>:7' */
66     /* Transition: '<S1>:8' */
67     stateChanged = true;
68     sf_abs_DW.is_c1 sf_abs = sf_abs_IN_N;
69     }
```

### Format of Traceability Comments for Stateflow Elements

The format of a traceability comment depends on the Stateflow element type.

#### State

**Syntax**

/* <ActionType> '<StateName>': '<elementHyperlink>' */

**Example**

/* During 'gear_state': '<S5>:2' */

This comment refers to the during action of the state `gear_state`, which has the hyperlink `<S5>:2`.

#### Transition

**Syntax**

/* Transition: '<elementHyperlink>' */

**Example**

/* Transition: '<S5>:12' */
This comment refers to a transition, which has the hyperlink <S5>:12.

**MATLAB Function**

**Syntax**

```c
/* MATLAB Function '<Name>': '<elementHyperlink>' */
```

Within the inlined code for a MATLAB function, comments that link to individual lines of the function have this syntax:

```c
/* '<elementHyperlink>' */
```

**Examples**

```c
/* MATLAB Function 'test_function': '<S50>:99' */
/* '<S50>:99:20' */
```

The first comment refers to the MATLAB function named test_function, which has the hyperlink <S50>:99.

The second comment refers to line 20 of the MATLAB function in your chart.

**Truth Table Block**

**Syntax**

```c
/* Truth Table Function '<Name>': '<elementHyperlink>' */
```

Within the inlined code for a Truth Table block, comments for conditions, decisions, and actions have this syntax:

```c
/* Condition '#<Num>': '<elementHyperlink>' */
/* Decision 'D<Num>': '<elementHyperlink>' */
/* Action '<Num>': '<elementHyperlink>' */
```

<Num> is the row or column number that appears in the Truth Table Editor.

**Examples**

```c
/* Truth Table Function 'truth_table_default': '<S10>:100' */
/* Condition '#1': '<S10>:100:8' */
/* Decision 'D1': '<S10>:100:16' */
/* Action '1': '<S10>:100:31' */
```
The first comment refers to a Truth Table block named truth_table_default, which has the hyperlink <S10>:100.

The other three comments refer to elements of that Truth Table block. Each condition, decision, and action in the Truth Table block has a unique hyperlink.

**Truth Table Function**

For syntax and examples, see “Truth Table Block” on page 74-26.

**Graphical Function**

Syntax

/* Graphical Function '<Name>': '<elementHyperlink>' */

Example

/* Graphical Function 'hello': '<S1>:123' */

This comment refers to a graphical function named hello, which has the hyperlink <S1>:123.

**Simulink Function**

Syntax

/* Simulink Function '<Name>': '<elementHyperlink>' */

Example

/* Simulink Function 'simfcn': '<S4>:10' */

This comment refers to a Simulink function named simfcn, which has the hyperlink <S4>:10.

**Event**

Syntax

/* Event: '<elementHyperlink>' */

Example

/* Event: '<S3>:33' */

This comment refers to an event, which has the hyperlink <S3>:33.

Link Generated Code to Requirements

Link generated code to model element requirements. Using configuration parameters, you can specify whether to include requirement descriptions as comments in the generated code.

**Open Model**

Open the rtwdemo_requirements model. The model contains Simulink® and Stateflow® elements with associated requirements.

```matlab
model='rtwdemo_requirements';
open_system(model);
```

**Requirements in Generated Code**

Requirements attached to various Simulink and Stateflow objects can appear in code generated by Embedded Coder(R) within their respective comments. The two steps are:

1) Add requirements to model.
2) Check option in configuration parameters.

**Step 1: Add Requirements to Model**

Requirements can be added to numerous types of objects in Simulink and Stateflow using the Requirements entry from the context menu. The following are requirements entered in this model (double-click to open):

- Simulink Block
- Simulink Signal Builder
- Stateflow State
- Stateflow Transition
- Stateflow Graphical Function

**Step 2: Check Requirements Options**

Open the model's configuration parameters and navigate to the Requirements section of the Code Generation settings. Double-click below to see these settings.

- Open Requirements Settings

**Additional Documentation**

Additional documentation is available for integrating requirements into generated code by double-clicking the link below.

- Requirements Documentation
View Requirements

You can view requirements linked to the model by using the Requirements Editor. In the Simulink Editor, select Analysis > Requirements > Requirements Editor. You can view requirements specific to model objects by using the object context menu. Right-click an element and select Requirements > Open Outgoing Links dialog .... To view the requirements, use these commands:

1. To view the requirements for the DiscretePulseGenerator block, right click on the DiscretePulseGenerator block and select Requirements > Open Outgoing Links dialog ... to open Outgoing Links Editor. Using Outgoing Links Editor, you can create, edit, and delete requirements traceability links.

   ```matlab
clockblock='rtwdemo_requirements/clock';
clockblockh=get_param(clockblock,'handle');
rmi('edit',clockblockh);
```

2. To view the requirements, open the Signal Builder block by double clicking on it.

   ```matlab
   sigbblock='rtwdemo_requirements/Signal Builder';
   open_system(sigbblock)
   ```
3. To view the requirements for the Stateflow® state, open the Outgoing Links Editor.

```matlab
state=find(sfroot,'-isa','Stateflow.State','-and','Tag','req_state');
rmi('edit',state.id);
```

4. To view the requirements for the Stateflow transition, open the Outgoing Links Editor.

```matlab
trans=find(sfroot,'-isa','Stateflow.Transition','-and','Tag','req_trans');
rmi('edit',trans.id);
```

5. To view the requirements for the Stateflow function, open the Outgoing Links Editor.
func=find(sfroot,'-isa','Stateflow.Function','-and','Tag','req_function');
rmii('edit',func.id);

Close the open windows.
close_system(sigbblock);

**Set Configuration Parameters**

Open the Configuration Parameters dialog box **Code Generation > Comments** pane. View the configuration parameter settings.

```matlab
model = bdroot;
slCfgPrmDlg(model,'Open');
slCfgPrmDlg(bdroot,'TurnToPage','Comments');
```

**Generate Code**

Generate code for the model.

```matlab
rtwbuild('rtwdemo_requirements')
```

### Starting build procedure for model: rtwdemo_requirements
### Successful completion of build procedure for model: rtwdemo_requirements

In the generated code, view the comments containing the requirements. To view all the requirements, click the hyperlinked requirement comment.

```matlab
rtwdemodbtype('rtwdemo_requirements_ert_rtw/rtwdemo_requirements.c',...
'/* Function for Chart:','return result;',1,0);
```

```c
/* Function for Chart: '<Root>/rebound_elimination' */
static real_T rebound_fcn(real_T prev_in, real_T prev_out, real_T curr_in) {
    real_T result;

    /* Graphical Function 'rebound_fcn': '<S2>:2': */
    /* 1. Result Computation */
    /* Transition: '<S2>:4' */
    if (prev_in == curr_in) {
        /* Transition: '<S2>:5' */
        result = curr_in;
    } else {
```
/ Transition: '<S2>:6' */
/* Transition: '<S2>:7' */
result = prev_out;

Close Model

rtwdemoclean;
close_system('rtwdemo_requirements',0);

Reload Existing Traceability Information

When you build a model, the traceability information is stored in the build folder. The format of the build folder for an ERT-based target is `model_ert_rtw`.

**Model-to-code** (Simulink Coder) parameter should be selected in the original build to be able to reload the traceability information in a new Simulink session. To reload existing traceability information for a model:

1. Reset the current working folder to the parent folder of the existing build folder.
2. In the Configuration Parameters dialog box, next to **Model-to-code**, click **Configure** (Simulink Coder).
3. In the Model-to-code navigation dialog box, in the **Build folder** field, type or browse to the build folder that contains the existing traceability information.

If you close and reopen a model, the **Navigate to Code** context menu option might not be available because Embedded Coder cannot find a build folder for your model in the current working folder. In that case, perform these steps:

1. To open the Model-to-code navigation dialog box, click **Configure**.
2. In the Model-to-code navigation dialog box, click **Browse**.
3. Browse to the build folder for your model and select the folder. The build folder path is displayed in the **Build folder** field.
If you selected **Model-to-code** for the build, clicking **Apply** or **OK** loads traceability information from the earlier build into your Simulink session.

To open the context menu and trace a model element to corresponding code, right-click a model element and select **C/C++ Code > Navigate to C/C++ Code**.

**Related Examples**
- “Open Code Generation Report” on page 48-9
Customize Traceability Reports

Even a relatively small model can generate hundreds of lines of C/C++ code. To help you navigate more easily between the generated code and your source model, Embedded Coder provides the traceability report section. When you enable traceability, Embedded Coder creates and displays an HTML code generation report. You can generate reports in the Configuration Parameters dialog box or at the command line.

In the Configuration Parameters dialog box, the **Code Generation > Report** pane lists parameters that you can select and clear to customize the content of your traceability reports.

Select or clear any combination of these parameters. These parameters are on by default.

- **Eliminated / virtual blocks** (Simulink Coder) (account for blocks that are untraceable)
- **Traceable Simulink blocks** (Simulink Coder)
- **Traceable Stateflow elements** (Simulink Coder)
- **Traceable MATLAB functions** (Simulink Coder)

If you select all parameters, you get a complete mapping between model elements and the generated code.

This figure shows the top section of the traceability report, which is generated when you select all traceability content parameters for model `rtwdemo_hyperlinks`.

Generate a Traceability Matrix

The traceability matrix provides traceability among model elements, generated code, and model requirements in a Microsoft Excel® file format.

If you have DO Qualification Kit software or IEC Certification Kit software and are using a Windows host, you can generate a traceability matrix into Microsoft Excel format directly from the traceability report.

Go to the Traceability Report section of the HTML code generation report and click Generate Traceability Matrix.

To select an existing matrix file to update or specify a matrix file to create, use the options in the Generate Traceability Matrix dialog box. Optionally, you can select and create an order to the columns that appear in the generated matrix. After specifying the location where you want the matrix file, click the Generate button.

For more information, see "Generating a Traceability Matrix" in either the DO Qualification Kit documentation (DO Qualification Kit) or the IEC Certification Kit documentation (IEC Certification Kit).

Related Examples

• “Reports for Code Generation” on page 48-2
Trace Generated Code to Blocks

Navigate and trace between generated code and its source model for verification.

**Open Example Model**

Open the example model `rtwdemo_hyperlinks`.

```matlab
model='rtwdemo_hyperlinks';
open_system(model)
```

---

**Code to Model Navigation**

Navigate from the generated code to the model.
1 In the Configuration Parameters dialog box, open the Code Generation > Report pane.

2 Verify that the following parameters are selected: Create code generation report, Open report automatically and Code-to-model.

3 In the model editor window, press Ctrl+B to generate code. After the code generation process is complete, the code generation report appears.

4 In the generated report, click the rtwdemo_hyperlinks.c link to see the code with embedded hyperlinks.

5 Click links in the code to trace generated code segments to the highlighted elements in the model. For example, if you click the hyperlink <Root>/Sum, the Sum block in the model is highlighted.

Model to Code Navigation

Navigate from the model to the generated code.

1 In the Configuration Parameters dialog box, open the Code Generation > Report pane.

2 Verify that the following parameters are selected: Create code generation report, Open report automatically and Model-to-code.

3 In the model editor window, press Ctrl+B to generate code. After the code generation process is complete, the code generation report appears.

4 In the model window, right-click any block and select Code Generation > Navigate to Code. The software highlights the generated code for this block in the code generation report.

5 Inspect the highlighted lines in the code generation report. The total number of highlighted lines is displayed next to each source file name in the left pane of the report. Use the Previous and Next buttons to navigate through the highlighted lines.

Note: Model-to-code navigation also works for Stateflow objects and MATLAB functions.

Note: The report displays a diagnostic message if there is no code to highlight for the selected block (for example, if you select a virtual block).

Traceability Report

Generate and inspect the Traceability Report.
1 In the Configuration Parameters dialog box, open the **Code Generation > Report** pane.

2 Verify that the following parameters are selected: **Create code generation report, Open report automatically**

3 Search for the traceability report parameters using keyword `GenerateTraceReport`. Verify all the listed parameters are selected.

4 In the model editor window, press **Ctrl+B** to generate code. After the code generation process is complete, the code generation report appears.

5 To see a report of the untraceable (not in the generated code) and traceable blocks in your model, on the left pane of the generated report click **Traceability Report**.

6 In the **Traceability Report**, inspect the **Eliminated / Virtual Blocks** and **Traceable Blocks** lists. For example, the **Scope** block is an untraceable block. It is listed under **Eliminated / Virtual Blocks** because the code generator does not generate code for this block.
Use Traceability in MATLAB Function Blocks

In this section...

| “Extent of Traceability in MATLAB Function Blocks” on page 74-42 |
| “Traceability Requirements” on page 74-42 |
| “Tutorial: Using Traceability in a MATLAB Function Block” on page 74-42 |

Extent of Traceability in MATLAB Function Blocks

Like other Simulink blocks, MATLAB Function blocks support bidirectional traceability, but extend navigation to lines of source code. That is, you can navigate between a line of generated code and its corresponding line of source code. In other Simulink blocks, you can navigate between a line of generated code and its corresponding object.

In addition, you can select to include the source code as comments in the generated code. When you select MATLAB source code as comments parameter, the MATLAB source code appears immediately after the associated traceability tag. For more information, see “Include MATLAB Code as Comments in Generated Code” on page 41-30.

For information about how traceability works in Simulink blocks, see “Verify Generated Code by Using Code Tracing” on page 74-2.

Traceability Requirements

To enable traceability comments in your code, you must have a license for Embedded Coder software. These comments appear only in code that you generate for an Embedded Real-Time (ERT) target.

Note Traceability is not supported for MATLAB files that you call from a MATLAB Function block.

Tutorial: Using Traceability in a MATLAB Function Block

This example shows how to trace between source code and generated code in a MATLAB Function block in the eml_fire model. Follow these steps:
1 Type `eml_fire` at the MATLAB prompt.
2 In the Simulink model window, select **Simulation > Model Configuration Parameters**.
3 In the **Code Generation** pane, go to the **Target selection** section and enter `ert.tlc` for the system target file. Then click **Apply**. Traceability comments appear hyperlinked in generated code only for embedded real-time (ert) targets.
4 In the **Code Generation > Report** pane, select the **Create code generation report** (Simulink Coder) parameter, if not already selected. This action automatically selects the “Open report automatically” (Simulink Coder), “Code-to-model” (Simulink Coder), and “Model-to-code” (Simulink Coder) parameters.
5 Verify that **Code-to-model** and **Model-to-code** parameters are enabled.
6 In the **Code Generation > Comments** pane, select the “MATLAB source code as comments” (Simulink Coder) and “Stateflow object comments” (Simulink Coder) parameters. These parameters control different parts of the traceability comment.
7 Go to the **Code Generation > Interface** pane. In the **Software environment** section, select the **continuous time** parameter. Then click **Apply**. Because this example model contains a block with a continuous sample time, you must perform this step before generating code.
8 In the model window, press **Ctrl+B**. This action generates source code and header files for the `eml_fire` model that contains the `flame` block. After the code generation process is complete, the code generation report appears automatically.
9 Click the `eml_fire.c` hyperlink in the report.
10 Scroll down through the code to see the traceability comments, which appear as links inside `/*...*/` brackets, as in this example.

```matlab
/* '<S2>:1:19' for x = 1 : WIDTH */
for (x = 0; x < 256; x++) {
  /* '<S2>:1:21' yb = y+2; */
  yb = iU;

  /* '<S2>:1:22' xb1 = x-1; */
  xb1 = x;
```
Click the `<S2>:1:19` hyperlink in this traceability comment:

```c
/* '<S2>:1:19' */
```

Line 19 of the function in the source code appears highlighted in the MATLAB Function Block Editor.

You can trace a line in a MATLAB function to lines of generated code. For example, right-click on line 21 of your function and select **Code Generation > Navigate to Code** from the context menu.

The code location for line 21 appears highlighted in `eml_fire.c`.

You can trace a line of generated code to a line of source code in a MATLAB function using the line number hyperlinks in the generated code.

**More About**

- “Include MATLAB Code as Comments in Generated Code” on page 41-30
Component Verification in Embedded Coder
Component Verification in Target Environment

After you generate production code for a component design, you need to integrate, compile, link, and deploy the code as a complete application on the embedded system. One approach is to manually integrate the code into an existing software framework that consists of an operating system, device drivers, and support utilities. The algorithm can include externally written legacy or custom code.

An easier approach to verifying a component in a target environment is to use processor-in-the-loop (PIL) simulation. For information about PIL simulations, see “SIL and PIL Simulations” on page 77-2.

Goals of Component Verification

Assuming that you have generated production source code and integrated required externally written code, such as drivers and a scheduler, you can verify that the integrated software operates as expected by testing it in the target environment. During testing, you can achieve either of the following goals, depending on whether you export code that is strictly ANSI C/C++ or mixes ANSI C/C++ with code optimized for a target environment.

<table>
<thead>
<tr>
<th>Goal</th>
<th>Type of Code Export</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximize code portability and configurability</td>
<td>ANSI C/C++</td>
</tr>
<tr>
<td>Simplify integration and maximize use of processor resources and code efficiency</td>
<td>Mixed code</td>
</tr>
</tbody>
</table>

Regardless of your goal, you must integrate required external drivers and scheduling software. To achieve real-time execution, you must integrate the real-time scheduling software.

To maximize code portability and configurability, limit the application code to ANSI/ISO C or C++ code only, as the following figure shows.
To simplify code integration and maximize code efficiency for a target environment, use Embedded Coder features for:

- Controlling code interfaces
- Exporting subsystems
- Including target-specific code, including compiler optimizations

The following figure shows a mix of ANSI C/C++ code with code that is optimized for a target environment.
Run Component Tests

The workflow for running software component tests in the target environment is:

1. Integrate external code, for example, for device drivers and a scheduler, with the generated C or C++ code for your component model. For more information, see “S-Functions and Code Generation” (Simulink Coder). For more specific references that depend on your verification goals, see the following table.
<table>
<thead>
<tr>
<th>For</th>
<th>See</th>
</tr>
</thead>
<tbody>
<tr>
<td>ANSI C/C++ code integration</td>
<td>“Integrate C Functions Using Legacy Code Tool” (Simulink). Also, open <code>rtwdemos</code> and navigate to the <strong>Custom Code</strong> folder.</td>
</tr>
</tbody>
</table>
| Mixed code integration | • “Generate Component Source Code for Export to External Code Base” on page 52-64 and example `rtwdemo_exporting_functions`  
• “Customize Generated C Function Interfaces” on page 38-2, “Customize Generated C++ Class Interfaces” on page 38-36, and example `rtwdemoFcnprotoCtrl`  

2. Simulate the integrated component model.
3. Generate code for the integrated component model.
4. Connect to data interfaces for the generated C code data structures. See “Exchange Data Between Generated and External Code Using C API” (Simulink Coder) and “Export ASAP2 File for Data Measurement and Calibration” (Simulink Coder). Also see examples `rtwdemo_capi` and `rtwdemo_asap2`.
5. Customize and control the build process, if required. See “Customize Post-Code-Generation Build Processing” (Simulink Coder), and example `rtwdemo_buildinfo`.
6. Create a zip file that contains generated code files, static files, and dependent data to build the generated code in an environment other than your host computer. See “Relocate Code to Another Development Environment” (Simulink Coder), and example `rtwdemo_buildinfo`. 
Component Verification With a Real-Time Target Environment in Embedded Coder

- “Real-Time Software Component Verification” on page 76-2
- “Real-Time Software Component Testing” on page 76-6
Real-Time Software Component Verification

One approach to verifying a software component is to build the component into a complete software system that can execute in real time in the target environment. A complete software system includes:

- Algorithm for the software component
- Scheduling algorithms
- Calls to drivers for board-specific devices

This single build approach is more time consuming to set up, but makes it easier to get the complete application running in the target environment.

The following figure shows code generated for an algorithm being built into a complete system executable for the target environment.
The workflow for testing component software as part of a complete real-time target environment is:

1 Develop a component model and generate source code for production.

For information on building in scheduling and real-time system support, see:

• “Time-Based Scheduling and Code Generation” (Simulink Coder) and “Modeling for Multitasking Execution” (Simulink Coder). For an example, open rtwdemos and navigate to the Multirate Support folder.
• “Asynchronous Events” (Simulink Coder) and example rtw.demo_async
• “Deploy Generated Standalone Executable Programs To Target Hardware” on page 62-2
• “Workflows for AUTOSAR” and example “Getting Started with AUTOSAR Code Generation”.

3 Customize post code generation build processing to accommodate third-party tools and processes, as required. See “Customize Post-Code-Generation Build Processing” (Simulink Coder) and example rtwdemo_buildinfo.

4 Integrate external code, for example, for device drivers and a scheduler, with the generated C or C++ code for your component model. For more information, see “S-Functions and Code Generation” (Simulink Coder). For more specific references depending on your verification goals, see the following table.

<table>

What Are SIL and PIL Simulations?

With Embedded Coder, you can run software-in-the-loop (SIL) and processor-in-the-loop (PIL) simulations of your model. These simulations generate source code for either the top model or part of the model. A SIL simulation compiles and runs the generated code on your development computer. A PIL simulation cross-compiles source code on your development computer, and then downloads and runs the object code on a target processor or an equivalent instruction set simulator.

With SIL and PIL simulations, you can:

- Test whether your model and generated code are numerically equivalent.
- Observe code coverage.
- Perform code execution profiling.

Why Use SIL and PIL?

Through SIL and PIL, you can early on test and fix defects. For example, you can model and test a system component in normal mode. Then, you can reuse your test suites in a SIL or PIL simulation that runs compiled generated code. To check numerical equivalence, you compare normal and SIL or PIL simulation results. You thereby avoid leaving the Simulink environment to test generated code on a separate infrastructure.

This table describes situations where you can use SIL and PIL.
<table>
<thead>
<tr>
<th>Situation</th>
<th>Use</th>
</tr>
</thead>
<tbody>

<td>SIL and PIL</td>
</tr>
<tr>
<td>Without target hardware, get a convenient alternative to PIL.</td>
<td>SIL</td>
</tr>
</tbody>
</table>
### Situation

With target hardware, for example, an evaluation board or instruction set simulator:

- Optimize the execution speed and memory footprint of your code. In this table, see the information about collecting execution profiling and stack profiling metrics.
- Investigate effects of compiler settings and optimizations, for example, deviation from ANSI C overflow behavior.

Normal simulation techniques do not account for restrictions and requirements that the hardware imposes, such as limited memory resources or behavior of target-specific optimized code.

For information about running PIL simulations on specific targets, see “Sample Custom Targets” (Simulink Coder) in the Simulink Coder documentation.

### Use

PIL

<table>

<td>PIL</td>
</tr>
</tbody>
</table>

**Note** The SIL and PIL simulation modes are not designed for the reduction of model simulation times. If you want to speed up the simulation of your model, use the rapid accelerator mode. For more information, see “What Is Acceleration?” (Simulink).

### How SIL and PIL Simulations Work

In a SIL or PIL simulation, code is generated for either the top model or part of the model. With SIL, this code is compiled for and executed on your development computer. With PIL, the code is cross-compiled for the target hardware and runs on the target processor.

Through a communication channel, Simulink sends stimulus signals to the code on your computer or target processor for each sample interval of the simulation.

- For a top model, Simulink uses stimulus signals from the base or model workspace.
- If you have designated only part of the model to simulate in SIL or PIL mode, then a part of the model remains in Simulink and code is not generated for this part of the
model. Typically, you configure this part of the model to provide test vectors for the software executing on the hardware. This part of the model can represent other parts of the algorithm or the environment in which the algorithm operates.

When your computer or target processor receives signals from Simulink, the processor executes the SIL or PIL algorithm for one sample step. The SIL or PIL algorithm returns output signals calculated during this step to Simulink through a communication channel. One sample cycle of the simulation is complete, and Simulink proceeds to the next sample interval. The process keeps repeating itself and the simulation progresses. SIL and PIL simulations do not run in real time. In each sample period, Simulink and the object code exchange I/O data.

### Comparison of SIL and PIL Simulations

<table>
<thead>
<tr>
<th>Type of SIL or PIL Simulation</th>
<th>What Happens in SIL Simulation</th>
<th>What Happens in PIL Simulation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specify through:</td>
<td>• Test behavior of generated source code on development computer. Simulation does not test code compiled for target hardware because code is compiled for the development computer (different compiler and different processor architecture than the target). • Generated production code compiled and executed on development computer as separate process, independent of MATLAB process. • Execution is host/host and nonreal time.</td>
<td>• Test object code that you intend to deploy in production on either real target hardware or an instruction set simulator. • On development computer, generated production code cross-compiled for target. Object code downloaded and executed on target processor or instruction set simulator. • Execution is host/target and nonreal time.</td>
</tr>

</tr>
<tr>
<td>Use SIL or PIL block created from subsystem.</td>
<td>• Simulation runs compiled object code through S-function. S-function communicates with object code executing as standalone application on development computer. SIL block execution is independent of the MATLAB process. • Execution is host/host and nonreal time.</td>
<td>• Simulation runs cross-compiled object code through S-function on development computer. S-function communicates with object code executing as standalone application on target processor or instruction set simulator. • Execution is host/target and nonreal time.</td>
</tr>
</tbody>
</table>

**Code Interfaces for SIL and PIL**

You generate standalone code when you perform, for example, a top-model or right-click subsystem build for a single deployable component. You can compile and link standalone code into a standalone executable or integrate it with other code. For more information on the standalone code interface, see “Configure Code Generation for Model Entry-Point Functions” (Simulink Coder).

When you generate code for a referenced model hierarchy, the software generates standalone executable code for the top model and a library module called a *model reference target* for each referenced model. When the code executes, the standalone executable invokes the applicable model reference targets to compute the referenced model outputs. For more information, see “Build Model Reference Targets” (Simulink Coder).

To integrate generated code with legacy code, use standalone code because the standalone code interface is documented.

**Note**  
SIL and PIL simulations do not provide direct support for custom code interfaces. You can incorporate these interfaces into Simulink as an S-function, for example, using the Legacy Code Tool, S-Function Builder, or handwritten code. Then, you can verify the custom code by using SIL and PIL simulations.
This table provides the interfaces that SIL and PIL simulations generate.

<table>
<thead>
<tr>
<th>SIL/PIL Simulation</th>
<th>Code Interface</th>
</tr>
</thead>
<tbody>
<tr>
<td>Top-model</td>
<td>SIL/PIL simulation generates the standalone code interface. If code exists, simulation calls standalone code for the model. If code does not exist, simulation generates standalone code.</td>
</tr>
<tr>
<td>Model block</td>
<td>If you set <strong>Code interface</strong> block parameter to <strong>Top model</strong>, SIL/PIL simulation generates standalone code interface. Simulation calls standalone code for the model if it exists. Otherwise, simulation generates standalone code by using <code>slbuild('model')</code> command. If you set <strong>Code interface</strong> block parameter to <strong>Model reference</strong>, SIL/PIL simulation generates model reference code interface. Simulation calls model reference target for Model block if it exists. Otherwise, simulation generates model reference target by using <code>slbuild('model', 'ModelReferenceRTWTargetOnly')</code> command.</td>
</tr>
<tr>

Exported functions in feedback loops

If your model has function-call subsystems and you export a subsystem that has context-dependent inputs (for example, feedback signals), the results of a SIL/PIL simulation with the generated code and the results of the normal mode simulation of your model can differ. One approach to make SIL/PIL and normal mode simulations yield identical results is to use Function-Call Feedback Latch blocks in your model. You can make context-dependent inputs become context-independent.

Embedded Coder generates a warning identifying context-dependent inputs of exported function-call subsystems if you set `Configuration Parameters > Diagnostics > Connectivity > Context-dependent inputs` to one of the following:

- Enable all as warnings
- Use local settings
- Disable all

For more information, see:

- “Control Generation of Subsystem Functions” (Simulink Coder)
- Function-Call Feedback Latch
- “Context-dependent inputs” (Simulink)

### Imported Data and Function Definitions

- “Imported Data” on page 77-9
- “GetSet Custom Storage Class” on page 77-10
- “Custom Storage Class of Type Other” on page 77-10
- “AUTOSAR Runtime Environment (RTE)” on page 77-13

### Imported Data

In SIL and PIL simulations, you can use signals, parameters, and data stores that specify storage classes with imported data definitions. The simulations define storage for imported data associated with:

- Signals at the root level of the component (on the I/O boundary).
Parameters in the base workspace or a data dictionary. For parameters in the model workspace:

- Top-model SIL/PIL and SIL/PIL block simulations define storage.
- Model block SIL/PIL simulations do not define storage. You must define storage and specify initial values that match MATLAB values.
- Global data stores.

SIL and PIL simulations do not define storage for other imported data. For example, the simulations do not define storage for imported data associated with:

- Internal signals (not on the I/O boundary)
- Local data stores

In these cases, define the storage through custom code included by the component under test or through the PIL `rtw.pil.RtIOStreamApplicationFramework` API.

See also “Tunable Parameters and SIL/PIL” on page 77-70.

**GetSet Custom Storage Class**

SIL and PIL simulations support the GetSet custom storage class. The SIL/PIL test harness provides C definitions of the Get and Set functions that are used during simulations. For more information, see “Access Data Through Functions with Custom Storage Class GetSet” on page 35-51.

**Custom Storage Class of Type Other**

To enable SIL and PIL support for the custom storage class where Type is set to Other, create a custom attributes class for the custom storage class and associate the custom attributes class with a Boolean property, SupportSILPIL, set to true.

```matlab
classdef CSCOtherAttributes < Simulink.CustomStorageClassAttributes
    properties(PropertyType = 'logical scalar')
        SupportSILPIL = true;
    end
end
```

For more information about custom attributes, see “Further Customize Generated Code by Writing TLC Code” on page 35-46 and “Finely Control Data Representation by Writing TLC Code for a Custom Storage Class” on page 35-48.
To build the SIL or PIL application interface, the code generator calls the `DataAccess` and `ClassAccess` functions in the associated custom TLC file to get required information. The code generator stores the extracted information in build artifacts in the build folder.

For a custom storage class that is not grouped:

- The code generator calls `DataAccess` with the request argument taking values of `define`, `declare`, `layout`, `contents`, `address`, or `set`.
- The code generator uses the string returned by `DataAccess(record, "define", "", "")` to define the variable in the SIL or PIL application if one of these is true:
  - The signal or parameter has an Imported data scope.
  - The model uses a model reference code interface.
  - The model uses a top model code interface, `EnableDataOwnership` is on, and the `Owner` attribute for the custom storage class is not empty and not equal to the name of the current model.
- The code generator uses the string returned by `DataAccess(record, "declare", "", ")` to declare the variable in the SIL or PIL application if the following are true:
  - The model uses a top model code interface.
  - The signal or parameter uses an Exported storage class.
  - `EnableDataOwnership` is off, or `EnableDataOwnership` is on and the `Owner` attribute for the custom storage class is empty or equal to the model name.
  - Code packaging is configured so that the variable is not declared in `model.h` or a header file that is included by `model.h`.

For a custom storage class that is grouped:

- The code generator calls `DataAccess` with the request argument taking values of `layout`, `address`, or `set`.
- The code generator calls `ClassAccess` with the request argument taking the value of `groupTypeDeclDefn`.
- You must provide the grouped type (struct) definition and the extern declaration of the grouped variable if one of these is true:
  - The signal or parameter has an Imported data scope.
  - The model uses a model reference code interface.
• The model uses a top model code interface, EnableDataOwnership is on, and the Owner attribute for the custom storage class is not empty and not equal to the name of the current model.

Provide the definition and declaration in a header file associated with the custom storage class by using the HeaderFile attribute or custom code that you include through the model.h file. To define the variable in the SIL or PIL application, the code generator uses the string returned by ClassAccess(record, "groupTypeDeclDefn").

• Static initialization can assume an order of struct elements that is different from the order that is generated if the data scope is Exported. When the code generator queries ClassAccess(record, "groupTypeDeclDefn"), it temporarily overrides the data initialization attribute of the custom storage class with the value None.

To determine whether the SIL or PIL application can access the variable in the code by address, the code generator uses the elements returned by DataAccess(record, "layout", ",", ","). To create the functionality in the application that transfers input or output port, tunable parameter, or global data store memory values between the development computer and target hardware, the code generator uses the output from:

• DataAccess(record, "address", idx, reim) if the first returned element is scalar, vector, row-mat, or col-mat.
• DataAccess(record, "contents", idx, reim) (or DataAccess(record, "set", idx, reim)) if the first returned element is other.

The code generator assumes that for row-mat and col-mat, matrices are stored in row-major format respectively. The assumption is independent of the array layout for the rest of the model. The code generator assumes that if the array layout of the storage implemented by the custom storage class differs from the rest of the model, the TLC file associated with the custom storage file performs the required transformations.

You can construct the custom TLC file associated with a custom storage class of type Other to perform other functions (in addition to returning the requested code fragments). For example, write directly to a custom file or call MATLAB functions that change the state of the base workspace. If you do not always want to execute these functions when DataAccess or ClassAccess are called, use the LibIsAccessingCustomDataForSILPIL(record) TLC function to distinguish between target code generation and requests for code fragments for the construction of the SIL or PIL application. For example:
%case "contents"
  %if !LibIsAccessingCustomDataForSILPIL(record)
    %matlab functionWithSideEffects()
  %endif
  %return LibDefaultCustomStorageContents(record, idx, reim)
%

See also Other custom storage class limitations on page 77-76.

**AUTOSAR Runtime Environment (RTE)**

You can use top-model and Model block SIL/PIL and SIL/PIL block simulations to perform model-based testing of an AUTOSAR software component. The generated code for the AUTOSAR software component is linked with a basic component-specific AUTOSAR Runtime Environment (RTE) to create a test application. This application tests AUTOSAR API calls made by the AUTOSAR software component.

**Note** For Model block SIL/PIL, to test the AUTOSAR interface, set the **Code interface** block parameter to **Top model**.

For more information, see “Verify AUTOSAR C Code with SIL and PIL”.

- “Choose a SIL or PIL Approach” on page 77-14
- “Configure and Run SIL Simulation” on page 77-18
- “Check Configuration” on page 77-13
Choose a SIL or PIL Approach

Consider a top model that consists of components A, B, C, and D:

- A and B are existing components for which code has previously been generated and tested.
- C, a referenced model, and D, a subsystem, are new components.

With software-in-the-loop (SIL) and processor-in-the-loop (PIL) simulations, you can use the following approaches to numerical equivalence testing:

- Test new components separately (before testing code from all components). See “Test Referenced Model Code” on page 77-16 and “Test Subsystem Code” on page 77-16.

For some forms of testing, you require a test harness model. The test harness model:
• Generates test vectors or stimulus inputs that feed the block under test.
• Makes it possible for you to observe or capture output from the block.

The following example shows a simple test harness model.

![Simple Test Harness Model](image)

The block under test is a Model block. The Sine Wave block generates the input for the Model block. Through the Scope block, you can observe the output from the Model block.

**Test Top-Model Code**

To test code generated from the top-model components together (A, B, C, and D), you can use top-model SIL/PIL or Model block SIL/PIL.

- **Top-model SIL/PIL:**
  1. Create test vectors or stimulus inputs in the MATLAB workspace (Simulink).
  2. Run the top model in normal, SIL, and PIL simulation modes. The software loads the test vectors or stimulus inputs from the MATLAB workspace.
  3. For each simulation mode, observe or capture outputs.
  4. Verify numerical equivalence by comparing normal outputs against SIL and PIL outputs.

- **Model block SIL/PIL:**
  1. Create a Model block that contains the top-model components.
  2. Insert the Model block in a simulation model, for example, your test harness model.
  3. Run simulations, switching the Model block between normal, SIL, and PIL modes. For the SIL and PIL simulation modes, set the **Code interface** Model block parameter to **Top model**.
  4. Verify numerical equivalence by comparing normal outputs against SIL and PIL outputs.
Test Referenced Model Code

To test code generated from the component C as part of a model reference hierarchy, use the Model block SIL/PIL approach:

- Insert the Model block C in a simulation model, for example, your test harness model.
- Run simulations, switching the Model block between normal, SIL, and PIL modes. For the SIL and PIL simulation modes, set the Code interface Model block parameter to Model reference.
- Verify numerical equivalence by comparing normal outputs against SIL and PIL outputs.

Test Subsystem Code

To test code generated from the subsystem D, use the SIL or PIL block approach:

1. Insert the subsystem in a simulation model, for example, your test harness model.
2. Run a normal mode simulation, capturing the outputs.
3. Create a SIL or PIL block from the subsystem.
4. In the model, replace the subsystem with the SIL or PIL block.
5. Run a simulation of the model, capturing the outputs.
6. Verify numerical equivalence by comparing normal mode subsystem outputs against SIL or PIL block outputs.

There are three ways of running SIL and PIL simulations. You can use:

- The top model.
- Model blocks.
- SIL and PIL blocks that you create from subsystems.

Simulation with Top Model

To configure and run a top-model SIL or PIL simulation:

1. Open your model.
2. Select either Simulation > Mode > Software-in-the-Loop (SIL) or Simulation > Mode > Processor-in-the-Loop (PIL). This option is available only if the model is configured for an ERT or AUTOSAR target. See “Model Configuration Parameters: Code Generation” (Simulink Coder) and “Generate AUTOSAR C Code and XML Component Descriptions” for configuration information.
3. If you have not already done so, in the Configuration Parameters dialog box, on the Data Import/Export pane:
   - In the Input check box and field, specify stimulus signals (or test vectors) for your top model.
   - Configure logging for model outputs, with either output logging or signal logging:
• In the **Output** check box and field, specify *output logging*.
• In the **Signal logging** check box and field, specify *signal logging*.
• Disable logging of Data Store Memory variables. The software does not support this option for this simulation mode. If you do not clear the **Data stores** check box, the software produces a warning when you run the simulation.

4 If you are configuring a SIL simulation, specify the portable word sizes option. You can then switch seamlessly between the SIL and PIL modes. Select **Code Generation > Verification > Enable portable word sizes.**

5 If required, configure:

• Code coverage.
• Code execution profiling.
• Creation of code generation report and static code metrics.

6 Start the simulation.

**Note** On a Windows operating system, the Windows Firewall can potentially block a SIL or PIL simulation. To allow the simulation, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

You cannot:

• Close the model while the simulation is running. To interrupt the simulation, in the Command Window, press **Ctrl+C**.
• Alter the model during the simulation. You can move blocks and lines as long as it does not alter the behavior of the model.

You can run a top-model SIL or PIL simulation with the command `sim(model)`. The software supports the `sim` command option `SrcWorkspace` for the value 'base'.

For a PIL simulation, you control the way code compiles and executes in the target environment through connectivity configurations.

With a top-model SIL or PIL simulation, Simulink creates a hidden model, `modelName_wrapper`. The simulation generates code for the model and uses the hidden model to call this code at each time step. As a result, in some circumstances, logged signals can have a `_wrapper` suffix. The simulation can also generate warnings that refer to the hidden model. For example:
Simulation with Model Blocks

To configure a Model block for a SIL or PIL simulation:

1. Open your model, for example, rtwdemo_sil_modelblock.
2. Right-click your Model block, for example, Counter A. In the context menu, select Block Parameters (ModelReference), which opens the Function Block Parameters dialog box.
3. From the Simulation Mode drop-down list, select the required mode, for example, Software-in-the-loop (SIL).
4. From the Code interface drop-down list, specify the code that you want to test, for example, Model reference.
5. Click OK. The software displays the simulation mode as a block label.

If you select Top model, the software displays the block label (SIL: Top).

6. If you are configuring a SIL simulation, specify the portable word sizes option. You can then switch seamlessly between the SIL and PIL modes. Select Code Generation > Verification > Enable portable word sizes.
7. If required, configure:
   • Code coverage.
   • Code execution profiling for your Model block, by configuring execution profiling for the top model.
   • Creation of code generation report and static code metrics.
8 Start the simulation.

**Note** On a Windows operating system, the Windows Firewall can potentially block a SIL or PIL simulation. To allow the simulation, use the Windows Security Alert dialog box. For example, in Windows 7, click *Allow access*.

For a PIL simulation, you control the way code compiles and executes in the target environment through connectivity configurations.

### Simulation with Blocks From Subsystems

To create a SIL or PIL block from a subsystem and use this block to test the code generated from the subsystem:

1. From the **Configuration Parameters > Code Generation > Advanced Parameters > Create block** drop-down list, select either SIL or PIL.
2. If required, configure code execution profiling.
3. Click **OK**.
4. In your model window, right-click the subsystem that you want to simulate.
5. Select **C/C++ Code > Build This Subsystem**.
6. Click **Build**, which starts the subsystem build process that creates a SIL or PIL block for the generated subsystem code.
7. Add the generated block to an environment or test harness model that supplies test vectors or stimulus input.
8. Run simulations with the environment or test harness model.

**Note** On a Windows operating system, the Windows Firewall can potentially block a SIL or PIL simulation. To allow the simulation, use the Windows Security Alert dialog box. For example, in Windows 7, click *Allow access*.

You cannot create a SIL or PIL block if you do one of the following:

- Disable the **CreateSILPILBlock** property.
- Select a code coverage tool.
Create block appears dimmed.

For a PIL simulation, you control the way code compiles and executes in the target environment through connectivity configurations.

Configure Hardware Implementation Settings

For a SIL simulation, you must configure hardware implementation settings, which enables generated code compilation for your development computer. These settings can differ from the hardware implementation settings that you use when building the model for your production hardware. Use one of these approaches.

<table>
<thead>
<tr>
<th>Approach</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Portable word sizes</td>
<td>Switch between SIL and PIL modes without regenerating code. You use the same generated source code files for the SIL simulation on your development computer and for production deployment on the target platform.</td>
</tr>
<tr>
<td></td>
<td>To configure a model to use portable word sizes, set:</td>
</tr>
<tr>
<td></td>
<td>• ProdEqTarget to 'on'.</td>
</tr>
<tr>
<td></td>
<td>• PortableWordSizes to 'on'.</td>
</tr>
<tr>
<td>Approach</td>
<td>Details</td>
</tr>
<tr>
<td>----------</td>
<td>---------</td>
</tr>
</tbody>
</table>
| When you generate code for a model with portable word sizes specified, the code generator conditionalizes data type definitions in `rtwtypes.h`:  
  ```c
  #ifdef PORTABLE_WORDSIZES /* PORTABLE_WORDSIZES defined */
  ...
  #else /* PORTABLE_WORDSIZES not defined */
  ...
  #endif /* PORTABLE_WORDSIZES */
  ```

  The template makefile that you use to build code for your target must not contain the `PORTABLE_WORDSIZES` definition.

  For the template makefile and toolchain approaches to building code, the software specifies `-DPORTABLE_WORDSIZES` for the compiler only for host-based builds.

  For information about the template makefile and toolchain approaches to building code, see “Choose Build Approach and Configure Build Process” (Simulink Coder).

Consider the case where your target uses code that your development computer cannot compile. When you switch from the PIL mode to the SIL mode and try to simulate the model, you see compilation errors. You can try to work around this problem by adding the source code files to the `SkipForSil` group in the build information object `RTW.BuildInfo`. The SIL build on the host platform does not compile source files present in the `SkipForSil` group. For information about how you add source code files to a group in the build information object, see:

- `addSourceFiles` in the Simulink Coder documentation
- “Customize Post-Code-Generation Build Processing” (Simulink Coder) in the Simulink Coder documentation
<table>
<thead>
<tr>
<th>Approach</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Numerical results can differ between generated code executing in a SIL simulation and generated code executing on the production hardware under one of these conditions:</td>
</tr>
<tr>
<td></td>
<td>• Your model contains blocks implemented in TLC, for which C integral promotion in expressions can behave differently between the MATLAB host and the production hardware target. Normal and PIL simulation results match, but SIL simulation results can differ.</td>
</tr>
<tr>
<td></td>
<td>• Your production hardware implements rounding to <strong>Floor</strong> for signed integer division, and divisions in your model use rounding mode <strong>Ceiling</strong>, <strong>Floor</strong>, <strong>Simplest</strong>, or <strong>Zero</strong>. Normal and PIL simulation results match, but SIL simulation results can differ.</td>
</tr>
<tr>
<td></td>
<td>• The byte ordering for your production hardware is <strong>Big Endian</strong>. Normal and PIL simulation results match, but SIL simulation results can differ. For example, when generated code depends on byte order and generated production code is implemented with the aim that its behavior matches normal simulation behavior.</td>
</tr>
<tr>
<td></td>
<td>• You use custom code with the Stateflow product. In this case, type conversion statements are not inserted into the custom code, which target overflow behavior on the host can require. Normal and PIL simulation results match, but SIL simulation results can differ.</td>
</tr>
<tr>
<td>Test hardware</td>
<td>Use this approach only when you want to work around a limitation of portable word sizes.</td>
</tr>
<tr>
<td></td>
<td>Set:</td>
</tr>
<tr>
<td></td>
<td>• <strong>PortableWordSizes</strong> to 'off'.</td>
</tr>
<tr>
<td></td>
<td>• <strong>ProdEqTarget</strong> to 'off'.</td>
</tr>
<tr>
<td></td>
<td>• <strong>TargetHWDeviceType</strong> to 'Custom Processor-&gt;MATLAB Host Processor'.</td>
</tr>
</tbody>
</table>
### Approach

**Details**

Use this approach only when the production hardware settings match your development computer architecture.

Set:

- **PortableWordSizes** to 'off'.
- **ProdEqTarget** to 'on'.
- **ProdHWDeviceType** to match your development computer architecture.

For information about test and production targets, see “Configure Run-Time Environment Options” (Simulink Coder) in the Simulink Coder documentation.

### Log Internal Signals of a Component

SIL and PIL component outputs are available for observation and comparison with other simulation mode outputs. If you want to examine an internal signal, you can enable internal signal logging for top-model or Model block SIL or PIL. With signal logging, you can:

- Collect signal logging outputs during SIL/PIL simulations, for example, `logsout`.
- Log the internal signals and the root-level outputs of a SIL/PIL component.
- Manage the SIL/PIL signal logging settings with the Simulink Signal Logging Selector.
- Use the Simulation Data Inspector to:
  - Observe streamed signals during normal, SIL, and PIL simulations.
  - Compare logged signals from normal, SIL, and PIL simulations.

For SIL and PIL signal logging:

- Set **Configuration Parameters** > **Data Import/Export** > **Format** to Dataset.
- Select the **Configuration Parameters** > **Code Generation** > **Interface** > **Generate C API for: signals** check box.

The C API determines the addresses of the internal signals that require logging.

You can use other methods to examine internal signals of the SIL or PIL component:
• Manually route the signal to the top level.
• Use global data stores to access internal signals:
  1. Inside the component, connect a Data Store Write block to the required signal.
  2. Outside the component, use a Data Store Read block to access the signal value.
• Use MAT-file logging. Note that:
  • MAT-file logging does not support signal logging. If signal logging is enabled, `logout` is generated but not stored in the MAT-file.
  • For PIL, the target environment must support MAT-file logging.

For more information, see:
• “Test Points” (Simulink)
• “Export Signal Data Using Signal Logging” (Simulink)
• “Local and Global Data Stores” (Simulink)
• “Global Data Store Example” (Simulink)
• “Log Program Execution Results” (Simulink Coder)

**Prevent Code Changes in Multiple Simulations**

Use Model block SIL/PIL or the SIL/PIL block with fast restart when you want to run multiple SIL or PIL simulations with:

• Varying test vectors (parameter sets and input data).
• Unchanged generated code, that is, none of the simulations regenerate or rebuild code after the initial build. For example, you want to avoid the incremental code generation that an initial value change can trigger.

For Model block SIL/PIL, you can also use one of these methods:

• In your test harness model, set **Configuration Parameters > Model Referencing > Rebuild** to **Never**. If the Model block **Code interface** parameter is **Model reference**, the software does not rebuild the referenced model code. (If the **Code interface** parameter is **Top model**, the software ignores the **Rebuild** setting.)
• Create a protected model and generate source or binary code. Then, insert the protected model in your test harness model. With this method, you can verify top-model code (with the standalone code interface) or model reference code.
For the alternative methods of running Model block SIL/PIL, the following table summarizes code generation behavior after the initial build.

<table>
<thead>
<tr>
<th>SIL and PIL Approach</th>
<th>Code Generation Behavior After Initial Build</th>
</tr>
</thead>
<tbody>
<tr>
<td>Model block</td>
<td><strong>Configuration Parameters</strong> &gt; <strong>Model Referencing</strong> &gt; <strong>Rebuild</strong> of test harness model set to <strong>Never</strong>.</td>
</tr>
<tr>
<td></td>
<td>1 Component (algorithm) code from initial build is not regenerated.</td>
</tr>
<tr>
<td></td>
<td>2 Component code makefile is not called.</td>
</tr>
<tr>
<td></td>
<td>3 SIL/PIL application files from initial build are not regenerated.</td>
</tr>
<tr>
<td></td>
<td>4 SIL/PIL application makefile is called.</td>
</tr>
<tr>
<td>Model block (protected model)</td>
<td>Source code from protected model.</td>
</tr>
<tr>
<td></td>
<td>You observe the same behavior except for feature 2. In this case, the component code makefile is run. The component code is recompiled and linked to produce new object code.</td>
</tr>
<tr>
<td></td>
<td>Binary code from protected model.</td>
</tr>
<tr>
<td></td>
<td>You observe features 1–4.</td>
</tr>
</tbody>
</table>

For more information, see:

- “Model Configuration Parameters: Model Referencing” (Simulink)
- “Create a Protected Model” (Simulink Coder)

**Speed Up Testing**

If your model has SIL/PIL blocks or Model blocks in SIL/PIL mode, you can speed up SIL/PIL testing by:

- Running the top-model simulation in accelerator mode (Simulink). This mode accelerates the simulation of model components that are not in SIL or PIL mode.
• Turning on fast restart (Simulink) with the **Fast restart** button on the Simulink Editor toolbar. After the first simulation, you can tune parameters and rerun simulations without model recompilation.

**Note** The SIL and PIL simulation modes are not designed for the reduction of model simulation times. If you want to speed up the simulation of your model, use the rapid accelerator mode. For more information, see “What Is Acceleration?” (Simulink).

### Simulation with Function Calls

Use the Simulink Function block and Function Caller block when you want to:

- Generate code that makes a function-call to external code, for example, driver or legacy code.
- Provide a subsystem that behaves like the external code in normal, SIL, or PIL simulations.

The example in “Configure Calls to AUTOSAR NVRAM Manager Service” shows how you can configure client calls to Basic Software (BSW) NVRAM Manager (NvM) service interfaces from your AUTOSAR software component. In a simulation, Simulink implements the BSW NvM calls through Simulink Function and preconfigured Function Caller blocks. For the final system, you link function-call stubs with external BSW function code that runs in the AUTOSAR Runtime Environment (RTE).

For more information, see “Simulink Function Blocks and Code Generation” (Simulink Coder).

There are three ways of running SIL and PIL simulations. You can use:

- The top model.
- Model blocks.
- SIL and PIL blocks that you create from subsystems.

### Simulation with Top Model

To configure and run a top-model SIL or PIL simulation:

1. Open your model.
2. Select either Simulation > Mode > Software-in-the-Loop (SIL) or Simulation > Mode > Processor-in-the-Loop (PIL). This option is available only if the model is configured for an ERT or AUTOSAR target. See “Model Configuration Parameters: Code Generation” (Simulink Coder) and “Generate AUTOSAR C Code and XML Component Descriptions” for configuration information.
3. If you have not already done so, in the Configuration Parameters dialog box, on the Data Import/Export pane:
   - In the Input check box and field, specify stimulus signals (or test vectors) for your top model.
   - Configure logging for model outputs, with either output logging or signal logging:
     - In the Output check box and field, specify output logging.
• In the **Signal logging** check box and field, specify *signal logging*.

• Disable logging of Data Store Memory variables. The software does not support this option for this simulation mode. If you do not clear the **Data stores** check box, the software produces a warning when you run the simulation.

**4** If you are configuring a SIL simulation, specify the portable word sizes option. You can then switch seamlessly between the SIL and PIL modes. Select **Code Generation > Verification > Enable portable word sizes**.

**5** If required, configure:

• Code coverage.

• Code execution profiling.

• Creation of code generation report and static code metrics.

**6** Start the simulation.

---

**Note** On a Windows operating system, the Windows Firewall can potentially block a SIL or PIL simulation. To allow the simulation, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

You cannot:

• Close the model while the simulation is running. To interrupt the simulation, in the Command Window, press **Ctrl+C**.

• Alter the model during the simulation. You can move blocks and lines as long as it does not alter the behavior of the model.

You can run a top-model SIL or PIL simulation with the command `sim(model)`. The software supports the `sim` command option `SrcWorkspace` for the value `'base'`.

For a PIL simulation, you control the way code compiles and executes in the target environment through connectivity configurations.

With a top-model SIL or PIL simulation, Simulink creates a hidden model, `modelName_wrapper`. The simulation generates code for the model and uses the hidden model to call this code at each time step. As a result, in some circumstances, logged signals can have a `_wrapper` suffix. The simulation can also generate warnings that refer to the hidden model. For example:

*Warning: The model 'modelName_wrapper' has the 'Configuration Parameters' ...*
Simulation with Model Blocks

To configure a Model block for a SIL or PIL simulation:

1. Open your model, for example, rtwdemo_sil_modelblock.
2. Right-click your Model block, for example, Counter A. In the context menu, select Block Parameters (ModelReference), which opens the Function Block Parameters dialog box.
3. From the Simulation Mode drop-down list, select the required mode, for example, Software-in-the-loop (SIL).
4. From the Code interface drop-down list, specify the code that you want to test, for example, Model reference.
5. Click OK. The software displays the simulation mode as a block label.

![Diagram of Model blocks]

If you select Top model, the software displays the block label (SIL: Top).

6. If you are configuring a SIL simulation, specify the portable word sizes option. You can then switch seamlessly between the SIL and PIL modes. Select Code Generation > Verification > Enable portable word sizes.

7. If required, configure:
   - Code coverage.
   - Code execution profiling for your Model block, by configuring execution profiling for the top model.
   - Creation of code generation report and static code metrics.

8. Start the simulation.
**Note** On a Windows operating system, the Windows Firewall can potentially block a SIL or PIL simulation. To allow the simulation, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

For a PIL simulation, you control the way code compiles and executes in the target environment through connectivity configurations.

**Simulation with Blocks From Subsystems**

To create a SIL or PIL block from a subsystem and use this block to test the code generated from the subsystem:

1. From the **Configuration Parameters > Code Generation > Advanced Parameters > Create block** drop-down list, select either SIL or PIL.
2. If required, configure code execution profiling.
3. Click **OK**.
4. In your model window, right-click the subsystem that you want to simulate.
5. Select **C/C++ Code > Build This Subsystem**.
6. Click **Build**, which starts the subsystem build process that creates a SIL or PIL block for the generated subsystem code.
7. Add the generated block to an environment or test harness model that supplies test vectors or stimulus input.
8. Run simulations with the environment or test harness model.

**Note** On a Windows operating system, the Windows Firewall can potentially block a SIL or PIL simulation. To allow the simulation, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

You cannot create a SIL or PIL block if you do one of the following:

- Disable the **CreateSILPILBlock** property.
- Select a code coverage tool.

**Create block** appears dimmed.
For a PIL simulation, you control the way code compiles and executes in the target environment through connectivity configurations.

**Log Internal Signals of a Component**

SIL and PIL component outputs are available for observation and comparison with other simulation mode outputs. If you want to examine an internal signal, you can enable internal signal logging for top-model or Model block SIL or PIL. With signal logging, you can:

- Collect signal logging outputs during SIL/PIL simulations, for example, `logslnt`.
- Log the internal signals and the root-level outputs of a SIL/PIL component.
- Manage the SIL/PIL signal logging settings with the Simulink Signal Logging Selector.
- Use the Simulation Data Inspector to:
  - Observe streamed signals during normal, SIL, and PIL simulations.
  - Compare logged signals from normal, SIL, and PIL simulations.

For SIL and PIL signal logging:

- Set **Configuration Parameters > Data Import/Export > Format** to Dataset.
- Select the **Configuration Parameters > Code Generation > Interface > Generate C API for: signals** check box.

The C API determines the addresses of the internal signals that require logging.

You can use other methods to examine internal signals of the SIL or PIL component:

- Manually route the signal to the top level.
- Use global data stores to access internal signals:
  1. Inside the component, connect a Data Store Write block to the required signal.
  2. Outside the component, use a Data Store Read block to access the signal value.
- Use MAT-file logging. Note that:
  - MAT-file logging does not support signal logging. If signal logging is enabled, `logslnt` is generated but not stored in the MAT-file.
  - For PIL, the target environment must support MAT-file logging.
For more information, see:

- “Test Points” (Simulink)
- “Export Signal Data Using Signal Logging” (Simulink)
- “Local and Global Data Stores” (Simulink)
- “Global Data Store Example” (Simulink)
- “Log Program Execution Results” (Simulink Coder)

**Prevent Code Changes in Multiple Simulations**

Use Model block SIL/PIL or the SIL/PIL block with fast restart when you want to run multiple SIL or PIL simulations with:

- Varying test vectors (parameter sets and input data).
- Unchanged generated code, that is, none of the simulations regenerate or rebuild code after the initial build. For example, you want to avoid the incremental code generation that an initial value change can trigger.

For Model block SIL/PIL, you can also use one of these methods:

- In your test harness model, set Configuration Parameters > Model Referencing > Rebuild to Never. If the Model block Code interface parameter is Model reference, the software does not rebuild the referenced model code. (If the Code interface parameter is Top model, the software ignores the Rebuild setting.)
- Create a protected model and generate source or binary code. Then, insert the protected model in your test harness model. With this method, you can verify top-model code (with the standalone code interface) or model reference code.

For the alternative methods of running Model block SIL/PIL, the following table summarizes code generation behavior after the initial build.
### SIL and PIL Approach

<table>
<thead>
<tr>
<th>Model block</th>
<th>Code Generation Behavior After Initial Build</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Configuration Parameters</strong> &gt; <strong>Model Referencing</strong> &gt; <strong>Rebuild</strong> of test harness model set to <strong>Never</strong>.</td>
<td>1 Component (algorithm) code from initial build is not regenerated.</td>
</tr>
<tr>
<td></td>
<td>2 Component code makefile is not called.</td>
</tr>
<tr>
<td></td>
<td>3 SIL/PIL application files from initial build are not regenerated.</td>
</tr>
<tr>
<td></td>
<td>4 SIL/PIL application makefile is called.</td>
</tr>
</tbody>
</table>

| Model block (protected model) | Source code from protected model. | You observe the same behavior except for feature 2. In this case, the component code makefile is run. The component code is recompiled and linked to produce new object code. |
| Binary code from protected model. | You observe features 1–4. |

For more information, see:

- “Model Configuration Parameters: Model Referencing” (Simulink)
- “Create a Protected Model” (Simulink Coder)

### Speed Up Testing

If your model has SIL/PIL blocks or Model blocks in SIL/PIL mode, you can speed up SIL/PIL testing by:

- Running the top-model simulation in accelerator mode (Simulink). This mode accelerates the simulation of model components that are not in SIL or PIL mode.
- Turning on fast restart (Simulink) with the **Fast restart** button on the Simulink Editor toolbar. After the first simulation, you can tune parameters and rerun simulations without model recompilation.
Note The SIL and PIL simulation modes are not designed for the reduction of model simulation times. If you want to speed up the simulation of your model, use the rapid accelerator mode. For more information, see “What Is Acceleration?” (Simulink).

Simulation with Function Calls

Use the Simulink Function block and Function Caller block when you want to:

- Generate code that makes a function-call to external code, for example, driver or legacy code.
- Provide a subsystem that behaves like the external code in normal, SIL, or PIL simulations.

The example in “Configure Calls to AUTOSAR NVRAM Manager Service” shows how you can configure client calls to Basic Software (BSW) NVRAM Manager (NvM) service interfaces from your AUTOSAR software component. In a simulation, Simulink implements the BSW NvM calls through Simulink Function and preconfigured Function Caller blocks. For the final system, you link function-call stubs with external BSW function code that runs in the AUTOSAR Runtime Environment (RTE).

For more information, see “Simulink Function Blocks and Code Generation” (Simulink Coder).

• “Simulation Mode Override Behavior in Model Reference Hierarchy” on page 77-39
• “SIL and PIL Limitations” on page 77-70
Simulation Mode Override Behavior in Model Reference Hierarchy

When the top model contains a Model block, the simulation mode of the top model can override the simulation mode of the Model block. The Model block itself can be a parent block containing child Model blocks at lower levels of its reference hierarchy. The simulation mode of the parent block can override the simulation mode of the child block.

You can specify the simulation mode of a top model to be normal, accelerator, rapid accelerator, SIL, or PIL. With a Model block, you can specify all modes except rapid accelerator. This table shows how the software determines the effective simulation mode of a Model block in a reference hierarchy.

<table>
<thead>
<tr>
<th>Mode of Top Model or Parent Block</th>
<th>Mode of Parent or Child Block in Reference Hierarchy</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Normal</td>
</tr>
<tr>
<td>Normal</td>
<td>Equivalent</td>
</tr>
<tr>
<td>Accelerator</td>
<td>Override</td>
</tr>
<tr>
<td>Rapid accelerator</td>
<td>Override</td>
</tr>
<tr>
<td>SIL</td>
<td>Override</td>
</tr>
<tr>
<td>PIL</td>
<td>Override</td>
</tr>
</tbody>
</table>

The different types of behavior are:

- **Equivalent** — Both parent and child Model block run in the same simulation mode.
- **Compatible** — The software simulates the child block in the mode specified for the child block, for example, when the simulation mode of the top model is normal or accelerator.
- **Error** — The simulation produces an error. For example, if a top model has simulation mode rapid accelerator but contains a child block in SIL or PIL mode, then running a simulation produces an error: the rapid accelerator mode cannot override the SIL and
PIL mode of child blocks. This behavior avoids the risk of “false positives”, that is, the simulation of a model in rapid accelerator mode does not lead to the conclusion that generated source or object code of child Model blocks is tested or verified.

- Override — The simulation mode of the top model or parent Model block overrides the simulation mode of the child block. For example, if a top model or parent Model block that you configured for a SIL simulation contains a child Model block with normal or accelerator simulation mode, then the software simulates the child block in SIL mode. The override behavior:

  - Allows a Model block in the reference hierarchy to have the SIL or PIL mode.
  - Makes lower-level referenced models execute in SIL or PIL mode if you simulate the top model or parent Model block in SIL or PIL mode. You do not have to switch the simulation mode of every model component in the hierarchy.

**Note** You can view your model hierarchy in the Model Dependency Viewer. In the Referenced Model Instances view, the software displays Model blocks differently to indicate their simulation modes, for example, normal, accelerator, SIL, and PIL. In this view, the software does not indicate the simulation mode of the top model.

Debug Generated Code During SIL Simulation

If a software-in-the-loop (SIL) simulation fails or you notice differences between the outputs of your original functions and the generated code, you can rerun the SIL simulation with a debugger enabled. By inserting breakpoints, you can observe the behavior of code sections, which can help you to understand the cause of the issue.

For a SIL simulation failure, you can also view information from the standard output and standard error streams in the Diagnostic Viewer. For example:

- Output from printf statements in your code.
- Error messages sent to stderr.
- Some low-level system messages.

During a SIL simulation, the SIL application redirects the stdout and stderr streams. When the application terminates, the Diagnostic Viewer displays the information from the redirected streams. The SIL application also provides a basic signal handler, which captures the POSIX® signals SIGFPE, SIGILL, SIGABRT, and SIGSEV. For this signal handler, the SIL application includes the file signal.h.

A SIL simulation supports these debuggers;

- On Windows, Microsoft Visual Studio debugger.
- On Linux, GNU Data Display Debugger (DDD).

**Note** You can perform SIL debugging only if the Simulink product family supports your Microsoft Visual C++ or GNU GCC compiler. For more information, see supported compilers.

To enable your debugger for a SIL simulation, on the Configuration Parameters > Code Generation > Verification pane, select the Enable source-level debugging for SIL check box.

If your top model has Model blocks, the Enable source-level debugging for SIL parameter for the top model overrides the corresponding parameter for referenced models.
When you run the SIL simulation, for example on a Windows computer, your `model.c` or `model.cpp` file opens in the Microsoft Visual Studio IDE with debugger breakpoints at the start of the `model_initialize` and `model_step` functions.

You can now use the debugger features to observe code behavior. For example, you can step through code and examine variables.

To end the debugging session:

1. Remove all breakpoints.
2. Click the Continue button (F5).

   The SIL simulation runs to completion and the Microsoft Visual Studio IDE closes.

Note In the Microsoft Visual Studio IDE, if you select **Debug > Stop Debugging**, the SIL simulation times out with the following error message:
The timeout of 1 seconds for receiving data from the rtiostream interface has been exceeded. There are multiple possible causes for this failure.

Target Connectivity Configurations for PIL

Use target connectivity configurations and the target connectivity API to customize processor-in-the-loop (PIL) simulation for your target environments.

Through a target connectivity configuration, you specify:

- A configuration name for a target connectivity API implementation.
- Settings that define the set of compatible Simulink models. For example, the set of models that have a particular system target file, template makefile, and hardware implementation.

A PIL simulation requires a target connectivity API implementation that integrates third-party tools for:

- Cross-compiling generated code, creating the PIL application that runs on the target hardware.
- Downloading, starting, and stopping the application on the target.
- Communicating between Simulink and the target.

You can have many different target connectivity configurations for PIL simulation. Register a connectivity configuration with Simulink by creating an sl_customization.m file and placing it on the MATLAB search path.

When you run a PIL simulation, the software determines which of the available connectivity configurations to use. The software looks for a connectivity configuration that is compatible with the model under test. If the software finds multiple or no
compatible connectivity configurations, the software generates an error message with information about resolving the problem.

**Create a Target Connectivity API Implementation**

This diagram shows the components of the PIL target connectivity API.

![Diagram showing PIL API Components](image)

You must provide implementations of the three API components:

- **Build API** — Specify the Simulink Coder toolchain or template makefile approach for building generated code.
- **Launcher API** — Control how Simulink starts and stops the PIL executable.
- **Communications API** — Customize connectivity between Simulink and the PIL target. Embedded Coder provides host-side support for TCP/IP and serial communications, which you can adapt for other protocols.
These steps outline how you create a target connectivity API implementation. The example code shown in the steps is taken from `ConnectivityConfig.m` in “Configure Processor-In-The-Loop (PIL) for a Custom Target” on page 77-108.

   
   ```
   ConnectivityConfig < rtw.connectivity.Config
   ```

2. In the subclass:
   
   ```
   • Instantiate `rtw.connectivity.MakefileBuilder`, which configures the build process.
   ```
   ```
   builder = rtw.connectivity.MakefileBuilder(componentArgs, ...
   targetApplicationFramework, ...
   exeExtension);
   ```
   ```
   • Create a subclass of `rtw.connectivity.Launcher`, which downloads and executes the application using a third-party tool.
   ```
   ```
   launcher = mypil.Launcher(componentArgs, builder);
   ```

3. Configure your `rtiostream` API implementation of the host-target communications on page 77-50 channel.
   
   ```
   • For the target side, you must provide the driver code for communications, for example, TCP/IP or serial communications. To integrate this code into the build process, create a subclass of `rtw.pil.RtIOStreamApplicationFramework`.
   ```
   ```
   • For the host side, you can use a supplied library for TCP/IP or serial communications. Instantiate `rtw.connectivity.RtIOStreamHostCommunicator`, which loads and initializes the library that you specify.
   ```
   ```
   hostCommunicator = rtw.connectivity.RtIOStreamHostCommunicator(componentArgs, ...
   launcher, ...
   rtiostreamLib);
   ```

4. If you require execution-time profiling of generated code, create a timer object that provides details of the hardware-specific timer and associated source files. See “Specify Hardware Timer” on page 77-56.

   **Note** Each time you modify a connectivity implementation, close and reopen the models to refresh them.
Register a Connectivity API Implementation

To register a target connectivity API implementation as a target connectivity configuration in Simulink:

1. Create or update an `sl_customization.m` file. In this file:
   - Create a target connectivity configuration object that specifies, for example, the configuration name for a target connectivity API implementation and compatible models.
   - Invoke `registerTargetInfo`.

2. Add the folder containing `sl_customization.m` to the search path and refresh your customizations.

   ```matlab
   addpath(sl_customization_path);
   sl_refresh_customizations;
   ```

For more information, see `rtw.connectivity.ConfigRegistry`.

Verify Target Connectivity Configuration

To verify your target connectivity configuration early on and independently of your model development and code generation, use the supplied `piltest` function. With the function, you can run a suite of tests. In the tests, the function runs various normal, SIL, and PIL simulations. The function compares results and produces errors if it detects differences between simulation modes.

Target Connectivity API Examples

For step-by-step examples, see:

- “Configure Processor-In-The-Loop (PIL) for a Custom Target” on page 77-108

  This example shows you how to create a custom PIL implementation using the target connectivity APIs. You can examine the code that configures the build process to support PIL, a downloading and execution tool, and a communication channel between host and target. To activate a full host-based PIL configuration, follow the steps in the example.

- “Create a Target Communication Channel for Processor-In-The-Loop (PIL) Simulation” on page 77-101
This example shows you how to implement a communication channel for use with the Embedded Coder product and your embedded target. This communication channel enables exchange of data between different processes. PIL simulation requires exchange of data between the Simulink software running on your development computer and deployed code executing on target hardware.

The `rtiostream` interface provides a generic communication channel that you can implement in the form of target connectivity drivers for a range of connection types. The example shows how to configure your own target-side driver for TCP/IP, to operate with the default host-side TCP/IP driver. The default TCP/IP communications allow high-bandwidth communication between host and target, which you can use for transferring data such as video.

**Note** If you customize the `rtiostream` TCP/IP implementation for your PIL simulations, you must turn off Nagle's algorithm for the server side of the connection. If Nagle's algorithm is not turned off, your PIL simulations can run at a significantly slower speed. The `matlabroot/rtw/c/src/rtiostream/rtiostreamtcpip/rtiostream_tcpip.c` file shows how you can turn off Nagle's algorithm:

```c
/* Disable Nagle's Algorithm*/
option = 1;
sockStatus = setsockopt(lFd,IPPROTO_TCP,TCP_NODELAY,(char*)&option,sizeof(option));
```

The code for your custom TCP/IP implementation can require modification.

The example also shows how to implement custom target connectivity drivers, for example, using serial, CAN, or USB for both host and target sides of the communication channel.

Host-Target Communication for PIL

In this section...

“Communications rtiostream API” on page 77-50
“Synchronize Host and Target” on page 77-51
“Test an rtiostream Driver” on page 77-52
“Word Addressable Target Hardware” on page 77-54

Communications rtiostream API

The rtiostream API supports communications for the target connectivity API. Use the rtiostream API to implement a communication channel that enables data exchange between different processes.

PIL simulation requires a host-target communications channel. This communications channel comprises driver code that runs on the host and target. The rtiostream API defines the signature of target-side and host-side functions that this driver code must implement.

The API is independent of the physical layer that sends the data. Possible physical layers include RS232, Ethernet, or Controller Area Network (CAN).

A full rtiostream implementation requires both host-side and target-side drivers. Code generation software includes host-side drivers for the default TCP/IP implementation and a version for serial communications. To use:

- The TCP/IP rtiostream communications channel, you must provide, or obtain from a third party, target-specific TCP/IP device drivers.
- The serial communications channel, you must provide, or obtain from a third party, target-specific serial device drivers.

For other communication channels and platforms, the code generation software does not provide default implementations. You must provide both the host-side and the target-side drivers.

The rtiostream API comprises the following functions:

- rtIOStreamOpen
• rtIOStreamSend
• rtIOStreamRecv
• rtIOStreamClose

For information about:

• Using rtiostream functions in a connectivity implementation, see “Create a Target Connectivity API Implementation” on page 77-45.
• Testing the rtiostream shared library methods from MATLAB code, see rtiostream_wrapper.
• Debugging and verifying the behavior of custom rtiostream interface implementations, see “Test an rtiostream Driver” on page 77-52.

**Synchronize Host and Target**

If you use the rtiostream API to implement the communications channel, the host and target must be synchronized, which prevents Simulink from transmitting and receiving data before the target application is fully initialized.

To synchronize the host and target for TCP/IP rtiostream implementations, use the setInitCommsTimeout method from rtw.connectivity.RtIOStreamHostCommunicator. This approach works well for connection-oriented TCP/IP rtiostream implementations because Simulink automatically waits until the target server is running.

With other rtiostream implementations, for example, serial, the Simulink side of the rtiostream connection opens without waiting for the target to be fully initialized. In this case, you must make your Launcher implementation wait until the target application is fully initialized. Use one of the following approaches to synchronize your host and target:

• Add a pause at the end of the Launcher implementation that makes the Launcher wait until target initialization is complete.
• In the Launcher implementation, use third-party downloader or debugger APIs that wait until target initialization is complete.
• Implement a handshaking mechanism in the Launcher/rtiostream implementation that confirms completion of target initialization.
**Test an rtiostream Driver**

Use a test suite to debug and verify the behavior of custom `rtiostream` interface implementations.

The test suite has the following advantages:

- Reduces time for integrating custom hardware that does not have built-in `rtiostream` support.
- Reduces time for testing custom `rtiostream` drivers.
- Helps analyze the performance of custom `rtiostream` drivers.

The test suite has two parts. One part of the test suite runs on the target.

**Note** After building the target application, download it to the target and run it.

To start this part, compile and link the following files, which are in the folder `matlabroot/toolbox/coder/rtiostream/src/rtiostreamtest` (open).

- `rtiostreamtest.c`
- `rtiostreamtest.h`
- `rtiostream.h`, located in the folder `matlabroot/rtw/c/src` (open)
- `rtiostream` implementation under investigation (for example, `rtiostream_tcpip.c`)
- `main.c`

To run the MATLAB part of the test suite, invoke `rtiostreamtest`. The syntax is as follows:

```
rtiostreamtest(connection, param1, param2)
```

- `connection` is a character vector indicating the communication method. It can have values 'tcp' or 'serial'.
- `param1` and `param2` have different values depending on the value of `connection`.
  - If `connection` is 'tcp', then `param1` and `param2` are hostname and port, respectively. For example, `rtiostreamtest('tcp', 'localhost', 2345).`
• If connection is 'serial', then param1 and param2 are COM port and baud rate, respectively. For example, `rtiostreamtest('serial', 'COM1', 9600).

You can run the MATLAB part of the test suite as follows:

```matlab
rtiostreamtest('tcp','localhost','2345')
```

An output in the following format appears in the MATLAB window:

```gamma
### Test suite for rtiostream ###
Initializing connection with target...

### Hardware characteristics discovered
Size of char : 8 bit
Size of short : 16 bit
Size of int : 32 bit
Size of long : 32 bit
Size of float : 32 bit
Size of double : 64 bit
Size of pointer : 64 bit
Byte ordering : Little Endian

### rtiostream characteristics discovered
Round trip time : 0.96689 ms
rtIOStreamRecv behavior : non-blocking

### Test results
Test 1 (fixed size data exchange): ......... PASS
Test 2 (varying size data exchange): ......... PASS

### Test suite for rtiostream finished successfully ###
```

Furthermore, the following profile appears.
Word Addressable Target Hardware

On the **Hardware Implementation** pane, when you specify **Device vendor** and **Device type** settings, you provide PIL simulations with memory addressing information about the target hardware.
For example, consider the case when **Device vendor** is set to Texas Instruments and **Device type** is set to C5000.

The settings specify that the target hardware uses 16-bit word addresses and big-endian word order. The rtiostream implementation operates with 16-bit words.

On the target hardware, if an `rtIOStream` function specifies a size of 1, then the target hardware must send or receive one 16-bit word (2 bytes). `sizeof(char)` and `sizeof(short)` return 1, which corresponds to one 16-bit word. The `rtIOStream` function expects the byte order within the word to be little-endian, that is, less significant bytes are transmitted before more significant bytes.

`rtiostreamtest` identifies the target hardware and handles data in terms of 16-bit words, for example, a byte value is transferred as a 16-bit word value.

Specify Hardware Timer

For processor-in-the-loop (PIL) code execution profiling, you must create a timer object that provides details of the hardware-specific timer and associated source files. You can use the Code Replacement Tool or the code replacement library API to specify this hardware-specific timer.

To specify the timer with the Code Replacement Tool:

1. Open the Code Replacement Tool. In the Command Window, enter `crtool`.
3. Create a new function entry. Under `Tables List`, right-click the new table. Then, from the context-menu, select `New entry > Function`.
4. In the middle view, select the new unnamed function.
5. On the `Mapping Information` pane:
   a. From the `Function` drop-down list, select `code_profile_read_timer`.
   b. Specify the count direction for your timer. For example, from the `Count direction` drop-down list, select `Up`.
   c. In the `Ticks per second` field, specify the number of ticks per second for your timer, for example, `1e+09`.
      The default value is 0. In this case, the software reports time measurements in terms of ticks, not seconds.
   d. In the `Name` field, specify a replacement function name, for example, `MyTimer`.
   e. Click `Apply`. 

---

77-56
To validate the function entry, click **Validate entry**.

6 On the **Build Information** pane, specify the required build information. See “Specify Build Information for Replacement Code” on page 64-61.

7 Save the table (**Ctrl+S**). When you save the table for the first time, use the Save As dialog box to specify the file name and location.

You must save the table in a location that is on the MATLAB search path. For example, you can save this file in the folder for your subclass of `rtw.connectivity.Config`.

The software stores your timer information as a code replacement library table.

8 Assuming you save the table as `MyCrlTable.m`, in your subclass of `rtw.connectivity.Config`, add the following line:

```matlab
setTimer(this, MyCrlTable)
```

# PIL Simulation Sequence

A processor-in-the-loop (PIL) simulation cross-compiles production source code, and then downloads and runs object code on your target hardware. The connectivity configuration that you create controls the way code is compiled and executed on the target. This table describes the sequence of stages in a PIL simulation.

<table>
<thead>
<tr>
<th>Stage</th>
<th>Description</th>
</tr>
</thead>
</table>
| 1 Start | For top-model PIL, on the Simulink Editor toolbar, you select the Processor-in-the-Loop (PIL) mode, and then click the Run button.  
For Model block PIL, you set the **Simulation mode** parameter of the Model block to Processor-in-the-loop (PIL), and then run a simulation of the harness model that contains the Model block.  
For the PIL block, you run a simulation of the harness model that contains the PIL block. |
| 2 Validate target connectivity | The software verifies that a target connectivity configuration is registered for PIL. Otherwise, the software produces an error. |
| 3 Generate production source code and build object code for target | The generated source code is identical to the code that is produced when you run the `slbuild` command.  
- For top-model PIL or Model block PIL with block parameter **Code interface** set to Top model, the generated code is identical to the code produced when you run `slbuild('model')`.  
- For Model block PIL with block parameter **Code interface** set to Model reference, the generated code is identical to the code produced when you run `slbuild('model', 'ModelReferenceRTWTargetOnly')`.  
The software builds object code for the target by using the template makefile or toolchain that you specify. |
<table>
<thead>
<tr>
<th>Stage</th>
<th>Description</th>
</tr>
</thead>
</table>
| 4     | Create instances of PIL API components  
The software instantiates your `rtw.connectivity.Config` class, which creates instances of `rtw.connectivity.MakefileBuilder`, `rtw.connectivity.Launcher`, `rtw.pil.RtIOStreamApplicationFramework`, and `rtw.connectivity.RtIOStreamHostCommunicator`. |
| 5     | Generate PIL files  
The generated PIL files are in the `pil` folder. At the end of the simulation, use the code generation report to view the files. |
| 6     | Build target application  
The software:  
- Uses your instance of `rtw.connectivity.MakefileBuilder` to build the target application.  
- Compiles the PIL interface file, `xil_interface.c`, and other PIL files into the target executable file. On a Windows system, for example, this file is called `modelName.exe`. The object code, including the executable file, is in the `pil` folder.  
- If configured, produces the code generation report. |
| 7     | Start target application  
The software uses `rtw.connectivity.Launcher` to start the application on the target. |
| 8     | Simulink engine interacts with PIL S-function  
The Simulink engine interacts with the PIL S-function in the same way that it interacts with a C S-function.  
From the host-side, the PIL S-function communicates with the target executable code through `rtIOStream` commands. On the target side, `xil_interface` executes generated code. |
| 9     | Stop target application  
The software uses `rtw.connectivity.Launcher` to stop the application on the target. |
<table>

Verification of Code Generation Assumptions

At the start of a software-in-the-loop (SIL) or processor-in-the-loop (PIL) simulation, the software verifies some configuration parameter settings with reference to the target hardware.

For example, the settings on the Configuration Parameters > Hardware Implementation pane specify target behavior, which result in the implementation of implicit assumptions in the generated code. Incorrect settings can lead to:

- Suboptimal code
- Code execution failure, incorrect code output, and nondeterministic code behavior

The software checks:

- The correctness of settings. For example, the integer bit length in the Number of bits: int field.
- Whether the settings are optimized. For example, the rounding of signed integer division in the Signed integer division rounds to field.

The simulation generates a Coder Assumptions page on page 52-17 for the code generation report, which provides a list of:

- Code generation assumptions that are checked
- Expected results for the assumption checks

This table shows when checks occur and outcomes when code generation assumptions are incorrect.
<table>

- “Check Code Generation Assumptions” on page 52-15
View SIL and PIL Files in Code Generation Report

With top-model and Model block SIL and PIL simulations, you can produce a code generation report and static code metrics that cover SIL and PIL files. The information helps you to:

- Understand and review the SIL and PIL testing process.
- See how your registered custom target connectivity files fit into the target application that runs during a SIL or PIL simulation.

This capability is not supported for simulations that you run with the PIL block.

To configure the creation of a code generation report and static code metrics, on the Configuration Parameters > Code Generation > Report pane, select the Create code generation report, Open report automatically, and Static code metrics check boxes. Then click OK.

At the end of the simulation, in the Code Generation Report window:

- To review code metrics, in the Contents view, click Static Code Metrics Report.
- To review SIL and PIL files, in the Generated Code view, expand the SIL/PIL files node. For example:
  - To review the S-function that runs on the host, click modelName_sbs.c or modelName_pbs.c.
  - To view the SIL or PIL interface that runs on the target, click xil_interface.c.
**Note** Do not use the SIL or PIL files in code development as these files can change over releases. Use supplied APIs for code development.

About SIL and PIL Limitations

With Embedded Coder, you can run software-in-the-loop (SIL) and processor-in-the-loop (PIL) simulations in three ways:

• Top-model SIL/PIL — Set the top-model simulation mode to Software-in-the-Loop (SIL) or Processor-in-the-Loop (PIL).
• Model block SIL/PIL — Set the Model block parameter **Simulation mode** to Software-in-the-loop (SIL) or Processor-in-the-loop (PIL).
• SIL/PIL block — Use SIL or PIL blocks in the model.

The following sections describe modeling and code generation features that are either unsupported or partially supported by SIL and PIL simulations.

General SIL and PIL Limitations

Tunable Parameters and SIL/PIL

For Model block SIL/PIL and SIL/PIL block simulations, you can tune tunable **workspace** parameters but not tunable **dialog box** parameters. For information about tuning parameters, see “Tune and Experiment with Block Parameter Values” (Simulink).

For a top model with tunable parameters, you can run a SIL/PIL simulation but you cannot tune the parameters during the simulation.

The software cannot define, initialize, or tune the following types of tunable workspace parameters.
<table>
<thead>
<tr>
<th>Parameter description</th>
<th>Software response</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parameters with storage class that applies &quot;static&quot; scope or &quot;const&quot; keyword. For example, Custom, Const, or ConstVolatile</td>
<td>Top-Model SIL/PIL: Warning</td>

<tr>
<td>Parameters with multiword, fixed-point data types</td>
<td>Top-Model SIL/PIL: Warning</td>
</tr>
<tr>
<td>Parameters with data types that have different sizes on host and target</td>
<td>Top-Model SIL/PIL: Warning</td>
</tr>
</tbody>
</table>

For C++ class code, SIL/PIL you can tune tunable workspace parameters when Parameter visibility is public. If Parameter visibility is private or protected, tuning is supported only if Parameter access is Method or Inlined method.

For top-model SIL/PIL and the SIL/PIL block, consider the case where all of the following conditions apply:

- **Code Generation > Interface > Code interface packaging** is Reusable function.
- **Code Generation > Interface > Use dynamic memory allocation for model initialization** is not selected.
- **Optimization > Default parameter behavior** is Tunable.
- In the Code Mapping Editor for the model, the default storage class for the Global parameters or Local parameters category is set to Default, and the model contains corresponding parameters that use the storage classes Auto or Model default.

If the SIL/PIL component cannot dynamically initialize tunable parameters in the rtP model parameter structure, you see an error message like the following:

```
Parameter Dialog: Initial Output in 'rtwdemo_sil_topmodel/CounterTypeA/count' is part of the imported "rtP" structure in the generated code but cannot be initialized by SIL or PIL. To avoid this error, make sure the parameter corresponds to a tunable workspace variable. Alternatively, set "Configuration Parameters > Code Generation > Interface > Code interface packaging" to 'Nonreusable function', or search for 'Use dynamic memory allocation'.
```
for model initialization'' in the Configuration Parameters dialog box and select the checkbox.

If you select Code Generation > Interface > Use dynamic memory allocation for model initialization, this limitation does not apply.

For Model block SIL/PIL, if you specify Code interface to be Top model, you can tune parameters while a simulation runs. If you tune parameters between successive runs of the simulation, the software generates new code for the later run. The new code uses your latest settings as initial parameter values.

For top model or Model block SIL/PIL, if you change the value of a MATLAB variable or parameter object (such as Simulink.Parameter) that you store in a workspace, Simulink Coder regenerates the C code.

Global and Local Data Stores

SIL/PIL supports global data stores. For components that are not export-function models, top-model SIL/PIL and SIL/PIL block simulations that access global data stores must be single rate. Otherwise, the software produces an error.

SIL/PIL does not support local data stores.

Model block SIL/PIL does not support local Data Store Memory blocks that have these parameter settings:

- **Share across model instances** – Selected.
- **Storage class** – Auto or Model default.

You cannot create SIL/PIL blocks from models that use local Data Store Memory blocks with the Share across model instances parameter selected.

SIL/PIL Does Not Check Simulink Coder Error Status

SIL/PIL does not check the Simulink Coder error status of the generated code under test. This error status flags exceptional conditions during execution of the generated code.

Blocks in the model can also set the Simulink Coder error status, for example, custom blocks that you create. SIL/PIL does not check this error status and report errors.

Missing Code Interface Description File Errors

SIL/PIL requires a code interface description file, which is created during code generation for the component under test. If the code interface description file is missing, the SIL/PIL
simulation cannot proceed. You see an error reporting that the file does not exist. If you select the unsupported option Classic call interface, this error can occur. Therefore, do not select the option.

To Workspace Block

If you enable MAT-file logging, top-model SIL/PIL and SIL/PIL blocks support To Workspace blocks.

Model block SIL/PIL does not support To Workspace blocks.

Cannot Connect SIL/PIL Outputs to Merge Block

If you connect Model block SIL/PIL or SIL/PIL block outputs to a Merge block, you see an error because S-function memory is not reusable.

Variant Condition Propagation with Variant Source and Variant Sink Blocks

Top-model SIL/PIL and SIL/PIL block simulations do not support the propagation of variant conditions across component boundaries.

Unsupported Blocks

SIL/PIL does not support the following blocks:

- Scope blocks, and all types of run-time display. For example, display of port values and signal values.
- Stop blocks. SIL/PIL ignores the Stop Simulation block and continues simulating.

Multiword Fixed-Point I/O

You cannot run SIL and PIL simulations of models that have multiword, fixed-point signals across component boundaries.

Fixed-Point Data Types Wider Than 32 Bits

SIL/PIL supports fixed-point data types that are wider than 32 bits. For example:

- 64-bit long and long long
- 64-bit execution profiling timer data type
- int64 and uint64 in MATLAB Coder SIL execution.
The following constraints apply:

- For 64-bit data type support, the data type must be representable as long or long long on the MATLAB host and the target. Otherwise, the software uses the multiword, fixed-point approach, which SIL/PIL does not support.
- The software does not support the 40-bit long data type of the TI’s C6000™ target.

Through the Configuration > Hardware Implementation pane, you can enable support for the 64-bit long long data type. For data types with widths between 33 and 40 bits (inclusive), the software implements the data types using the 40-bit long data type, which SIL/PIL does not support.

Data Type Replacement

The software does not support replacement data type names that you define for the built-in data type boolean if these names map to the int or uint built-in data type.

Continuous Sample Times

Top-model SIL/PIL and SIL/PIL block do not support continuous sample times at the SIL or PIL component boundary. However, they support continuous sample times within the component.

Model block SIL/PIL does not support continuous sample times.

Variable-Size Signals

Model block SIL/PIL simulations support variable-size signals only if Diagnostics > Model Referencing > Propagate sizes of variable-size signals is During execution.

Top-model SIL/PIL and SIL/PIL block simulations treat variable-size signals at the I/O boundary of the SIL/PIL component as fixed-size signals, which can lead to errors during propagation of signal sizes. To avoid such errors, use only fixed-size signals at the I/O boundary of the SIL/PIL component.

There can be cases where no error occurs during propagation of signal sizes. In these cases, the software treats variable-size input signals as zero-size signals.

Internal Signal Logging

SIL/PIL blocks do not support signal logging. For a workaround, see “Log Internal Signals of a Component” on page 77-25.
The following internal signal logging limitations apply to top-model and Model block SIL/PIL simulations.

<table>
<thead>
<tr>
<th>Limitation</th>
<th>Applies To</th>
</tr>
</thead>
<tbody>
<tr>
<td>Only signals that are included in the C API are logged during SIL/PIL simulation. To observe the signals in the generated code, you can configure the signals as test points. For each signal, select the <strong>Signal Properties &gt; Test point</strong> check box.</td>
<td>Yes</td>
</tr>
<tr>

</tr>
</tbody>
</table>

**Custom Storage Class of Type Other**

SIL/PIL simulations support the custom storage class where **Type** is set to **Other** on page 77-10. These limitations apply:

- If the code fragments returned by the TLC file associated with the custom storage class are incomplete, the SIL/PIL application might fail to compile, or produce incorrect results.
- Custom storage classes with **Imported** scope and **Pointer** access are supported, but you must provide code to initialize the pointer. For example, you can modify the response to `DataAccess(record, "define", ",", ",")` to provide a definition of the storage implementation, and initialize the pointer to the address of the implementation variable.
To determine whether a variable is `const` and therefore not tunable, the build process for the SIL/PIL application uses the memory section definition in the custom storage class. If the custom storage class defines a variable as `const` and is not associated with a `const` memory section, the target application might fail to compile, or produce an error during the simulation. In this case, associate the custom storage class with a memory section for which `Is const` is specified, for example, `MemConst`. Alternatively, if `SupportSILPIL` is an instance-specific parameter in the custom attributes class, for the associated signal or parameter, set `CoderInfo.CustomAttributes.SupportSILPIL` to `false`.

**Unsupported Implementation Errors**

If you use a data store, signal, or parameter implementation that SIL/PIL does not support, you can see errors like the following:

The following *data interfaces* have implementations that are not supported by SIL or PIL.

*data interfaces* can be global data stores, *inports*, *outports*, or *parameters*.

The model output port has been optimized through virtual output port optimization. See “Virtualized Output Ports Optimization” on page 68-17. The error occurs because the properties (for example, data type, dimensions) of the signal or signals entering the virtual root output port have been modified by routing the signals in one of the following ways:

- Through a Mux block.
- Through a block that changes the signal data type. To check the consistency of data types in the model, display Port Data Types by selecting **Display > Signals & Ports > Port Data Types** (see “Port Data Types” (Simulink)).
- Through a block that changes the signal dimensions. To check the consistency of data types in the model, display dimensions by selecting **Display > Signal & Ports > Signal Dimensions**.

Dimension changes from scalar (1) to matrix [1x1], and, matrix [1x1] to scalar (1), can lead to this error. It is difficult to inspect the model for such changes because **Display > Signal & Ports > Signal Dimensions** does not distinguish between (1) and [1x1] dimensions. Both signals are displayed as scalar signals. Check your model and workspace objects carefully. Make sure that you specify scalar dimensions consistently.

The following model causes this error by changing the output port signal data type.
Hardware Implementation

PIL does not support multiword data types where the word order differs from the target byte order. The PIL simulation fails, displaying undefined behavior.

PIL requires that you configure the correct Hardware Implementation settings for the target environment, including byte ordering for targets. If you do not specify the correct byte ordering, the PIL simulation fails, displaying undefined behavior.

Non-ASCII Characters in Folder Name

If the name of the current working folder contains non-ASCII characters, you cannot run a SIL simulation.

State Logging

SIL/PIL does not support state logging (Simulink).

Bus Elements Mapped to Imported Bit-Field Definitions

If you map Simulink bus elements to bit fields through an imported header file, a SIL or PIL simulation produces a build error. For example, if your model has an Inport block connected to a bus that is a Simulink.Bus object with these properties:

• Name — myBus
• **Bus elements** — An array of Simulink.BusElement objects with these properties.

<table>
<thead>
<tr>
<th>Name</th>
<th>DataType</th>
<th>Complexity</th>
<th>Dimensions</th>
</tr>
</thead>
<tbody>
<tr>
<td>bitField0</td>
<td>boolean</td>
<td>real</td>
<td>1</td>
</tr>
<tr>
<td>bitField1</td>
<td>boolean</td>
<td>real</td>
<td>1</td>
</tr>
<tr>
<td>bitField2</td>
<td>boolean</td>
<td>real</td>
<td>1</td>
</tr>
<tr>
<td>bitField3</td>
<td>boolean</td>
<td>real</td>
<td>1</td>
</tr>
<tr>
<td>bitField4</td>
<td>boolean</td>
<td>real</td>
<td>1</td>
</tr>
<tr>
<td>bitField5</td>
<td>boolean</td>
<td>real</td>
<td>1</td>
</tr>
</tbody>
</table>

• **Data scope** — Imported

• **Header file** — busSpecification.h. This file contains myBus, which defines C bit-field data types for the bus elements.

```c
typedef struct myBus
{
    unsigned int bitField0 : 1;
    unsigned int bitField1 : 1;
    unsigned int bitField2 : 1;
    unsigned int bitField3 : 1;
    unsigned int bitField4 : 1;
    unsigned int bitField5 : 1;
} myBus;
```

**Size Mismatch Between Simulink and Target Hardware Data Types**

When a Simulink data type and the corresponding target hardware data type differ in size, a SIL or PIL simulation produces an error. This size mismatch can occur if you map a Simulink data type to the target hardware data type through definitions in an imported header file. For example, if you create a data type alias, T_BOOL, which is a Simulink.AliasType object with these properties:

• **Base type** — boolean.
• **Mode** — Built in, boolean.
• **Data scope** — Imported.
• **Header file** — myDefinitions.h. This file defines T_BOOL as an enumerated data type:

```c
typedef enum _BOOL_TYPE
{
```
FALSE = 0,
TRUE = 1
} BOOL_TYPE;

typedef BOOL_TYPE T_BOOL;

In this case, the compiler for the target hardware determines the size of T_BOOL, which can differ from the size of the Simulink data type, boolean.

SIL Simulations with Target-Specific Custom Code

Target-specific custom code that is not portable for execution on your development computer can produce compilation or run-time failures during a SIL simulation.

For example, SIL does not support the use of custom code that explicitly casts pointers to integer-type variables that are smaller than the length of a pointer variable on your development computer. Consider using one of these alternatives:

- Run a PIL simulation.
- If you have custom code that casts pointers to a 32-bit integer type, for your development computer, set up a PIL target connectivity configuration that uses a toolchain that is configured to build a 32-bit binary application.

Top-Model SIL/PIL Limitations

Top-Model Root-Level Logging

Top-model SIL/PIL supports signal logging for signals connected to root-level inports and outports. The C API is not required. Root-level logging has the following limitations:

- The characteristics of the logged data such as data type, sample time, and dimensions must match the characteristics of the root-level inports and outports (rather than the characteristics of the connected signal).

In some cases, there can be differences in data type and dimensions between the signal being logged and the root inport or outport that the signal is connected to. Consider the following examples.

- If a signal being logged has matrix dimensions \([1\times 5]\) but the outport connected to the signal has vector dimensions (5), then the data logged during a SIL or PIL simulation has vector dimensions (5).
• If a signal being logged has scalar dimensions but the outport connected to the signal has matrix dimensions \([1 \times 1]\), then the data logged during a SIL or PIL simulation has matrix dimensions \([1 \times 1]\).

• Signals connected to duplicated inports are not logged during SIL/PIL simulation. No warning is issued.

  During normal simulation, signals connected directly to duplicated inports are logged.

• The Signal Logging Selector / DataLoggingOverride override mechanism is not supported.

• Normal and SIL/PIL simulations log bus signals with names that are different when all of the following conditions apply:

  • The SaveOutput or SignalLogging configuration parameter is on.
  • The names of the elements in the bus signal are different from the corresponding names in the bus object. For example, when the InheritFromInputs parameter for a Bus Creator block is set to 'on'.

• The software inserts the suffix, _wrapper for output logging, if the save format is Structure, Structure with time, or Dataset and you run the sim command without specifying the single-output format. The software adds _wrapper to the block name for signals in yout. If the save format is Array, the software does not add the suffix. For example:

```
>> yout.signals
ans =
values: [11x1 double]
dimensions: 1
label: 'SignalLogging'
blockName: 'sillogging_wrapper/OutputLogging'
```

To avoid this behavior, run command-line simulations with the sim command specifying the single-output format. See “Run Simulations Programmatically” (Simulink).

**Model in Compiled State During Top-Model SIL/PIL**

During a top-model SIL/PIL simulation, the software places the model in a compiled state – see model. This action can result in a conflict over global resources between the model and the generated SIL/PIL code. In this case, differences between normal mode and SIL/PIL simulation outputs can result.
For example, consider a model that uses UDP blocks from the DSP System Toolbox. These blocks open UDP sockets, which can lead to resource contention between the model and the generated SIL/PIL code.

**Callback Support**

SIL/PIL does not support the callbacks (model or block) StartFcn and StopFcn.

**Note** Top-model SIL/PIL supports the callback InitFcn.

**Incremental Build**

When you start a top-model SIL/PIL simulation, the software regenerates code if it detects changes to your model. The software detects changes by using a checksum for the model. The software does not detect changes that you make to:

- The HeaderFile property of a Simulink.AliasType object
- Legacy S-functions

If you make these changes, build (Ctrl-B) your model again before starting the next PIL simulation.

**Model Block SIL/PIL Limitations**

**Top-Model Code Testing**

The following limitations apply:

- Because model arguments do not apply to a top model, when the Code interface block parameter is set to Top model, the software does not support the Model arguments block parameter.

- Conditional execution does not apply to a top model. If a Model block is set up to execute conditionally and the Code interface block parameter is set to 'Top model', the software produces an error when you run a SIL or PIL simulation.

- For sample time independent models, you must set Configuration Parameters > Solver > Periodic sample time constraint to Ensure sample time independent.
Conditionally Executed Subsystem

You see an error if:

- You place your Model block, in either SIL or PIL simulation mode, in a conditionally executed subsystem and the referenced model is multirate (that is, has multiple sample times). Single-rate, referenced models (with only a single sample time) are not affected.
- Your Model block, in either SIL or PIL simulation mode, has blocks that depend on absolute time and is conditionally executed.

Outputs with Constant Sample Time

If the block parameter Code interface is Top model, Model block SIL/PIL supports outputs with constant sample time.

Noninlined S-Functions

Model-block SIL/PIL simulations do not support noninlined S-functions.

Referenced Models That Use Same Target Connectivity Configuration

Consider a top model with two or more Model blocks that reference models that use the same target connectivity configuration. If the Model blocks are in PIL mode simultaneously, you cannot run a simulation of the top model. An error occurs.

SIL and PIL Instances of a Referenced Model

Consider a top model that contains two instances of a Model block that reference the same model. If one instance is in SIL mode and the other instance is in PIL mode, you cannot run a simulation of the top model. An error occurs.

SIL/PIL Block Limitations

PIL Block Mux

The PIL block supports mux signals, except mixed data-type mux signals that expand into individual signals during a right-click subsystem build.
**Code Coverage**

SIL block simulations do not support the generation of code coverage results. PIL block support for code coverage depends on your target connectivity configuration and third-party product support.

**Subsystem with Inherited Sample Time Blocks**

When you create a SIL/PIL block from a subsystem that has blocks with inherited sample times, the generated code and SIL/PIL wrapper acquire the sample time of the original parent model. If you use the SIL/PIL block in a context that does not allow explicit sample times, for example, within a triggered subsystem, you see an error.

Try one of these workarounds:

- Before you create the SIL/PIL block, in the parent model, set **Configuration Parameters > Solver > Periodic sample time constraint** to **Ensure sample time independent**.
- Using the subsystem, create a Model block that is independent of sample time. With this block, run Model block SIL/PIL simulations.

**See Also**

**Related Examples**

- “SIL and PIL Simulations” on page 77-2
- “Choose a SIL or PIL Approach” on page 77-14
Test Generated Code with SIL and PIL Simulations

Test numerical equivalence between model components and production code that you generate from the components by using software-in-the-loop (SIL) and processor-in-the-loop (PIL) simulations.

With a SIL simulation, you test source code on your development computer. With a PIL simulation, you test the compiled object code that you intend to deploy in production by running the object code on real target hardware or an instruction set simulator. To determine whether model components and generated code are numerically equivalent, compare SIL and PIL results against normal mode results.

There are three ways of running SIL and PIL simulations. You can use the top model, Model blocks, or SIL and PIL blocks that you create from a subsystem. See “Choose a SIL or PIL Approach” on page 77-14.

Target Connectivity Configuration for PIL

Before you can run PIL simulations, you must configure target connectivity. The target connectivity configuration enables the PIL simulation to:

- Build the target application.
- Download, start, and stop the application on the target.
- Support communication between Simulink and the target.

To produce a target connectivity configuration, you can use the supplied target connectivity API. For details, see “Create PIL Target Connectivity Configuration for Simulink” on page 77-44.

For supported hardware, you can use target support packages. For details, see “Embedded Coder Supported Hardware” on page 81-2.

SIL or PIL Simulation with a Top Model

Test generated model code by running a top-model SIL or PIL simulation. With this approach:

- You test code generated from the top model, which uses the standalone code interface.
- You configure the model to load test vectors or stimulus inputs from the MATLAB workspace.
• You can easily switch the top model between the normal, SIL, and PIL simulation modes.

Open a simple counter top model.

```plaintext
model='rtwdemo_sil_topmodel';
close_system(model,0);
open_system(model)
```
To focus on numerical equivalence testing, turn off:
- Model coverage
- Code coverage
- Execution time profiling

```matlab
set_param(gcs, 'RecordCoverage','off');
coverageSettings = get_param(model, 'CodeCoverageSettings');
coverageSettings.CoverageTool='None';
set_param(model, 'CodeCoverageSettings',coverageSettings);
set_param(model, 'CodeExecutionProfiling','off');
```

Configure the input stimulus data.

```matlab
[ticks_to_count, reset, counter_mode, count_enable] = ...
    rtwdemo_sil_topmodel_data(T);
```

Configure logging options in the model.

```matlab
set_param(model, 'LoadExternalInput','on');
set_param(model, 'ExternalInput','ticks_to_count, reset, counter_mode, count_enable');
set_param(model, 'SignalLogging', 'on');
set_param(model, 'SignalLoggingName', 'logsOut');
```

Run a normal mode simulation.

```matlab
set_param(model,'SimulationMode','normal')
[~, ~, yout_normal] = sim(model,10);
```

Run a top-model SIL simulation.

```matlab
set_param(model,'SimulationMode','Software-in-the-Loop (SIL)')
[~, ~, yout_sil] = sim(model,10);
```

### Starting SIL simulation for component: rtwdemo_sil_topmodel
### Stopping SIL simulation for component: rtwdemo_sil_topmodel

Unless up-to-date code for this model exists, new code is generated and compiled. The generated code runs as a separate process on your computer.
Plot and compare the results of the normal and SIL simulations. Observe that the results match.

```matlab
fig1 = figure;
subplot(3,1,1), plot(yout_normal), title('Counter Output for Normal Simulation')
subplot(3,1,2), plot(yout_sil), title('Counter Output for SIL Simulation')
subplot(3,1,3), plot(yout_normal-yout_sil), ...
    title('Difference Between Normal and SIL');
```

Clean up.

```matlab
close_system(model,0);
if ishandle(fig1), close(fig1), end
clear  fig1
```
simResults = {'yout_sil','yout_normal','model','T',... 'ticks_to_count','reset'};
save([model '_results'],simResults{:});
clear(simResults{:},'simResults')

**SIL or PIL Simulation with a Model Block**

Test generated model code by using a test harness model that runs a Model block in SIL mode. With this approach:

- You can test code that is generated from a top model or a referenced model. The code from the top model uses the standalone code interface. The code from the referenced model uses the model reference code interface. For more information, see “Code Interfaces for SIL and PIL” on page 77-6.
- You use a test harness model or a system model to provide test vector or stimulus inputs.
- You can easily switch a Model block between the normal, SIL, and PIL simulation modes.

Open an example model that has two Model blocks which reference the same model. In a simulation, you run one Model block in SIL mode and the other Model block in normal mode.

```
model='rtwdemo_sil_modelblock';
open_system(model);
```
Test Top-Model Code

For the Model block in SIL mode, specify generation of top-model code, which uses the standalone code interface.

```
set_param([model '/CounterA'], 'CodeInterface', 'Top model');
```

Run a simulation of the test harness model.
out = sim(model,20);

### Starting build procedure for model: rtwdemo_sil_counter
### Successful completion of build procedure for model: rtwdemo_sil_counter
### Preparing to start SIL simulation ...
Building with 'Microsoft Visual C++ 2017 (C)'.
MEX completed successfully.
### Updating code generation report with SIL files ...
### Starting SIL simulation for component: rtwdemo_sil_counter
### Stopping SIL simulation for component: rtwdemo_sil_counter

The model block in SIL mode runs as a separate process on your computer. In the working folder, you see that standalone code is generated for the referenced model unless generated code from a previous build exists.

Compare the behavior of Model blocks in normal and SIL modes. The results match.

yout = find(out,'logsOut');
yout_sil = yout.get('counterA').Values.Data;
yout_normal = yout.get('counterB').Values.Data;
fig1 = figure;
subplot(3,1,1), plot(yout_normal), title('Counter Output for Normal Simulation')
subplot(3,1,2), ...
    plot(yout_sil), title('Counter Output for Model Block SIL (Top-Model) Simulation')
subplot(3,1,3), plot(yout_normal-yout_sil), ...
    title('Difference Between Normal and SIL');
Test Model Reference Code

For the Model block in SIL mode, specify generation of referenced model code, which uses the model reference code interface.

```matlab
set_param([model '/CounterA'], 'CodeInterface', 'Model reference');
```

Run a simulation of the test harness model.

```matlab
out2 = sim(model,20);
```

The model block in SIL mode runs as a separate process on your computer. In the working folder, you see that model reference code is generated unless code from a previous build exists.

Compare the behavior of Model blocks in normal and SIL modes. The results match.

```matlab
yout2 = find(out2,'logsOut');
yout2_sil = yout2.get('counterA').Values.Data;
yout2_normal = yout2.get('counterB').Values.Data;
fig1 = figure;
subplot(3,1,1), plot(yout2_normal), title('Counter Output for Normal Simulation')
subplot(3,1,2), plot(yout2_sil), title('Counter Output for Model Block SIL (Model Reference) Simulation')
subplot(3,1,3), plot(yout2_normal-yout2_sil), title('Difference Between Normal and SIL');```
Clean up.

close_system(model,0);
if ishandle(fig1), close(fig1), end, clear fig1
simResults={'out','yout','yout_sil','yout_normal', ...
   'out2','yout2','yout2_sil','yout2_normal', ...
   'SilCounterBus','T','reset','ticks_to_count','Increment'};
save([model '_results'],simResults{:});
clear(simResults{::},'simResults')

**SIL or PIL Block Simulation**

Test generated subsystem code by using a SIL or PIL block in a simulation. With this approach:
• You test code generated from subsystems, which uses the standalone code interface.
• You provide a test harness or a system model to supply test vector or stimulus inputs.
• You replace your original subsystem with the generated SIL or PIL block.

Open a simple model, which consists of a control algorithm and a plant model in a closed loop. The control algorithm regulates the output from the plant.

```matlab
model='rtwdemo_sil_block';
close_system(model,0)
open_system(model)
```

Run a normal mode simulation

```matlab
out = sim(model,10);
yout_normal = find(out,'yout');
clear out
```

Configure the build process to create the SIL block for testing.

```matlab
set_param(model,'CreateSILPILBlock','SIL');
```

To test the behavior on production hardware, specify a PIL block.

To create the SIL block, generate code for the control algorithm subsystem. You see the SIL block at the end of the build process. Its input and output ports match those of the control algorithm subsystem.
close_system('untitled',0);
rtwbuild([model '/Controller'])

### Starting build procedure for model: Controller
### Successful completion of build procedure for model: Controller

Building with 'Microsoft Visual C++ 2017 (C)'.
MEX completed successfully.

Alternatively, you can right-click the subsystem and select C/C++ Code > Build This Subsystem. In the dialog box that opens, click Build.

To perform a SIL simulation of the controller and plant model in a closed loop, replace the original control algorithm with the new SIL block. To avoid losing your original subsystem, do not save your model in this state.

controllerBlock = [model '/Controller'];
blockPosition = get_param(controllerBlock,'Position');
delete_block(controllerBlock);
add_block('untitled/Controller',[controllerBlock '(SIL)'],
    'Position', blockPosition);
close_system('untitled',0);
clear controllerBlock blockPosition

Run the SIL simulation.

out = sim(model,10);

### Preparing to start SIL block simulation: rtwdemo_sil_block/Controller(SIL) ...
### Starting SIL simulation for component: rtwdemo_sil_block/Controller
### Stopping SIL simulation for component: rtwdemo_sil_block/Controller

The control algorithm uses single-precision, floating-point arithmetic. You can expect the order of magnitude for differences between SIL and normal simulations to be close to the machine precision for single-precision data.

77-97
Define an error tolerance for SIL simulation results that is based on the machine precision for the single-precision, normal simulation results.

```matlab
machine_precision = eps(single(yout_normal));
tolerance = 4 * machine_precision;
```

Compare normal and SIL simulation results. In the third plot, the differences between the simulations lie well within the defined error tolerance.

```matlab
yout_sil = find(out,'yout');
tout = find(out,'tout');
fig1 = figure;
subplot(3,1,1), plot(yout_normal), title('Controller Output for Normal Simulation')
subplot(3,1,2), plot(yout_sil), title('Controller Output for SIL Simulation')
subplot(3,1,3), plot(tout,abs(yout_normal-yout_sil),'g-', tout,tolerance,'r-'), ...  title('Normal and SIL Difference and Error Tolerance');
```
Clean up.

close_system(model,0);
if ishandle(fig1), close(fig1), end
clear fig1
simResults={'out','yout_sil','yout_normal','tout','machine_precision'};
save([model '_results'],simResults{:});
clear(simResults{:},'simResults')

**Hardware Implementation Settings**

When you run a SIL simulation, you must configure your hardware implementation settings (characteristics such as native word sizes) to allow compilation for your development computer. These settings can differ from the hardware implementation
settings that you use when building the model for your production hardware. To avoid the need to change hardware implementation settings between SIL and PIL simulations, enable portable word sizes. For more information, see “Configure Hardware Implementation Settings” on page 77-22.

Create a Target Communication Channel for Processor-In-The-Loop (PIL) Simulation

Implement a communication channel for processor-in-the-loop (PIL) simulation.

The communication channel enables exchange of data between different processes. The communication channel supports capabilities that require the exchange of data between the Simulink® software environment that runs on your development computer (host) and deployed code that runs on target hardware. For example, a PIL simulation.

You learn about the rtiostream interface and how it provides a generic communication channel that you can implement in the form of target connectivity drivers for different connection types. This example describes how to use the default TCP/IP implementation.

Two entities, Station A and Station B, use the rtiostream interface to set up a communication channel and exchange data. For this example, Station A and Station B are configured within the same process on your desktop computer.

The target connectivity drivers support an on-target PIL simulation. In the simulation, Station A and Station B represent the target and host computers that exchange data via the communication channel. On the host side, the target connectivity driver is implemented as a shared library that is loaded and called from within the MATLAB® product. On the target side, the driver is source code or a library that is linked to the application that runs on the target.

Additionally, you can:

- Configure your own target-side driver for TCP/IP to operate with the default host-side TCP/IP driver.
- Configure the supplied host-side driver for serial communications.
- Implement custom target connectivity drivers, for example, by using CAN or USB for host and target sides of the communication channel.

See also “Test Generated Code with SIL and PIL Simulations” on page 77-85 and “Configure Processor-In-The-Loop (PIL) for a Custom Target” on page 77-108.

View Source Code for the Default TCP/IP Implementation

The file rtiostream_tcpip.c implements client-side and server-side TCP/IP communication. A startup parameter configures the driver to operate in either client or server mode.
can use this source file as a starting point for a custom implementation. Each side of the communication channel requires only one or the other of the server or client implementations. If the client and server drivers run on different architectures, consider placing the driver code for each architecture in a separate source file.

The header file rtiostream.h contains prototypes for the functions rtIOStreamOpen/Send/Recv/Close. Include it (using #include) for custom implementations.

Extract the location of TCP/IP driver source code.

```matlab
tiostreamtcpip_dir = fullfile(matlabroot,'rtw','c','src','rtiostream',... 'rtiostreamtcpip');
```

View rtiostream_tcpip.c.

```matlab
edit(fullfile(tiostreamtcpip_dir,'rtiostream_tcpip.c'));
```

View rtiostream.h.

```matlab
edit(fullfile(matlabroot,'rtw','c','src','rtiostream.h'));
```

**Location of Shared Library Files**

To access the target connectivity drivers from the MATLAB product, you must compile them to a shared library. The shared library must be located on your system path. A shared library for the default TCP/IP drivers is located in matlabroot/bin/$ARCH ($ARCH is your system architecture, for example, win64).

The shared library filename extension and location depends on your operating system.

```matlab
 [~,~,sharedLibExt] = coder.BuildConfig.getStdLibInfo;
```

Identify the shared library for Station A and Station B.

```matlab
libTcpip = ['libmwrtiostreamtcpip' sharedLibExt];
disp(libTcpip)
```

**Test the Target Connectivity Drivers**

If you are implementing a custom target connectivity driver, it is helpful to test it from within the MATLAB product. The following example shows how to load the default TCP/IP target connectivity drivers and use them for data exchange between Station A and Station B.
To access the drivers, you can use the MEX-file \texttt{rtiostream\_wrapper}. With this MEX-file, you can load the shared library and access the rtiostream functions to open and close an rtiostream channel, and send and receive data.

Station A and Station B run on the host computer. Station A is configured as a TCP/IP server and Station B as a TCP/IP client. For host to target communication, you typically configure the host as a TCP/IP client and the target as a TCP/IP server.

Choose a port number for TCP.

\begin{verbatim}
if usejava('jvm')
    \% Find a free port
    tempSocket = java.net.ServerSocket(0);
    port = num2str(tempSocket.getLocalPort);
    tempSocket.close;
else
    \% Use a hard-coded port
    port = '14646';
end
\end{verbatim}

Open the Station A rtiostream as a TCP/IP server.

\begin{verbatim}
stationA = rtiostream\_wrapper(libTcpip,'open',...
    '-client', '0',...
    '-blocking', '0',...
    '-port', port);
\end{verbatim}

If the communication channel opens, the return value is a handle to the connection. A return value of -1 indicates an error.

Check the return value.

\begin{verbatim}
assert(stationA\!\!=\!-1)
\end{verbatim}

Open the Station B rtiostream as a TCP/IP client.

\begin{verbatim}
stationB = rtiostream\_wrapper(libTcpip,'open',...
    '-client', '1',...
    '-blocking', '0',...
    '-port', port,...
    '-hostname', 'localhost');
\end{verbatim}

If the communication channel opens, the return value is a handle to the connection. A return value of -1 indicates an error.
Check the return value.
assert(stationB==(-1))

**Send Data from Station B to Station A**

The target connectivity drivers send a stream of data in 8-bit bytes. For processors that are not byte-addressable, the data is sent in the smallest addressable word size.

Send message data from Station B to Station A.

```
msgOut = uint8('Station A, this is Station B. Are you there? OVER');
```

```
[retVal, sizeSent] = rtiostream_wrapper(libTcpip,...
    'send',...
    stationB,...
    msgOut,...
    length(msgOut));
```

A return value of zero indicates success.
assert(retVal==0);

Make sure that bytes in the message were sent.
assert(sizeSent==length(msgOut));

Allow time for data transmission to be completed.
pause(0.2)

Receive data in Station A.
```
[retVal, msgRecvd, sizeRecvd] = rtiostream_wrapper(libTcpip,...
    'recv',...
    stationA,...
    100);
```

A return value of zero indicates success.
assert(retVal==0);

Make sure that bytes in the message were received.
assert(sizeRecvd==sizeSent);
Display the received data.

disp(char(msgRecvd))

**Send a Response from Station A to Station B**

Send response data from Station A to Station B.

```matlab
text = 'Station B, this is Station A. Yes, I''m here! OVER.';
msgOut = uint8(text);
[~ , sizeSent] = rtiostream_wrapper(libTcpi,...
    'send',...
    stationA,...
    msgOut,...
    length(msgOut));
```

Allow time for data transmission to be completed.

```matlab
pause(0.2)
```

Receive data in Station B.

```matlab
[~ , msgRecvd, sizeRecvd] = rtiostream_wrapper(libTcpi,...
    'recv',...
    stationB,...
    100);
```

Display the received data.

disp(char(msgRecvd))

**Close Connection and Unload Shared Libraries**

Close rtiostream on Station B.

```matlab
retVal = rtiostream_wrapper(libTcpi,'close',stationB);
```

A return value of zero indicates success.

```matlab
assert(retVal==0);
```

Close rtiostream on Station A.

```matlab
retVal = rtiostream_wrapper(libTcpi,'close',stationA);
```

A return value of zero indicates success.
assert(retVal==0)

Unload the shared library.

rtiostream_wrapper(libTcpip, 'unloadlibrary');

**Host-Side Driver for Serial Communications**

You can use the supplied host-side driver for serial communications as an alternative to the drivers for TCP/IP. To configure the serial driver, see rtiostream_wrapper in the Embedded Coder® reference documentation.

**Configure Your Own Target-Side Driver**

If your target has an Ethernet connection and you have a TCP/IP stack available, follow these steps:

1. Write a wrapper for your TCP/IP stack that makes it available via the rtiostream interface defined in rtiostream.h.
2. Write a test application for your target that sends and receives some data.
3. Use the rtiostream_wrapper MEX-file and host-side TCP/IP driver to test your driver software that is running on the target.
4. When you have a working target-side driver, include the driver source files in the build for your automatically generated code.

You can configure your target-side driver to operate only as a TCP/IP server because the default host-side driver for PIL is configured as a TCP/IP client.

If you need to use a communications channel that is not already supported on the host-side, write drivers for host and target. In this case, you can still use the rtiostream_wrapper MEX-file for testing your rtiostream drivers.

**Configure Your Own Host-Side Driver**

You can implement the target connectivity drivers by using different communication channels. For example, you can implement host-target communications via a special serial connection, which requires that you provide drivers for the host and target.

On the host side, you can test the drivers by using the rtiostream_wrapper MEX-file. If your driver includes diagnostic output from printf statements and rtiostream_wrapper loads the shared library, you must replace the printf statements with mexPrintf statements.
When you have a working host-side device driver, you must make it available within the Simulink software environment. For PIL simulation, register the shared host-side shared library via sl_customization.

Configure Processor-In-The-Loop (PIL) for a Custom Target

Create a target connectivity configuration by using target connectivity APIs. With a target connectivity configuration, you can run PIL simulations on custom embedded hardware.

You learn how to:

• Adapt the build process to support PIL.
• Configure a tool for downloading and starting execution of a PIL executable on your target hardware.
• Configure a communication channel between host and target to support PIL simulation on the target.

Start with a model configured for software-in-the-loop (SIL) simulation. This example guides you through the process of creating a target connectivity configuration so that you can simulate the model in PIL mode. The example runs entirely on your host computer. You can follow the same steps to create a connectivity configuration for your own embedded target hardware.

See also “Test Generated Code with SIL and PIL Simulations” on page 77-85 and “Create a Target Communication Channel for Processor-In-The-Loop (PIL) Simulation” on page 77-101.

Preliminaries

Later in this example, you will add a folder to the search path. Create the folder path.

```matlab
sl_customization_path = fullfile(matlabroot,'toolbox','rtw','rtwdemos','pil_demo');
```

If this folder is already on the search path, remove it.

```matlab
if strfind(path,sl_customization_path)
    rmpath(sl_customization_path)
end
```

Reset customizations.
sl_refresh_customizations

Create a temporary folder (in your system's temporary folder) for the build and inspection process.

currentDir = pwd;
rtwdemodir();

**Test Generated Code with SIL Simulation**

Simulate a model configured for SIL. Verify the generated code compiled for your host computer by comparing the SIL simulation behavior with the normal simulation behavior.

Make sure that the example model is newly opened.

close_system('rtwdemo_sil_modelblock',0);
close_system('rtwdemo_sil_counter',0)
open_system('rtwdemo_sil_modelblock')

The CounterA Model block displays the text (SIL), which indicates that its referenced model is configured for SIL simulation.

Run a simulation of the system.

set_param('rtwdemo_sil_modelblock','StopTime','10');
sim('rtwdemo_sil_modelblock');

**Target Connectivity Configuration**

Start work on a target connectivity configuration for PIL.

Make a local copy of the target connectivity configuration classes.

src_dir = ...
    fullfile(matlabroot,'toolbox','coder','simulinkcoder','+coder','+mypil');
if exist(fullfile('.','+mypil'),'dir')
    rmdir('+mypil','s')
end
mkdir +mypil
copyfile(fullfile(src_dir,'Launcher.m'), '+mypil');
copyfile(fullfile(src_dir,'TargetApplicationFramework.m'), '+mypil');
copyfile(fullfile(src_dir,'ConnectivityConfig.m'), '+mypil');

Make the copied files writable.
Update the package name to reflect the new location of the files.

```
coder.mypil_Utils.UpdateClassName(...
   './+mypil/ConnectivityConfig.m',...
   'coder.mypil',...
   'mypil');
```

Verify that you now have a folder `+mypil` in the current folder, which has the files Launcher.m, TargetApplicationFramework.m, and ConnectivityConfig.m.

```
dir './+mypil'
```

**Review Code to Launch the PIL Executable**

The class that configures a tool for launching the PIL executable is mypil.Launcher. Open this class in the editor.

```
edit(which('mypil.Launcher'))
```

Review the content of this file. The method setArgString supplies additional command-line parameters to the executable. These parameters can include a TCP/IP port number. For an embedded processor implementation, you can choose to hard-code these settings.

**Configure the Overall Target Connectivity Configuration**

View the class mypil.ConnectivityConfig.

```
edit(which('mypil.ConnectivityConfig'))
```

Review the content of this file. You should be able to identify:

- The creation of an instance of rtw.connectivity.RtiOSStreamHostCommunicator that configures the host side of the TCP/IP communications channel.
- A call to the setArgString method of Launcher that configures the target side of the TCP/IP communications channel.
- A call to setTimer that configures a timer for execution time measurement

To define your own target-specific timer for execution time profiling, you must use the Code Replacement Library to specify a replacement for the function code_profile_read_timer. Use a command-line API or the crtool user interface.
**Review the Target-Side Communications Drivers**

View the file rtiostream_tcpip.c.

```matlab
rtiostreamtcpip_dir=fullfile(matlabroot,'rtw','c','src','rtiostream',...
                          'rtiostreamtcpip');
edit(fullfile(rtiostreamtcpip_dir,'rtiostream_tcpip.c'))
```

Scroll down to the end of this file. See that this file contains a TCP/IP implementation of the functions rtIOStreamOpen rtIOStreamSend, and rtIOStreamRecv. These functions are required for the target hardware to communicate with your host computer. You must provide an implementation for each of these functions that is specific to your target hardware and communication channel.

**Add Target-Side Communications Drivers to the Connectivity Configuration**

The class that configures additional files to include in the build is mypil.TargetApplicationFramework. Open this class in the editor.

```matlab
edit(which('mypil.TargetApplicationFramework'))
```

**Use sl_customization to Register the Target Connectivity Configuration**

To use the new target connectivity configuration, you must provide an sl_customization file. The sl_customization file registers your new target connectivity configuration and specifies the required conditions for its use. The conditions specified in this file can include the name of your system target file and your hardware implementation settings.

You can view the sl_customization file. For this example, you do not have to make changes to the file.

```matlab
edit(fullfile(sl_customization_path,'sl_customization.m'))
```

Add the sl_customization folder to the search path and refresh the customizations.

```matlab
addpath(sl_customization_path);
sl_refresh_customizations;
```

**Test Generated Code with PIL Simulation**

Run the PIL simulation.

```matlab
close_system('rtwdemo_sil_modelblock',0)
open_system('rtwdemo_sil_modelblock')
```
set_param('rtwdemo_sil_modelblock/CounterA','SimulationMode','processor-in-the-loop (pil)');
set_param('rtwdemo_sil_modelblock','StopTime','10');
sim('rtwdemo_sil_modelblock');

Review the preceding messages. Confirm that the simulation ran without errors. You have now implemented a target connectivity configuration for PIL. You can use the same APIs to implement a connectivity configuration for your own combination of embedded processor, download tool, and communications channel.

**Cleanup**

Remove the search path for this example.

```matlab
rmpath(sl_customization_path)
```

Reset customizations.

```matlab
sl_refresh_customizations
```

Close the models.

```matlab
close_system('rtwdemo_sil_modelblock',0)
close_system('rtwdemo_sil_counter',0)
```

```matlab
rtwdemoclean;
cd(currentDir)
```

Field-Oriented Control of Permanent Magnet Synchronous Machine

This example shows the basic workflow and key APIs for generating C code from a motor control algorithm, and for verifying its compiled behavior and execution time. You will use Processor-in-the-loop (PIL) simulation to gain confidence that the C code will perform as expected when you integrate it with embedded software that interfaces with the motor hardware. Although this workflow uses a motor control application for a specific processor, you can apply this workflow to virtually any application or processor.

We use a Field-Oriented Control algorithm for a Permanent Magnet Synchronous Machine to show this workflow. This control technique is common in motor drive systems for hybrid electric vehicles, manufacturing machinery, and industrial automation.

Overview

In this example, generate and verify C code from a control algorithm model, which you can integrate with additional embedded software required to interface to motor hardware.
You will use a simulation environment to model and verify the behavior of a closed-loop motor control system. Once the control system behavior is within specification, you will generate C code from the controller model. After inspecting the code, you will assess its functional behavior and execution time using processor-in-the-loop (PIL) testing.

To facilitate PIL testing, you will select test signals to exercise the controller model and establish reference outputs. You will review an example PIL implementation for a Texas Instruments™ F28335 processor that communicates with Simulink® on the host computer over a serial connection. You can use this example as a starting point to create a PIL implementation for your own processor. You will run the controller model in PIL mode to measure execution time and verify execution behavior of the code running on the embedded processor against the simulation reference outputs.

In the final implementation on the embedded processor, you would integrate the generated controller C code with additional embedded software, such as peripherals and interrupts, required to interface with the motor hardware.

Notes
• Simscape™ Electrical is required for system simulation in the section "Verify Behavior through Simulation." It is not required for other tasks.

• The Texas Instruments™ F28335 PIL implementation is a reference approach that you can apply to virtually any processor. However, if you wish to use this implementation directly, you will need additional support files, compilers, and tools from Texas Instruments™. You can find more information about those in "Create PIL Implementation and Register with Simulink®" section of this example. This reference PIL implementation does not require the Texas Instrument C2000™ Embedded Target feature of Embedded Coder®, but C2000™ users are encouraged to install Texas Instruments C2000 Support Package using supportPackageInstaller.

Verify Behavior through System Simulation

In this section, you will verify the controller in a closed loop system simulation.

The system model test bench consists of test inputs, the embedded processor, the power electronics and motor hardware, and visualizations. You can use the system model to exercise the controller and explore its expected behavior. You can use the following commands to execute the model and plot logged signals.

```matlab
open_system('rtwdemo_pmsmfoc_system')
sim('rtwdemo_pmsmfoc_system')
rtwdemo_pmsmfoc_plotsignals(logsout)
```
Field-Oriented Control of Permanent Magnet Synchronous Machine System Test Bench

Model Description: Field-Oriented Control of Permanent Magnet Synchronous Machine

Demonstrates a Field-Oriented Control algorithm with Space Vector Modulation for a Permanent Magnet Synchronous Machine (PMSM).

The test bench can be used to evaluate the system performance. Examples include turning the motor on, searching for a valid rotor position, transitioning to closed loop operation, and changing speed and torque during closed loop control.

The Embedded Processor subsystem contains the controller algorithm (which supports C code generation) as well as simulation models of peripherals.
The plots show that the motor is stationary until the `motor_on` signal is true. The motor then spins in an open loop until a known position is detected, which is indicated by the encoder index pulse. The controller then transitions to closed loop operation and the motor reaches a steady state speed.

**Explore Model Architecture**

In this section, you will explore the model architecture including how data is specified, how the controller is partitioned from the test bench, and how controller is scheduled. This architecture facilitates system simulation, algorithmic code generation, and PIL testing.
A data definition file creates the MATLAB® data required for simulation and code generation. This data file is automatically run within the PreLoadFcn callback of the system test bench model.

```matlab
edit('rtwdemo_pmsmfoc_data.m')
```

Within the system test bench model, the embedded processor is modeled as a combination of the peripherals and the controller software.

```matlab
open_system('rtwdemo_pmsmfoc_system/Embedded Processor')
```

### Embedded Processor

Models hardware on the embedded processor, including the controller algorithm software specification and peripherals.

The controller software is specified in a separate model. Within this model, the Mode_Scheduler subsystem uses Stateflow® to schedule different modes of operation of the Motor_Control algorithm.

```matlab
open_system('rtwdemo_pmsmfoc')
```
Within the Motor_Control subsystem, sensor signals are converted to engineering units and passed to the core controller algorithm. The controller algorithm calculates voltages. The voltages are then converted to a driver signal.

open_system('rtwdemo_pmsmfoc/Motor_Control')
The primary control law is a field-oriented controller. The controller has a low rate outer loop that controls the speed, and a higher rate inner loop that controls the current.

`open_system('rtwdemo_pmsmfoc/Motor_Control/Field_Oriented_Controller')`
The Velocity Controller outer loop is executed as a multiple of the Current Control loop time. You can view the MATLAB® variables, which specify these sample times:

```matlab
fprintf('High rate sample time = %f seconds\n', ctrlConst.TsHi)
fprintf('Low rate sample time  = %f seconds\n', ctrlConst.TsLo)
```

High rate sample time = 0.000040 seconds
Low rate sample time  = 0.005000 seconds

Notice that the highest rate in the controller algorithm is 25 kHz.

```matlab
fprintf('High rate frequency = %5.0f Hz\n', 1/c ctrlConst.TsHi)
```

High rate frequency = 25000 Hz
Generate Controller C Code for Integration into Embedded Application

In this section, you will generate and visually inspect the C code function for the controller.

To ease integration, the controller model is configured in single-tasking mode so that the generated code can be invoked using one function call. This function handles the lower and higher rates. The generated controller function must be executed at the high rate sample time.

The function prototype is specified in the model configuration parameters and the input and output ports are passed as arguments. You can view the function specification for the controller algorithm.

```matlab
mdlFcn = RTW.getFunctionSpecification('rtwdemo_pmsmfoc');
disp(mdlFcn.getPreview('init'))
disp(mdlFcn.getPreview('step'))

Controller_Init ( )
error = Controller ( motor_on, command_type, current_request, * sensors, * pwm_compare )
```

Through use of a global structure in the generated code, you can access the field-oriented controller proportional and integral gains. This global structure is specified in the data definition file.

```matlab
disp(ctrlParams.Value)
disp(ctrlParams.CoderInfo)
```

```
Current_P: 10
Current_I: 10000
Velocity_P: 0.0050
Velocity_I: 0.0150
Position_P: 0.1000
Position_I: 0.6000
StartupAcceleration: 1
StartupCurrent: 0.2000
RampToStopVelocity: 20
AdcZeroOffsetDriverUnits: 2.2523e+03
AdcDriverUnitsToAmps: 0.0049
EncoderToMechanicalZeroOffsetRads: 0
PmsmPolePairs: 4
```

```matlab
Simulink.CoderInfo
StorageClass: 'ExportedGlobal'
```
You generate C code from the model as follows.

```
rtwbuild('rtwdemo_pmsmfoc')
```

Use the generated report to inspect the generated C code file and verify that the correct step and initialization functions were generated. Also verify that the parameter structure was created as a global variable.
Establish Reference Behavior for Controller Model

In this section, you will establish test inputs and a reference output to help verify behavior and profile execution time during PIL testing. You will make a local copy of the controller model then load a set of test input signals that exercise the different modes within the controller. You will then configure the controller model to attach these logged signals to input ports, execute the controller model, and log the output port signal to the workspace.

Configuration parameters of the controller model used to establish the reference behavior and test environment will change as described below. Blocks and parameters used to specify the controller model's design and generate production code will not change. However, to avoid modifying any part of the installed controller model, save the model and change its name to `rtwdemo_pmsmfoc_local.slx`.

```matlab
save_system('rtwdemo_pmsmfoc','rtwdemo_pmsmfoc_local.slx')
close_system('rtwdemo_pmsmfoc_system',0);
close_system('rtwdemo_pmsmfoc',0);
```
To profile execution times, select a set of test inputs that will execute the paths of interest within the controller. One way to acquire these test inputs and reference output is to log them from the system simulation model.

```matlab
in.motor_on = logsout.getElement('motor_on').Values;
in.command_type = logsout.getElement('command_type').Values;
in.command_value = logsout.getElement('command_value').Values;
in.sensors = logsout.getElement('sensors').Values;
display(in)

in =

struct with fields:
```

Numeralis Equivalence Checking in Embedded Coder
These signals can now be attached to the input ports and imported into the controller model such that it can execute directly and independently from the system model. An advantage of this approach is that the controller model can be tested and verified as a standalone component, facilitating reuse and integration with other system models or closed-loop test benches. To elaborate, or prepare, the controller model for testing, change its Configuration Parameters to attach input signals and log signals in the MATLAB® workspace. These changes can be made graphically in the model's Configuration Parameters dialog, or programmatically as shown below.

```matlab
set_param('rtwdemo_pmsmfoc_local', 'LoadExternalInput', 'on', 'ExternalInput', 'in.motor_on, in.command_type, in.command_value, in.sensors', 'StopTime', '0.06', 'ZeroInternalMemoryAtStartup', 'on', 'SimulationMode', 'normal')

save_system('rtwdemo_pmsmfoc_local.slx')
```

You can now execute the controller model and plot the signal associated with the PWM Compare output port.

```matlab
sim('rtwdemo_pmsmfoc_local')
controller_mode = logsout.getElement('controller_mode').Values;
pwm_compare_ref = logsout.getElement('pwm_compare').Values;
rtwdemo_pmsmfoc_plotpwmcompare(controller_mode, pwm_compare_ref)
```
The logged output will be used as the reference behavior for PIL testing.

Notice that the plot is annotated with information about the mode of the controller at each time step. This mode information will be useful when interpreting execution profiling information.

**Create PIL Implementation**

In this section, you will study and use an example PIL implementation. You will begin by reviewing prerequisite help documentation from Embedded Coder®. You will then copy the example PIL implementation into your local directory and register it with Simulink®. You will review the approach used to develop the PIL implementation and can explore the associated files to gain additional insight. If you are using a Spectrum Digital Inc. eZdsp
F28335 board with Code Composer v4 and a serial connection, you will be able to configure this PIL implementation to directly work with the controller model. If you are using a different processor, you can use this PIL implementation as a starting point to create your own implementation.

The fundamentals of creating a custom PIL implementation are described in Creating a Connectivity Configuration for a Target. You should familiarize yourself with the basic concept of using the rtiostream API to facilitate communication between Simulink® (host-side) and the embedded processor (target-side) during PIL testing. Note that Embedded Coder® provides host-side drivers for the default TCP/IP implementation (for all platforms supported by Simulink®) as well as a Windows® only version for serial communication. Building the generated code is accomplished using a makefile as described in Customizing Template Makefiles. To create a PIL implementation you will need to perform several tasks in the embedded environment including writing a target-side communications driver, writing a makefile to build the generated code, and automating download and execution of the built executable.
Using the above approach, a PIL implementation was created for a Spectrum Digital Inc. eZdsp F28335 board. Below is a summary of the target connectivity API components used in this implementation.

- **Host-Side Communication** - The host-side connectivity driver is configured to use serial communication.
- **Target-Side Communication** - The target-side communication is achieved using a hand written serial implementation of the rtiostream functions as well as timer access functions.
- **Build Process** - A makefile based approach is used to build the executable application.
- **Launcher** - Downloading and running the executable is accomplished using the Debug Server Scripting (DSS) utility of Code Composer Studio™ v4 (CCSv4).

The PIL implementation was iteratively developed in three stages. Below is a description of these stages and the tasks performed in these stages. You may find it helpful to follow a similar approach when developing your own PIL implementation.

**Stage 1: Create serial communication application with CCSv4**

- Install CCSv4 and verify that it can connect with the F28335 eZdsp board.
- Write an embedded application that sends and receives serial data.
- Test the serial communication between the host computer and the embedded application.
- Identify the commands and options for the compiler, linker, and archiver to build the application using a makefile.
- Download and run the application from a Windows® Command Prompt using the DSS utility.

**Stage 2: Implement and test embedded serial rtiostream and launch automation with MATLAB®**

- Extend the serial application to implement the rtiostream API functions for echoing data. Write the rtIOStreamOpen to perform general board initialization, including configuring the serial port.
- Verify sending and receiving serial data with the embedded processor from MATLAB® using the rtiostream_wrapper function.
- Download and run the application from MATLAB® using the system command to call the DSS utility.
Stage 3: Implement and test connectivity configuration with Simulink®

- Create a connectivity configuration class to configure the host-side serial communication, specify which target-side code files from the rtiostream application should be included in the build process, specify how to access a timer that will be used to collect profiling data, and integrate calling the DSS utility to launch the embedded application.

- Create a tool specification makefile (target_tools.mk) which specifies the commands and options for the compiler, linker, and archiver. This makefile is included by the template makefile (target_tools.mk).

- Create a template makefile (ec_target.tmf) that includes target_tools.mk.

- Identify parameters which may be installation dependent and store them as MATLAB® preferences.

- Create a Simulink® customization file which specifies when the PIL implementation is valid

The files associated with this PIL implementation are included with Embedded Coder®, but are not on the MATLAB® path. To explore these files, you can copy them into a local directory. You can register this PIL implementation by adding this directory to the MATLAB® path and refreshing the Simulink® customizations.

```matlab
%copyfile(fullfile(matlabroot,'toolbox','rtw','rtwdemos','examplePilF28335'),'examplePilF28335','f')
addpath(genpath(fullfile(matlabroot,'toolbox','rtw','rtwdemos','examplePilF28335')))
sl_refresh_customizations
```

MATLAB® preferences are used to specify path information and the host serial COM port number. If you are using this PIL implementation directly, you must specify these preferences as appropriate for your configuration.

Note that the TI_F28xxx_SysSWDir preference points to a directory provided by Texas Instruments™ in their C2000™ Experimenter Kit Application Software (sprc675.zip). These files are not included with Embedded Coder®.

```matlab
setpref('examplePilF28335','examplePilF28335Dir', fullfile(matlabroot,'toolbox','rtw','rtw','rtwdemos','examplePilF28335'));
setpref('examplePilF28335','CCSRootDir', 'C:\Program Files\Texas Instruments\');
setpref('examplePilF28335','TI_F28xxx_SysSWDir', 'C:\Program Files\Texas Instruments\');
setpref('examplePilF28335','targetConfigFile', fullfile(matlabroot,'toolbox','rtw','rtw','rtwdemos','examplePilF28335'));
setpref('examplePilF28335','baudRate', 115200);
setpref('examplePilF28335','cpuClockRateMHz', 150);
setpref('examplePilF28335','boardConfigPLL', 10);
setpref('examplePilF28335','COMPort', 'COM4');
```
The PIL implementation is now ready to be used.

**Prepare Controller Model for PIL Testing**

In this section you will configure the controller model to use the PIL implementation. You will review the customization file used to register the PIL implementation, set the configuration parameters of the model to use the PIL implementation, and enable logging controller outputs and execution profiling data.

When you begin a simulation in PIL mode, Simulink® will check if any of the registered PIL implementations are valid. A customization file specifies which configuration parameters correspond to a valid PIL implementation. You can explore the customization file for this implementation by invoking the following command.

```matlab
edit(fullfile(matlabroot,'toolbox','rtw','rtwdemos','examplePilF28335','sl_customization.m'))
```

Notice that this file specifies setting for the hardware device and the template makefile which are required to use this PIL implementation. You can modify the configuration parameters in the controller model to match these settings. These changes can be made graphically in the model's Configuration Parameters dialog, or programmatically as shown below.

```matlab
set_param('rtwdemo_pmsmfoc_local',
    'ProdHWDeviceType', 'Texas Instruments->C2000',
    'TemplateMakefile', 'ec_target.tmf',
    'GenCodeOnly', 'off',
    'SimulationMode', 'processor-in-the-loop (pil)')
```

You can specify collecting execution profiling information during PIL testing by logging the simulation output values as the variable `pilOut` and logging the execution profiling information as the variable `executionProfile`. These changes can be made graphically in the model's Configuration Parameters dialog, or programmatically as shown below.

```matlab
set_param('rtwdemo_pmsmfoc_local',
    'CodeExecutionProfiling', 'on',
    'CodeExecutionProfileVariable', 'executionProfile',
    'CodeProfilingSaveOptions', 'AllData');
save_system('rtwdemo_pmsmfoc_local.slx')
```

The controller model is now ready to be run in PIL mode.

**Test Behavior and Execution Time of Generated Code**

In this section you will run the controller model in PIL mode and explore the behavioral and execution profiling results. You will verify that the behavior of the compiled controller
code matches the reference simulation behavior, and then verify that the execution of the code meets timing requirements.

You can run the model and plot the PIL simulation results. When you start the model for the first time, Embedded Coder® will generate code for the algorithm, link the algorithm code with the serial communication interface code, build the embedded application, download the application to the board, and begin the on-target simulation. Note that during subsequent PIL simulations, code is only regenerated if the model changes. Due to the overhead associated with the serial communication interface, the PIL simulation may run slower than the model in normal mode.

The MATLAB® commands below are intentionally commented out as they require connection to hardware and use of embedded development tools described previously. If you have the hardware connected and embedded development tools installed, uncomment and execute these lines to run the model, plot the results, and verify the behavior is numerically equivalent to the simulation running in normal mode. Otherwise, continue reviewing this section to learn about PIL execution analysis options.

```matlab
% UNCOMMENT THE BELOW LINES TO RUN THE SIMULATION AND PLOT THE RESULTS
% if exist('slprj','dir'), rmdir('slprj','s'); end
% sim('rtwdemo_pmsmfoc_local')
% pwm_compare_pil = logsout.getElement('pwm_compare').Values;
% rtwdemo_pmsmfoc_plotpwmcompare_pil(controller_mode, pwm_compare_pil, executionProfile)
```
The upper plot is the output of the controller, PWM Compare. Note that the outputs in PIL mode look the same as the outputs of the simulation in normal mode shown in the section "Establish Reference Behavior for Controller Model". You can subtract the outputs of normal mode simulation from the PIL mode simulation output to verify that they are numerically equivalent:

% UNCOMMENT THE BELOW LINE TO VERIFY NUMERICAL EQUIVALENCE OF THE OUTPUTS
% pilErrorWithRespectToReference = sum(abs(pwm_compare_pil.Data - pwm_compare_pil.Data))

pilErrorWithRespectToReference =

0 0 0
The lower plot is the amount of time spent executing the controller model at each simulation time step. The "Stand By" state requires the least time. Small periodic spikes in execution time occur because the controller is multi-rate and single tasking. The periodic spikes correspond to the time required to run both the base rate and 5 millisecond rate code in the same task.

Since the controller must be executed at 25 kHz on the embedded processor, the algorithm must complete its execution within 40 microseconds (minus additional headroom requirements by other code, which may also be executing on the final application.) The profiling results indicate that the algorithm will execute within the time allotted for this configuration of the embedded environment.

The generated code is now verified to provide numerically equivalent results and meets the execution timing requirements for this test case.

```matlab
close_system('rtwdemo_pmsmfoc_local',0);
close_system('power_utile',0);
```

The MATLAB® preferences used in this PIL implementation are persistent between MATLAB® sessions. If you want to remove these preferences, run the following commands.

```matlab
rmpref('examplePilF28335');
rmexamplePilF28335hooks();
```

**Conclusion**

This example showed system level simulation and algorithmic code generation using a Field-Oriented Control algorithm for a Permanent Magnet Synchronous Machine to explore functional behavior of the controller algorithm. It also showed a general approach for target integration, functional testing, and execution profiling for any embedded processor. Once the algorithm was behaviorally correct, code was generated from the controller model, tested on the target processor and profiled. The algorithm code is now
verified and can be integrated with embedded software that interfaces with the motor hardware for further testing.

Check Configuration

Use the `cgv.Config` class to check model settings for a SIL or PIL simulation. You can review your model configuration and determine the settings that you must change. By default, `cgv.Config` changes configuration parameter values to the value that it recommends, but does not save the model. Alternatively, you can:

- Change configuration parameter values to the values that `cgv.Config` recommends, and save the model. Specify this approach using the `SaveModel` property.
- List the values that `cgv.Config` recommends for the configuration parameters, but not change the configuration parameters or the model. Specify this approach using the `ReportOnly` property.

**Note**

- Execution in the target environment can require additional modifications to configuration parameter values or the model.
- Do not use referenced configuration sets in models that you are changing using `cgv.Config`. If the model uses a referenced configuration set, update the model with a copy of the configuration set. Use the `getRefConfigSet` method of the `Simulink.ConfigSetRef` class.
- If you use `cgv.Config` on a model that executes a callback function, the callback function can change configuration parameter values each time the model loads. The callback function can revert changes that `cgv.Config`. For more information, see “Callbacks for Customized Model Behavior” (Simulink).

To verify that your model is configured for SIL or PIL:

1. Construct a `cgv.Config` object that changes the configuration parameter values without saving the model. For example, to configure your model for SIL:

   ```
c = cgv.Config('vdp', 'connectivity', 'sil');
```

**Tip**

- You can obtain a list of changes without changing the configuration parameter values. When you construct the object, include the `ReportOnly`, `on` property name and value pair:
• You can change the configuration parameter values and save the model. When you construct the object, include the 'SaveModel', 'on' property name and value pair.

2 Determine and change the configuration parameter values that the object recommends using the configModel method. For example:

   c.configModel();

3 Display a report of the changes that configModel makes. For example:

   c.displayReport();

4 Review the changes.

5 To apply the changes to your model, save the model.

• “Verify Numerical Equivalence with CGV” on page 77-139
• “Verify Numerical Equivalence Between Two Modes of Execution of a Model” on page 77-141
Verify Numerical Equivalence with CGV

Before verifying numerical equivalence:

• Configure your model for SIL or PIL simulation.
• Use the cgv.Config class of the CGV API to verify the model configuration for SIL or PIL simulation.
• Configure your model for code generation. For more information, see “Configure Model for Code Generation Objectives by Using Code Generation Advisor” on page 42-2.
• Save your model. If you modify a model without saving it, CGV can issue an error.

To verify numerical equivalence:

• Set up the tests for the first execution environment. For example, simulation.
• Use run to run the tests for the first execution environment.
• Set up the tests for the second execution environment. For example, top-model PIL.
• Use cgv.CGV.run to run the tests for the second execution environment.
• Use getOutputData to get the output data for each execution environment.
• Use getSavedSignals to display the signal names in the output data. (optional)
• Build a list of signal names for input to other cgv.CGV methods. (optional)
• Use createToleranceFile to create a file correlating tolerance information with output signal names. (optional)
• Use compare to compare the output signals of the first and second execution environments for numerical equivalence.

Note Simulink Test is a separate product that provides additional capabilities for SIL and PIL testing, for example, test sequence construction and test management.

Verify Numerical Equivalence Between Two Modes of Execution of a Model

In this section...

“Configure the Model” on page 77-141
“Execute the Model” on page 77-142
“Compare All Output Signals” on page 77-143
“Compare Individual Output Signals” on page 77-144
“Plot Output Signals” on page 77-145

The following example describes configuring, executing, and comparing the results of the rtwdemo_cgv model in normal and software-in-the-loop (SIL) simulation modes.

Configure the Model

The first task for verifying numerical equivalence is to check the configuration of your model.

1 Open the rtwdemo_cgv model.

   cgvModel = 'rtwdemo_cgv';
   load_system(cgvModel);

2 Save the model to a working directory.

   save_system(cgvModel, fullfile(pwd, cgvModel));
   close_system(cgvModel); % avoid original model shadowing saved model

3 Use the cgv.Config to create a cgv.Config object. Specify parameters that check and modify configuration parameter values and save the model for top-model SIL mode of execution.

   cgvCfg = cgv.Config('rtwdemo_cgv', 'connectivity', 'sil', 'SaveModel', 'on');

4 Use the configModel method to review your model configuration and to change the settings to configure your model for SIL. When 'connectivity' is set to 'sil', the system target file is automatically set to 'ert.tlc'. If you specified the parameter/value pair, ('SaveModel', 'on') when you created the cgvCfg object, the cgv.Config.configModel method saves the model.
**Note** CGV runs on models that are open. If you modify a model without saving it, CGV can issue an error.

cgvCfg.configModel(); % Evaluate, change, and save your model for SIL

5 Display a report of the changes that cgv.Config.configModel makes to the model.

cgvCfg.displayReport(); % In this example, this reports no changes

**Execute the Model**

Use the CGV API to execute the model in two modes. The two modes in this example are normal mode simulation and SIL mode. In each execution of the model, the CGV object for each mode captures the output data and writes the data to a file.

1 If you have not already done so, follow the steps described in “Configure the Model” on page 77-141.

2 Create a cgv.CGV object that specifies the rtwdemo_cgv model in normal mode simulation.

cgvSim = cgv.CGV(cgvModel, 'connectivity', 'sim');

**Note** When the top model is set to normal simulation mode, the CGV API sets referenced models in PIL mode to accelerator mode.

3 Provide the input file to the cgvSim object.

cgvSim.addInputData(1, [cgvModel '_data']);

4 Before execution of the model, specify the MATLAB files to execute or MAT-files to load. This step is optional.

cgvSim.addPostLoadFiles({[cgvModel '_init.m']});

5 Specify a location where the object writes all output data and metadata files for execution. This step is optional.

cgvSim.setOutputDir('cgv_output');

6 Execute the model.

result1 = cgvSim.run();

7 Get the output data associated with the input data.

outputDataSim = cgvSim.getOutputData(1);
For the next mode of execution, SIL, repeat steps 2–7.

cgvSil = cgv.CGV(cgvModel, 'Connectivity', 'sil');
cgvSil.addInputData(1, [cgvModel '_data']);
cgvSil.addPostLoadFiles({[cgvModel '_init.m']});
cgvSil.setOutputDir('cgv_output');
result2 = cgvSil.run();

**Compare All Output Signals**

After setting up and running the test, compare the outputs by doing the following:

1. If you have not already done so, configure and test the model, as described in “Configure the Model” on page 77-141 and “Execute the Model” on page 77-142.

2. Test that the execution result of the model:
   ```matlab
   if ~result1 || ~result2
       error('Execution of model failed.);
   end
   ```

3. Use the `getOutputData` method to get the output data from the `cgv.CGV` objects.
   ```matlab
   simData = cgvSim.getOutputData(1);
silData = cgvSil.getOutputData(1);
   ```

4. Display a list of signals by name using the `getSavedSignals` method.
   ```matlab
   cgvSim.getSavedSignals(simData);
   ```

5. Using the list of signals, build a list of signals in a cell array of character vectors. The signal list can contain a number of signals.
   ```matlab
   signalList = {'simData.getElement(4).Values.Data'};
   ```

6. Use the `createToleranceFile` method to create a file, in this example, 'localtol', correlating tolerance information with output signal names.
   ```matlab
   toleranceList = {{'absolute', 0.5}};
cgv.CGV.createToleranceFile('localtol', signalList, toleranceList);
   ```

7. Compare the output data signals. By default, the `compare` method looks at all signals which have a common name between both executions. If a tolerance file is present, `cgv.CGV.compare` uses the associated tolerance for a specific signal during comparison; otherwise the tolerance is zero. In this example, the 'Plot' parameter is set to 'mismatch'. Therefore, only mismatched signals produce a plot.
   ```matlab
   [matchNames, ~, mismatchNames, ~] = ...
cgv.CGV.compare(simData, silData, 'Plot', 'mismatch', ...
   'Tolerancefile', 'localtol');
   fprintf('%d Signals match, %d Signals mismatch\n', ...
   length(matchNames), length(mismatchNames));
   ```
disp('Mismatched Signal Names:');
disp(mismatchNames);

At the MATLAB command line, you see:

14 Signals match, 1 Signals mismatch
Mismatched Signal Names:
   'simData.getElement(4).Values.Data'

A plot results from the signal mismatch.

The lower plot displays the numeric difference between the results.

**Compare Individual Output Signals**

After setting up and running the test, compare the outputs of individual signals by doing the following:
1 If you have not already done so, configure and test the model, as described in “Configure the Model” on page 77-141 and “Execute the Model” on page 77-142.

2 Use the `getOutputData` method to get the output data from the `cgv.CGV` objects.
   ```matlab
   simData = cgvSim.getOutputData(1);
silData = cgvSil.getOutputData(1);
   ```

3 Use the `getSavedSignals` method to display the output data signal names. Build a list of specific signal names in a cell array of character vectors. The signal list can contain a number of signals.
   ```matlab
cgv.CGV.getSavedSignals(simData);
signalList = {'simData.getElement(2).Values.Data(:,1)'};
   ```

4 Use the specified signals as input to the `compare` method to compare the signals from separate runs.
   ```matlab
   [matchNames, - , mismatchNames, -] = ...
cgv.CGV.compare(simData, silData, 'Plot', 'mismatch', ...
   'signals', signalList);
   fprintf( '%d Signals match, %d Signals mismatch
', ...
   length(matchNames), length(mismatchNames));
   if ~isempty(mismatchNames)
   disp( 'Mismatched Signal Names:');
disp(mismatchNames);
   end
   ```

At the MATLAB command line, the result is:

3 Signals match, 0 Signals mismatch

**Plot Output Signals**

After setting up and running the test, use the `plot` method to plot output signals.

1 If you have not already done so, configure and test the model, as described in “Configure the Model” on page 77-141 and “Execute the Model” on page 77-142.

2 Use the `getOutputData` method to get the output data from the `cgv.CGV` objects.
   ```matlab
   simData = cgvSim.getOutputData(1);
   ```

3 Use the `getSavedSignals` method to display the output data signal names. Build a list of specific signal names in a cell array of character vectors. The signal list can contain a number of signals.
   ```matlab
cgv.CGV.getSavedSignals(simData);
signalList = {'simData.getElement(2).Values.Data(:,1)'};
   ```
4 Use the specified signal list as input to the `plot` method to compare the signals from separate runs.

```matlab
[signalNames, signalFigures] = cgv.CGV.plot(simData, ...
    'Signals', signalList);
```

**Related Examples**

- “Verify Numerical Equivalence with CGV” on page 77-139
- “Check Configuration” on page 77-137
Using Code Generation Verification API

Configure and run normal, software-in-the-loop (SIL), and processor-in-the-loop (PIL) simulations, and compare results.

Note: Simulink Test is a separate product that provides additional capabilities for SIL and PIL testing, for example, test sequence construction and test management.

Review the Model

The rtwdemo_cgv model uses buses, scalars, and vectorized data, plus error injection to create differences between test executions.

Note: Before executing the code in this example, change to a writable folder. If you are not working in a writable folder, code generation errors occur.

To open rtwdemo_cgv, in the MATLAB® Command Window, enter the following commands.

```matlab
baseVars = who;  % For future cleanup.
cgvModel = 'rtwdemo_cgv';
close_system(cgvModel,0);
open_system(cgvModel);
```
The model contains a hierarchical bus with three nested buses. This arrangement of buses produces complex hierarchical data at the first logged outport. At the second outport, the model injects errors in the signal at fixed intervals. These errors produce different results between two runs. The signal at the third outport is a vector of four values per sample to help show the comparison support.

**Verify the Model Configuration**

CGV provides a class, cgv.Config, to check whether models have a configuration that is compatible with execution in a SIL or PIL environment using an ert target. This model has already been modified using the cgv.Config class.
Execute Under CGV

Run in Normal and SIL Modes

The model executes in three modes under CGV: normal, SIL, and PIL. In each case, the CGV object captures the output data and writes it to a file. For more information, see CGV Documentation. To execute the model in normal and SIL simulation modes, enter:

cgvSim = cgv.CGV( cgvModel, 'Connectivity', 'Normal');
cgvSim.addInputData(1, [cgvModel '_data']);
% This next CGV function, addPostLoadFiles(), allows you to specify MATLAB(R)
% programs to execute, or mat-files to load, before execution of the model.
cgvSim.addPostLoadFiles({[cgvModel '_init.m']});
cgvSim.setOutputDir('cgv_output');
cgvSim.activateConfigSet( 'CS1_default');
result1 = cgvSim.run();

% CGV provides methods to simplify numerical equivalence checking.
% The copySetup method creates an exact duplicate of an existing CGV object without
% results data. You can change the SimulationMode using setMode() and then
% execute again.
cgvSil = cgvSim.copySetup();
cgvSil.setMode( 'SIL');
% You can provide a baseline file to CGV for comparing the simulation
% output. In this example, the comparison results set the status to
% 'failed', because the ErrorsInjected signal differs between simulations.
cgvSil.addBaseline( 1, 'rtwdemo_cgv_results');
result2 = cgvSil.run();

% To see the name(s) of the signal(s) that did match, use getMismatches.
% Mismatched signal names are only available if a baseline was added and
% the comparison failed.
if strcmp( cgvSil.getStatus( 1), 'failed')
    disp( 'Mismatched Signal Names:');
    [signalNames, plotFiles] = cgvSil.getMismatches( 1);
    fprintf( 1, 'Signal Names: %s\n', signalNames{:} );
    fprintf( 1, 'Path to plot files: %s\n', plotFiles{:});
    assert(numel(signalNames)==1,'Expected exactly one mismatch');
end

Run in PIL Mode

Next, the model runs a PIL simulation, using your embedded processor. A universal embedded processor does not exist. Therefore, PIL support is provided by using the host computer where MATLAB® is running. The host processor is treated as an embedded target.

A customization file is executed that maps this model's PIL execution onto the SIL infrastructure. After the customization file is executed, CGV execution displays PIL messages for the mode. SIL messages display the connectivity target.

The configuration set for the model is already configured with: Hardware Implementation > Test hardware > Test hardware is the same as production hardware is checked. Code Generation > Verification > Enable portable word sizes is checked. These settings work in SIL and in PIL when PIL is mapped onto the SIL connectivity target.

### Connectivity configuration for "C:\TEMP\Bdoc18b_943130_7372\ib632619\2\tpdb386d9e\ex96023632\rtwdemo_cgv_ert_rtw": CS1_default ###
### Updating code generation report with PIL files ...
### Starting application: 'rtwdemo_cg_ert_rtw\pil\rtwdemo_cg\exe'
End CGV execution: status completed.

Remove Customization

To prevent problems with other models, immediately remove the customization used to show PIL mode.

delete( 'sl_customization.m');
sl_refresh_customizations();

Check that execution did not terminate with an error

The run() function returns a Boolean value, which is true if the execution completes without model compilation or simulation error. Before accessing the data, check the result returned from each execution.

if ~result1 || ~result2 || ~result3
    disp('Execution of model failed.');?>
end

simData   = cgvSim.getOutputData(1);
silData   = cgvSil.getOutputData(1);
pilData   = cgvPil.getOutputData(1);
Compare Results

The executions are now complete. Compare the results. The comparison code supports a plot with filters. Plots display both the data and the difference.

CGV functions display signals names (as used in the command window) and create a file correlating tolerance information with signal names.

Show Signal Names from Normal Simulation

Display a list of signal names from the saved data.

Note: cgv.CGVC GV.compare ignores signals that appear in only one data set. For example, the compare function ignores a logged internal signal hi0 that appears in the output of a normal simulation, but does not appear in the output of a SIL simulation.

cgv.CGVC GV.getSavedSignals( simData);

Create a Tolerance File

The CGV createToleranceFile function creates a file correlating tolerance information with signal names. For the options available to configure tolerances, see cgv.CGVC GV.createToleranceFile. By default, tolerances are zero. Therefore the signals must match exactly. This example allows a delta of 0.5 on the ErrorsInjected signal.
signalList = {'simData.ErrorsInjected.Data' }; 
toleranceList = { { 'absolute', 0.5} }; 
cgv.CGV.createToleranceFile( 'localtol', signalList, toleranceList );

**Compare Signals**

By default, the cgv.CGV.compare function looks at signals that have a common name between both executions. In the following code, the simData.hi0.Data signals are not compared, because the signals do not appear in silData.

The second and fourth return parameters of the compare function are for matched figures and mismatched figures. Tildes (~) represent these parameters because this example does not use the return values.

A plot results from the mismatch on signal simData.ErrorsInjected.Data.

```
[matchNames, ~, mismatchNames, ~] = ... 
gev.CGV.compare( simData, silData, 'Plot', 'mismatch', ... 
' Tolerancefile', 'localtol');
fprintf( '%d Signals match, %d Signals mismatch
', ... 
length(matchNames), length(mismatchNames));
assert(length(mismatchNames) == 1,'Expected exactly one mismatch');
assert(length(matchNames) == 14, 'Expected exactly 14 matches');

disp( 'Mismatched Signal Names:');
disp(mismatchNames');
```

14 Signals match, 1 Signals mismatch
Mismatched Signal Names:
' simData.getEleement(4).Values.Data'
Compare Individual Signals

The cgv.CGV.compare function also compares only the specified signals. In this example, the function compares only three signals.

```matlab
[matchNames, ~, mismatchNames, ~] = ...
cgv.CGV.compare( simData, silData, 'Plot', 'mismatch', ...
    'Signals', {'simData.getElement(3).Values.hi1.mid0.lo1.Data',...
    'simData.getElement(3).Values.hi1.mid0.lo2.Data', ...
    'simData.getElement(2).Values.Data(:,3)'})
fprintf( '%d Signals match, %d Signals mismatch
', ...
    length(matchNames), length(mismatchNames))
assert(isempty(mismatchNames),'Expected no mismatches');
if ~isempty(mismatchNames)
    disp( 'Mismatched Signal Names:')
    disp(mismatchNames');
```
end

% Since a mismatch does not occur for these signals, a plot is not generated.
3 Signals match, 0 Signals mismatch

Additional Plotting Support

To create a plot of a list of signals, call cgv.CGV.plot. For example,

```matlab
[signalNames, signalFigures] = cgv.CGV.plot( simData, ...
    'Signals', {'simData.getElement(2).Values.Data(:,1)'});
```

View Signal Data in the Simulation Data Inspector Tool

To open the Simulation Data Inspector tool, at the MATLAB® command line, enter Simulink.sdi.view. To import the signal data, in the Simulation Data Inspector tool, select
**File > Import Data**, which opens the Data Import tool. Select **Import from > Base workspace**, to view and select the signals saved in simData and silData.

**Clear Your Workspace**

Clear the variables from the workspace:

```matlab
newBaseVars = who;
addedVars = setdiff(newBaseVars, baseVars);
clearCmd = ['clear ' sprintf(' %s ', addedVars{:})];
eval(clearCmd);
clear newBaseVars addedVars clearCmd
rtwdemoclean;
```

### Numerical Consistency

In the Model-Based Design workflow (Simulink Code Inspector), you use MathWorks products to generate code for numerical applications that employ fixed-point and floating-point arithmetic.

- To develop models, you use MATLAB, Simulink, and Stateflow.
- To generate source code, you use Simulink Coder and Embedded Coder.
- To test numerical equivalence between your model and generated code, you compare model and generated code simulation results. For example, normal mode simulation results compared with software-in-the-loop (SIL) simulation results.

The results from the model and generated code simulations are numerically consistent if:

- In fixed-point applications, the results agree in a bit-wise comparison.
- In floating-point applications, the results agree with an error tolerance that you specify.

Use the Simulation Data Inspector to compare results. To determine whether discrepancies exist or are significant, you can specify absolute and relative tolerance values:

- For fixed-point applications, you can specify an absolute tolerance of zero.
- For floating-point applications, you can specify tolerance with respect to a reference value or signal. The choice of reference depends on your application. Consider these examples:
  - An algorithm that solves a linear algebraic equation by iterative, feed-forward error calculations. You can specify tolerance with respect to \( \text{eps} \).
• A Proportional-Integral-Derivative (PID) controller for a closed-loop system. For transient behavior, you can specify tolerance with criteria from a standard. For steady-state behavior, you can specify tolerance with reference to the PID controller characteristics.

Programmatically, you can specify absolute and relative tolerance values through the absTol and relTol properties of the Simulink.sdi.Signal object.

**Numerical Consistency in Complex Systems**

For complex systems, numerical differences between model and generated code simulations can be a result of block-level differences propagating through the system. If you observe numerical differences at the system level:

1. Identify blocks for which block-level numerical differences exceed the error tolerance.
2. Investigate each identified block.

Consider the following plant-controller model.
• T produces reference or test signals.
• C is the controller component. The controller output is the plant input. C can be a Model block that comprises multiple Model blocks.
• P is the plant component. The plant output is subtracted from the reference signal to produce the controller input.

To test numerical equivalence between the model controller and the generated code version:

1. Run the model in normal mode, and, using the Simulation Data Inspector, record the output of C.
2. Specify SIL mode for C. Rerun the simulation, recording the output of C.
3. Using the Simulation Data Inspector, compare normal and SIL mode outputs with reference to your specified error tolerance.
If the Simulation Data Inspector comparison indicates a match, the model and generated code results are numerically consistent.

If the normal and SIL mode outputs do not match:

1. Within C, enable signal logging for block outputs.
2. Run the model in normal mode.
3. Rerun the simulation with C in SIL mode.
4. Using the Simulation Data Inspector, compare the logged output signals with reference to your specified error tolerance. See “Compare Simulation Data” (Simulink).
5. Identify blocks for which normal and SIL mode output differences exceed the error tolerance.
6. Analyze each identified block and look for the cause. For example, the generated code might use a different math library than MATLAB.

**Note** If the comparison of a large number of signals is required, you can automate the workflow with Simulink Test. See “Code Generation Verification Workflow with Simulink Test” (Simulink Test).

**Reasons for Block-Level Numerical Differences**

In fixed-point and floating-point application development, there are factors that can affect numerical agreement between block-level results from model and generated code simulations.

Some factors can affect both fixed-point and floating-point applications. For example, the use of:

- Code generation optimization.
- Custom code.
- Code replacement library entries whose results differ from MATLAB results.
- Code replacement libraries that implement different algorithms.

Other factors affect only floating-point applications. For example:

- Numerical soundness of algorithm.
• Algorithm sensitivity to input.
• Closed loop and open loop behavior.

Code Verification Through Software-in-the-Loop and Processor-in-the-Loop Execution

MATLAB Coder supports software-in-the-loop (SIL) and processor-in-the-loop (PIL) execution, which enables you to verify production-ready source code and compiled object code. With these execution modes, you can reuse test vectors developed for your MATLAB functions to verify the numerical behavior of library code.

In SIL execution, through a MATLAB SIL interface, the software compiles and runs library code on your development computer. In PIL execution, through a MATLAB PIL interface, the software cross-compiles and runs production object code on a target processor or an equivalent instruction set simulator. Before you run a PIL execution, you must set up a PIL connectivity configuration for your target.

The workflow for generating and verifying code is:

1. Set up MATLAB Coder.
2. Fix errors detected at design time.
3. Generate MEX function.
4. Test MEX function.
5. Generate C/C++ library code.
6. Verify generated C/C++ code through SIL or PIL execution — requires Embedded Coder license.

In step 4, you verify code that is generated for execution within MATLAB. However, this code is different from the standalone code generated for libraries. In step 6, with an Embedded Coder license, you use SIL or PIL execution to verify the standalone code.

Software-in-the-Loop Execution with the MATLAB Coder App

Use software-in-the-loop (SIL) execution to verify the numerical behavior of the generated C/C++ code with reference to your original MATLAB functions.

1. To open the MATLAB Coder app, on the MATLAB Toolstrip Apps tab, under Code Generation, click the app icon.

2. To open your project, click , and then click Open existing project. Select the project. For example, kalman_filter01.prj.

3. On the Generate Code page, click the Generate arrow.

4. In the Generate dialog box:
   a. Set Build type to Static Library or Dynamic Library.
   b. In the Output file name field, use the default value. For example, kalman01.
   c. Specify Language.
   d. Clear the Generate code only check box.
   e. In the Hardware Board field, use the default value (MATLAB Host Computer).

   You do not have to specify the Toolchain setting. By default, the MATLAB Coder app locates an installed toolchain.

5. To generate the C or C++ code, click Generate.

6. Click Verify Code.

7. In the command field, specify the test file that calls the original MATLAB functions, for example, test01_ui.m.

8. If required, select the Enable source-level debugging for SIL check box.

9. To start the SIL execution, click Run Generated Code.

The MATLAB Coder app:

- Generates a standalone library, for example, codegen\lib\kalman01.
- Generates SIL interface code, for example, codegen\lib\kalman01\sil.
- Runs the test file, replacing calls to the MATLAB function with calls to the generated code in the library.
• Displays messages from the SIL execution in the **Test Output** tab.

10 Verify that the results from the SIL execution match the results from the original MATLAB functions.

11 To terminate the SIL execution process, click **Stop SIL Verification**. Alternatively, on the **Test Output** tab, click the link that follows To terminate execution.

**Note** On a Windows operating system, the Windows Firewall can potentially block a SIL or PIL execution. To allow the execution, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

**More About**

Software-in-the-Loop Execution From Command Line

Use software-in-the-loop (SIL) execution to verify the numerical behavior of the generated C/C++ code with reference to your original MATLAB functions.

To set up and start a SIL execution from the command line:

2. Configure the object for SIL.
3. Use the `codegen` function to generate library code for your MATLAB function and the SIL interface.
4. Use the `coder.runTest` function to run the test file for your original MATLAB function.

To terminate the SIL execution, use the `clear function_sil` or `clear mex` command.

The following example shows how you can set up and run a SIL execution from the command line.

**SIL Execution of Code Generated for a Kalman Estimator**

1. **Copy MATLAB code for Kalman estimator**

   From `docroot\toolbox\coder\examples\kalman`, copy the following files to your working folder:

   - `kalman01.m` — MATLAB function for the Kalman estimator
   - `test01_ui.m` — MATLAB file to test `kalman01.m`
   - `plot_trajectory.m` — File that plots actual target trajectory and Kalman estimator output
   - `position.mat` — Input data

   ```
   src_dir = ...
   fullfile(docroot,'toolbox','coder','examples','kalman');
   
copyfile(fullfile(src_dir,'kalman01.m'), '.')
copyfile(fullfile(src_dir,'test01_ui.m'), '.')
copyfile(fullfile(src_dir,'plot_trajectory.m'), '.')
copyfile(fullfile(src_dir,'position.mat'), '.')
   ```
For a description of the Kalman estimator in this example, see “C Code Generation at the Command Line” (MATLAB Coder).

2 **Configure SIL execution**

   a From your working folder, create a `coder.EmbeddedCodeConfig` object.

      ```
      config = coder.config('lib');
      config.GenerateReport = true; % Optional, documents code in HTML report
      ```

   b Configure the object for SIL.

      ```
      config.VerificationMode = 'SIL';

      % Check that production hardware setting is the default
      % i.e. 'Generic->MATLAB Host Computer'
      disp(config.HardwareImplementation.ProdHWDeviceType);
      ```

   c If required, enable the Microsoft Visual Studio debugger for SIL execution:

      ```
      config.SILDebugging = true;
      ```

3 **Generate code and run SIL execution**

   Generate library code for the `kalman01` MATLAB function and the SIL interface, and run the MATLAB test file, `test01_ui`. The test file uses `kalman01_sil`, the generated SIL interface for `kalman01`.

   ```
   codegen -config config -args {zeros(2,1)} kalman01 -test test01_ui
   ```

   The software creates the following output folders:

   - `codegen\lib\kalman01` — Standalone code for `kalman01`.
   - `codegen\lib\kalman01\sil` — SIL interface code for `kalman01`.

   Verify that the output of this run matches the output from the original `kalman01.m` function.

   **Note** On a Windows operating system, the Windows Firewall can potentially block a SIL or PIL execution. To allow the execution, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.
4 Debug code during SIL execution

If you enable the Microsoft Visual Studio debugger, then running the test file opens the Microsoft Visual Studio IDE with debugger breakpoints at the start of the `kalman01_initialize` and `kalman01` functions.

You can use the debugger features to observe code behavior. For example, you can step through code and examine variables.

To end the debugging session:

- a Remove all breakpoints.
- b Click the Continue button (F5).

The SIL execution runs to completion.

5 Terminate SIL execution

Terminate the SIL execution process.

```
clear kalman01_sil;
```

You can also use the command `clear mex`, which clears MEX functions from memory.

More About

Debug Generated Code During SIL Execution

If a SIL execution fails or you notice differences between the outputs of your original functions and the generated code, you can rerun the SIL execution with a debugger enabled. By inserting breakpoints, you can observe the behavior of code sections, which might help you to understand the cause of the problem.

For a SIL execution failure, you can also view information from the standard output and standard error streams in the MATLAB Command Window. For example:

- Output from `printf` statements in your code.
- If you enable run-time error detection, messages sent to `stderr`.
- Some low-level system messages.

**Note** During a SIL execution, the SIL application redirects the `stdout` and `stderr` streams. When the application terminates, the MATLAB Command Window displays the information from the redirected streams. The SIL application also provides a basic signal handler, which captures the POSIX signals SIGFPE, SIGILL, SIGABRT, and SIGSEV. For this signal handler, the SIL application includes the file `signal.h`.

A SIL execution supports the following debuggers:

- On Windows, Microsoft Visual Studio debugger.
- On Linux, GNU Data Display Debugger (DDD).

**Note** You can perform SIL debugging only if your Microsoft Visual C++ or GNU GCC compiler is supported by the MATLAB product family. For more information, see supported compilers.

To run a SIL execution with debugging enabled:

2. Select the Enable source-level debugging for SIL check box.
3. Click Run Generated Code.
On a Windows computer, your `user_fn.c` or `user_fn.cpp` file opens in the Microsoft Visual Studio IDE with debugger breakpoints at the start of the `user_fn_initialize` and `user_fn` functions.

You can now use the debugger features to observe code behavior. For example, you can step through code and examine variables.

To end the debugging session:

1. Remove all breakpoints.
2. Click the Continue button (F5).

   The SIL execution runs to completion.

3. To terminate the SIL execution process, on the Test Output tab, click the link that follows To terminate execution, for example, clear `kalman01_sil`.

   The Microsoft Visual Studio IDE closes automatically.

**Note** If you select Debug > Stop Debugging, the SIL execution times out with the following error message:
Communications error: failed to send data to the target. There might be multiple reasons for this failure.

Create PIL Target Connectivity Configuration for MATLAB

In this section...

| “Target Connectivity Configurations for PIL” on page 79-12 |
| “Create a Target Connectivity API Implementation” on page 79-13 |
| “Register Target Connectivity Configuration” on page 79-14 |
| “Verify Target Connectivity Configuration” on page 79-15 |

Target Connectivity Configurations for PIL

Use target connectivity configurations and the target connectivity API to customize processor-in-the-loop (PIL) execution for your target environments.

Through a target connectivity configuration, you specify:

- A target connectivity configuration name for a target connectivity API implementation.
- Settings that define compatible MATLAB code. For example, the code that is generated for a particular hardware implementation.

A PIL execution requires a target connectivity PIL API implementation that integrates third-party tools for:

- Building the PIL application that runs on the target hardware
- Downloading, starting, and stopping the application on the target
- Communicating between MATLAB and the target

You can have many different connectivity configurations for PIL execution. Register a connectivity configuration with MATLAB by creating an `rtwTargetInfo.m` file and placing it on the MATLAB search path.

In a PIL execution, the software determines which of the available connectivity configurations to use. The software looks for a connectivity configuration that is compatible with the MATLAB code under test. If the software finds multiple or no compatible connectivity configurations, the software generates an error message with information about resolving the problem.
Create a Target Connectivity API Implementation

This diagram shows the components of the PIL target connectivity API.

You must provide implementations of the three API components:

- **Build API** — Specify a toolchain approach for building generated code.
- **Launcher API** — Control how MATLAB starts and stops the PIL executable.
- **Communications API** — Customize connectivity between MATLAB and the PIL target. Embedded Coder provides host-side support for TCP/IP and serial communications, which you can adapt for other protocols.

These steps outline how you create a target connectivity API implementation. The example code shown in the steps is taken from the `ConnectivityConfig.m` file used in "Processor-in-the-Loop Execution From Command Line" on page 79-28.

   ```matlab
   ConnectivityConfig < rtw.connectivity.Config
   ```

2. In the subclass:

   [Further steps and code examples are omitted for brevity.]
• Instantiate `rtw.connectivity.MakefileBuilder`, which configures the build process.

```matlab
builder = rtw.connectivity.MakefileBuilder(componentArgs, ...
    targetApplicationFramework, ...
    exeExtension);
```

• Create a subclass of `rtw.connectivity.Launcher`, which downloads and executes the application using a third-party tool.

```matlab
launcher = mypil.Launcher(componentArgs, builder);
```

3 Configure your `rtiostream` API implementation of the host-target communications on page 79-16 channel.

• For the target side, you must provide the driver code for communications, for example, code for TCP/IP or serial communications. To integrate this code into the build process, create a subclass of `rtw.pil.RtIOStreamApplicationFramework`.

• For the host side, you can use a supplied library for TCP/IP or serial communications. Instantiate `rtw.connectivity.RtIOStreamHostCommunicator`, which loads and initializes the library that you specify.

```matlab
hostCommunicator = rtw.connectivity.RtIOStreamHostCommunicator(...
    componentArgs, ...
    launcher, ...
    rtiostreamLib);
```

4 If you require execution-time profiling of generated code, create a timer object that provides details of the hardware-specific timer and associated source files. See “Specify Hardware Timer” on page 79-22.

**Register Target Connectivity Configuration**

To register a target connectivity API implementation as a target connectivity configuration in MATLAB:

1 Create or update an `rtwTargetInfo.m` file. In this file:

• Create a target connectivity configuration object that specifies, for example, the configuration name for a target connectivity API implementation and compatible MATLAB code.

• Invoke `registerTargetInfo`. 

79-14
Add the folder containing `rtwTargetInfo.m` to the search path and refresh the MATLAB Coder library registration information.

For more information, see `rtw.connectivity.ConfigRegistry`.

**Verify Target Connectivity Configuration**

To verify your target connectivity configuration early on and independently of your algorithm development and code generation, use the `piltest` function. With the function, you can run a suite of tests. The function:

- Runs the MATLAB function and performs PIL executions.
- Compares results and produces errors if it detects differences.

For an example, see “PIL Execution of Code Generated for a Kalman Estimator” on page 79-28.

Host-Target Communication for PIL

In this section...

"Communications rtiostream API” on page 79-16
"Synchronize Host and Target” on page 79-17
"Test an rtiostream Driver” on page 79-18

Communications rtiostream API

The rtiostream API supports communications for the target connectivity API. Use the rtiostream API to implement a communication channel that enables data exchange between different processes.

PIL verification requires a host-target communications channel. This communications channel comprises driver code that runs on the host and target. The rtiostream API defines the signature of target-side and host-side functions that must be implemented by this driver code.

The API is independent of the physical layer that sends the data. Possible physical layers include RS232, Ethernet, or Controller Area Network (CAN).

A full rtiostream implementation requires both host-side and target-side drivers. Code generation software includes host-side drivers for the default TCP/IP implementation as well as a version for serial communications. To use:

- The TCP/IP rtiostream communications channel, you must provide, or obtain from a third party, target-specific TCP/IP device drivers.
- The serial communications channel, you must provide, or obtain from a third party, target-specific serial device drivers.

For other communication channels and platforms, the code generation software does not provide default implementations. You must provide both the host-side and the target-side drivers.

The rtiostream API comprises the following functions:

- rtIOStreamOpen
- rtIOStreamSend
• rtIOStreamRecv
• rtIOStreamClose

For information about:

• Using rtiostream functions in a connectivity implementation, see “Create a Target Connectivity API Implementation” on page 79-13.
• Testing the rtiostream shared library methods from MATLAB code, see rtiostream_wrapper.
• Debugging and verifying the behavior of custom rtiostream interface implementations, see “Test an rtiostream Driver” on page 79-18.

**Synchronize Host and Target**

If you use the rtiostream API to implement the communications channel, the host and target must be synchronized, which prevents MATLAB from transmitting and receiving data before the target application is fully initialized.

To synchronize the host and target for TCP/IP rtiostream implementations, use the setInitCommsTimeout method from rtw.connectivity.RtIOStreamHostCommunicator. This approach works well for connection-oriented TCP/IP rtiostream implementations because MATLAB automatically waits until the target server is running.

With other rtiostream implementations, for example, serial, the MATLAB side of the rtiostream connection opens without waiting for the target to be fully initialized. In this case, you must make your Launcher implementation wait until the target application is fully initialized. Use one of the following approaches to synchronize your host and target:

• Add a pause at the end of the Launcher implementation that makes the Launcher wait until target initialization is complete.
• In the Launcher implementation, use third-party downloader or debugger APIs that wait until target initialization is complete.
• Implement a handshaking mechanism in the Launcher / rtiostream implementation that confirms completion of target initialization.
Test an rtiostream Driver

Use a test suite to debug and verify the behavior of custom rtiostream interface implementations.

The test suite has the following advantages:

- Reduces time for integrating custom hardware that does not have built-in rtiostream support.
- Reduces time for testing custom rtiostream drivers.
- Helps analyze the performance of custom rtiostream drivers.

The test suite has two parts. One part of the test suite runs on the target.

**Note** After building the target application, download it to the target and run it.

To start this part, compile and link the following files, which are in the folder `matlabroot/toolbox/coder/rtiostream/src/rtiostreamtest` (open).

- rtiostreamtest.c
- rtiostreamtest.h
- rtiostream.h, located in the folder `matlabroot/rtw/c/src` (open)
- rtiostream implementation under investigation (for example, rtiostream_tcpip.c)
- main.c

To run the MATLAB part of the test suite, invoke rtiostreamtest. The syntax is as follows:

rtiostreamtest(connection,param1,param2)

- connection is a character vector indicating the communication method. It can have values 'tcp' or 'serial'.
- param1 and param2 have different values depending on the value of connection.
  - If connection is 'tcp', then param1 and param2 are hostname and port, respectively. For example, rtiostreamtest('tcp', 'localhost', 2345).
• If connection is 'serial', then param1 and param2 are COM port and baud rate, respectively. For example, rtiostreamtest('serial', 'COM1', 9600).

You can run the MATLAB part of the test suite as follows:

```matlab
rtiostreamtest('tcp','localhost','2345')
```

An output in the following format appears in the MATLAB window:

```matlab
### Test suite for rtiostream ###
Initializing connection with target...

### Hardware characteristics discovered
Size of char    : 8 bit
Size of short   : 16 bit
Size of int     : 32 bit
Size of long    : 32 bit
Size of float   : 32 bit
Size of double  : 64 bit
Size of pointer : 64 bit
Byte ordering   : Little Endian

### rtiostream characteristics discovered
Round trip time : 0.96689 ms
rtIOStreamRecv behavior : non-blocking

### Test results
Test 1 (fixed size data exchange): ........... PASS
Test 2 (varying size data exchange): ........... PASS

### Test suite for rtiostream finished successfully ###

Furthermore, the following profile appears.

Specify Hardware Timer

For processor-in-the-loop (PIL) code execution profiling, you must create a timer object that provides details of the hardware-specific timer and associated source files. You can use the Code Replacement Tool or the code replacement library API to specify this hardware-specific timer.

To specify the timer with the Code Replacement Tool:

1. Open the Code Replacement Tool. In the Command Window, enter `crtool`.
2. Create a new code replacement table. Select **File > New table**.
3. Create a new function entry. Under **Tables List**, right-click the new table. Then, from the context-menu, select **New entry > Function**.
4. In the middle view, select the new unnamed function.
5. On the **Mapping Information** pane:
   a. From the **Function** drop-down list, select `code_profile_read_timer`.
   b. Specify the count direction for your timer. For example, from the **Count direction** drop-down list, select **Up**.
   c. In the **Ticks per second** field, specify the number of ticks per second for your timer, for example, `1e+09`.

   The default value is 0. In this case, the software reports time measurements in terms of ticks, not seconds.
   d. In the **Name** field, specify a replacement function name, for example, **MyTimer**.
   e. Click **Apply**.
To validate the function entry, click **Validate entry**.

6. On the **Build Information** pane, specify the required build information. See “Specify Build Information for Replacement Code” on page 64-61.

7. Save the table (**Ctrl+S**). When you save the table for the first time, use the Save As dialog box to specify the file name and location.

You must save the table in a location that is on the MATLAB search path. For example, you can save this file in the folder for your subclass of `rtw.connectivity.Config`.

The software stores your timer information as a code replacement library table.

8. Assuming you save the table as `MyCrlTable.m`, in your subclass of `rtw.connectivity.Config`, add the following line:

```matlab
setTimer(this, MyCrlTable)
```

Processor-in-the-Loop Execution with the MATLAB Coder App

Use processor-in-the-loop (PIL) execution to verify the numerical behavior of cross-compiled object code with reference to your original MATLAB functions.

Before you run a PIL execution, you must define a target connectivity configuration. In “Processor-in-the-Loop Execution From Command Line” on page 79-28, steps 1 and 2 of the example PIL Execution of Code Generated for a Kalman Estimator show how you can set up and register a connectivity configuration for PIL execution on your development computer.

1  To open the MATLAB Coder app, on the MATLAB Toolstrip Apps tab, under Code Generation, click the app icon.

2  To open your project, click , and then click Open existing project. Select the project. For example, kalman_filter.prj.

3  On the Generate Code page, click the Generate arrow.

4  In the Generate dialog box:

   a  Set Build type to Static Library or Dynamic Library.

   b  In the Output file name field, use the default value. For example, kalman01.

   c  Clear the Generate code only check box.

   d  From the Hardware Board drop-down list, select None - Select device below.

   e  In the Device fields, specify vendor and type. These settings must match the target hardware settings in the rtwTargetInfo.m file of your target connectivity configuration. For host-based PIL, select settings that match your host computer. For example:

      • For a Windows 64-bit system, set Device vendor to Intel and Device type to x86-64 (Windows64). In addition, set Enable long long to Yes.

      • For a Linux 64-bit system, set Device vendor to Intel and Device type to x86-64 (Linux 64).

      • For a Mac OS X system, set Device vendor to Intel and Device type to x86-64 (Mac OS X).
You do not have to specify the Toolchain setting. By default, the MATLAB Coder app locates an installed toolchain.

5 To generate the C or C++ code, click Generate.

6 Click Verify Code.

7 In the command field, specify the test file that calls the original MATLAB functions, for example, test01_ui.m.

8 To start the PIL execution, click Run Generated Code.

The MATLAB Coder app:

- Generates a standalone library, for example, codegen\lib\kalman01.
- Generates PIL interface code, for example, codegen\lib\kalman01\pil.
- Runs the test file, replacing calls to the MATLAB function with calls to the generated code in the library.
- Displays messages from the PIL execution in the Test Output tab.

9 Verify that the results from the PIL execution match the results from the original MATLAB functions.

10 To terminate the PIL execution process, click Stop PIL Verification. Alternatively, on the Test Output tab, click the link that follows To terminate execution.

**Note** On a Windows operating system, the Windows Firewall can potentially block a SIL or PIL execution. To allow the execution, use the Windows Security Alert dialog box. For example, in Windows 7, click Allow access.

More About

Processor-in-the-Loop Execution From Command Line

Use processor-in-the-loop (PIL) execution to verify code that you intend to deploy in production.

To set up and start a PIL execution from the command line:

1. Create, register, and verify your target connectivity configuration.
2. Create a `coder.EmbeddedCodeConfig` object.
3. Configure the object for PIL.
4. Use the `codegen` function to generate library code for your MATLAB function and the PIL interface.
5. Use the `coder.runTest` function to run the test file for your original MATLAB function.

To terminate the PIL execution, use the `clear function_pil` or `clear mex` command.

The following example shows how you can use line commands to set up and run a PIL execution on your development computer.

PIL Execution of Code Generated for a Kalman Estimator

1. Create a target connectivity API implementation
   a. In your current working folder, make a local copy of the connectivity classes.
      ```matlab
      src_dir = ...;
      fullfile(matlabroot,'toolbox','coder','simulinkcoder','+coder','+mypi1');
      if exist(fullfile('.', '+mypi1'),'dir')
        rmdir('+mypi1','s')
      end
      mkdir '+mypi1'
      copyfile(fullfile(src_dir,'Launcher.m'), '+mypi1');
      copyfile(fullfile(src_dir,'TargetApplicationFramework.m'), '+mypi1');
      copyfile(fullfile(src_dir,'ConnectivityConfig.m'), '+mypi1');
      
      b. Make the copied files writable.
      fileattrib(fullfile('+mypi1', '*'),'+w');
      
      c. Update the package name to reflect the new location of the files.
      ```
coder.mypil.Utils.UpdateClassName(...
    './+mypil/ConnectivityConfig.m',...
    'coder.mypil',...
    'mypil');

d  Check that you now have a folder +mypil in the current folder, which includes three files, Launcher.m, TargetApplicationFramework.m, and ConnectivityConfig.m.

    dir './+mypil'

e  Review the code that starts the PIL application. The mypil.Launcher class configures a tool for starting the PIL executable. Open this class in the editor.

    edit(which('mypil.Launcher'))

Review the content of this file. For example, consider the setArgString method. This method allows additional command line parameters to be supplied to the application. These parameters can include a TCP/IP port number. For an embedded processor implementation, you might have to hard code these settings.

f  The class mypil.ConnectivityConfig configures target connectivity.

    edit(which('mypil.ConnectivityConfig'))

Review the content of this file. For example:

• The creation of an instance of rtw.connectivity.RtIOStreamHostCommunicator that configures the host side of the TCP/IP communications channel.

• A call to the setArgString method of Launcher that configures the target side of the TCP/IP communications channel.

• A call to setTimer that configures a timer for execution time measurement. To define your own target-specific timer for execution time profiling, you must use the Code Replacement Library to specify a replacement for the function code_profile_read_timer.

g  Review the target-side communication drivers.

    rtiostreamtcpip_dir=fullfile(matlabroot,'rtw','c','src','rtiostream',...
            'rtiostreamtcpip');
    edit(fullfile(rtiostreamtcpip_dir,'rtiostream_tcpip.c'))

Scroll down to the end of this file. The file contains a TCP/IP implementation of the functions rtIOStreamOpen, rtIOStreamSend, and rtIOStreamRecv.
These functions are required for target communication with the host. For each of these functions, you must provide an implementation that is specific to your target hardware and communication channel.

The `mypil.TargetApplicationFramework` class adds target-side communication drivers to the connectivity configuration.

```plaintext
edit(which('mypil.TargetApplicationFramework'))
```

The file specifies additional files to include in the build.

2 Register a target connectivity configuration

Use an `rtwTargetInfo.m` file to:

- Create a target connectivity configuration object.
- Invoke `registerTargetInfo`, which registers the target connectivity configuration.

The target connectivity configuration object specifies, for example:

- The configuration name and associated API implementation. See `rtw.connectivity.ConfigRegistry`.
- A toolchain for your target hardware. This example assumes that the target hardware is your host computer, and uses the toolchain supplied for host-based PIL verification. For information about toolchains, see “Custom Toolchain Registration” (MATLAB Coder).

a Insert the following code into your `rtwTargetInfo.m` file, and save the file in the current working folder or in a folder that is on the MATLAB search path:

```plaintext
function rtwTargetInfo(tr)
% Register PIL connectivity config: mypil.ConnectivityConfig

tr.registerTargetInfo(@loc_createConfig);

% local function
function config = loc_createConfig

% Create object for connectivity configuration
config = rtw.connectivity.ConfigRegistry;
% Assign connectivity configuration name
config.ConfigName = 'My PIL Example';
% Associate the connectivity configuration with the connectivity
```
% API implementation
config.ConfigClass = 'mypil.ConnectivityConfig';

% Specify toolchains for host-based PIL
config.Toolchain = rtw.connectivity.Utils.getHostToolchainNames;

% Through the HardwareBoard and TargetHWDeviceType properties,
% define compatible code for the target connectivity configuration
config.HardwareBoard = {};  % Any hardware board
config.TargetHWDeviceType = {'Generic->32-bit x86 compatible' ...  
    'Generic->Custom' ... 
    'Intel->x86-64 (Windows64)' , ... 
    'Intel->x86-64 (Mac OS X)' , ... 
    'Intel->x86-64 (Linux 64)'};

b  Refresh the MATLAB Coder library registration information.
   RTW.TargetRegistry.getInstance('reset');

3 Verify target connectivity configuration

Use the supplied piltest function to verify your target connectivity configuration.

a  Create a coder.EmbeddedCodeConfig object for verifying the target
    connectivity configuration.
   configVerify = coder.config('lib');

b  Specify the manufacturer and test hardware type. For example, PIL execution on
    a 64-bit Windows development computer requires:

   configVerify.HardwareImplementation.TargetHWDeviceType =...  
      'Intel->x86-64 (Windows64)';
   configVerify.HardwareImplementation.ProdLongLongMode = true;

c  Run piltest.
   piltest(configVerify, 'ConfigParam', {'ProdLongLongMode'} )

4 Copy MATLAB code for Kalman estimator

Copy the MATLAB code to your working folder.

src_dir = ...
   fullfile(docroot,'toolbox','coder','examples','kalman');

copyfile(fullfile(src_dir,'kalman01.m'), '.')
copyfile(fullfile(src_dir,'test01_ui.m'), '.')
copyfile(fullfile(src_dir,'plot_trajectory.m'), '.')
copyfile(fullfile(src_dir,'position.mat'), '.')

For a description of the Kalman estimator in this example, see “C Code Generation at the Command Line” (MATLAB Coder).

5 Configure the PIL execution

a Create a coder.EmbeddedCodeConfig object.

```matlab
config = coder.config('lib');
```

b Configure the object for PIL.

```matlab
config.VerificationMode = 'PIL';
```

c Specify production hardware, which must match one of the test hardware settings in rtwTargetInfo.m. For PIL execution on your development computer, specify settings that match the computer. For example, if your computer is a Windows 64-bit system, specify:

```matlab
config.HardwareImplementation.ProdHWDeviceType = ...
    'Intel->x86-64 (Windows64)';
```

c On a Linux 64-bit system, set ProdHWDeviceType to 'Intel->x86-64 (Linux 64)'.

c On a Mac OS X system, set ProdHWDeviceType to 'Intel->x86-64 (Mac OS X)'.

6 Generate code and run PIL execution

Generate library code for the kalman01 MATLAB function and the PIL interface, and run the MATLAB test file, test01_ui. The test file uses kalman01_pil, the generated PIL interface for kalman01.

```matlab
codegen -config config -args {zeros(2,1)} kalman01 -test test01_ui
```

The software creates the following output folders:

- codegen/lib/kalman01 — Standalone code for kalman01.
- codegen/lib/kalman01/pil — PIL interface code for kalman01.

Verify that the output of this run matches the output from the original kalman01.m function.
Note On a Windows operating system, the Windows Firewall can potentially block a SIL or PIL execution. To allow the execution, use the Windows Security Alert dialog box. For example, in Windows 7, click Allow access.

7 Terminate PIL execution

Terminate the PIL execution process.

clear kalman01_pil;

More About

Verification of Code Generation Assumptions

The settings on the More Settings > Hardware tab specify target behavior, which result in the implementation of implicit assumptions in the generated code. Incorrect settings can lead to:

- Suboptimal code
- Code execution failure, incorrect code output, and nondeterministic code behavior

At the start of a processor-in-the-loop (PIL) execution, the software verifies the Hardware tab settings with reference to the target hardware. The software checks:

- The correctness of settings. For example, the integer bit length in the Sizes > int field.
- Whether the settings are optimized. For example, the rounding of signed integer division in the Signed integer division rounds to field.

If required, the software generates warnings and errors.

### Feature | Supported
--- | ---
Global data | Yes. SIL and PIL execution supports four types of storage classes on page 89-2 for MATLAB Coder global variables. The synchronization (MATLAB Coder) of global data between MATLAB and the SIL or PIL application depends on the type of storage class that you specify:

- **ExportedGlobal** (default) — The synchronization of global data between MATLAB and a SIL or PIL application is identical to the synchronization between MATLAB and a MEX function.

- **ExportedDefine** — There is no synchronization of global data between MATLAB and the SIL or PIL application. The application uses the values of the global variables in MATLAB at the time of code generation.

- **ImportedExtern** and **ImportedExternPointer** — There is no synchronization of global data between MATLAB and the SIL or PIL application. The application uses initial values of global variables, which you specify in the external code. If the global variables are not initialized in the external code, the SIL or PIL execution results are undefined.

Constant global data | Yes
Reentrant code | Yes

**Related Examples**
Speed Up SIL/PIL Execution by Disabling Constant Input Checking and Global Data Synchronization

By default, a SIL or PIL execution performs constant input checking and global data synchronization. Constant input checking compares the value that a test file provides for a constant input argument with the value specified at code generation time. If the values do not match, an error occurs. Global data synchronization makes the values of global variables in the SIL or PIL execution environment consistent with the values in the MATLAB workspace. If a global variable is constant and its value in the SIL or PIL execution environment differs from its value in the MATLAB workspace, an error occurs.

It is possible to speed up a SIL or PIL execution by disabling constant input checking or global data synchronization. However, if you disable these features, the SIL or PIL execution results might differ from the results in MATLAB.

Disable Constant Input Checking or Global Data Synchronization at the Command Line

In a coder.EmbeddedCodeConfig object that you configured for SIL or PIL execution:

- To disable constant input checking, set the SILPILCheckConstantInputs property to false. For example, for an object `cfg`, use this code:

  ```matlab
cfg.SILPILCheckConstantInputs = false;
```

- To disable global data synchronization, set the SILPILSyncGlobalData property to false. For example, for an object `cfg`, use this code:

  ```matlab
cfg.SILPILSyncGlobalData = false;
```

Disable Constant Input Checking or Global Data Synchronization in the MATLAB Coder App

In the settings for a project that you set up for SIL or PIL execution, on the Debugging tab:

- To disable constant input checking, set Check constant inputs in SIL/PIL to No.
- To disable global data synchronization, set Synchronize global data in SIL/PIL to No.

- “Code Coverage Tool Support” on page 80-26
- “Tips and Limitations” on page 80-27
- “Collect Code Coverage Metrics with a Third-Party Tool” on page 80-32
Simulink Code Coverage Metrics

If you have a Simulink Coverage license, you can run a SIL or PIL simulation that produces code coverage metrics for generated model code. The simulation performs several types of code coverage analysis.

### Statement Coverage for Code Coverage

Statement coverage determines the number of source code statements that execute when the code runs. Use this type of coverage to determine whether every statement in the program has been invoked at least once.

Statement coverage = \( \frac{\text{Number of executed statements}}{\text{Total number of statements}} \) * 100

**Statement Coverage Example**

This code snippet contains five statements. To achieve 100% statement coverage, you need at least three test cases. Specifically, tests with positive x values, negative x values, and x values of zero.

```c
if (x > 0)
    printf( "x is positive" );
else if (x < 0)
    printf( "x is negative" );
else
    printf( "x is 0" );
```
Condition Coverage for Code Coverage

Condition coverage analyzes statements that include conditions in source code. Conditions are C/C++ Boolean expressions that contain relation operators (<, >, <=, or >=), equation operators (!= or ==), or logical negation operators (!), but that do not contain logical operators (&& or ||). This type of coverage determines whether every condition has been evaluated to all possible outcomes at least once.

Condition coverage = (Number of executed condition outcomes / Total number of condition outcomes) *100

Condition Coverage Example

In this expression:

\[ y = x<=5 \ \&\& \ x!=7; \]

there are these conditions:

x<=5
x!=7

Decision Coverage for Code Coverage

Decision coverage analyzes statements that represent decisions in source code. Decisions are Boolean expressions composed of conditions and one or more of the logical C/C++ operators && or ||. Conditions within branching constructs (if/else, while, do-while) are decisions. Decision coverage determines the percentage of the total number of decision outcomes the code exercises during execution. Use this type of coverage to determine whether all decisions, including branches, in your code are tested.

Note The decision coverage definition for DO-178C compliance differs from the Simulink Coverage definition. For decision coverage compliance with DO-178C, select the Condition Decision structural coverage level for Boolean expressions not containing && or || operators.

Decision coverage = (Number of executed decision outcomes / Total number of decision outcomes) *100
**Decision Coverage Example**

This code snippet contains three decisions:

```c
y = x<=5 && x!=7;                // decision #1

if( x > 0 )                    // decision #2
    printf( "decision #2 is true" );
else if( x < 0 && y )                // decision #3
    printf( "decision #3 is true" );
else
    printf( "decisions #2 and #3 are false" );
```

**Modified Condition/Decision Coverage (MCDC) for Code Coverage**

Modified condition/decision coverage (MCDC) is the extent to which the conditions within decisions are independently exercised during code execution.

- All conditions within decisions have been evaluated to all possible outcomes at least once.
- Every condition within a decision independently affects the outcome of the decision.

MCDC coverage = (Number of conditions evaluated to all possible outcomes affecting the outcome of the decision / Total number of conditions within the decisions) *100

**Modified Condition/Decision Coverage Example**

For this decision:

```
X || ( Y && Z )
```

the following set of test cases delivers 100% MCDC coverage.

<table>
<thead>
<tr>
<th>Test case</th>
<th>X</th>
<th>Y</th>
<th>Z</th>
</tr>
</thead>
<tbody>
<tr>
<td>#1</td>
<td>0</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>#2</td>
<td>0</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>#3</td>
<td>0</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>#4</td>
<td>1</td>
<td>0</td>
<td>1</td>
</tr>
</tbody>
</table>
Cyclomatic Complexity for Code Coverage

Cyclomatic complexity is a measure of the structural complexity of code that uses the McCabe complexity measure. To compute the cyclomatic complexity of code, code coverage uses this formula:

\[ c = \sum_{1}^{N} (o_n - 1) \]

\( N \) is the number of decisions in the code. \( o_n \) is the number of outcomes for the \( n^{th} \) decision point. Code coverage adds 1 to the complexity number for each C/C++ function.

Coverage Example

For this code snippet:

```c
void evalNum( int x ){
    if (x > 0)
        printf( "x is positive" );
    else if (x < 0)
        printf( "x is negative" );
    else
        printf( "x is 0" );
}
```

the cyclomatic complexity is 3.

Relational Boundary for Code Coverage

Relational boundary code coverage examines code that has relational operations. Relational boundary code coverage metrics align with those for model coverage, as described in “Relational Boundary Coverage” (Simulink Coverage). Fixed-point values in your model are integers during code coverage.
See Also

Related Examples

If you have Embedded Coder and Simulink Coverage, you can analyze coverage for generated code during a software-in-the-loop (SIL) or processor-in-the-loop (PIL) simulation.

<table>
<thead>
<tr>
<th>In this section…</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Enable SIL or PIL Code Coverage for a Model” on page 80-7</td>
</tr>
<tr>
<td>“Simulink Coverage Code Coverage Measurement Workflows” on page 80-8</td>
</tr>
<tr>
<td>“Review the Coverage Results for Models in SIL or PIL Mode” on page 80-9</td>
</tr>
<tr>
<td>“Limitations” on page 80-10</td>
</tr>
</tbody>
</table>

Enable SIL or PIL Code Coverage for a Model

To record SIL or PIL code coverage for a model:

1. In the Configuration Parameters dialog box, on the left pane, click **Code Generation**. From the list, select **Verification**.
2. Under **Code profiling**, clear **Measure function execution times**.
3. Under **Code coverage for SIL or PIL**, for the **Third-party tool** select None (use Simulink Coverage).
Simulink Coverage Code Coverage Measurement Workflows

To measure code coverage, use either of these workflows:

- The top model is in SIL mode or PIL mode. Simulink Coverage measures code coverage for the top model, depending on `RecordCoverage`. Simulink Coverage also measures code coverage for referenced models, depending on `CovModelRefEnable`.
- The top model is in Normal mode and contains at least one reference model in SIL or PIL mode. Simulink Coverage measures code coverage for the referenced model if
CovModelRefEnable is 'on', 'all', or 'filtered' and RecordCoverage is 'off'.

**Review the Coverage Results for Models in SIL or PIL Mode**

In the code coverage report, each hyperlink opens a report with more details on the coverage analysis for the model. The code coverage results in these reports are similar to the coverage results for C/C++ code in S-function blocks, as described in “View Coverage Results for Custom C/C++ Code in S-Function Blocks” (Simulink Coverage). You can navigate from code coverage results to the associated model blocks by using the links within the detailed code coverage reports.

Each detailed code coverage report also contains syntax highlighted code with coverage information.
Limitations

Coverage for models in SIL and PIL mode has these limitations:

- The model must meet the requirements listed in “Enable SIL or PIL Code Coverage for a Model” on page 80-7.
- Code coverage results must not include external C/C++ files in read-only folders.

Related Examples

- “Software-in-the-Loop Code Coverage” (Simulink Coverage)
Configure Code Coverage with Third-Party Tools

During a top-model or Model block SIL or PIL simulation, you can collect code coverage metrics for generated code using a third-party tool. Embedded Coder supports the following tools:

- **LDRA Testbed** from LDRA Software Technology. For information about installing and using this tool, go to www.ldra.com.

  The software supports LDRA Testbed code coverage for SIL and PIL.

- **BullseyeCoverage** from Bullseye Testing Technology. For information about installing and using this tool, go to www.bullseye.com.

  The software supports BullseyeCoverage code coverage for SIL and, in certain cases, PIL.

To configure a code coverage tool for a top-model or Model block SIL or PIL simulation:

1. Select **Simulation > Model Configuration Parameters > Code Generation > Verification**.

2. From the **Third-party tool** drop-down list, select a tool, for example, BullseyeCoverage or LDRA Testbed.

3. Click **Configure** to open the Code Coverage Settings dialog box.

4. In the **Installation folder** field, specify the location where your coverage tool is installed. If you click **Browse**, the Select Installation Folder dialog box opens, which allows you to navigate to the folder where your coverage tool is installed. The software detects and displays the tool version.

By default, the following parameters are enabled:
• **Code coverage for this model** — Generate coverage data for the current (top) model.

• **Code coverage for referenced models** — Generate data for models referenced by the current (top) model.

If your top model has Model blocks, these parameters of the top model override the corresponding parameters of referenced models.

5 Click **OK**. You return to the **Verification** pane.

6 To view cumulative code coverage results within a code generation report, in the **Configuration Parameters > Code Generation > Report** pane, select the following check boxes:

• **Create code generation report**
• **Open report automatically**

7 Click **OK**. You return to the model window.

With LDRA Testbed:

• The evaluation of cumulative code coverage begins from the point when you last added a new file to the existing set of source files. For example, existing code coverage results are deleted when you:
  • Run a simulation with a new model using the existing code generation folder.
  • Run a simulation that results in additional source code files being instrumented.
• If you switch between SIL and PIL simulations of a model, the software generates separate cumulative code coverage results for the SIL and PIL simulations.

For a model in a reference hierarchy, the software does not support simultaneous function execution time measurement and code coverage.

View Code Coverage Information at the End of SIL or PIL Simulations

In this section...

| “View LDRA Testbed Results” on page 80-14 |
| “View BullseyeCoverage Results” on page 80-16 |

If you configure third-party code coverage for a SIL or PIL simulation, when the simulation is complete, the code generation report opens automatically and you see hyperlinks in the Command Window.

View LDRA Testbed Results

If you specified the LDRA Testbed, you see three links in the Command Window:

```plaintext
### Starting SIL simulation for component: rtwdemo_sil_topmodel
### Stopping SIL simulation for component: rtwdemo_sil_topmodel
### Starting analysis of coverage data
### Use the following links to view code coverage results:
   LDRA Testbed GUI
   LDRA Testbed Code Coverage Overview Report
   HTML code generation report with code coverage annotations
### Completed code coverage analysis
>>
```

To go to the LDRA Testbed GUI, click the **LDRA Testbed GUI** link.

To open the LDRA Testbed Report with your Web browser, click the **LDRA Testbed Code Coverage Overview Report** link.
For information about using this report, refer to the LDRA Testbed documentation.

LDRA Testbed analysis results for all code in the current code generation folder belong to a set. In this set, you can find analysis results for models that share the same code generation folder. The LDRA Testbed Code Coverage Overview Report link identifies the location of the LDRA Testbed analysis results, which is determined by:

- The LDRA Testbed configuration.
- The name of the LDRA Testbed set associated with the current code generation folder.

To view summary data and code annotations with coverage information in the code generation report, click the HTML code generation report with code coverage annotations link.
View BullseyeCoverage Results

If you specified the BullseyeCoverage tool, you see two links in the Command Window:

```plaintext
### Starting SIL simulation for component: rtwdemo_sil_topmodel
### Stopping SIL simulation for component: rtwdemo_sil_topmodel
### Processing code coverage data
### Use the following links to view code coverage results:
   BullseyeCoverage browser (coverage for last run)
   HTML code generation report (cumulative coverage)
### Completed code coverage analysis
>>
```

To view the coverage report using the BullseyeCoverage Browser, click the BullseyeCoverage browser (coverage for last run) link.

![BullseyeCoverage Browser](image)

The BullseyeCoverage Browser shows coverage data for instrumented files associated with your latest top-model simulation. The coverage data shown in the browser is not cumulative and pertains only to the most recent simulation. For information about the BullseyeCoverage Browser, go to www.bullseye.com.

To view summary data and code annotations with coverage information in the code generation report, click the HTML code generation report (cumulative coverage) link.

Configure Code Coverage Programmatically

You can configure code coverage for your model using command-line APIs. A typical workflow with BullseyeCoverage is:

1  Using `get_param`, retrieve the object containing coverage settings for the current model, for example, `gcs`.

   ```
   >> covSettings = get_param(gcs, 'CodeCoverageSettings')
   covSettings =
   CodeCoverageSettings with properties:
   TopModelCoverage: 'on'
   ReferencedModelCoverage: 'off'
   CoverageTool: 'BullseyeCoverage'
   ```

   The property `TopModelCoverage` determines whether the software generates code coverage data for just the top model, while `ReferencedModelCoverage` determines whether the software generates coverage data for models referenced by the top model. If neither property is 'on', then no code coverage data is generated during a SIL simulation.

   If LDRA Testbed is the specified code coverage tool, then the property `CoverageTool` is 'LDRA Testbed'.

   When you save your model, the properties `TopModelCoverage`, `ReferencedModelCoverage`, and `CoverageTool` are also saved.

2 Check the class of `covSettings`.

   ```
   >> class(covSettings)
   ans =
   coder.coverage.CodeCoverageSettings
   ```

3 Turn on coverage for referenced models.

   ```
   >> covSettings.ReferencedModelCoverage='on';
   ```

4 Using `set_param`, apply the new coverage settings to the model.

   ```
   >>set_param(gcs,'CodeCoverageSettings', covSettings);
   ```

5 Assuming you have installed the BullseyeCoverage tool, specify the installation path.

   ```
   >>coder.coverage.BullseyeCoverage.setPath('C:\Program Files\BullseyeCoverage')
   ```
For LDRA Testbed, use `coder.coverage.LDRA.setPath('C:\...').`

Check that the path is saved as a preference.

```matlab
>> coder.coverage.BullseyeCoverage.getPath
```

For LDRA Testbed, use `coder.coverage.LDRA.getPath`.

**Code Coverage Summary and Annotations**

**In this section...**

“LDRA Testbed Coverage” on page 80-20
“BullseyeCoverage Information” on page 80-23

If you specify a code coverage tool for a SIL or PIL simulation, the software produces a code generation report that provides summary data and code annotations with coverage information. Each code annotation is associated with a code feature and indicates the nature of the feature coverage during code execution.

The code generation report also allows you to navigate easily between blocks in your model and the corresponding sections in the source code.

**LDRA Testbed Coverage**

The cumulative coverage data in a code generation report is derived from instrumented files associated with your latest top-model simulation and coverage data collected from simulations with other top models that share referenced models with your current top model.

The software provides LDRA Testbed annotations in the code generation report to help you to review code coverage.
**Note** Do not use the code generation report alone to verify that you have achieved your coverage goals. You must refer to the LDRA Testbed Report.

This example shows three kinds of annotations. On lines 134, 139, 140, and 141, the annotation * indicates that statement coverage for each of these lines of code is not complete.

```c
if (x != 0) {
    if (y > 0) {
        if (z < 0) {
            // Some code
        }
    }
}
```

Placing the cursor over the annotation =>b produces a tooltip.

This tooltip indicates that only one branch destination is covered. The code within the curly brackets, which starts at column 45 of line 134, is not executed. As the if statement on line 139 lies within this code, the corresponding annotation => states that the branch is not covered.

This table describes the LDRA Testbed code annotations that you might see in a code generation report produced by a SIL and PIL simulations.

<table>
<thead>
<tr>

</table>
BullseyeCoverage Information

The cumulative coverage data in a code generation report is derived from instrumented files associated with your latest top-model simulation and coverage data collected from simulations with other top models that share referenced models with your current top model.

The software provides BullseyeCoverage annotations in the code generation report to help you to review code coverage.

This example shows two kinds of annotations. At line 41, TF indicates that the if decision had both true and false outcomes during the simulation. At line 52, =>F indicates that the if decision was false only during the simulation.

This table describes the BullseyeCoverage code annotations that you might see in a code generation report produced by a SIL simulation.
<table>
<thead>
<tr>
<th>Code feature</th>

Tips and Limitations

Model Build and SIL/PIL Blocks Not Supported

Code coverage does not support:

- The model build process, for example, the Ctrl+B command.
- SIL or PIL blocks.

Code coverage settings are ignored by the Ctrl+B command and SIL or PIL blocks.

BullseyeCoverage License Wait

When you build your model, you might have to wait for a BullseyeCoverage license. If you want to see information about the wait, before you build your model, select Configuration Parameters > Verbose build.

Current Working Folder Cannot be UNC Path

If your MATLAB current working folder is a Universal Naming Convention (UNC) path, code coverage fails.

Characters in matlabroot and File Path

If matlabroot or the path to your generated files contains a space or the . (period) character, code coverage might fail.

Header Files with Identical Names

Consider a model that is configured for LDRA Testbed code coverage. During the build process, if the software detects two header files with the same name in the folder for generated code, the software generates an error.

Code Coverage for Source Files in Shared Utility Folders

The software supports code coverage for source files generated in shared utility folders. If you configure code coverage for a model that uses shared utility code generation, when
you build the model, you also build all source files in the shared utilities folder with code coverage enabled.

Whenever you build a model, the code coverage settings of the model must be consistent with source files that you previously built in the shared utilities folder. Otherwise, the software reports that code in the shared utilities folder is inconsistent with the current model configuration and must be rebuilt. For example, if you run a SIL simulation for a model with code coverage enabled and then run a SIL simulation for another model with code coverage disabled, the software must rebuild all source files in the shared utilities folder.

**BullseyeCoverage Behavior with Inline Macros**

The BullseyeCoverage tool, by default, does not provide code coverage data for inline macros.

For example, if a model generates a file `slprj/ert/_sharedutils/rt_SATURATE.h` that contains the macro

```c
#define rt_SATURATE(sig,ll,ul) (((sig) >= (ul)) ? (ul) : (((sig) <= (ll)) ? (ll) : (sig)) )
```

and the macro is in `sat_ert_rtw/sat.c`, then the coverage report provides a measurement for `sat.c`, but no coverage data for the conditions within the macro `rt_SATURATE`.

To configure the BullseyeCoverage tool to provide code coverage data for inline macros:

1. Open the BullseyeCoverage Browser.
2. Select **Tools > Options** to open the Options dialog box.
3. On the **Build** tab, select the **Instrument macro expansions** check box.
4. Click **OK**.
5. Rerun your simulation.

Alternatively, you can add the text `-macro` to the BullseyeCoverage configuration file. For more information, go to www.bullseye.com/help.

**SIL and PIL Simulations with Open LDRA Testbed**

If you enable code coverage with the LDRA Testbed tool, you must verify that the LDRA Testbed GUI is not open when you run your SIL or PIL simulation. If the set name in the
LDRA Testbed GUI differs from the set name used by the SIL or PIL simulation, the SIL or PIL simulation fails.

**Minor SIL and PIL Differences for LDRA Testbed**

The target connectivity API supports code coverage with LDRA Testbed for top-model and Model block PIL.

There are minor differences in the code coverage information collected during SIL and PIL simulations. In particular, with PIL, the software does not explicitly show function exit point coverage. However, you can infer the coverage of function exit points by examining statement coverage.

**PIL Zero Coverage LDRA Testbed Annotations**

For a PIL simulation with LDRA Testbed code coverage specified, there might be some source files where the recorded coverage is zero. In this case, the software provides summary information indicating that:

- There is coverage to measure.
- The coverage is zero.
You do not see information for individual probes on each line. The displayed summary information has an associated annotation tooltip:

0 out of \(N\) coverage probes were exercised (detailed breakdown unavailable)

### PIL Support for BullseyeCoverage

Code coverage with BullseyeCoverage is available for top-model and Model block PIL provided your PIL application can write directly to the host file system. Your target for the PIL application must provide `fopen` and `fread` access to the host file system.

If code coverage is not available when you run the PIL application on your target hardware, you might be able to collect code coverage measurements by running the PIL application on an instruction set simulator that supports direct file I/O with the host file system.

### Modify Legacy Code

If you modify legacy code and rerun a SIL or PIL simulation, the legacy code is recompiled. However, the code from the model may be up-to-date. In this case, the code generation report is not updated and does not show the modified legacy code. Instead, the code coverage information for the modified legacy code is displayed with reference to the original legacy code. You must regenerate the report. For more information, see “Limitation” (Simulink Coder).

### IDE Link Does Not Support LDRA Testbed

When you generate code for IDE Link, you cannot use LDRA Testbed for SIL or PIL code coverage. Specifically, this limitation applies when you use the following settings together:

- **Configuration Parameters > Code Generation > System target file:** `idelink_ert.tlc`
- **Configuration Parameters > Code Generation > Verification > Third-party tool:** LDRA Testbed.

Collect Code Coverage Metrics with a Third-Party Tool

If Simulink® Coverage™ is installed, you can collect code coverage metrics during a software-in-the-loop (SIL) or processor-in-the-loop (PIL) simulation - see “Collect Code Coverage Data” (Simulink Coverage). In this example, you can collect code coverage metrics with a third-party tool, i.e., BullseyeCoverage or LDRA Testbed. You must install the third-party tool - see “Code Coverage Tool Support” on page 80-26.

This screen shot shows a code coverage report obtained by running a SIL simulation with a code coverage tool enabled. The annotations depend on the code coverage tool that you specify.
In this example, you measure model coverage during normal mode simulation and repeat the same simulation in SIL mode to measure code coverage. By using the hyperlinks in the model coverage and code coverage reports, you can compare model coverage and code coverage results.
For SIL and PIL simulation examples, see “Test Generated Code with SIL and PIL Simulations” on page 77-85.

**Initial Setup**

Make sure the model is newly opened.

```matlab
model='rtwdemo_sil_topmodel';
close_system(model,0)
open_system(model)
```
Remove existing build folders.
buildFolder=RTW.getBuildDir(model);
if exist(buildFolder.BuildDirectory,'dir')
    rmdir(buildFolder.BuildDirectory,'s');
end

Configure generation of model coverage report.

set_param(model, 'RecordCoverage','on')
clear covCumulativeData

Set up the stimulus data.

T=0.1; % sample time
[ticks_to_count, reset, counter_mode, count_enable, ...
    counter_mode_values_run1, counter_mode_values_run2, ...
    count_enable_values_run1, count_enable_values_run2] = ...
    rtwdemo_sil_topmodel_data(T);

**Run a Simulation in Normal Mode**

The model is configured to collect model coverage metrics. When a simulation is complete, the model coverage report opens. Use the coverage display window to navigate from blocks in the model to the corresponding sections of the coverage report.

counter_mode.signals.values = counter_mode_values_run1;
count_enable.signals.values = count_enable_values_run1;
set_param(model,'SimulationMode','normal');

Set up Simulation Data Inspector for interactive viewing and comparison of simulation results.

Simulink.sdi.view;
Simulink.sdi.clear;

Run the simulation.

simout_normal_run1 = sim(model, 'ReturnWorkspaceOutputs', 'on');

Capture the results.

Simulink.sdi.createRun('Run 1 (normal mode)', 'namevalue',...
    {'simout_normal_run1'}, {simout_normal_run1});

**Run a Second Simulation in Normal Mode**

For the first simulation, the report shows that the achieved coverage is less than 100%. Run a second simulation with different input signals that increase the level of MC/DC
coverage to 100%. Note that the model coverage report is configured to show cumulative coverage across both simulation runs.

counter_mode.signals.values = counter_mode_values_run2;
count_enable.signals.values = count_enable_values_run2;
set_param(model,'SimulationMode','normal');

simout_normal_run2 = sim(model, 'ReturnWorkspaceOutputs', 'on');

Simulink.sdi.createRun('Run 2 (normal mode)', 'namevalue',
    {'simout_normal_run2'}, {simout_normal_run2});

**Configure the Model to Measure Code Coverage**

Before running a SIL simulation, check the availability of third-party tools, and configure the model to collect code coverage metrics. If a third-party tool is not available, the model uses Simulink® Verification and Validation™.

covToolPath = '';
ldraPath = coder.coverage.LDRA.getPath;
bullseyePath = coder.coverage.BullseyeCoverage.getPath;

coverageSettings = get_param(model,'CodeCoverageSettings');
coverageSettings.TopModelCoverage='on';
if ~isempty(ldraPath)
    coverageSettings.CoverageTool='LDRA Testbed';
elseif ~isempty(bullseyePath)
    coverageSettings.CoverageTool='BullseyeCoverage';
else
    coverageSettings.CoverageTool='None';
end
set_param(model,'CodeCoverageSettings',coverageSettings);

**Run Simulations in SIL Mode**

The normal mode simulations produce coverage metrics for the model. With a SIL simulation, you can apply the same input stimulus signals to the generated code and measure code coverage.

Run the first simulation in SIL mode.

counter_mode.signals.values = counter_mode_values_run1;
count_enable.signals.values = count_enable_values_run1;
set_param(model,'SimulationMode','software-in-the-loop');
set_param(model,'CodeExecutionProfiling','off');
set_param(model,'CodeProfilingInstrumentation','off');
simout_sil_run1 = sim(model, 'ReturnWorkspaceOutputs', 'on');
Simulink.sdi.createRun('Run 1 (SIL mode)', 'namevalue', ...
    {'simout_sil_run1'}, {simout_sil_run1});

### Starting build procedure for model: rtwdemo_sil_topmodel
### Successful completion of build procedure for model: rtwdemo_sil_topmodel
### Preparing to start SIL simulation ... 
Building with 'Microsoft Visual C++ 2017 (C)'.
MEX completed successfully.
### Updating code generation report with SIL files ...
### Starting SIL simulation for component: rtwdemo_sil_topmodel
### Stopping SIL simulation for component: rtwdemo_sil_topmodel
### Completed code coverage analysis

Run the second simulation in SIL mode.

counter_mode.signals.values = counter_mode_values_run2;
count_enable.signals.values = count_enable_values_run2;
set_param(model,'SimulationMode','software-in-the-loop');
set_param(model,'CodeExecutionProfiling','off');
set_param(model,'CodeProfilingInstrumentation','off');
simout_sil_run2 = sim(model, 'ReturnWorkspaceOutputs', 'on');
Simulink.sdi.createRun('Run 2 (SIL mode)', 'namevalue', ...
    {'simout_sil_run2'}, {simout_sil_run2});

### Starting build procedure for model: rtwdemo_sil_topmodel
### Generated code for 'rtwdemo_sil_topmodel' is up to date because no structural, parameter or code replacement library changes were found.
### Successful completion of build procedure for model: rtwdemo_sil_topmodel
### Preparing to start SIL simulation ... 
### Starting SIL simulation for component: rtwdemo_sil_topmodel
### Stopping SIL simulation for component: rtwdemo_sil_topmodel
### Completed code coverage analysis

When a simulation is complete, click the link in the Command Window to open the code coverage report and view the cumulative code coverage results. The link is available only if you have a third-party tool installed.

Use hyperlinks in the code coverage report to go to corresponding locations in the block diagram. Then, by using the coverage display window, you can open corresponding sections of the model coverage report. Compare model coverage and code coverage results.
The Simulation Data Inspector opens automatically, allowing interactive viewing and analysis of the results. Use the Compare and Inspect panes to confirm that the SIL and normal mode logged signals are identical for both runs.

**Concluding Remarks**

In this example, you:

- Collected model coverage metrics during a normal mode simulation.
- Collected code coverage metrics during a SIL simulation.
- Navigated between the code coverage and model coverage reports.
- Cross-checked metrics from both reports.

About ASAP2 File Customization

The Embedded Coder product provides a number of Target Language Compiler (TLC) files to enable you to customize the ASAP2 file generated from a Simulink model.

ASAP2 File Structure on the MATLAB Path

The ASAP2 related files are organized within the folders identified below:

- TLC files for generating ASAP2 file

  The matlabroot/rtw/c/tlc/mw (open) folder contains TLC files that generate ASAP2 files, asamlib.tlc, asap2lib.tlc, asap2main.tlc, and asap2grouplib.tlc. These files are included by the selected System target file. (See “Targets Supporting ASAP2” on page 57-3.)

- ASAP2 target files

  The matlabroot/toolbox/rtw/targets/asap2/asap2 (open) folder contains the ASAP2 system target file and other control files.

- Customizable TLC files

  The matlabroot/toolbox/rtw/targets/asap2/asap2/user (open) folder contains files that you can modify to customize the content of your ASAP2 files.

- ASAP2 templates

  The matlabroot/toolbox/rtw/targets/asap2/asap2/user/templates (open) folder contains templates that define each type of CHARACTERISTIC in the ASAP2 file.
Customize the Contents of the ASAP2 File

The ASAP2 related TLC files enable you to customize the appearance of the ASAP2 file generated from a Simulink model. Most customization is done by modifying or adding to the files contained in the `matlabroot/toolbox/rtw/targets/asap2/asap2/user` (open) folder. This section refers to this folder as the `asap2/user` folder.

The user-customizable files provided are divided into two groups:

- The *static* files define the parts of the ASAP2 file that are related to the environment in which the generated code is used. They describe information specific to the user or project. The static files are not model dependent.
- The *dynamic* files define the parts of the ASAP2 file that are generated based on the structure of the source model.

The procedure for customizing the ASAP2 file is as follows:

1. Make a copy of the `asap2/user` folder before making modifications.
2. Remove the old `asap2/user` folder from the MATLAB path, or add the new `asap2/user` folder to the MATLAB path above the old folder. The MATLAB session uses the ASAP2 setup file, `asap2setup.tlc`, in the new folder.
   
   `asap2setup.tlc` specifies the folders and files to include in the TLC path during the ASAP2 file generation process. Modify `asap2setup.tlc` to control the folders and folders included in the TLC path.
3. Modify the static parts of the ASAP2 file. These include
   
   - Project and header symbols, which are specified in `asap2setup.tlc`
   - Static sections of the file, such as file header and tail, `A2ML`, `MOD_COMMON`, and so on. These are specified in `asap2userlib.tlc`.
   - Specify the appearance of the dynamic contents of the ASAP2 file by modifying the existing ASAP2 templates or by defining new ASAP2 templates. Sections of the ASAP2 file affected include

   `RECORD_LAYOUT`: modify parts of the ASAP2 template files.

   `CHARACTERISTIC`: modify parts of the ASAP2 template files. For more information on modifying the appearance of `CHARACTERISTIC` records, see “ASAP2 Templates” on page 82-4.
- **MEASUREMENT**: These are specified in `asap2userlib.tlc`.
- **COMPU_METHOD**: These are specified in `asap2userlib.tlc`.

## ASAP2 Templates

The appearance of CHARACTERISTIC records in the ASAP2 file is controlled using a different template for each type of CHARACTERISTIC. The `asap2/user` folder contains template definition files for scalars, 1-D Lookup Table blocks and 2-D Lookup Table blocks. You can modify these template definition files, or you can create additional templates as required.

The procedure for creating a new ASAP2 template is as follows:

1. Create a template definition file. See “Create Template Definition Files” on page 82-4.
2. Include the template definition file in the TLC path. The path is specified in the ASAP2 setup file, `asap2setup.tlc`.

### Create Template Definition Files

This section describes the components that make up an ASAP2 template definition file. This description is in the form of code examples from `asap2lookup1d.tlc`, the template definition file for the `Lookup1D` template. This template corresponds to the `Lookup1D` parameter group.

**Note** When creating a new template, use the corresponding parameter group name in place of `Lookup1D` in the code shown.

#### Template Registration Function

The input argument is the name of the parameter group associated with this template:

```
%<LibASAP2RegisterTemplate("Lookup1D")>
```

#### RECORD_LAYOUT Name Definition Function

Record layout names (aliases) can be arbitrarily specified for each data type. This function is used by the other components of this file.

```
%function ASAP2UserFcnRecordLayoutAlias_Lookup1D(dtId) void
  %switch dtId
```
%case tSS_UINT8
  %return "Lookup1D_UBYTE"
...
%endswitch
%endfunction

**Function to Write RECORD_LAYOUT Definitions**

This function writes RECORD_LAYOUT definitions associated with this template. The function is called by the built-in functions involved in the ASAP2 file generation process. The function name must be defined as shown, with the template name after the underscore:

%function ASAP2UserFcnWriteRecordLayout_Lookup1D() Output
  /begin RECORD_LAYOUT
  %<ASAP2UserFcnRecordLayoutAlias_Lookup1D(tSS_UINT8)>
  ... end RECORD_LAYOUT
%endfunction

**Function to Write the CHARACTERISTIC**

This function writes the CHARACTERISTIC associated with this template. The function is called by the built-in functions involved in the ASAP2 file generation process. The function name must be defined as shown, with the template name after the underscore.

The input argument to this function is a pointer to a parameter group record. The example shown is for a Lookup1D parameter group that has two members. The references to the associated X and Y data records are obtained from the parameter group record as shown.

This function calls a number of built-in functions to obtain the required information. For example, LibASAP2GetSymbol returns the symbol (name) for the specified data record:

%function ASAP2UserFcnWriteCharacteristic_Lookup1D(paramGroup) Output
  %assign xParam = paramGroup.Member[0].Reference
  %assign yParam = paramGroup.Member[1].Reference
  %assign dtId = LibASAP2GetDataTypeId(xParam)
  /begin CHARACTERISTIC
  /* Name */ %<LibASAP2GetSymbol(xParam)>
  /* Long identifier */ "%<LibASAP2GetLongID(xParam)>
  ...

Customize Computation Method Names

In generated ASAP2 files, computation methods translate the electronic control unit (ECU) internal representation of measurement and calibration quantities into a physical model oriented representation. Simulink Coder software provides the ability to customize the names of computation methods. You can provide names that are more intuitive, enhancing ASAP2 file readability, or names that meet organizational requirements.

To customize computation method names, use the MATLAB function `getCompuMethodName`, which is defined in `matlabroot/toolbox/rtw/targets/asap2/asap2/user/getCompuMethodName.m`.

The `getCompuMethodName` function constructs a computation method name. The function prototype is

\[
\text{cmName} = \text{getCompuMethodName}(\text{dataTypeName}, \text{cmUnits})
\]

where `dataTypeName` is the name of the data type associated with the computation method, `cmUnits` is the units as specified in the Unit property of a Simulink.Parameter or Simulink.Signal object (for example, rpm or m/s), and `cmName` returns the constructed computation method name.

The default constructed name returned by the function has the format

\[
<\text{localPrefix}><\text{datatype}>_<\text{cmUnits}>
\]

where

- `<\text{local}\_\text{Prefix}>` is a local prefix, CM_, defined in `matlabroot/toolbox/rtw/targets/asap2/asap2/user/getCompuMethodName.m`.
- `<\text{datatype}>` and `<\text{cmUnits}>` are the arguments you specified to the `getCompuMethodName` function.

Additionally, in the generated ASAP2 file, the constructed name is prefixed with `<ASAP2CompuMethodName\_Prefix>`, a model prefix defined in `matlabroot/toolbox/rtw/targets/asap2/asap2/user/asap2setup.tlc`.

For example, if you call the `getCompuMethodName` function with the `dataTypeName` argument 'int16' and the `cmUnits` argument 'm/s', and generate an ASAP2 file for a
model named myModel, the computation method name would appear in the generated file as follows:

```
/begin COMPU_METHOD
    /* Name of CompuMethod */ myModel_CM_int16_m_s
    /* Units */ "m/s"

... 
/end COMPU_METHOD
```

### Suppress Computation Methods for FIX_AXIS

Versions 1.51 and later of the ASAP2 specification state that for certain cases of lookup table axis descriptions (integer data type and no doc units), a computation method is not required and the Conversion Method parameter must be set to the value NO_COMPU_METHOD. You can control whether or not computation methods are suppressed when not required using the Target Language Compiler (TLC) option ASAP2GenNoCompuMethod. This TLC option is disabled by default. If you enable the option, ASAP2 file generation does not generate computation methods for lookup table axis descriptions when not required, and instead generates the value NO_COMPU_METHOD. For example:

```
/begin CHARACTERISTIC
    /* Name            */
    lu1d_fix_axisTable_data

... 
/begin AXIS_DESCR
    ...
    /* Conversion Method */
    NO_COMPU_METHOD

... 
/end CHARACTERISTIC
```

The ASAP2GenNoCompuMethod option is defined in `matlabroot/toolbox/rtw/targets/asap2/asap2/user/asap2setup.tlc`.

Control Build Process Compiling and Linking

After generating code for a model, the build process determines whether to compile and link an executable program. Various factors guide this determination:

- **Generate code only** option
  
  When you select this option, the code generator produces code for the model, including a makefile.

- **Generate makefile** option
  
  When you clear this option, the code generator does not produce a makefile for the model. You must specify post-code generation processing, including compilation and linking, as a user-defined command, as explained in “Customize Post-Code-Generation Build Processing” on page 83-14.

- **Makefile-only target**
  
  The Microsoft Visual C++ Project Makefile versions of the grt and Embedded Coder target configurations generate a Visual C++ project makefile (`model.mak`). To build an executable, you must open `model.mak` in the Visual C++ IDE and compile and link the model code.

- **HOST template makefile variable**
  
  The template makefile variable `HOST` identifies the type of system upon which your executable is intended to run. The variable can be set to one of three possible values: PC, UNIX, or ANY.

  By default, `HOST` is set to UNIX in template makefiles designed for use with The Open Group UNIX platforms (such as `grt_unix.tmf`), and to PC in the template makefiles designed for use with development systems for the PC (such as `grt_vc.tmf`).

  If the Simulink software is running on the same type of system as the system specified by the `HOST` variable, then the executable is built. Otherwise,

  - If `HOST = ANY`, an executable is still built. This option is useful when you want to cross-compile a program for a system other than the one that the Simulink software is running on.
  - Otherwise, processing stops after generating the model code and the makefile; the following message is displayed on the MATLAB command line.

### Make will not be invoked - template makefile is for a different host
The template makefile variable `TGT_FCN_LIB` specifies compiler command-line options. The line in the makefile is `TGT_FCN_LIB = |>TGT_FCN_LIB<|`. Use this token in a makefile conditional statement to specify a standard math library as a compiler option. Possible `|>TGT_FCN_LIB<|` token values are:

<table>

Cross-Compile Code Generated on Microsoft Windows

To generate code with the code generator on a Microsoft Windows system but compile the generated code on a different supported platform, you can do so by modifying your TMF and model configuration parameters. For example, you would need to follow this process if you develop applications with the MATLAB and Simulink products on a Windows system, but you run your generated code on a Linux system.

To set up a cross-compilation development environment, do the following (here a Linux system is the destination platform):

1. On your Windows system, copy the UNIX TMF for your target to a local folder. This folder is your working folder for initiating code generation. For example, you could copy the file `matlabroot/rtw/c/grt/grt_unix.tmf` to `D:/work/my_grt_unix.tmf`.

2. Make the following changes to your copy of the TMF:
   - Add the following line near the `SYS_TARGET_FILE =` line:
     ```
     MAKEFILE_FILESEP = /
     ```
   - Search for the line `ifeq ($(OPT_OPTS),$(DEFAULT_OPT_OPTS))` and, for each occurrence, remove the conditional logic and retain only the `else` code. That is, remove everything from the `if` to the `else`, inclusive, and the closing `endif`. Only the lines from the `else` portion remain. This logic forces the run-time libraries to build for a Linux system.

3. Open your model and make the following changes in the **Code Generation** pane of the Configuration Parameters dialog box:
   - Specify the name of your new TMF in the “Template makefile” (Simulink Coder) text box (for example, `my_grt_unix.tmf`).
   - Select **Generate code only** and click **Apply**.

4. Generate the code.

5. If the build folder (folder from which the model was built) is not already Linux accessible, copy it to a Linux accessible path. For example, if your build folder for the generated code was `D:\work\mymodel_grt_rtw`, copy that entire folder tree to a path such as `/home/user/mymodel_grt_rtw`.

6. If the MATLAB folder tree on the Windows system is Linux accessible, skip this step. Otherwise, copy the include and source folders to a Linux accessible drive partition, for example, `/home/user/myinstall`. These folders appear in the makefile after
ADD_INCLUDES = and can be found by searching for $(MATLAB_ROOT). Paths that
contain $(MATLAB_ROOT) must be copied. Here is an example list (your list varies
depending on your model):

$(MATLAB_ROOT)/rtw/c/grt
$(MATLAB_ROOT)/extern/include
$(MATLAB_ROOT)/simulink/include
$(MATLAB_ROOT)/rtw/c/src
$(MATLAB_ROOT)/rtw/c/tools

Also, paths containing $(MATLAB_ROOT) in the build rules (lines with %.o :) must
be copied. For example, based on the build rule

%.o : $(MATLAB_ROOT)/rtw/c/src/ext_mode/tcpip/%.c

copy the following folder:

$(MATLAB_ROOT)/rtw/c/src/ext_mode/tcpip

**Note** The path hierarchy relative to the MATLAB root must be maintained. For
example, c:\MATLAB\rtw\c\tools\* would be copied to /home/user/mlroot/rtw/c/tools/*.  

For some blocksets, it is easiest to copy a higher-level folder that includes the
subfolders listed in the makefile. For example, the DSP System Toolbox product
requires the following folders to be copied:

$(MATLAB_ROOT)/toolbox/dspblks
$(MATLAB_ROOT)/toolbox/rtw/dspblks

7 Make the following changes to the generated makefile:

- Set both MATLAB_ROOT and ALT_MATLAB_ROOT equal to the Linux accessible
  path to matlabroot (for example, home/user/myinstall).
- Set COMPUTER to the computer value for your platform, such as GLNX86. Enter
  help computer in the MATLAB Command Window for a list of computer values.
- In the ADD_INCLUDES list, change the build folder (designating the location of the
generated code on the Windows system) and parent folders to Linux accessible
  include folders. For example, change D:\work\mymodel_grt_rtw\ to /home/
  user/mymodel_grt_rtw.

Also, if matlabroot is a UNC path, such as \my-server\myapps\matlab, 
replace the hard-coded MATLAB root with $(MATLAB_ROOT).
From a Linux shell, compile the code you generated on the Windows system. You can compile by running the generated `model.bat` file or by typing the make command line as it appears in the `.bat` file.

**Note** If errors occur during makefile execution, you can run the `dos2unix` utility on the makefile (for example, `dos2unix mymodel.mk`).

**See Also**

**Related Examples**

- Use packNGo to Relocate Code to Another Development Environment (Simulink Coder)
Control Library Location and Naming During Build

When you generate precompiled, non-precompiled, and model reference libraries, you can control the library location and library name by using configuration parameters. These parameters control values in generated makefiles during model builds:

- For build processes that use the toolchain approach, control the generated library location by using the `TargetPreCompLibLocation` configuration parameter.
- For build processes that use the template makefile approach, control the generated library location by using the `TargetPreCompLibLocation` configuration parameter and control the generated library name by using the `TargetLibSuffix` configuration parameter.

Library Control Parameters

Use the library control parameters to:

- Specify the location of precompiled libraries, such as blockset libraries or the Simulink Coder block library. Typically, a target has cross-compiled versions of these libraries and places them in a target-specific folder.
- Control the suffix applied to library file names (for example, `_target.a` or `_target.lib`).

Targets can set the parameters inside the system target file (STF) select callback. For example:

```matlab
function mytarget_select_callback_handler(varargin)
    hDig=varargin{1};
    hSrc=varargin{2};
    slConfigUISetVal(hDig, hSrc, 'TargetPreCompLibLocation', 'c:\mytarget\precomplibs');
    slConfigUISetVal(hDig, hSrc, 'TargetLibSuffix', '_target.library');
```

The TMF has corresponding expansion tokens:

```
|>EXPAND_LIBRARY_LOCATION<|
|>EXPAND_LIBRARY_SUFFIX<|
```

Alternatively, you can use a call to the `set_param` function. For example:

```matlab
set_param(model,'TargetPreCompLibLocation','c:\mytarget\precomplibs');
```
**Note** If your model contains referenced models, you can use the make option USE_MDLREF_LIBPATHS to control whether libraries used by the referenced models are copied to the build folder of the parent model. For more information, see “Control the Location of Model Reference Libraries” on page 83-10.

### Identify Library File Type for Toolchain Approach

The toolchain approach for model builds does not use the value of the TargetLibSuffix configuration parameter to select the library file name suffix and extension.

With the toolchain approach, the final binary name is composed of the `modelname`, the `compilername`, and the `extension` provided by the build tool description in the toolchain definition:

```plaintext
model_compilername_extension
```

You can identify the static library file name extension from the build tool description in the toolchain definition. To get this information for the default toolchain, use this procedure:

1. Get the default toolchain name. For example, enter:
   ```plaintext
tc_name = coder.make.getDefaultToolchain()
```
2. Get the default toolchain handle. For example, enter:
   ```plaintext
tc = coder.make.getToolchainInfoFromRegistry(tc_name)
```
3. Get the handle to the toolchain object. For example, enter:
   ```plaintext
tool_archiver = tc.getBuildTool('Archiver');
```
4. Get the extension. For example, enter:
   ```plaintext
   ext_archiver = tool_archiver.getFileExtension('Static Library');
   ```

**Note** If you do not set the TargetLibSuffix parameter, template makefile and toolchain approaches produce the same static library file name `extension`. See “Customize Library File Suffix and File Type” (Simulink Coder).

### Specify the Location of Precompiled Libraries

Use the `TargetPreCompLibLocation` configuration parameter to:
• Override the precompiled library location specified in the `rtwmakecfg.m` file (see “Use `rtwmakecfg.m` API to Customize Generated Makefiles” on page 83-26 for details)

• Precompile and distribute target-specific versions of product libraries (for example, the DSP System Toolbox product)

For a precompiled library, such as a blockset library or the Simulink Coder block library, the location specified in `rtwmakecfg.m` is typically a location specific to the blockset or the Simulink Coder product. The code generator expects that the library exists in this location and links against the library during builds.

For some applications, such as custom targets, it is preferable to locate the precompiled libraries in a target-specific or other alternate location rather than in the location specified in `rtwmakecfg.m`. For a custom target, the code generator expects that the target-specific cross-compiler creates the library, and you place the library in the target-specific location. Compile and place libraries supported by the target in the target-specific location, so they can be used during the build process.

You can set up the `TargetPreCompLibLocation` parameter in its select callback. The path that you specify for the parameter must be a fully qualified, absolute path to the library location. Relative paths are not supported. For example:

```matlab
slConfigUISetVal(hDlg, hSrc, 'TargetPreCompLibLocation', ...
               'c:\mytarget\precomplibs');
```

Alternatively, you set the parameter with a call to the `set_param` function. For example:

```matlab
set_param(model,'TargetPreCompLibLocation', ...
          'c:\mytarget\precomplibs');
```

During makefile generation, the build process replaces the tokens with the location from the `rtwmakecfg.m` file. For example, if the library name in the `rtwmakecfg.m` file is `rtwlib`, the template makefile build approach expands the token from:

```makefile
LIBS += |>EXPAND_LIBRARY_LOCATION<|\|>EXPAND_LIBRARY_NAME<|\|_target.library
```

to:

```makefile
LIBS += c:\mytarget\precomplibs\rtwlib_target.library
```

By default, `TargetPreCompLibLocation` is an empty character vector. The build process uses the location in `rtwmakecfg.m` for the token replacement.
Control the Location of Model Reference Libraries

On platforms other than the Apple Macintosh platform, when building a model that uses referenced models, the default build process includes:

- Copy libraries that the referenced models use to the build folder of the parent model.
- Assign the file names of the libraries to `MODELREF_LINK_LIBS` in the generated makefile.

For example, if a model includes a referenced model `sub`, the build process assigns the library name `sub_rtwlib.lib` to `MODELREF_LINK_LIBS`. The build process copies the library file to the build folder of the parent model. This definition is then used in the final link line, which links the library into the final product (usually an executable). This technique minimizes the length of the link line.

On the Macintosh platform, and optionally on other platforms, the build process includes:

- No copying of libraries that the referenced models use to the build folder of the parent model.
- Assign the relative paths and file names of the libraries to `MODELREF_LINK_LIBS` in the generated makefile.

When using this technique, the build process assigns a relative path such as `../slprj/grt/sub/sub_rtwlib.lib` to `MODELREF_LINK_LIBS`. The build process uses the path to gain access to the library file at link time.

To change to the nondefault behavior on platforms other than the Macintosh platform, select the Configuration Parameters > Code Generation > Make command field. Enter:

```make
make_rtw USE_MDLREF_LIBPATHS=1
```

If you specify other Make command arguments, such as `OPTS=\"-g\"`, the order in which you specify the multiple arguments does not matter.

To return to the default behavior, set `USE_MDLREF_LIBPATHS` to 0, or remove it.

Control the Suffix Applied to Library File Names

With the template makefile approach for model builds, use the `TargetLibSuffix` configuration parameter to control the suffix applied to library names (for example,
_target.lib or _target.a). The specified suffix scheme must include a period (.). You can apply TargetLibSuffix to the following libraries:

- Libraries on which a target depends, as specified in the rtwmakecfg.m API. You can use TargetLibSuffix to change the suffix of both precompiled and non-precompiled libraries configured from the rtwmakecfg API. For details, see “Use rtwmakecfg.m API to Customize Generated Makefiles” on page 83-26.

In this case, a target can set the parameter in its select callback. For example:

```matlab
slConfigUISetVal(hDlg, hSrc, 'TargetLibSuffix','
'_target.library');
```

Alternatively, you can use a call to the set_param function. For example:

```matlab
set_param(model,'TargetLibSuffix','_target.library');
```

During the TMF-to-makefile conversion, the build process replaces the token | >EXPAND_LIBRARY_SUFFIX<| with the specified suffix. For example, if the library name specified in the rtwmakecfg.m file is 'rtwlib', the TMF expands from:

```matlab
LIBS += |>EXPAND_LIBRARY_LOCATION<|>|EXPAND_LIBRARY_NAME<|\|>|EXPAND_LIBRARY_SUFFIX<|
```

To:

```matlab
LIBS += c:\mytarget\precomplibs\rtwlib_target.library
```

By default, TargetLibSuffix is set to an empty character vector. In this case, the build process replaces the token | >EXPAND_LIBRARY_SUFFIX<| with an empty character vector.

- Shared utility library and the model libraries created with model reference. For these cases, associated makefile variables do not require the | >EXPAND_LIBRARY_SUFFIX<| token. Instead, the build process includes TargetLibSuffix implicitly. For example, for a top model named topmodel with referenced models named refmodel1 and refmodel2, the TMF of the top model is expanded from:

```matlab
SHARED_LIB    = |>SHARED_LIB<|
MODELLIB      = |>MODELLIB<|
MODELREF_LINK_LIBS = |>MODELREF_LINK_LIBS<|
```

To:

```matlab
SHARED_LIB    = \..\slproj\rt\_sharedutils\rtwshared_target.library
MODELLIB      = topmodellib_target.library
```
MODELREF_LINK_LIBS = \n    refmodel1_rtwlib_target.library refmodel2_rtwlib_target.library

By default, the TargetLibSuffix parameter is an empty character vector. In this case, the build process chooses a default suffix for these three tokens using a file extension of .lib on Windows hosts and .a on UNIX hosts. (For model reference libraries, the default suffix also includes _rtwlib.) For example, on a Windows host, the expanded makefile values are:

SHARE_LIB = ..\slprj\ert\sharedutils\rtwshared.lib
MODLLIB = topmodellib.lib
MODELREF_LINK_LIBS = refmodel1_rtwlib.lib refmodel2_rtwlib.lib
Recompile Precompiled Libraries

You can recompile precompiled libraries included as part of the code generator, such as `rtwlib` or `dsplib`, by using a supplied MATLAB function, `rtw_precompile_libs`. You can consider recompiling precompiled libraries to customize compiler settings for various platforms or environments. For details on using `rtw_precompile_libs`, see “Precompile S-Function Libraries” on page 52-60.
Customize Post-Code-Generation Build Processing

The code generator provides a set of tools, including a build information object, you can use to customize build processing that occurs after code generation. You can use such customizations for target development or the integration of third-party tools into your application development environment.

Workflow for Setting Up Customizations

The following figure and the steps that follow show the general workflow for setting up post-code-generation customizations.

1. Program the post code generation command on page 83-15.
2. Define the post code generation command on page 83-16.
3  Suppress makefile generation on page 83-20, if applicable.
4  Build the model.
5  Modify the command and rebuild the model until the build results are acceptable.

**Build Information Object**

At the start of a model build, the build process logs the following build option and dependency information to a temporary build information object:

- Compiler options
- Preprocessor identifier definitions
- Linker options
- Source files and paths
- Include files and paths
- Precompiled external libraries

You can retrieve information from and add information to this object by using an extensive set of functions. For a list of available functions and detailed function descriptions, see “Build Process Customization” (Simulink Coder). “Program a Post Code Generation Command” on page 83-15 explains how to use the functions to control post code generation build processing.

**Program a Post Code Generation Command**

For certain applications, you could want to control aspects of the build process after the code generation. For example, you can use this approach if you develop your own target, or you want to apply an analysis tool to the generated code before continuing with the build process. You can apply this level of control to the build process by programming and then defining a post code generation command.

A post code generation command is a MATLAB language file that typically calls functions that get data from or add data to the build information object of the model. You can program the command as a script or function.
If you program the command as a:

| Script | Then the: Script can gain access to the model name and the build information directly |
| Function | Function can pass the model name and the build information as arguments |

If your post code generation command calls user-defined functions, make sure that the functions are on the MATLAB path. If the build process cannot find a function you use in your command, the build process errors out.

You can then call a combination of build information functions, as listed in “Build Process Customization” (Simulink Coder), to customize the post code generation build processing of the model.

The following example shows a fragment of a post code generation command that gets the file names and paths of the source and include files generated for a model for analysis.

```matlab
function analyzegencode(buildInfo)
    % Get the names and paths of source and include files generated for the model and then analyze them.
    % buildInfo - build information for my model.

    % Define cell array to hold data.
    MyBuildInfo={};

    % Get source file information.
    MyBuildInfo.srcfiles=getSourceFiles(buildInfo, true, true);
    MyBuildInfo.srcpaths=getSourcePaths(buildInfo, true);

    % Get include (header) file information.
    MyBuildInfo.incfiles=getIncludeFiles(buildInfo, true, true);
    MyBuildInfo.incpaths=getIncludePaths(buildInfo, true);

    % Analyze generated code.
    .
    .
    .
```

**Define a Post Code Generation Command**

After you program a post code generation command, inform the build process that the command exists and to add it to the build processing of the model. Define the command with the `PostCodeGenCommand` model configuration parameter. When you define a post
code generation command, the build process evaluates the command after generating and writing the generated code to disk and before generating a makefile.

As the following syntax lines show, the arguments that you specify when setting the configuration parameter varies depending on whether you program the command as a script, function, or set of functions.

**Note** When defining the command as a function, you can specify an arbitrary number of input arguments. To pass the name and build information of the model to the function, specify identifiers `modelName` and `buildInfo` as arguments.

**Script**

```matlab
set_param(model, 'PostCodeGenCommand', ...
    'pcgScriptName');
```

**Function**

```matlab
set_param(model, 'PostCodeGenCommand', ...
    'pcgFunctionName(modelName)');
```

**Multiple Functions**

```matlab
pcgFunctions=...
    'pcgFunction1Name(modelName)';
    pcgFunction2Name(buildInfo);
set_param(model, 'PostCodeGenCommand', ...
    pcgFunctions);
```

The following call to `set_param` defines `PostCodGenCommand` to evaluate the function `analyzegencode`.

```matlab
set_param(model, 'PostCodeGenCommand', ...
    'analyzegencode(buildInfo)');
```

**Customize Build Process with PostCodeGenCommand and Relocate Generated Code to an External Environment**

This example shows how to use the Build Information API and the **Post Code Generation Command** parameter, `PostCodeGenCommand`.

The `PostCodeGenCommand` parameter value is `rtwdemo_buildinfo_data`. This value directs the build process to invoke the function after code generation.
The example also demonstrates how to use the rtwmakecfg.m API.
For more information, click on the documentation links in the model.

**Open Example Model**

Open the example model rtwdemo_buildinfo.

```matlab
open_system(fullfile('rtwdemo_buildinfo'));
```

**Generate Code from Model**

Double-click on the **Generate Code Using Simulink Coder** button to generate code for the GRT target.

Or, if Embedded Coder is installed, double-click on the **Generate Code Using Embedded Coder** button to generate code for the ERT target.
The build process generates a BuildInfo.html file to document the build information object.

**Examine the Build Process Customizations and Output**

Use the links in the model to examine the build process customizations and the post code generation query of the build information object.

To view the BuildInfo.html file in a Web browser, click on **Open BuildInfo.html**.

The example uses the PostCodeGenCommand parameter of the model to generate the html file from the build information object. The file provides hyperlinks to open the source files (generated code) from the model. To view the PostCodeGenCommand parameter value, type:

```matlab
get_param('rtwdemo_buildinfo','PostCodeGenCommand');
```

This value indicates a function to execute in the **Post Code Gen Command** stage.

```matlab
rtwdemo_buildinfo_data(buildInfo);
```

To study how the example uses the rtwmakecfg API, click on **Open rtwmakecfg.m** or type:

```matlab
dit rtwmakecfg.m;
```

To study the API for the buildInfo.mat object, click on **Open rtwdemo_buildinfo_data.m** or type:

```matlab
edit rtwdemo_buildinfo_data.m;
```

The buildInfo.mat object is available at:

```matlab
rtwdemo_<target>_rtw\buildInfo.mat
```

At the end of the rtwdemo_buildinfo_data.m post code generation function, the function invokes packNGo to package the source and objects identified in the buildInfo object for relocation.

**Further Study Topics**

- “Build Process Customization” (Simulink Coder)

• “Use rtwmakecfg.m API to Customize Generated Makefiles” (Simulink Coder)
• “Relocate Code to Another Development Environment” (Simulink Coder)

Suppress Makefile Generation

The code generator lets you suppress makefile generation during the build process. For example, you can use this support when you integrate tools into the build process that do not use makefiles.

To instruct the code generator not to produce a makefile, do one of the following:

• Clear the Generate makefile option on the Code Generation pane of the Configuration Parameters dialog box.
• Set the value of the configuration parameter GenerateMakefile to off.

When you suppress makefile generation,

• You cannot explicitly specify a make command or template makefile.
• Specify your own instructions for a post code generation processing, including compilation and linking, in a post code generation command as explained in “Program a Post Code Generation Command” on page 83-15 and “Define a Post Code Generation Command” on page 83-16.
Configure Generated Code with TLC

You can use the Target Language Compiler (TLC) to fine-tune your generated code. TLC supports extended code generation variables and options in addition to parameters available on the Code Generation pane on the Configuration Parameters dialog box. There are two ways to set TLC variables and options, as described in this section.

**Note** Do not customize TLC files in the folder `matlabroot/rtw/c/tlc` even though the capability exists to do so. It is possible that such TLC customizations are not applied during the code generation process. Such customizations can lead to unpredictable results.

Assigning Target Language Compiler Variables

The `%assign` statement lets you assign a value to a TLC variable, as in:

```
%assign MaxStackSize = 4096
```

This assignment is also known as creating a `parameter name/parameter value pair`

For a description of the `%assign` statement, see “Target Language Compiler Directives” (Simulink Coder). Write your `%assign` statements in the Configure RTW code generation settings section of the system target file.

The following table lists the code generation variables you can set with the `%assign` statement.
## Target Language Compiler Optional Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MaxStackSize=N</td>
<td>When the <strong>Enable local block outputs</strong> (Simulink Coder) check box is selected, the total allocation size of local variables that are declared by block outputs in the model cannot exceed MaxStackSize (in bytes). MaxStackSize can be a positive integer. If the total size of local block output variables exceeds this maximum, the remaining block output variables are allocated in global, rather than local, memory. The default value for MaxStackSize is <code>rtInf</code>, that is, unlimited stack size. <strong>Note:</strong> Local variables in the generated code from sources other than local block outputs, such as from a Stateflow diagram or MATLAB Function block, and stack usage from sources such as function calls and context switching are not included in the MaxStackSize calculation. For overall executable stack usage metrics, do a target-specific measurement by using run-time (empirical) analysis or static (code path) analysis with object code.</td>
</tr>
<tr>
<td>MaxStackVariableSize=N</td>
<td>When the <strong>Enable local block outputs</strong> check box is selected, this selection limits the size of a local block output variable declared in the code to N bytes, where N&gt;0. A variable whose size exceeds MaxStackVariableSize is allocated in global, rather than local, memory. The default is 4096.</td>
</tr>
<tr>
<td>WarnNonSaturatedBlocks=value</td>
<td>Flag to control display of overflow warnings for blocks that have saturation capability, but have it turned off (not selected) in their dialog box. Options include:</td>
</tr>
<tr>
<td></td>
<td>• 0 — Warning is not displayed.</td>
</tr>
<tr>
<td></td>
<td>• 1 — Displays one warning for the model during code generation</td>
</tr>
<tr>
<td></td>
<td>• 2 — Displays one warning that contains a list of offending blocks</td>
</tr>
</tbody>
</table>
Set Target Language Compiler Options

You can specify TLC command-line options for code generation using the model parameter TLCOptions in a set_param function call. For information about these options, see “Specify TLC for Code Generation” (Simulink Coder) and “Configure TLC” (Simulink Coder).

Use makecfg to Customize Generated Makefiles for S-Functions

With the toolchain and template makefile approach for building code, you can customize generated makefiles for S-functions. Through the customization, you can specify additional items for the S-function build process:

- Source files and folders
- Include files and folders
- Library names
- Preprocessor macro definitions
- Compiler flags
- Link objects

1. To customize the generated makefile:
   - For all S-functions in the build folder (Simulink Coder), create a `makecfg.m` file.
   - For a specific S-function in the build folder, create a `specificSFunction_makecfg.m` file.

2. In the file that you create, use `RTW.BuildInfo` (Simulink Coder) functions to specify additional items for the S-function build process. For example, you can use:
   - `addCompileFlags` to specify compiler options.
   - `addDefines` to specify preprocessor macro definitions.

3. Save the created file in the build folder.

After code generation, in the build folder, the code generator searches for `makecfg.m` and `specificSFunction_makecfg.m` files. If the files are present in the build folder, the code generator uses these files to customize the generated makefile, `model.mk`.

For example, consider a build folder that contains `signalConvert.mexa64` (S-function binary file) and `signalConvert.tlc` (inlined S-function implementation) after the TLC phase (Simulink Coder) of the build process. The S-function requires an additional source code file, `filterV1.c`, which is located in `anotherFolder`. You can create a file, `signalConvert_makecfg.m`, that uses `RTW.BuildInfo` functions to specify `filterV1.c` for the build process.

```matlab
function signalConvert_makecfg(objBuildInfo)
```
absolute = fullfile('$(START_DIR)', 'anotherFolder');

addIncludePaths(objBuildInfo, absolute);
addSourcePaths(objBuildInfo, absolute);
addSourceFiles(objBuildInfo,'filterV1.c');

- “Import Calls to External Code into Generated Code with Legacy Code Tool” (Simulink Coder)
- “Use rtwmakecfg.m API to Customize Generated Makefiles” (Simulink Coder)
Use `rtwmakecfg.m` API to Customize Generated Makefiles

Both the toolchain approach and the template makefile approach for builds let you add the following items to generated makefiles:

- Source folders
- Include folders
- Library names
- Module objects

**About the `rtwmakecfg` Function**

Using an `rtwmakecfg` function, you add this information to the makefile during the build operation for S-functions. The `rtwmakecfg` function is useful when specifying added sources and libraries to build a model that contains one or more of your S-function blocks.

To add information pertaining to an S-function to the makefile:

1. Create the MATLAB language `rtwmakecfg` function in the `rtwmakecfg.m` file. The code generator associates this file with your S-function based on its folder location. “Create the `rtwmakecfg` Function” on page 83-26 describes the requirements for the `rtwmakecfg` function and the data it returns.

2. If you are using the template makefile approach, modify the TMF of your target such that it supports macro expansion for the information that the `rtwmakecfg` function returns. “Modify the Template Makefile for `rtwmakecfg`” on page 83-29 describes the required modifications. If you are using the toolchain approach, the information that the `rtwmakecfg` function returns is used by the generated makefile; no further configuration is required.

After the TLC phase of the build process, when generating a makefile, the code generator searches for an `rtwmakecfg.m` file in the folder that contains the S-function MEX file. If it finds the file, the build process calls the `rtwmakecfg` function.

**Create the `rtwmakecfg` Function**

Create the `rtwmakecfg.m` file containing the `rtwmakecfg` function in the same folder as your S-function component (a MEX-file with a platform-dependent extension, such
as `.mexext` on Microsoft Windows systems). The function must return a structured array that contains these fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>makeInfo.includePath</code></td>
<td>A cell array that specifies additional include folder names, organized as a row vector. The build process expands the folder names into include instructions in the generated makefile.</td>
</tr>
<tr>
<td><code>makeInfo.sourcePath</code></td>
<td>A cell array that specifies additional source folder names, organized as a row vector. Include the folder names of files entered into the <strong>S-function modules</strong> field on the S-Function Block Parameters dialog box or into the <code>SFunctionModules</code> parameter of the block if they are not in the same folder as the S-function. The build process expands the folder names into make rules in the generated makefile.</td>
</tr>
<tr>
<td><code>makeInfo.sources</code></td>
<td>A cell array that specifies additional source file names (C or C++), organized as a row vector. Do not include the name of the S-function or any files entered into the <strong>S-function modules</strong> field on the S-Function Block Parameters dialog box or into the <code>SFunctionModules</code> parameter of the block. The build process expands the file names into make variables that contain the source files. Specify only file names (with extension). Specify path information with the <code>sourcePath</code> field.</td>
</tr>
<tr>
<td><code>makeInfo.linkLibsObjs</code></td>
<td>A cell array that specifies additional, fully qualified paths to object or library files against which the generated code links. The build process does not compile the specified objects and libraries. However, it includes them when linking the final executable. This inclusion can be useful for incorporating libraries that you do not want the build process to recompile or for which the source files are not available. You can also use this element to integrate source files from languages other than C and C++. This integration is possible if you first create a C compatible object file or library outside of the build process.</td>
</tr>
</tbody>
</table>
### Field Descriptions

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>makeInfo.precompile</code></td>
<td>A Boolean flag that indicates whether the libraries specified in the <code>rtwmakecfg.m</code> file exist in a specified location (<code>precompile==1</code>) or if you must create the libraries in the build folder during the build process (<code>precompile==0</code>).</td>
</tr>
<tr>
<td><code>makeInfo.library</code></td>
<td>A structure array that specifies additional run-time libraries and module objects, organized as a row vector. The build process expands the information into make rules in the generated makefile. For a list of the library fields, see the next table.</td>
</tr>
</tbody>
</table>

The `makeInfo.library` field consists of the following elements.

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>makeInfo.library(n).Name</code></td>
<td>A character array that specifies the name of the library (without an extension).</td>
</tr>
<tr>
<td><code>makeInfo.library(n).Location</code></td>
<td>A character array that specifies the folder in which the library is located when precompiled. For more information, see the description of <code>makeInfo.precompile</code> in the preceding table. A target can use the <code>TargetPreCompLibLocation</code> parameter to override this value. See “Specify the Location of Precompiled Libraries” (Simulink Coder).</td>
</tr>
<tr>
<td><code>makeInfo.library(n).Modules</code></td>
<td>A cell array that specifies the C or C++ source file base names (without an extension) that comprise the library. Do not include the file extension. The makefile appends the object extension.</td>
</tr>
</tbody>
</table>

**Note** The `makeInfo.library` field must fully specify each library and how to build it. The modules list in the `makeInfo.library(n).Modules` element cannot be empty. To specify a link-only library, use the `makeInfo.linkLibsObjs` field instead.

**Example:**

```matlab
disp(['Running rtwmakecfg from folder: ',pwd]);
makeInfo.includePath = { fullfile(pwd, 'somedir2') };
makeInfo.sourcePath = {fullfile(pwd, 'somedir2'), fullfile(pwd, 'somedir3')};
makeInfo.sources = { 'src1.c', 'src2.cpp'};
```
Note If a path that you specify in the `rtwmakecfg.m` API contains spaces, the build process does not convert the path to its nonspace equivalent. If the build environments you intend to support do not support spaces in paths, refer to “Enable Build Process for Folder Names with Spaces” (Simulink Coder).

Modify the Template Makefile for `rtwmakecfg`

To expand the information that an `rtwmakecfg` function generates, modify the following sections in the TMF of your target:

- Include Path
- C Flags and/or Additional Libraries
- Rules

It is possible that these TMF code examples do not apply to your make utility. For additional examples, see the GRT or ERT TMFs located in `matlabroot/rtw/c/grt` (open) or `matlabroot/rtw/c/ert` (open).

Add Folder Names to the Makefile Include Path

The following TMF code example adds folder names to the include path in the generated makefile:

```
ADD_INCLUDES = \
|>START_EXPAND_INCLUDES<| -I|>EXPAND_DIR_NAME<| \n|>END_EXPAND_INCLUDES<|
```

Also, the `ADD_INCLUDES` macro must be added to the INCLUDES line.

```
INCLUDES = -I. -I.. $(ADD_INCLUDES) $(USER_INCLUDES)
```

Add Library Names to the Makefile

The following TMF code example adds library names to the generated makefile.

```
LIBS = 
|>START_PRECOMP_LIBRARIES<|
```
LIBS += |>EXPAND_LIBRARY_NAME|.a |>END_PRECOMP_LIBRARIES<|
|>START_EXPAND_LIBRARIES<|
LIBS += |>EXPAND_LIBRARY_NAME|.a |>END_EXPAND_LIBRARIES<|

For more information, see “Control Library Location and Naming During Build” on page 83-7.

Add Rules to the Makefile

The TMF code example adds rules to the generated makefile.

|>START_EXPAND_RULES<|
$(BLD)/%.o: |>EXPAND_DIR_NAME<|/%.c $(SRC)/$(MAKEFILE) rtw_proj.tmw
   @$(BLANK)
   @echo ### |>EXPAND_DIR_NAME<|$*.c
   $(CC) $(CFLAGS) $(APP_CFLAGS) -o $(BLD)$(DIRCHAR)$*.o \
   |>EXPAND_DIR_NAME<|$(DIRCHAR)$*.c > $(BLD)$(DIRCHAR)$*.lst
|>END_EXPAND_RULES<|

|>START_EXPAND_LIBRARIES<|MODULES_|>EXPAND_LIBRARY_NAME<| = \n|>START_EXPAND_MODULES<|   |>EXPAND_MODULE_NAME<|.o \
|>END_EXPAND_MODULES<|

$(MODULES_|>EXPAND_LIBRARY_NAME<|:%.o=$(BLD)/%.o)
   @$(BLANK)
   @echo ### Creating $@
   $(AR) -r $@ $(MODULES_|>EXPAND_LIBRARY_NAME<|:%.o=$(BLD)/%.o)
|>END_PRECOMP_LIBRARIES<|
Register Custom Toolchain and Build Executable

This example shows how to register and use a toolchain to build an executable. This example uses the Intel® compiler. However, the concepts and programming interface apply for other toolchains. Once you register a toolchain, you can configure a model such that the code generator uses that toolchain to build an executable for the model.

**Toolchain**

A toolchain is a collection of tools required to compile, link, download, and run code on a specified platform. A toolchain consists of multiple tools, such as a compiler, linker, and archiver. You can configure the tools in a toolchain with multiple options and group tool specifications into types of configurations.

**Create a New Folder and Copy Relevant Files**

The following code creates a folder in your current working folder (pwd). The new folder contains files for this example. If you do not want to affect the current folder, or cannot generate files in this folder, change your working folder before invoking the command.

```matlab
copyfile(fullfile(matlabroot,'toolbox','rtw','rtwdemos','toolchain_demo'),'toolchain_demo','f')
cd toolchain_demo
```

**Open a Model**

Open the `rtwdemo_counter` model. By default, this model is configured to use the Generic Real-Time Target (GRT) configuration and the toolchain approach for building an executable. The capability demonstrated in this example is available for models configured to use the Toolchain approach.

```matlab
model = 'rtwdemo_counter';
open_system(model)
```
Choose a Toolchain

In the model window, click Simulation > Model Configuration Parameters to open the Configuration Parameters dialog box. Select Code Generation. The Toolchain settings section contains parameters for configuring a toolchain. From the Toolchain drop-down list, select the toolchain installed on your development system for building an executable from the code generated from your model.

By default, the Faster Runs build configuration is selected. Click Show settings to see the toolchain flags specified for building the generated code. Choose a build configuration based on your current application development goal.

Close the Configuration Parameters dialog box.

Create a ToolchainInfo Object

This example shows how you can register a custom toolchain and add it as a selectable Toolchain option.
The first step to registering a custom toolchain is to create a `ToolchainInfo` object that contains information about the toolchain. Methods are available to set toolchain specifications. You can share a `ToolchainInfo` object across installations.

Open the toolchain definition file for an Intel compiler. This file creates a `ToolchainInfo` object that contains information about the Intel toolchain on a 64-bit Windows® platform.

```matlab
edit intel_tc
type intel_tc
```

```matlab
function tc = intel_tc
%INTEL_TC Creates an Intel v14 ToolchainInfo object.
% This file can be used as a template to define other toolchains on Windows.

% Copyright 2012-2016 The MathWorks, Inc.

tc = coder.make.ToolchainInfo('BuildArtifact', 'nmake makefile');
tc.Name = 'Intel v14 | nmake makefile (64-bit Windows)';
tc.Platform = 'win64';
tc.SupportedVersion = '14';

tc.addAttribute('TransformPathsWithSpaces');
tc.addAttribute('RequiresCommandFile');
tc.addAttribute('RequiresBatchFile');

%% ------------------------------
%% Setup
%% ------------------------------
% Below we are using %ICPP_COMPILER14% as root folder where Intel Compiler is installed. You can either set an environment variable or give full path to the compilervars.bat file.
tc.ShellSetup{1} = 'call %ICPP_COMPILER14%in\compilervars.bat intel64';

%% ------------------------------
%% Macros
%% ------------------------------
tc.addMacro('MW_EXTERNLIB_DIR', 
'$(MATLAB_ROOT)\extern\lib\' tc.Platform '\microsoft');
tc.addMacro('MW_LIB_DIR', 
'$(MATLAB_ROOT)\lib\' tc.Platform);
tc.addMacro('CFLAGS_ADDITIONAL', 
'-D_CRT_SECURE_NO_WARNINGS');
tc.addMacro('CPPFLAGS_ADDITIONAL', 
'-EHs -D_CRT_SECURE_NO_WARNINGS');
tc.addMacro('LIBS_TOOLCHAIN', 
'$(conlibs)');
tc.addMacro('CVARSFLAG', 
'');
```
tc.addIntrinsicMacros({'ldebug', 'conflags', 'cflags'});

% ------------------------------

cfg.setOption( 'Shared Library Linker',      horzcat(sharedLinkerOpts, debugFlag.Linker));
cfg.setOption( 'Archiver',                  horzcat(archiverOpts,     debugFlag.Archiver));

tc.setBuildConfigurationOption('all', 'Download',      '');
tc.setBuildConfigurationOption('all', 'Execute',       '');
tc.setBuildConfigurationOption('all', 'Make Tool',     '-f $(MAKEFILE)');

You can display the errors and warnings in the diagnostics messages pane from builds generated by custom compilers. For more information, see “Diagnostic Message Pane” (Simulink).

Run the toolchain definition file to generate the ToolchainInfo object.

tc = intel_tc;

Save the ToolchainInfo object tc to a MAT file.

save intel_tc tc

**Register the Custom Toolchain**

After you create the ToolchainInfo object for the new toolchain, register it. Register a toolchain in RTW.TargetRegistry. To register the toolchain, write an rtwTargetInfo.m file. Then, add that file to the MATLAB path so the system loads it automatically.

```
type rtwTargetInfo
```
function rtwTargetInfo(tr)
%RTWTARGETINFO Registration file for custom toolchains.

% Copyright 2012-2016 The MathWorks, Inc.

tr.registerTargetInfo(@loc_createToolchain);
end

% ------------------------------------------------------------------------
% Create the ToolchainInfoRegistry entries
% ------------------------------------------------------------------------
function config = loc_createToolchain

cconfig(1) = coder.make.ToolchainInfoRegistry;
config(1).Name = 'Intel v14 | nmake makefile (64-bit Windows)';
config(1).FileName = fullfile(fileparts(mfilename('fullpath')), 'intel_tc.mat');
config(1).TargetHWDeviceType = {'*'};
config(1).Platform = {computer('arch')};
end

Reset the TargetRegistry to use the new rtwTargetInfo.m file.

RTW.TargetRegistry.getInstance('reset');

Choose the Custom Toolchain

Reopen the Configuration Parameters dialog box. Click Toolchain. You should see the new toolchain in the list. Select the Intel v14 toolchain.

Programmatically, you can accomplish the same task with the following commands:

```matlab
cs = getActiveConfigSet(model);
set_param(cs, 'Toolchain', tc.Name)
```

Verify your selection.

```matlab
toolchain = get_param(cs, 'Toolchain')
```

```matlab
toolchain =
'Intel v14 | nmake makefile (64-bit Windows)'
```
Build the Model Using the Custom Toolchain

You can now build the model with the new custom toolchain.

Note: If you do not have the Intel toolchain installed, you can use the following command to generate the code and makefile only.

```matlab
set_param(cs, 'GenCodeOnly', 'on')
```

Build the model to generate the code and makefile that uses the new toolchain.

```matlab
rtwbuild(model)
```

### Starting build procedure for model: rtwdemo_counter
### Successful completion of code generation for model: rtwdemo_counter

Obtain the build directory information.

```matlab
dirInfo = RTW.getBuildDir(model);
```

Examine the generated makefile.

```matlab
type(fullfile(dirInfo.BuildDirectory, [model '.mk']))
```

Once the build process is finished, and you had Intel compilers installed, you can run the generated executable.

```plaintext
if ispc
    system([model '.exe'])
else
```
```plaintext
    system(model)
end

**Restore**

You can optionally remove the folder you created earlier.

cd ..

`rmdir('toolchain_demo', 's')`

Reset the TargetRegistry to remove the toolchain that you registered above.

`RTW.TargetRegistry.getInstance('reset');`

Close the model.

close_system(model, 0)

Clear the variables introduced in the workspace.

clear INC K LIMIT RESET model tc cs toolchain
```
Customize Build Process with STF_make_rtw_hook File

The build process lets you supply optional custom code in hook methods that are executed at specified points in the code generation and make process. You can use hook methods to add target-specific actions to the build process.

STF_make_rtw_hook File

You can modify hook methods in a file generically referred to as STF_make_rtw_hook.m, where STF is the name of a system target file, such as ert or mytarget. This file implements a function, STF_make_rtw_hook, that dispatches to a specific action, depending on the hookMethod argument passed in.

The build process calls STF_make_rtw_hook, passing in the hookMethod argument and other arguments. You implement only those hook methods that your build process requires.

If your model contains reference models, you can implement an STF_make_rtw_hook.m for each reference model as required. The build process calls each STF_make_rtw_hook for reference models, processing these files recursively (in dependency order).

Conventions for Using the STF_make_rtw_hook File

For the build process to call the STF_make_rtw_hook, check that the following conditions are met:

- The STF_make_rtw_hook.m file is on the MATLAB path.
- The file name is the name of your system target file (STF), appended to the text make_rtw_hook.m. For example, if you generate code with a custom system target file mytarget.tlc, name your hook file mytarget_make_rtw_hook.m, and name the hook function implemented within the file mytarget_make_rtw_hook.
- The hook function implemented in the file uses the function prototype described in “STF_make_rtw_hook.m Function Prototype and Arguments” on page 83-50.

STF_make_rtw_hook.m Function Prototype and Arguments

The function prototype for STF_make_rtw_hook is:

```matlab
function STF_make_rtw_hook(hookMethod, modelName, rtwRoot, templateMakefile, buildOpts, buildArgs, buildInfo)
```
The arguments are defined as:

- **hookMethod**: Character vector specifying the stage of build process from which the `STF_make_rtw_hook` function is called. The following flow chart summarizes the build process, highlighting the hook points. Valid values for `hookMethod` are 'entry', 'before_tlc', 'after_tlc', 'before_make', 'after_make', 'exit', and 'error'. The `STF_make_rtw_hook` function dispatches to the relevant code with a `switch` statement.
- **modelName**: Character vector specifying the name of the model. Valid at all stages of the build process.
- **rtwRoot**: Reserved.
- **templateMakefile**: Name of template makefile.
- **buildOpts**: A MATLAB structure containing the fields described in the following list. Valid for the 'before_make', 'after_make', and 'exit' stages only. The buildOpts fields include:
  - **modules**: Character vector specifying a list of additional files to compile.
  - **codeFormat**: Character vector specifying the value of the CodeFormat TLC variable for the target. (ERT-based targets must use the 'Embedded-C' value for the CodeFormat TLC variable and use the corresponding 'ert.tlc' value in the rtwgensettings.DerivedFrom field.)
  - **noninlinedSFcns**: Cell array specifying a list of noninlined S-functions in the model.
  - **compilerEnvVal**: Character vector specifying the compiler environment variable value (for example, C:\Applications\Microsoft Visual).  
  - **buildArgs**: Character vector containing the argument to make_rtw. When you invoke the build process, buildArgs is copied from the argument following "make_rtw" in the Configuration Parameters + Code Generation + Make command field.

For example, the following make arguments from the Make command field

```
make_rtw VAR1=0 VAR2=4
```

generate the following:

```
% make -f untitled.mk VAR1=0 VAR2=4
```

The buildArgs argument does not apply for toolchain approach builds because these builds do not allow adding make arguments to the make_rtw call. On the compiler command line, to provide custom definitions (for example, VAR1=0 VAR2=4) that apply for both TMF approach and toolchain approach builds, use the Configuration Parameters > Code Generation > Custom Code > Defines field.

- **buildInfo**: The MATLAB structure that contains the model build information fields. Valid for the 'after_tlc', 'before_make', 'after_make', and 'exit' stages only. For information about these fields and functions to access them, see “Build Process Customization” (Simulink Coder).
Applications for STF_make_rtw_hook.m

Here are some examples of how to apply the STF_make_rtw_hook.m hook methods.

In general, you can use the 'entry' hook to initialize the build process, for example, to change or validate settings before code is generated. One application for the 'entry' hook is to rerun the auto-configuration script that initially ran at target selection time to compare model parameters before and after the script executes, for validation purposes.

The other hook points, 'before_tlc', 'after_tlc', 'before_make', 'after_make', 'exit', and 'error' are useful for interfacing with external tool chains, source control tools, and other environment tools.

For example, you could use the STF_make_rtw_hook.m file at a stage after 'entry' to obtain the path to the build folder. At the 'exit' stage, you could then locate generated code files within the build folder and check them into your version control system. You can use 'error' to clean up static or global data used by the hook function when an error occurs during code generation or the build process.

**Note** The build process temporarily changes the MATLAB working folder to the build folder for stages 'before_make', 'after_make', 'exit', and 'error'. Your STF_make_rtw_hook.m file must not make incorrect assumptions about the location of the build folder. At a point after the 'entry' stage, you can obtain the path to the build folder. In the following MATLAB code example, the build folder path is returned as a character vector to the variable buildDirPath.

```matlab
buildDirPath = rtwprivate('get_makertwsettings',gcs,'BuildDirectory');
```

**Note** Any change to model configuration within STF_make_rtw_hook.m file (including switching Variants) might lead to unexpected results in code generation.

Control Code Regeneration Using STF_make_rtw_hook.m

When you rebuild a model, by default, the build process performs checks to determine whether changes to the model or relevant settings require regeneration of the top model code. (For details on the criteria, see “Control Regeneration of Top Model Code” on page 53-46.) If the checks determine that top model code generation is required, the build process fully regenerates and compiles the model code. If the checks indicate that the top
model generated code is current with respect to the model, and model settings do not require full regeneration, the build process omits regeneration of the top model code.

Regardless of whether the top model code is regenerated, the build process subsequently calls the build process hooks, including `STF_make_rtw_hook` functions and the post code generation command. The following mechanisms allow you to perform actions related to code regeneration in the `STF_make_rtw_hook` functions:

- To force code regeneration, use the following function call from the 'entry' hook:
  ```matlab
  rtw.targetNeedsCodeGen('set', true);
  ```
- In hooks from 'before_tlc' through 'exit', the `buildOpts` structure passed to the hook has a Boolean field `codeWasUpToDate`. The field is set to `true` if model code was up to date and code was not regenerated, or `false` if code was not up to date and code was regenerated. You can customize hook actions based on the value of this field. For example:

  ```matlab
  ... 'before_tlc'
    if buildOpts.codeWasUpToDate
      % Perform hook actions for up to date model
    else
      % Perform hook actions for full code generation
    end
  ...
  ```

**Use STF_make_rtw_hook.m for Your Build Procedure**

To create a custom `STF_make_rtw_hook` hook file for your build procedure, copy and edit the example `ert_make_rtw_hook.m` file, which is located in the folder `matlabroot/toolbox/coder/embeddedcoder` (open), as follows:

1. Copy `ert_make_rtw_hook.m` to a folder in the MATLAB path. Rename it in accordance with the naming conventions described in “Conventions for Using the STF_make_rtw_hook File” on page 83-50. For example, to use it with the GRT target `grt.tlc`, rename it to `grt_make_rtw_hook.m`.
2. Rename the `ert_make_rtw_hook` function within the file to match the file name.
3. Implement the hooks that you require by adding code to case statements within the `switch hookMethod` statement.
Customize Build Process with sl_customization.m

The Simulink customization file `sl_customization.m` is a mechanism that allows you to use MATLAB to customize the build process interface. The Simulink software reads the `sl_customization.m` file, if present on the MATLAB path, when it starts and the customizations specified in the file are applied to the Simulink session. For more information on the `sl_customization.m` customization file, see “Registering Customizations” (Simulink).

The `sl_customization.m` File

The `sl_customization.m` file can be used to register installation-specific hook functions to be invoked during the build process. The hook functions that you register through `sl_customization.m` complement System Target File (STF) hooks (described in “Customize Build Process with STF_make_rtw_hook File” on page 83-50) and post-code generation commands (described in “Customize Post-Code-Generation Build Processing” on page 83-14).

The following figure shows the relationship between installation-level hooks and the other available mechanisms for customizing the build process.
Register Build Process Hook Functions Using sl_customization.m

To register installation-level hook functions that are invoked during the build process, you create a MATLAB function called sl_customization.m and include it on the MATLAB path of the Simulink installation that you want to customize. The sl_customization function accepts one argument: a handle to a customization manager object. For example,

```matlab
function sl_customization(cm)
```

As a starting point for your customizations, the sl_customization function must first get the default (factory) customizations, using the following assignment statement:

```matlab
hObj = cm.RTWBuildCustomizer;
```

You then invoke methods to register your customizations. The customization manager object includes the following method for registering build process hook customizations:

- `addUserHook(hObj, hookType, hook)`

  Registers the MATLAB hook script or function specified by hook for the build process stage represented by hookType. The valid values for hookType are 'entry', 'before_tlc', 'after_tlc', 'before_make', 'after_make', and 'exit'.

Use this method to register installation-specific hook functions in your instance of the sl_customization function.

The Simulink software reads the sl_customization.m file when it starts. If you subsequently change the file, you must restart the Simulink session or enter the following command in the Command Window to enable the changes:

```matlab
sl_refresh_customizations
```

**Variables Available for sl_customization.m Hook Functions**

The following variables are available for sl_customization.m hook functions to use:

- `modelName` — The name of the Simulink model (valid for all stages)
- `dependencyObject` — An object containing the dependencies of the generated code (valid only for the 'after_make' stage)

A hook script can directly access the valid variables. A hook function can pass the valid variables as arguments to the function. For example:
Example of Build Process Customization with sl_customization.m

The sl_customization.m file shown in the example, **sl_customization.m for Build Process Customizations**, uses the addUserHook method to specify installation-specific build process hooks to be invoked at the 'entry' and 'after_tlc' stages of the build process. For the hook function source code, see the **CustomRTWEntryHook.m** and **CustomRTWPostProcessHook.m** examples.

**Example 83.1. sl_customization.m for Build Process Customizations**

```matlab
function sl_customization(cm)
    % Register user customizations
    hObj = cm.RTWBuildCustomizer;

    % Register build process hooks
    hObj.addUserHook('entry', 'CustomRTWEntryHook(modelName);');
    hObj.addUserHook('after_tlc', 'CustomRTWPostProcessHook(modelName);');
end
```

**Example 83.2. CustomRTWEntryHook.m**

```matlab
function [str, status] = CustomRTWEntryHook(modelName)
    str = sprintf('Custom entry hook for model ''%s''.', modelName);
    disp(str)
    status = 1;
end
```

**Example 83.3. CustomRTWPostProcessHook.m**

```matlab
function [str, status] = CustomRTWPostProcessHook(modelName)
    str = sprintf('Custom post process hook for model ''%s''.', modelName);
    disp(str)
    status = 1;
end
```

If you include the above three files on the MATLAB path of the Simulink installation that you want to customize, the coded hook function messages appear in the displayed output for builds. For example, if you open the ERT-based model rtwdemo_udt, open the **Code Generation** pane of the Configuration Parameters dialog box, and press **Ctrl+B** to initiate a build, the following messages are displayed:

```matlab
>> rtwdemo_udt
```
Custom entry hook for model 'rtwdemo_udt.'
Custom post process hook for model 'rtwdemo_udt.'
### Successful completion of build procedure for model: rtwdemo_udt
>>
Replace STF_rtw_info_hook Supplied Target Data

Prior to MATLAB Release 14, custom targets supplied target-specific information with a hook file (referred to as STF_rtw_info_hook.m). The STF_rtw_info_hook specified properties such as word sizes for integer data types (for example, char, short, int, and long), and C implementation-specific properties of the custom target.

The STF_rtw_info_hook mechanism has been replaced by the Hardware Implementation pane of the Configuration Parameters dialog box. Using this dialog box, you can specify properties that were formerly specified in your STF_rtw_info_hook file.

For backward compatibility, existing STF_rtw_info_hook files are available. However, you should convert your target and models to use of the Hardware Implementation pane. See “Configure Production and Test Hardware” (Simulink Coder).

About Embedded Target Development

Target files bundled with the code generator are suitable for many different applications and development environments. Third-party targets provide additional versatility. In addition, you have the option of implementing a custom target.

To implement a target based on the ARM Cortex®-A or ARM Cortex-M processor, install the corresponding support package and see the Target SDK: Embedded Coder Support Package for ARM Cortex-A Processors, “Develop a Target” (Embedded Coder Support Package for ARM Cortex-A Processors) or Embedded Coder Support Package for ARM Cortex-M Processors, “Develop a Target” (Embedded Coder Support Package for ARM Cortex-M Processors). Otherwise, use these functions and topics.

Custom Targets

You might want to implement a custom target for one of the following reasons:

- To enable end users to generate executable production code for a specific CPU or development board, using a specific development environment (compiler/linker/debugger).
- To support I/O devices on the target hardware by incorporating custom device driver blocks into your models.
- To configure the build process for a special compiler (such as a cross-compiler for an embedded microcontroller or DSP board) or development/debugging environment.

The code generator provides a point of departure for the creation of custom embedded targets, for the basic purposes above. This manual covers the tasks and techniques you need to implement a custom embedded target.

Types of Targets

The following sections describe several types of targets intended for different use cases

- “About Target Types” on page 84-3
- “Rapid Prototyping Targets” on page 84-3
- “Production Targets” on page 84-3
- “Verifying Targets With SIL and PIL Simulation” on page 84-4
About Target Types

There is a progression of capabilities from baseline or rapid prototyping targets to production targets. Initially, you might want to implement a rapid prototyping target. Later, you can enhance the target to be more full-featured. For example, you might want to add support for software-in-the-loop (SIL) or processor-in-the-loop (PIL) simulation at some point for verifying your embedded target. The target types are not mutually exclusive. An embedded target can support more than one of these use cases, or additional uses not outlined here.

The discussion of target types is followed by “Recommended Features for Embedded Targets” on page 84-4, which contains a suggested list of features and general guidelines for embedded target development.

Rapid Prototyping Targets

A rapid prototyping target or baseline target offers a starting point for targeting a production processor. A rapid prototyping target integrates coded generator software with one or more popular cross-development environments (compiler/linker/debugger tool chains). A rapid prototyping target provides a starting point from which you can customize the target for application needs.

Target files provided for this type of target should be readable, easy to understand, and fully commented and documented. Specific attention should be paid to the interface to the intended cross-development environment. This interface should be implemented using the preferred approach for that particular development system. For example, some development environments use traditional make utilities, while others are based on project-file builds that can be automated under control of the code generator.

When you use a rapid prototyping target, you need to include your own device driver and legacy code and modify linker memory maps to suit your needs. You should be familiar with the targeted development system.

Production Targets

A production target supports embedded application development for a production processor. It includes the capability to create program executables that interact immediately with the external world. In general, ease of use is more important than simplicity or readability of generated code files, because it is assumed that you do not want or need to modify the files.
Desirable features for a production target include:

• Significant I/O driver support, provided out of the box
• Easy downloading of generated standalone executable programs with third-party debuggers
• User-controlled placement of an executable in FLASH or RAM memory
• Support for code visibility and tuning on target hardware

**Verifying Targets With SIL and PIL Simulation**

You can use software-in-the-loop (SIL) or processor-in-the-loop (PIL) simulation to verify generated code and validate the target compiler/processor environment.

You can use SIL and PIL simulation modes to verify automatically generated code by comparing the results with a normal mode simulation. With SIL, you can easily verify the behavior of production-intent source code on your host computer; however, it is generally not possible to verify exactly the same code that will subsequently be compiled for your target hardware because the code must be compiled for your host platform (i.e. a different compiler and different processor architecture than the target). With PIL simulation, you can verify exactly the same code that you intend to deploy in production, and you can run the code either on real target hardware or on an instruction set simulator.

For examples describing how to run processor-in-the-loop testing to verify a custom target, see “Sample Custom Targets” on page 84-9.

For more information on SIL and PIL simulation, see “SIL and PIL Simulations” on page 77-2.

**HIL Simulation**

A specialized use case is the generation of executables intended for use in hardware-in-the-loop (HIL) simulations. In a HIL simulation, parts of a pure simulation are gradually replaced with hardware components as components are refined and fabricated. HIL simulation offers an efficient design process that eliminates costly iterations of part fabrication.

**Recommended Features for Embedded Targets**

• “Basic Target Features” on page 84-5
Basic Target Features

- You can base targets on the generic real-time (GRT) target or the Embedded Real-Time (ERT) target that is included in the Embedded Coder product.

If your target is based on the ERT target, it should use 'Embedded-C' value for the CodeFormat TLC variable, and it should inherit the options defined in the ERT target's system target file with the following lines in the TLC file:

```plaintext
%% Assign code format
%assign CodeFormat = "Embedded-C"

%/ BEGIN_RTW_OPTIONS
    rtwgensettings.DerivedFrom = 'ert.tlc';
END_RTW_OPTIONS
%/ %----------------------------
```

By following these recommendations, your target has the production code generation capabilities of the ERT target.

See “Customize System Target Files” on page 84-28 for further details on the inheritance mechanism, setting the CodeFormat, and other details.

- The most fundamental requirement for an embedded target is that it generate a real-time executable from a model or subsystem. Typically, an embedded target generates a timer interrupt-based, bareboard executable (although targets can be developed for an operating system environment as well).

Your target should support code generator concepts of single-tasking and multitasking solver modes for model execution. Tasking support is available with the ERT target, but you should thoroughly understand how it works before implementing an ERT-based target.

For information on timer interrupt-based execution, see “Absolute and Elapsed Time Computation” (Simulink Coder) and “Asynchronous Events” (Simulink Coder).

- You should generate the target executable's main program module, rather than using a static main module (such as the static rt_main.c or rt_cppclass_main.cpp module provided with the software). A generated main.c or .cpp can be made much
more readable and more efficient, since it omits preprocessor checks and other extra code.

For information on generated and static main program modules, see “Deploy Generated Standalone Executable Programs To Target Hardware” on page 62-2.

• Follow the guidelines in “Folder and File Naming Conventions” on page 84-11.

Integration with Target Development Environments

• Most cross-development systems run under a Microsoft Windows PC host. Your target should support the Windows operating system as the host environment.

Some cross-development systems support one or more versions of The Open Group UNIX platforms, allowing for UNIX host support as well.

• Your embedded target must support at least one embedded development environment. The interface to a development environment can take one of several forms. The toolchain approach and template makefile approach generate standard makefiles to work with your development environment. For general information about these build approaches, see “Choose Build Approach and Configure Build Process” (Simulink Coder). For detailed information about the structure of template makefiles, see “Customize Template Makefiles” on page 84-62.

It is important to consider the license requirements and restrictions of the development environment vendor. You may need to modify files provided by the vendor and ship them as part of the embedded target.

See “Interface to Development Tools” on page 84-104 for further information.

Observing Execution of Target Code

• Your target should support a mechanism you can use to observe the target code as it runs in real time (outside of a debugger).

You can use the rtiostream API to implement a communication channel to enable exchange of data between different processes. For an example of creating a communication channel for target connectivity, see “Create a Target Communication Channel for Processor-In-The-Loop (PIL) Simulation” on page 77-101. This rtiostream communication channel is required to enable processor-in-the-loop (PIL) on a new target. See “Communications rtiostream API” on page 77-50.

One industry-standard approach is to use the CAN bus, with an ASAP2 file and CAN Calibration Protocol (CCP). There are several host-based graphical front-end tools
available that connect to a CCP-enabled target and provide data viewing and parameter tuning. Supporting these tools requires implementation of CAN hardware drivers and CCP protocol for the target, as well as ASAP2 file generation. Your target can leverage the ASAP2 support provided with the code generator.

Another option is to support Simulink external mode simulation. For more information, see the “Host-Target Communication with External Mode Simulation” (Simulink Coder).

**Deployment and Hardware Issues**

- Device driver support is an important issue in the design of an embedded target. Device drivers are Simulink blocks that support either hardware I/O capabilities of the target CPU, or I/O features of the development board.

  If you are developing a rapid prototyping target, consider providing minimal driver support, on the assumption that end users develop their own drivers. If you are developing a production target, you should provide full driver support.

  See “Device Drivers” (Simulink Coder).

- Automatic download of generated code to the target hardware makes a target easier to use. Typically a debugger utility is used; if the chosen debugger supports command script files, this can be straightforward to implement. “STF_make_rtw_hook.m” on page 84-20 describes a mechanism to execute code from the build process. You can use this mechanism to make `system()` calls to invoke utilities such as a debugger. You can invoke other simple downloading utilities in a similar fashion.

  If your development system supports COM automation, you can control the download process by that mechanism. Using COM automation is discussed in “Interface to Development Tools” on page 84-104.

- Executables that are mapped to RAM memory are typical. You can provide optional support for FLASH or RAM placement of the executable by using your target's code generation options. To support this capability, you might need multiple linker command files, multiple debugger scripts, and possibly multiple makefiles or project files. Also include the ability to automatically switch between these files, depending on the RAM/FLASH option value.

- Select a popular, widely available evaluation or prototype board for your target processor. Consider enclosed and ruggedized versions of the target board. Also consider board level support for the various on-chip I/O capabilities of the target CPU, and the availability of development systems that support the selected board.

Sample Custom Targets

There are technical solutions on the MathWorks Web site that you can use as a starting point to create your own target solution. The solutions provide guides to the following tasks for creating custom targets:

- Methods of embedding code onto a custom processor
- Creating a system target file
- Customizing the makefile and main file
- Adding compiler, chip, and board specific information
- Integrating legacy code and device drivers
- Creating blocks and libraries
- Implementing processor-in-the-loop (PIL) testing.

1 Start by downloading the embedded targets development guide zip file from this web page:

   Is there an example guide on developing an embedded target...?

   The zip file provides example files and a guide to developing a custom embedded target. The guide is divided into two parts, one on creating a generic custom target and another on creating a target for the Freescale™ S12X processor using the Cosmic Compiler.

   Read the example guide along with this document to understand the tasks for developing embedded targets.

2 For more detailed example files for specific processors, see:

   - Is there an example Freescale S12X target... using the Cosmic Compiler?
   - Is there an example Freescale S12X target... using the CodeWarrior Compiler?

   These example kits contain example models, code generation files, and instruction guides on generating and testing code for the processor. The Cosmic example illustrates the use of the target connectivity API for processor-in-the-loop (PIL) testing. The CodeWarrior example does not have PIL but shows CAN Calibration Protocol (CCP) and Simulink external mode.

   The intent of the example kits is to provide working examples that you can use as a base to create your own target solution. The intent is not to provide a full featured
and maintained Embedded Target product like those provided by MathWorks or third-party products, as listed on the Embedded Coder Hardware Support Web page.

You can watch videos showing overviews of both the example kits at the following links:

- www.mathworks.com/videos/programming-the-freescale-s12x-target-68811.html

For another example target for the ARM9 (STR9) processor, see Is there an example ARM9 (STR9) target... using the GNU ARM Compiler and Hitex STR9-comStick?.

If you have questions on specific targets, please email mytarget@mathworks.com.

The example kits and this document describe Embedded Coder features such as customized ert system target files and processor-in-the-loop testing, but you can study the examples as a starting point for use with Simulink Coder targets.

Target Development Folders, Files, and Builds

Target development mechanics work with a number of folder and file types. The following topics provide the information to develop custom targets, configure folder usage, and use custom targets in the build process.

Folder and File Naming Conventions

You can use a single folder for your custom target files, or if desired you can use subfolders, for example containing files associated with specific development environments or tools.

For a custom target implementation, the recommended folder and file naming conventions are

- Use only lowercase in folder names, filenames, and extensions.
- Do not embed spaces in folder names. Spaces in folder names cause errors with many third-party development environments.
- Include desired folders in the MATLAB path
- Do not place your custom target folder anywhere in the MATLAB folder tree (that is, in or under the `matlabroot` folder). If you place your folder under `matlabroot` you risk losing your work if you install a new MATLAB version (or reinstall the current version).

The following sections explain how to organize your target folders and files and add them to your MATLAB path. They also provide high-level descriptions of the files.

In this document, `mytarget` is a placeholder name that represents folders and files that use the target's name. The names `dev_tool1`, `dev_tool2`, and so on represent subfolders containing files associated with development environments or tools. This document describes an example structure where the folder `mytarget` contains subfolders for `mytarget`, `blocks`, `dev_tool1`, `dev_tool2`. The top level folder `mytarget` is the `target root folder`.

Components of a Custom Target

- “Overview” on page 84-12
- “Code Components” on page 84-12
- “Control Files” on page 84-14
Overview

The components of a custom target are files located in a hierarchy of folders. The top-level folder in this structure is called the *target root folder*. The target root folder and its contents are named, organized, and located on the MATLAB path according to conventions described in “Folder and File Naming Conventions” on page 84-11.

The components of a custom target include

- Code components: C source code that supervises and supports execution of generated model code.
- Control files:
  - A system target file (STF) to control the code generation process.
  - File(s) to control the building of an executable from the generated code. In a traditional make-based environment, a template makefile (TMF) generates a makefile for this purpose. Another approach is to generate project files in support of a modern integrated development environment (IDE) such as the Freescale Semiconductor CodeWarrior IDE.
  - Hook files: Optional TLC and MATLAB program files that can be invoked at well-defined stages of the build process. Hook files let you customize the build process and communicate information between various phases of the process.
- Other target files: Files that let you integrate your target into the MATLAB environment. For example, you can provide an info.xml file to make your target block libraries and examples available from a MATLAB session.

The next sections introduce key concepts and terminology you need to know to develop each component. References to more detailed information sources are provided.

Code Components

An executable program containing code generated from a Simulink model consists of a number of code modules and data structures. These fall into two categories.

Application Components

Application components are those which are specific to a particular model; they implement the functions represented by the blocks in the model. Application components are not specific to the target. Application components include

- Modules generated from the model
• User-written blocks (S-functions)
• Parameters of the model that are visible, and can be interfaced to, external code

**Execution Support Files**

A number of code modules and data structures, referred to collectively as the *execution support files*, are responsible for managing and supporting the execution of the generated program. The execution support files modules are not automatically generated. Depending on the requirements of your target, you must implement certain parts of the execution support files. Execution Support Files summarizes the execution support files.

### Execution Support Files

<table>
<thead>
<tr>
<th>You Provide...</th>
<th>The Code Generator Provides...</th>

<td>Example device drivers</td>
</tr>
<tr>
<td>Data logging, parameter tuning, signal monitoring, and external mode support</td>
<td>Data logging, parameter tuning, signal monitoring, and external mode APIs</td>
</tr>
</tbody>
</table>

### User-Written Execution Support Files

The code generator provides most of the execution support files. Depending on the requirements of your target, you must implement some or all of the following elements:

• A timer *interrupt service routine* (ISR). The timer runs at the program's base sample rate. The timer ISR is responsible for operations that must be completed within a single clock period, such as computing the current output sample. The timer ISR usually calls the `rt_OneStep` function.

  If you are targeting a real-time operating system (RTOS), your generated code usually executes under control of the timing and task management mechanisms provided by the RTOS. In this case, you may not have to implement a timer ISR.

• The *main program*. Your main program initializes the blocks in the model, installs the timer ISR, and executes a background task or loop. The timer periodically interrupts
the main loop. If the main program is designed to run for a finite amount of time, it is also responsible for cleanup operations — such as memory deallocation and masking the timer interrupt — before terminating the program.

If you are targeting a real-time operating system (RTOS), your main program most likely spawns tasks (corresponding to the sample rates used in the model) whose execution is timed and controlled by the RTOS.

Your main program typically is based on a generated or static main program. For details on the structure of the execution support files, code execution, and guidelines for customizing main programs, see “Deploy Generated Standalone Executable Programs To Target Hardware” on page 62-2.

- **Device drivers.** Drivers communicate with I/O devices on your target hardware. In production code, device drivers are normally implemented as inlined S-functions.
- **Other interrupt handlers.** If your models need to support asynchronous events, such as hardware generated interrupts and asynchronous read and write operations, you must supply interrupt handlers. The Interrupt Templates library provides examples.
- **Data logging, parameter tuning, signal monitoring, and external mode support.** It is atypical to implement rapid prototyping features such as external mode support in an embedded target. However, it is possible to support these features by using standard code generator APIs. See “Data Exchange Interfaces” (Simulink Coder) for details.

### Control Files

The code generation and build process is directed by a number of TLC and MATLAB files collectively called *control files*. This section introduces and summarizes the main control files.

**Top-Level Control File (make_rtw)**

The build process is initiated when you press Ctrl+B. At this point, the build process parses the Make command field of the Code Generation pane of the Configuration Parameters dialog box, expecting to find the name of a MATLAB command that controls the build process (as well as optional arguments to that command). The default command is `make_rtw`, and the default top-level control file for the build process is `make_rtw.m`.

**Note** `make_rtw` is an internal MATLAB command used by the build process. Normally, target developers do not need detailed knowledge of how `make_rtw` works. (The details for target developers are described in “Target Development and the Build Process” on...
You should not invoke make_rtw directly from MATLAB code, and you should not customize make_rtw.m.

The make_rtw.m file contains the logic required to execute your target-specific control files, including a number of hook points for execution of your custom code. make_rtw does the following:

- Passes optional arguments in to the build process
- Performs required preprocessing before code generation
- Executes the STF to perform code generation (and optional HTML report generation)
- Processes the TMF to generate a makefile
- Invokes a make utility to execute the makefile and build an executable
- Performs required post-processing (such as generating calibration data files or downloading the generated executable to the target)

**System Target File (STF)**

The Target Language Compiler (TLC) generates target-specific C or C++ code from a partial description of your Simulink block diagram (model.rtw). The Target Language Compiler reads model.rtw and executes a program consisting of several target files (.tlc files.) The STF, at the top level of this program, controls the code generation process. The output of this process is a number of source files, which are fed to your development system's make utility.

You need to create a customized STF to set code generation parameters for your target. You should copy, rename, and modify the standard ERT system target file (matlabroot/rtw/c/ert/ert.tlc).

The detailed structure of the STF is described in “Customize System Target Files” on page 84-28.

**Note** The STF selects whether the target supports the toolchain approach or template makefile approach for code generation. See “Customize System Target Files” on page 84-28.
Template Makefile (TMF)

A TMF provides information about your model and your development system. The build process uses this information to create a makefile (.mk file) that builds an executable program.

Some targets implement more than one TMF, in order to support multiple development environments (for example, two or more cross-compilers) or multiple modes of code generation (for example, generating a binary executable versus generating a project file for your compiler).

The Embedded Coder software provides a large number of TMFs suitable for different types of development computer systems. These TMFs are located in `matlabroot/rtw/c/ert` (open). The standard TMFs are described in “Template Makefiles and Make Options” (Simulink Coder).

The detailed structure of the TMF is described in “Customize Template Makefiles” on page 84-62.

**Note** The STF selects whether the target supports the toolchain approach or template makefile approach for code generation. See “Customize System Target Files” on page 84-28.

Hook Files

The build process allows you to supply optional hook files that are executed at specified points in the code generation and make process. You can use hook files to add target-specific actions to the build process.

The hook files must follow well-defined naming and location requirements. “Folder and File Naming Conventions” on page 84-11 describes these requirements.

Key Folders Under Target Root (mytarget)

- “Target Root Folder (mytarget)” on page 84-17
- “Target Folder (mytarget/mytarget)” on page 84-17
- “Target Block Folder (mytarget/blocks)” on page 84-17
- “Development Tools Folder (mytarget/dev_tool1, mytarget/dev_tool2)” on page 84-18
• “Target Source Code Folder (mytarget/src)” on page 84-19

**Target Root Folder (mytarget)**

This folder contains the key subfolders for the target (see “Folder and File Naming Conventions” on page 84-11). You can also locate miscellaneous files (such as a readme file) in the target root folder. The following sections describe required and optional subfolders and their contents.

**Target Folder (mytarget/mytarget)**

This folder contains files that are central to the target, such as the system target file (STF) and template makefile (TMF). “Key Files in Target Folder (mytarget/mytarget)” on page 84-19 summarizes the files that should be stored in mytarget/mytarget, and provides pointers to detailed information about these files.

**Note** mytarget/mytarget should be on the MATLAB path.

**Target Block Folder (mytarget/blocks)**

If your target includes device drivers or other blocks, locate the block implementation files in this folder. mytarget/blocks contains

- Compiled block MEX-files
- Source code for the blocks
- TLC inlining files for the blocks
- Library models for the blocks (if you provide your blocks in one or more libraries)

**Note** mytarget/blocks should be on the MATLAB path.

You can also store example models and supporting files in mytarget/blocks. Alternatively, you can create a mytarget/mytargetdemos folder, which should also be on the MATLAB path.

To display your blocks in the standard Simulink Library Browser and/or integrate your example models into the MATLAB session environment, you can create the files described below and store them in mytarget/blocks.
**mytarget/blocks/slbblocks.m**

This file allows a group of blocks to be integrated into the Simulink Library and Simulink Library Browser.

**Example 84.1. Example slblocks.m File**

```matlab
function blkStruct = slblocks
% Information for "Blocksets and Toolboxes" subsystem
blkStruct.Name = sprintf('Embedded Target\n for MYTARGET');
blkStruct.OpenFcn = 'mytargetlib';
blkStruct.MaskDisplay = 'disp(''MYTARGET'');

% Information for Simulink Library Browser
Browser(1).Library = 'mytargetlib';
Browser(1).Name = 'Embedded Target for MYTARGET';
Browser(1).IsFlat = 1;% Is this library "flat" (i.e. no subsystems)?

blkStruct.Browser = Browser;
```

**mytarget/blocks/demos.xml**

This file provides information about the components, organization, and location of example models. MATLAB software uses this information to place the example in the MATLAB session environment.

**Example 84.2. Example demos.xml File**

```xml
<?xml version="1.0" encoding="utf-8"?>
<demos>
  <name>Embedded Target for MYTARGET</name>
  <type>simulink</type>
  <icon>$toolbox/matlab/icons/boardicon.gif</icon>
  <description source = "file">mytarget_overview.html</description>

  <demosection>
    <label>Multirate model</label>
    <demoitem>
      <label>MYTARGET demo</label>
      <file>mytarget_overview.html</file>
      <callback>mytarget_model</callback>
    </demoitem>
  </demosection>
</demos>
```

**Development Tools Folder (mytarget/dev_tool1, mytarget/dev_tool2)**

These folders contain files associated with specific development environments or tools (dev_tool1, dev_tool2, etc.). Normally, your target supports at least one such development environment and invokes its compiler, linker, and other utilities during the
build process. mytarget/dev_tool1 includes linker command files, startup code, hook functions, and other files required to support this process.

For each development environment, you should provide a separate folder.

Target Source Code Folder (mytarget/src)

This folder is optional. If the complexity of your target requires it, you can use mytarget/src to store common source code and configuration code (such as boot and startup code).

Key Files in Target Folder (mytarget/mytarget)

- “Introduction” on page 84-19
- “mytarget.tlc” on page 84-19
- “mytarget.tmf” on page 84-20
- “mytarget_genfiles.tlc” on page 84-20
- “mytarget_main.c” on page 84-20
- “STF_make_rtw_hook.m” on page 84-20
- “STF_rtw_info_hook.m (obsolete)” on page 84-21
- “info.xml” on page 84-21
- “mytarget_overview.html” on page 84-21

Introduction

The target folder mytarget/mytarget contains key files in your target implementation. These include the system target file, template makefile, main program module, and optional M and TLC hook files that let you add target-specific actions to the build process. The following sections describe the key target folder files.

mytarget.tlc

mytarget.tlc is the system target file (STF). Functions of the STF include

- Making the target visible in the System Target File Browser
- Definition of code generation options for the target (inherited and target-specific)
- Providing an entry point for the top-level control of the TLC code generation process

You should base your STF on ert.tlc, the STF provided by Embedded Coder software.
“Customize System Target Files” on page 84-28 gives detailed information on the structure of the STF, and also gives instructions on how to customize an STF to

- Display your target in the System Target File Browser
- Add your own target options to the Configuration Parameters dialog box
- Tailor the code generation and build process to the requirements of your target

**mytarget.tmf**

mytarget.tmf is the template makefile for building an executable for your target.

For basic information on the structure and operation of template makefiles, see “Customize Template Makefiles” on page 84-62.

If your target development environment requires automation of a modern integrated development environment (IDE) rather than use of a traditional make utility, see “Interface to Development Tools” on page 84-104.

**mytarget_genfiles.tlc**

This file is optional. mytarget_genfiles.tlc is useful as a central file from which to invoke target-specific TLC files that generate additional files as part of your target build process. For example, your target may create sub-makefiles or project files for a development environment, or command scripts for a debugger to do automatic downloads. See “Using mytarget_genfiles.tlc” on page 84-45 for details.

**mytarget_main.c**

A main program module is required for your target. To provide a main module, you can either

- Modify the rt_main.c or rt_cppclass_main.cpp module provided by the software
- Generate mytarget_main.c or .cpp during the build process

For a description of the operation of main programs, see “Deploy Generated Standalone Executable Programs To Target Hardware” on page 62-2. The section also contains guidelines for generating and modifying a main program module.

**STF_make_rtw_hook.m**

STF_make_rtw_hook.m is an optional hook file that you can use to invoke target-specific functions or executables at specified points in the build process. STF_make_rtw_hook.m
implements a function that dispatches to a specific action depending on the method argument that is passed into it.

“Customize Build Process with STF_make_rtw_hook File” (Simulink Coder) describes the operation of the STF_make_rtw_hook.m hook file in detail.

**STF_ftw_info_hook.m (obsolete)**

Prior to Release 14, custom targets supplied target-specific information with a hook file (referred to as STF_ftw_info_hook.m). The STF_ftw_info_hook specified properties such as word sizes for integer data types (for example, char, short, int, and long), and C implementation-specific properties of the custom target.

The STF_ftw_info_hook mechanism has been replaced by the **Hardware Implementation** pane of the Configuration Parameters dialog box. Using this dialog box, you can specify the properties that were formerly specified in your STF_ftw_info_hook file.

For backward compatibility, existing STF_ftw_info_hook files are still available. However, you should convert your target and models to use the **Hardware Implementation** pane. See “Configure Run-Time Environment Options” (Simulink Coder).

**info.xml**

This file provides information to MATLAB software that specifies where to display the target toolbox in the MATLAB session environment. For more information, see “Display Custom Documentation” (MATLAB).

**mytarget_overview.html**

By convention, this file serves as home page for the target examples.

The `<description>` field in demos.xml should point to mytarget_overview.html (see “mytarget/blocks/demos.xml” on page 84-18).

**Example mytarget_overview.html File**

```html
<html>
<head><title>Embedded Target for MYTARGET</title></head>
<body>
<p style="color:#990000; font-weight:bold; font-size:x-large">Embedded Target for MYTARGET Example Model</p>

This example provides a simple model that allows you to generate an executable for a supported target board. You can then download and run the executable and
Additional Files for Externally Developed Targets

• “Introduction” on page 84-22
• “mytarget/mytarget/mytarget_setup.m” on page 84-22
• “mytarget/mytarget/doc” on page 84-22

Introduction

If you are developing an embedded target that is not installed into the MATLAB tree, you should provide a target setup script and target documentation within `mytarget/mytarget` for the convenience of your users. The following sections describe the required materials and where to place them.

**mytarget/mytarget/mytarget_setup.m**

This file script adds paths for your target to the MATLAB path. Your documentation should instruct users to run the script when installing the target.

You should include a call to the MATLAB function `savepath` in your `mytarget_setup.m` script. This function saves the added paths, so users need to run `mytarget_setup.m` only once.

The following code is an example `mytarget_setup.m` file.

```matlab
function mytarget_setup()
    curpath = pwd;
    tgtpath = curpath(1:end-length('\mytarget'));
    addpath(fullfile(tgtpath, 'mytarget'));
    addpath(fullfile(tgtpath, 'dev_tool1'));
    addpath(fullfile(tgtpath, 'blocks'));
    addpath(fullfile(tgtpath, 'mytargetdemos'));
    savepath;
    disp('MYTARGET Target Path Setup Complete.');
end
```

**mytarget/mytarget/doc**

You should put the documentation related to your target in the folder `mytarget/mytarget/doc`.

Target Development and the Build Process

• “About the Build Process” on page 84-23
• “Build Process Phases and Information Passing” on page 84-23
• “Additional Information Passing Techniques” on page 84-24

About the Build Process

To develop an embedded target, you need a thorough understanding of the build process. Your embedded target uses the build process and may require you to modify or customize the process. A general overview of code generation and the build process is given in “Code Generation” (Simulink Coder) and “Build Process” (Simulink Coder).

This section supplements that overview with a description of the build process as customized by the Embedded Coder software. The emphasis is on points in the process where customization hooks are available and on passing information between different phases of the process.

This section concludes with “Additional Information Passing Techniques” on page 84-24, describing assorted tips and tricks for passing information during the build process.

Build Process Phases and Information Passing

It is important to understand where (and when) the build process obtains required information. Sources of information include

- The model.rtw file, which provides information about the generating model. The information in model.rtw is available to target TLC files.
- The code generation panes of the Configuration Parameters dialog box. Options (both general and target-specific) are provided through check boxes, menus, and edit fields. You can associate options with TLC variables in the rtwoptions data structure. Use the Configuration Parameters > Code Generation > Custom Code > Additional build information > Defines field to define makefile tokens.
- The selected toolchain (for toolchain approach builds) or selected template makefile.tmf (for template makefile approach builds); these generate the model-specific makefile.
- Environment variables on the host computer. Environment variables provide additional information about installed development tools.
- Other target-specific files such as target-related TLC files, linker command files, or project files.
It is also important to understand the several phases of the build process and how to pass information between the phases. The build process comprises several high-level phases:

- Execution of the top-level file (slbuild.m or rtwbuild.m) to sequence through the build process for a target
- Conversion of the model into the TLC input file (model.rtw)
- Generation of the target code by the TLC compiler
- Compilation of the generated code with make or other utilities
- Transmission of the final generated executable to the target hardware with a debugger or download utility

It is helpful to think of each phase of the process as a different “environment” that maintains its own data. These environments include

- MATLAB code execution environment (MATLAB)
- Simulink
- Target Language Compiler execution environment
- makefile
- Development environments such as and IDE or debugger

In each environment, you might get information from the various sources mentioned above. For example, during the TLC phase, execute MATLAB file might execute to obtain information from the MATLAB environment. Also, a given phase may generate information for a subsequent phase.

See “Key Files in Target Folder (mytarget/mytarget)” on page 84-19 for details on the available MATLAB file and TLC hooks for information passing, with code examples.

**Additional Information Passing Techniques**

This section describes a number of useful techniques for passing information among different phases of the build process.

**tlcvariable Field in rtwoptions Structure**

Parameters on the code generation panes of the Configuration Parameters dialog box can be associated with a TLC variable, and specified in the tlcvariable field of the option's entry in the rtwoptions structure. The variable value is passed on the command line when TLC is invoked. This provides a way to make code generation parameters and their values available in the TLC phase.
See “System Target File Structure” on page 84-29 for further information.

**makevariable Field in rtwoptions Structure**

You can associate code generation parameters with a template makefile token, that you specify in the `makevariable` field of the option's entry in the `rtwoptions` structure. If a token of the same name as the `makevariable` name exists in the TMF, the token is updated with the option value when the final makefile is created. If the token does not exist in the TMF, the `makevariable` is passed in on the command line when make is invoked. Thus, in either case, the `makevariable` is available to the makefile.

See “System Target File Structure” on page 84-29 for further information.

**Accessing Host Environment Variables**

You can access host shell environment variables at the MATLAB command line by entering the `getenv` command. For example:

```matlab
getenv ('MSDEVDIR')
```

```
ans =
D:\Applications\Microsoft Visual Studio\Common\MSDev98
```

To access the same information from TLC, use the `FEVAL` directive to invoke `getenv`.

```matlab
%assign eVar = FEVAL("getenv","<varname>")
```

**Supplying Development Environment Information to Your Template Makefile**

An embedded target must tie the build process to target-specific development tools installed on a host computer. For the make process to run these tools, the TMF must be able to determine the name of the tools, the path to the compiler, linker, and other utilities, and possibly the host operating system environment variable settings.

Require the end user to modify the target TMF. The user enters path information (such as the location of a compiler executable), and possibly host operating system environment variables, as make variables. This allows the TMF to be tailored to specific needs.

**Using MATLAB Application Data**

Application data provides a way for applications to save and retrieve data stored with the GUI. This technique enables you to create what is essentially a user-defined property for an object, and use this property to store data for use in the build process. If you are
unfamiliar with this technique for creating graphical user interfaces, see “Store Data as Application Data” (MATLAB).

The following code examples illustrates the use of application data to pass information to TLC.

This file, tlc2appdata.m, stores the data passed in as application data under the name passed in (appDataName).

```matlab
function k = tlc2appdata(appDataName,data)
    disp([mfilename,': ',appDataName,' ', data]);
    setappdata(0,appDataName,data);
    k = 0;  % TLC expects a return value for FEVAL.
```

The following sample TLC file uses the FEVAL directive to invoke tlc2appdata.m to store arbitrary application data, under the name z80.

```matlab
%% test.tlc
%%
%assign myApp = "z80"
%assign myData = "314159"
%assign dummy = FEVAL("tlc2appdata",myApp,myData)
```

To test this technique:

1. Create the tlc2appdata.m file as shown. Check that tlc2appdata.m is stored in a folder on the MATLAB path.
2. Create the TLC file as shown. Save it as test.tlc.
3. Enter the following command at the MATLAB prompt to execute the TLC file:
   ```
   tlc test.tlc
   ```
4. Get the application data at the MATLAB prompt:
   ```
   k = getappdata(0,'z80')
   ```

   The function returns the value 314159.
5. Enter the following command.
   ```
   who
   ```

   Note that application data is not stored in the MATLAB workspace. Also observe that the z80 data is not visible. Using application data in this way has the advantage that
it does not clutter the MATLAB workspace. Also, it helps prevent you from accidentally deleting your data, since it is not stored directly in your workspace.

A real-world use of application data might be to collect information from the `model.rtw` file and store it for use later in the build process.

**Adding Block-Specific Information to the Makefile**

The `rtwmakecfg` mechanism provides a method for inlined S-functions such as driver blocks to add information to the makefile. This mechanism is described in “Use `rtwmakecfg.m` API to Customize Generated Makefiles” (Simulink Coder).

- “About Embedded Target Development” (Simulink Coder)
Customize System Target Files

This section provides information on the structure of the STF, guidelines for customizing an STF, and a basic tutorial that helps you get a skeletal STF up and running.

Control Code Generation With the System Target File

The system target file (STF) exerts overall control of the code generation stage of the build process. The STF also lets you control the presentation of your target to the end user. The STF provides

- Definitions of variables that are fundamental to the build process, such as the value for the CodeFormat TLC variable
- The main entry point to the top-level TLC program that generates code
- Target information for display in the System Target File Browser
- A mechanism for defining target-specific code generation options (and other parameters related to the build process) and for displaying them in the Configuration Parameters dialog box
- A mechanism for inheriting options from another target (such as the Embedded Real-Time (ERT) target)

Note that, although the STF is a Target Language Compiler (TLC) file, it contains embedded MATLAB code. Before creating or modifying an STF, you should acquire a working knowledge of TLC and of the MATLAB language. “Target Language Compiler” (Simulink Coder) and “Scripts vs. Functions” (MATLAB) describe the features and syntax of both the TLC and MATLAB languages.

While reading this section, you may want to refer to the STFs provided with the code generator. Most of these files are stored in the target-specific folders under matlabroot/rtw/c (open). Additional STFs are stored under matlabroot/toolbox/rtw/targets (open).

System Target File Naming and Location Conventions

An STF must be located in a folder on the MATLAB path for the target to be displayed in the System Target File Browser and invoked in the build process. Follow the location and naming conventions for STFs and related target files given in “Folder and File Naming Conventions” on page 84-11.

  targetComponentClass = 'Simulink.ERTTargetCC';
  END_CONFIGSET_Target_COMPONENT
%/  
If you are creating a custom target based on an existing STF, you must remove the
targetComponentClass section (bounded by the directives
BEGIN_CONFIGSET_TARGET_COMPONENT and END_CONFIGSET_TARGET_COMPONENT).
This section is reserved for the use of targets developed internally by MathWorks.

Header Comments

These lines at the head of the file are formatted as TLC comments. They provide required
information to the System Target File Browser and to the build process. Note that you
must place the browser comments at the head of the file, before other comments or TLC
statements.
The presence of the comments enables the code generator to detect STFs. When the System Target File Browser is opened, the code generator scans the MATLAB path for TLC files that have formatted header comments. The comments contain the following directives:

- SYSTLC: The descriptor that appears in the browser.
- TMF: Name of the template makefile (TMF) to use during build process. When the target is selected, this filename is displayed in the “Template makefile” (Simulink Coder) field of the Code Generation pane of the Configuration Parameters dialog box.
- MAKE: make command to use during build process. When the target is selected, this command is displayed in the Make command field of the Code Generation pane of the Configuration Parameters dialog box.
- EXTMODE: Name of external mode interface file (if any) associated with your target. If your target does not support external mode, use no_ext_comm.

The following header comments are from \texttt{matlabroot/rtw/c/ert/ert.tlc}.

\begin{verbatim}
%% SYSTLC: Embedded Coder TMF: ert_default_tmf MAKE: make_rtw 
%% EXTMODE: ext_comm
%% SYSTLC: Create Visual C/C++ Solution File for Embedded Coder
%% TMF: RTW.MSVCBuild MAKE: make_rtw EXTMODE: ext_comm
 .
 .
 .
\end{verbatim}

\textbf{Note}

- Limitation: Each comment can only contain a maximum of two lines, as shown in the preceding example.
- If you do not specify the TMF or EXTMODE fields in the system target file, the file is still valid. To change the values for the parameters Template makefile (TemplateMakefile) and External mode (ExtMode), you can instead use the callback function specified by rtwgensettings.SelectCallback.

Note that you can specify more than one group of directives in the header comments. Each such group is displayed as a different target configuration in the System Target File Browser. In the above example, the first two lines of code specify the default configuration of the ERT target. The next two lines specify a configuration that creates and builds a Microsoft Visual C++ Solution (.sln) file. The figure below shows how these configurations appear in the System Target File Browser.
See “Create a Custom Target Configuration” on page 84-48 for an example of customized header comments.

**TLC Configuration Variables**

This section of the STF assigns global TLC variables that relate to the overall code generation process.

For an embedded target, in most cases you should simply use the global TLC variable settings used by the ERT target (ert.tlc). It is especially important that your STF use the 'Embedded-C' value for the CodeFormat TLC variable and uses the corresponding `rtwgensettings.DerivedFrom = 'ert.tlc'` in the `RTW_OPTIONS` section of the TLC file. Verify that values are assigned to the following variables:

- **CodeFormat**: The CodeFormat TLC variable selects generated code features. The 'Embedded-C' value for this variable is used by the ERT target. Your ERT-based target should specify 'Embedded-C' as the value for CodeFormat. This selection is designed for production code, minimal memory usage, static memory allocation, and a simplified interface to generated code.

  For information on other values for the CodeFormat TLC variable, see “Compare System Target File Support Across Products” (Simulink Coder).

- **Language**: The only valid value is C, which enables support for C or C++ code generation as specified by the configuration parameter TargetLang.

- **TargetType**: The code generator defines the preprocessor symbols RT and NRT to distinguish simulation code from real-time code. These symbols are used in conditional compilation. The TargetType variable determines whether RT or NRT is defined.
Most targets are intended to generate real-time code. They assign `TargetType` as follows.

```
%assign TargetType = "RT"
```

Some targets, such as the model reference simulation target, accelerated simulation target, RSim target, and S-function target, generate code for use in nonreal time only. Such targets assign `TargetType` as follows.

```
%assign TargetType = "NRT"
```

**TLC Program Entry Point and Related `%includes`**

The code generation process normally begins with `codegenentry.tlc`. The STF invokes `codegenentry.tlc` as follows.

```
%include "codegenentry.tlc"
```

**Note** `codegenentry.tlc` and the lower-level TLC files assume that `CodeFormat`, `TargetType`, and `Language` have been assigned. Set these variables before including `codegenentry.tlc`.

If you need to implement target-specific code generation features, you should include the TLC file `mytarget_genfiles.tlc` in your STF. This file provides a mechanism for executing custom TLC code before and after invoking `codegenentry.tlc`. For information on this mechanism, see

- “Using `mytarget_genfiles.tlc`” on page 84-45 for an example of custom TLC code for execution after the main code generation entry point.
- “Target Development and the Build Process” on page 84-23 for general information on the build process, and for information on other build process customization hooks.

Another way to customize the code generation process is to call lower-level functions (normally invoked by `codegenentry.tlc`) directly, and include your own TLC functions at each stage of the process. This approach should be taken with caution. See “TLC Files” (Simulink Coder) for more information.

The lower-level functions called by `codegenentry.tlc` are

- `genmap.tlc`: maps block names to corresponding language-specific block target files.
• **commonsetup.tlc**: sets up global variables.
• **commonentry.tlc**: starts the process of generating code.

**RTW_OPTIONS Section**

The RTW_OPTIONS section is bounded by the directives:

```%
   BEGIN_RTW_OPTIONS
   
   END_RTW_OPTIONS
%
```

The first part of the RTW_OPTIONS section defines an array of rtwoptions structures. This structure is discussed in “Using rtwoptions to Display Custom Target Options” on page 84-37.

The second part of the RTW_OPTIONS section defines rtwgensettings, a structure defining the build folder name and other settings for the code generation process. See “rtwgensettings Structure” on page 84-34 for information about rtwgensettings.

**rtwgensettings Structure**

The final part of the STF defines the rtwgensettings structure. This structure stores information that is written to the `model.rtw` file and used by the build process. The rtwgensettings fields of most interest to target developers are

- **rtwgensettings.Version**: Use this property to enable rtwoptions callbacks and to use the Callback API in rtwgensettings.SelectCallback.

**Note** To use callbacks, you *must* set:

```matlab
twgensettings.Version = '1';
```

Add the statement above to the **Configure RTW code generation settings** section of the system target file.
• `rtwgensettings.DerivedFrom`: This structure field defines the system target file from which options are to be inherited. See “Inheriting Target Options” on page 84-44.

• `rtwgensettings.SelectCallback`: This structure field specifies a `SelectCallback` function. You must set `rtwgensettings.Version = '1';` or your callback will be ignored. `SelectCallback` is associated with the target rather than with any of its individual options. The `SelectCallback` function is triggered when the user selects a target with the System Target File browser.

The `SelectCallback` function is useful for setting up (or disabling) configuration parameters specific to the target.

The following code installs a `SelectCallback` function:

```matlab
rtwgensettings.SelectCallback = 'my_select_callback_handler(hDlg,hSrc)';
```

The arguments to the `SelectCallback` function (`hDlg`, `hSrc`) are handles to private data used by the callback API functions.

**Note** If you have developed a custom target and you want it to be compatible with model referencing, you must implement a `SelectCallback` function to declare model reference compatibility. See “Support Model Referencing” on page 84-84.

• `rtwgensettings.ActivateCallback`: this property specifies an `ActivateCallback` function. The `ActivateCallback` function is triggered when the active configuration set of the model changes. This could happen during model loading, and also when the user changes the active configuration set.

The following code installs an `ActivateCallback` function:

```matlab
rtwgensettings.ActivateCallback = 'my_activate_callback_handler(hDlg,hSrc)';
```

The arguments to the `ActivateCallback` function (`hDlg`, `hSrc`) are handles to private data used by the callback API functions.

• `rtwgensettings.PostApplyCallback`: this property specifies a `PostApplyCallback` function. The `PostApplyCallback` function is triggered when the user clicks the **Apply** or **OK** button after editing options in the Configuration Parameters dialog box. The `PostApplyCallback` function is called after the changes have been applied to the configuration set.

The following code installs an `PostApplyCallback` function:

```matlab
rtwgensettings.PostApplyCallback = 'my_postapply_callback_handler(hDlg,hSrc)';
```
The arguments to the PostApplyCallback function (hDlg, hSrc) are handles to private data used by the callback API functions.

- `rtwgensettings.BuildDirSuffix`: Most targets define a folder name suffix that identifies build folders created by the target. The build process appends the suffix defined in the `rtwgensettings.BuildDirSuffix` field to the model name to form the name of the build folder. For example, if you define `rtwgensettings.BuildDirSuffix` as follows

  ```
  rtwgensettings.BuildDirSuffix = '_mytarget_rtw'
  ```

  the build folders are named `model_mytarget_rtw`.

### Additional Code Generation Options

“Configure Generated Code with TLC” (Simulink Coder) describes additional TLC code generation variables. End users of a target can assign these variables by entering a MATLAB command of the form

```matlab
set_param(modelName,'TLCOptions','-aVariable=value');
```

(For more information, see “Specify TLC for Code Generation” (Simulink Coder).)

However, the preferred approach is to assign these variables in the STF using statements of the form:

```
%assign Variable = val
```

For readability, we recommend that you add such assignments in the section of the STF after the comment `Configure RTW code generation settings`.

### Model Reference Considerations

See “Support Model Referencing” on page 84-84 for important information on STF and other modifications you may need to make to support the code generator model referencing features.

### Define and Display Custom Target Options

- “Using rtwoptions to Display Custom Target Options” on page 84-37
- “Example System Target File With Customized rtwoptions” on page 84-42
- “Inheriting Target Options” on page 84-44
Using rtwoptions to Display Custom Target Options

You control the options to display in the **Code Generation** pane of the Configuration Parameters dialog box by customizing the **rtwoptions** structure in your system target file.

The fields of the **rtwoptions** structure define variables and associated user interface elements to be displayed in the Configuration Parameters dialog box. Using the **rtwoptions** structure array, you can define target-specific options displayed in the dialog box and organize options into categories. You can also write callback functions to specify how these options are processed.

When the **Code Generation** pane opens, the **rtwoptions** structure array is scanned and the listed options are displayed. Each option is represented by an assigned user interface element (check box, edit field, menu, or push button), which displays the current option value.

The user interface elements can be in an enabled or disabled (grayed-out) state. If an option is enabled, the user can change the option value.

You can also use the **rtwoptions** structure array to define special NonUI elements that cause callback functions to be executed, but that are not displayed in the **Code Generation** pane. See “NonUI Elements” on page 84-42 for details.

The elements of the **rtwoptions** structure array are organized into groups. Each group of items begins with a header element of type **Category**. The default field of a **Category** header must contain a count of the remaining elements in the category.

The **Category** header is followed by options to be displayed on the **Code Generation** pane. The header in each category is followed by one or more option definition elements.

Each category of target options corresponds to options listed under **Code Generation** in the Configuration Parameters dialog box.

The table **rtwoptions Structure Fields Summary** summarizes the fields of the **rtwoptions** structure.

### Example rtwoptions Structure

The following **rtwoptions** structure is excerpted from an example system target file, `matlabroot/toolbox/rtw/rtwdemos/rtwoptions_demo/usertarget.tlc`. The code defines an **rtwoptions** structure array. The default field of the first (header) element is set to 4, indicating the number of elements that follow the header.
rtwoptions(1).prompt = 'userPreferred target options (I)';
rtwoptions(1).type = 'Category';
rtwoptions(1).enable = 'on';
rtwoptions(1).default = 4;  % number of items under this category
% excluding this one.
rtwoptions(1).popupstrings = '';  % At the first item, user has to
rtwoptions(1).tlcvariable = '';  % initialize all supported fields
rtwoptions(1).tooltip = '';  
rtwoptions(1).callback = '';  
rtwoptions(1).makevariable = '';

rtwoptions(2).prompt = 'Execution Mode';
rtwoptions(2).type = 'Popup';
rtwoptions(2).default = 'Real-Time';
rtwoptions(2).popupstrings = 'Real-Time|UserDefined';
rtwoptions(2).tlcvariable = 'tlcvariable1';
rtwoptions(2).tooltip = ['See this text as tooltip'];

rtwoptions(3).prompt = 'Log Execution Time';
rtwoptions(3).type = 'Checkbox';
rtwoptions(3).default = 'on';
rtwoptions(3).tlcvariable = 'RL32LogTETModifier';
rtwoptions(3).tooltip = ['']; % no tooltip

rtwoptions(4).prompt = 'Real-Time Interrupt Source';
rtwoptions(4).type = 'Popup';
rtwoptions(4).default = 'Timer';
rtwoptions(4).popupstrings = 'Timer|5|6|7|8|9|10|11|12|13|14|15';
rtwoptions(4).tlcvariable = 'tlcvariable3';
rtwoptions(4).callback = 'usertargetcallback(hDlg, hSrc, ''tlcvariable3'');
rtwoptions(4).tooltip = ['See TLC file for how to use reserved '...
' keyword ''hDlg'', and ''hSrc''.''];

rtwoptions(5).prompt = 'Signal Logging Buffer Size in Doubles';
rtwoptions(5).type = 'Edit';
rtwoptions(5).default = '100000';
rtwoptions(5).tlcvariable = 'tlcvariable2';
rtwoptions(5).tooltip = [''];

The first element adds a **userPreferred target options (I)** pane under **Code
Generation** in the Configuration Parameters dialog box. The pane displays the options
defined in rtwoptions(2), rtwoptions(3), rtwoptions(4), and rtwoptions(5).
If you want to define a large number of options, you can define multiple Category groups within a single system target file.

Note the rtwoptions structure and callbacks are written in MATLAB code, although they are embedded in a TLC file. To verify the syntax of your rtwoptions structure definitions and code, you can execute the commands at the MATLAB prompt by copying and pasting them to the MATLAB Command Window.

To learn more about usertarget.tlc and the example callback files provided with it, see “Example System Target File With Customized rtwoptions” on page 84-42. For more examples of target-specific rtwoptions definitions, see the target.tlc files under matlabroot/rtw/c (open).
rtwoptions Structure Fields Summary lists the fields of the `rtwoptions` structure.
### rtwoptions Structure Fields Summary

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>callback</td>
<td>For examples of callback usage, see “Example System Target File With Customized rtwoptions” on page 84-42.</td>
</tr>
<tr>
<td>closecallback</td>
<td>Do not use closecallback. Use rtwgensettings.PostApplyCallback instead (see “rtwgensettings Structure” on page 84-34). closecallback is ignored. For examples of callback usage, see “Example System Target File With Customized rtwoptions” on page 84-42.</td>
</tr>
<tr>
<td>default</td>
<td>Default value of the option (empty if the type is Pushbutton).</td>
</tr>
<tr>
<td>enable</td>
<td>Must be ‘on’ or ‘off’. If ‘on’, the option is displayed as an enabled item; otherwise, as a disabled item.</td>
</tr>
<tr>
<td>makevariable</td>
<td>Template makefile token (if any) associated with the option. The makevariable is expanded during processing of the template makefile. See “Template Makefile Tokens” on page 84-62.</td>
</tr>
<tr>
<td>modelReferenceParameter-Check</td>
<td>Specifies whether the option must have the same value in a referenced model and its parent model. If this field is unspecified or has the value ‘on’ the option values must be the same. If the field is specified and has the value ‘off’ the option values can differ. See “Controlling Configuration Option Value Agreement” on page 84-89.</td>
</tr>
<tr>
<td>NonUI</td>
<td>Element that is not displayed, but is used to invoke a close or open callback. See “NonUI Elements” on page 84-42.</td>
</tr>
<tr>
<td>opencallback</td>
<td>Do not use opencallback. Use rtwgensettings.SelectCallback instead (see “rtwgensettings Structure” on page 84-34). For examples of callback usage, see “Example System Target File With Customized rtwoptions” on page 84-42.</td>
</tr>
</tbody>
</table>

84-41
Field Name | Description
--- | ---
popupstrings | If type is Popup, popupstrings defines the items in the menu. Items are delimited by the "|" (vertical bar) character. The following example defines the items of the MAT-file variable name modifier menu used by the GRT target. 'rt_|_rt|none'
prompt | Label for the option.
tlcvariable | Name of TLC variable associated with the option.
tooltip | Help text displayed when mouse is over the item.
type | Type of element: Checkbox, Edit, NonUI, Popup, Pushbutton, or Category.

**NonUI Elements**

Elements of the rtwoptions array that have type NonUI exist solely to invoke callbacks. A NonUI element is not displayed in the Configuration Parameters dialog box. You can use a NonUI element if you want to execute a callback that is not associated with a user interface element, when the dialog box opens or closes. See the next section, “Example System Target File With Customized rtwoptions” on page 84-42 for an example.

**Note** The default value of an element of type NonUI or Edit determines the set of values allowed for that element.

- If the default value is '0' or '1':
  - For type NonUI, the element stores a Boolean value.
  - For type Edit, the element stores a value of type int32.
- If the default value contains an integer other than '0' or '1', the element stores a value of type int32.
- If the default value does not contain an integer, the element is evaluated as a character vector.

**Example System Target File With Customized rtwoptions**

A working system target file, with MATLAB file callback functions, has been provided as an example of how to use the rtwoptions structure to display and process custom
options on the Code Generation pane. The examples are compatible with the callback API.

The example target files are in the folder (open):

```
matlabroot/toolbox/rtw/rtwdemos/rtwoptions_demo
```

The example target files include:

- `usertarget.tlc`: The example system target file. This file illustrates how to define custom menus, check boxes, and edit fields. The file also illustrates the use of callbacks.

- `usertargetcallback.m`: A MATLAB file callback invoked by a menu.

Refer to the example files while reading this section. The example system target file, `usertarget.tlc`: illustrates the use of `rtwoptions` to display the following custom target options:

- The **Execution Mode** menu.
- The **Log Execution Time** check box.
- The **Real-Time Interrupt Source** menu. The menu executes a callback defined in an external file, `usertargetcallback.m`. The TLC variable associated with the menu is passed in to the callback, which displays the menu's current value.
- The edit field **Signal Logging Buffer Size in Doubles**.

Try studying the example code while interacting with the example target options in the Configuration Parameters dialog box. To interact with the example target file,

1. Make `matlabroot/toolbox/rtw/rtwdemos/rtwoptions_demo`(open) your working folder.
2. Open a model of your choice.
3. Open the Configuration Parameters dialog box and select the Code Generation pane.
4. Click **Browse**. The System Target File Browser opens. Select `usertarget.tlc`. Then click **OK**.
5. Observe that the Code Generation pane contains a custom sub-tab: `userPreferred target options (I)`.
6. As you interact with the options in this category and open and close the Configuration Parameters dialog box, observe the messages displayed in the MATLAB
Command Window. These messages are printed from code in the STF, or from callbacks invoked from the STF.

**Inheriting Target Options**

`ert.tlc` provides a basic set of Embedded Coder code generation options. If your target is based on `ert.tlc`, your STF should normally inherit the options defined in ERT.

Use the `rtwgensettings.DerivedFrom` field in the `rtwgensettings` structure to define the system target file from which options are to be inherited. You should convert your custom target to use this mechanism as follows.

Set the `rtwgensettings.DerivedFrom` field value as in the following example:

```plaintext
rtwgensettings.DerivedFrom = 'stf.tlc';
```

where `stf` is the name of the system target file from which options are to be inherited. For example:

```plaintext
rtwgensettings.DerivedFrom = 'ert.tlc';
```

When the Configuration Parameters dialog box executes this line of code, it includes the options from `stf.tlc` automatically. If `stf.tlc` is a MathWorks internal system target file that has been converted to a new layout, the dialog box displays the inherited options using the new layout.

**Handling Unsupported Options**

If your target does not support all of the options inherited from `ert.tlc`, you should detect unsupported option settings and display a warning or error message. In some cases, if a user has selected an option your target does not support, you may need to abort the build process. For example, if your target does not support the **Generate an example main program** option, the build process should not be allowed to proceed if that option is selected.

Even though your target may not support all inherited ERT options, it is required that the ERT options are retained in the **Code Generation** pane of the Configuration Parameters dialog box. Do not simply remove unsupported options from the `rtwoptions` structure in the STF. Options must be in the dialog box to be scanned by the code generator when it performs optimizations.

For example, you may want to prevent users from turning off the **Single output/update function** option. It may seem reasonable to remove this option from the dialog box and
simply assign the TLC variable CombineOutputUpdateFcns to on. However, if the option is not included in the dialog box, the code generator assumes that output and update functions are not to be combined. Less efficient code is generated as a result.

**Tips and Techniques for Customizing Your STF**

- “Introduction” on page 84-45
- “Required and Recommended %includes” on page 84-45
- “Handling Aliases for Target Option Values” on page 84-46
- “Supporting Multiple Development Environments” on page 84-48

**Introduction**

The following sections include information on techniques for customizing your STF, including

- How to invoke custom TLC code from your STF
- Approaches to supporting multiple development environments

**Required and Recommended %includes**

If you need to implement target-specific code generation features, we recommend that your STF include the TLC file mytarget_genfiles.tlc.

Once your STF has set up the required TLC environment, you must include codegenentry.tlc to start the standard code generation process.

mytarget_genfiles.tlc provides a mechanism for executing custom TLC code after the main code generation entry point. See “Using mytarget_genfiles.tlc” on page 84-45.

**Using mytarget_genfiles.tlc**

mytarget_genfiles.tlc (optional) is useful as a central file from which to invoke target-specific TLC files that generate additional files as part of your target build process. For example, your target may create sub-makefiles or project files for a development environment, or command scripts for a debugger to do automatic downloads.

The build process can then invoke these generated files either directly from the make process, or after the executable is created. This is done with the STF_make_rtw_hook.m mechanism, as described in “Customize Build Process with STF_make_rtw_hook File” (Simulink Coder).
The following TLC code shows an example mytarget_genfiles.tlc file.

```tlc
%selectfile NULL_FILE
%assign ModelName = CompiledModel.Name

%%% Create Debugger script
%assign model_script_file = "%<ModelName>.cfg"
%assign script_file = "debugger_script_template.tlc"

%if RTWVerbose
  %selectfile STDOUT
  ### Creating %<model_script_file>
  %selectfile NULL_FILE
%endif

%include "%<script_file>"
%openfile bld_file = "%<model_script_file>"
%<CreateDebuggerScript()>
%closefile bld_file
```

**Handling Aliases for Target Option Values**

This section describes utility functions that can be used to detect and resolve alias values or legacy values when testing user-specified values for the target device type (ProdHWDeviceType) and the code replacement library (CodeReplacementLibrary).

**RTW.isHWDeviceTypeEq**

To test if two target device type values represent the same hardware device, invoke the following function:

```matlab
result = RTW.isHWDeviceTypeEq(type1,type2)
```

where `type1` and `type2` are character vectors containing target device type values or aliases.

The `RTW.isHWDeviceTypeEq` function returns true if `type1` and `type2` are character vectors representing the same hardware device. For example, the following call returns true:

```matlab
RTW.isHWDeviceTypeEq('Specified','Generic->Custom')
```
For a description of the target device type option `ProdHWDeviceType`, see the command-line information for the `Hardware Implementation` pane parameters “Device vendor” (Simulink) and “Device type” (Simulink).

**RTW.resolveHWDeviceType**

To return the device type value for a hardware device, given a value that might be an alias or legacy value, invoke the following function:

```matlab
result = RTW.resolveHWDeviceType(type)
```

where `type` is a character vector containing a target device type value or alias.

The `RTW.resolveHWDeviceType` function returns the device type value of the device. For example, the following calls both return `'Generic->Custom'`:

```matlab
RTW.resolveHWDeviceType('Specified')
RTW.resolveHWDeviceType('Generic->Custom')
```

For a description of the target device type option `ProdHWDeviceType`, see the command-line information for the `Hardware Implementation` pane parameters “Device vendor” (Simulink) and “Device type” (Simulink).

**RTW.isTflEq**

To test if two code replacement library (CRL) names represent the same CRL, invoke the following function:

```matlab
result = RTW.isTflEq(name1,name2)
```

where `name1` and `name2` are character vectors containing CRL values or aliases.

The `RTW.isTflEq` function returns true if `name1` and `name2` are character vectors representing the same code replacement library. For example, the following call returns true:

```matlab
RTW.isTflEq('GNU','GNU C99 extensions')
```

For a description of the `CodeReplacementLibrary` parameter, see “Code replacement library” (Simulink Coder).

**RTW.resolveTflName**

To return the CRL value for a code replacement library, given a value that might be an alias or legacy value, invoke the following function:
result = RTW.resolveTflName(name)

where name is a character vector containing a CRL value or alias.

The RTW.resolveTflName function returns the value of the referenced code replacement library. For example, the following calls both return 'GNU C99 extensions':

RTW.resolveTflName('GNU')
RTW.resolveTflName('GNU C99 extensions')

For a description of the CodeReplacementLibrary parameter, see “Code replacement library” (Simulink Coder).

Supporting Multiple Development Environments

Your target may require support for multiple development environments (for example, two or more cross-compilers) or multiple modes of code generation (for example, generating a binary executable versus generating a project file for your compiler).

One approach to this requirement is to implement multiple STFs. Each STF invokes a template makefile for the development environment. This amounts to providing two separate targets.

Create a Custom Target Configuration

- “Creating Target Folders” on page 84-51
- “Create ERT-Based, Toolchain Compliant STF” on page 84-52
- “Create ERT-Based TMF” on page 84-58
- “Create Test Model and S-Function” on page 84-58
- “Verify Target Operation” on page 84-59

Introduction

This tutorial can supplement the example target guides described in “Sample Custom Targets” on page 84-9. For an introduction and example files, try the example targets first.
This tutorial guided you through the process of creating an ERT-based target, my_ert_target. This exercise illustrates several tasks, which are typical for creating a custom target:

- Setting up target folders and modifying the MATLAB path.
- Making modifications to a standard STF and TMF such that the custom target is visible in the System Target File Browser, inherits ERT options, displays target-specific options, and generates code with the default host-based compiler.
- Testing the build process with the custom target, using a simple model that incorporates an inlined S-function.

During this exercise, you implement an operational, but skeletal, ERT-based target. This target can be useful as a starting point in a complete implementation of a custom embedded target.

**my_ert_target Overview**

In the following sections, you create a skeletal target, my_ert_target. The target inherits and supports the standard options of the ERT target and displays additional target-specific options in the Configuration Parameters dialog box (see “Target-Specific Options for my_ert_target” on page 84-50).
Target-Specific Options for my_ert_target

my_ert_target supports a toolchain-based build, generating code and executables that run on the host system. my_ert_target uses the lcc compiler on a Microsoft Windows platform. The chosen compiler is readily available and is distributed with the code generator. On a Microsoft Windows platform, if you use a different compiler, you can set up lcc temporarily as your default compiler through the following MATLAB command:

```
mex -setup
```

The software displays links for supported compilers that are installed on your computer. Click the lcc link.
**Note** On Linux systems, make sure that you have an installed C compiler. If so, you can use Linux folder syntax to complete this exercise.

`my_ert_target` can also support template makefile-based builds. For more information about using this target with the template makefile approach, see “Create ERT-Based TMF” on page 84-58.

You can test `my_ert_target` with a model that is compatible with the ERT target (see “Configure a System Target File” on page 43-2). Generated programs operate identically to ERT generated programs.

To simplify the testing of your target, test with `targetmodel`, a very simple fixed-step model (see “Create Test Model and S-Function” on page 84-58). The S-Function block in `targetmodel` uses the source code from the `timestwo` example, and generates fully inlined code. See “S-Function Examples” (Simulink) and “Inline S-Functions with TLC” (Simulink Coder) for further discussion of the `timestwo` example S-function.

### Creating Target Folders

Create folders to store the target files and add them to the MATLAB path, following the recommended conventions (see “Folder and File Naming Conventions” on page 84-11). You also create a folder to store the test model, S-function, and generated code.

This example assumes that your target and model folders are located within the folder `c:/work`. Do not place your target and model folders within the MATLAB folder tree (that is, in or under the `matlabroot` folder).

To create the folders and make them accessible:

1. **Create a target root folder, `my_ert_target`.** From the MATLAB Command Window on a Windows platform, enter:
   ```
   cd c:/work
   mkdir my_ert_target
   ```

2. **Within the target root folder, create a subfolder to store your target files.**
   ```
   mkdir my_ert_target/my_ert_target
   ```

3. **Add these folders to your MATLAB path.**
   ```
   addpath c:/work/my_ert_target
   addpath c:/work/my_ert_target/my_ert_target
   ```

4. **Create a folder, `my_targetmodel`, to store the test model, S-function, and generated code.**
Create ERT-Based, Toolchain Compliant STF

Create an STF for your target by copying and modifying the standard STF for the ERT target. Then, validate the STF by viewing the new target in the System Target File Browser and in the Configuration Parameters dialog box.

Editing the STF

To edit the STF, use these steps:

1. Change your working folder to the folder you created in “Creating Target Folders” on page 84-51.

   cd c:/work/my_ert_target/my_ert_target

2. Place a copy of matlabroot/rtw/c/ert/ert.tlc in c:/work/my_ert_target/my_ert_target and rename it to my_ert_target.tlc. The file ert.tlc is the STF for the ERT target.

3. Open my_ert_target.tlc in a text editor of your choice.

4. Customize the STF, replacing the header comment lines with directives that make your STF visible in the System Target File Browser and define the associated TMF, make command, and external mode interface file (if any). For more information about these directives, see “Header Comments” on page 84-30.

Replace the header comments in my_ert_target.tlc with the following header comments.

   %% SYSTLC: My ERT-based Target TMF: my_ert_target_lcc.tmf MAKE: make_rtw \%
   %% EXTMODE: no_ext_comm

5. The file my_ert_target.tlc inherits the standard ERT options, using the mechanism described in “Inheriting Target Options” on page 84-44. Therefore, the existing rtwoptions structure definition is superfluous. Edit the RTW_OPTIONS section such that it includes only the following code.

   /%
   BEGIN_RTW_OPTIONS
   %----------------------------------------%
  |% Configure RTW code generation settings %
   %----------------------------------------%
   rtwgensettings.BuildDirSuffix = '_ert_rtw';
   END_RTW_OPTIONS
   %/
6 Delete the code after the end of the RTW_OPTIONS section, which is delimited by the directives BEGIN_CONFIGSET_TARGET_COMPONENT and END_CONFIGSET_TARGET_COMPONENT. This code is for use only by internal MathWorks developers.

7 Modify the build folder suffix in the rtwgenSettings structure in accordance with the conventions described in “rtwgensettings Structure” on page 84-34.

To set the suffix to a character vector for the _my_ert_target custom target, change the line

```
rtwgensettings.BuildDirSuffix = '_ert_rtw'
```

to

```
rtwgensettings.BuildDirSuffix = '_my_ert_target_rtw'
```

8 Modify the rtwgenSettings structure to inherit options from the ERT target and declare Release 14 or later compatibility as described in “rtwgensettings Structure” on page 84-34. Add the following code to the rtwgenSettings definition:

```
rtwgensettings.DerivedFrom = 'ert.tlc';
rtwgensettings.Version = '1';
```

9 Add an rtwoptions structure that defines a target-specific options category with three check boxes just after the BEGIN_RTW_OPTIONS directive. The following code shows the complete RTW_OPTIONS section, including the previous rtwgenSettings changes.

```
/%
   BEGIN_RTW_OPTIONS
   rtwoptions(1).prompt         = 'My Target Options';
   rtwoptions(1).type           = 'Category';
   rtwoptions(1).enable         = 'on';
   rtwoptions(1).default        = 3;   % number of items under this category
                     % excluding this one.
   rtwoptions(1).popupstrings  = '';  % excluding this one.
   rtwoptions(1).tlcvariable   = '';
   rtwoptions(1).tooltip       = '';
   rtwoptions(1).callback      = '';
   rtwoptions(1).makevariable  = '';
   rtwoptions(2).prompt         = 'Demo option 1';
   rtwoptions(2).type           = 'Checkbox';
   rtwoptions(2).default        = 'off';
   rtwoptions(2).tlcvariable    = 'DummyOpt1';
   rtwoptions(2).tooltip        = ['Demo option1 (non-functional)'];
   rtwoptions(2).callback       = '';
   rtwoptions(2).makevariable  = '';
```
rtwoptions(3).prompt = 'Demo option 2';
rtwoptions(3).type = 'Checkbox';
rtwoptions(3).default = 'off';
rtwoptions(3).tlcvariable = 'DummyOpt2';
rtwoptions(3).makevariable = '';
rtwoptions(3).tooltip = ['Demo option2 (non-functional)'];
rtwoptions(3).callback = '';

rtwoptions(4).prompt = 'Demo option 3';
rtwoptions(4).type = 'Checkbox';
rtwoptions(4).default = 'off';
rtwoptions(4).tlcvariable = 'DummyOpt3';
rtwoptions(4).makevariable = '';
rtwoptions(4).tooltip = ['Demo option3 (non-functional)'];
rtwoptions(4).callback = ';

% Configure RTW code generation settings
%--------------------------------------------------------------------------
rtwgensettings.BuildDirSuffix = '_my_ert_target_rtw';
rtwgensettings.DerivedFrom = 'ert.tlc';
rtwgensettings.Version = '1';
rtwgensettings.SelectCallback = 'enableToolchainCompliant(hSrc, hDlg)';
%SelectCallback provides toolchain approach support, but requires custom function
%Omit this SelectCallback if using the template makefile approach

END_RTW_OPTIONS
%
10 Save your changes to my_ert_target.tlc and close the file.

Create ToolchainCompliant Function

To enable builds using the toolchain approach, you create a function that corresponds to the SelectCallback near the end of the custom STF. This function sets properties for toolchain compliance.

function enableToolchainCompliant(hSrc, hDlg)
    hCS = hSrc.getConfigSet();

    % The following parameters enable toolchain compliance.
    slConfigUISetVal(hDlg, hSrc, 'UseToolchainInfoCompliant', 'on');
    hCS.setProp('GenerateMakefile','on');

    % The following parameters are not required for toolchain compliance.
    % But, it is recommended practice to set these default values and
    % disable the parameters (as shown).
    hCS.setProp('RTWCompilerOptimization','off');
    hCS.setProp('MakeCommand','make_rtw');
    hCS.setPropEnabled('RTWCompilerOptimization',false);
    hCS.setPropEnabled('MakeCommand',false);
end
**Note** If you are using the template makefile approach, omit calling the function enabling toolchain-compliance from your STF file. Instead, use the information in “Create ERT-Based TMF” on page 84-58.

**Viewing the STF**

At this point, you can verify that the target inherits and displays ERT options as follows:

1. Create a new model.
2. Open the Model Explorer or the Configuration Parameters dialog box.
3. Select the **Code Generation** pane.
4. Click **Browse** to open the System Target File browser.
5. In the file browser, scroll through the list of targets to find the new target, `my_ert_target.tlc`. (This step assumes that your MATLAB path contains `c:/work/my_ert_target/my_ert_target`, as previously set in “Creating Target Folders” on page 84-51.)
6. Select **My ERT-based Target** and click **OK**.

7. The **Code Generation** pane now shows that the model is configured for the `my_ert_target.tlc` target. The **System target file**, **Language**, **Toolchain**, and **Build configuration** fields should appear:
Select the **My Target Options** pane. The target displays the three check box options defined in the `rtwoptions` structure.
9 Select the **Code Generation** pane and reopen the System Target File Browser.

10 Select the Embedded Coder target (`ert.tlc`). The target displays the standard ERT options.

11 Close the model. You do not need to save it.

The STF for the skeletal target is complete. If you are using the toolchain approach, you are ready to invoke the build process for your target.

If you prefer to use the template makefile approach, the reference to a TMF, `my_ert_target_lcc.tmf`, in the STF header comments prevents you from invoking the build process for your target until the TMF file is in place. First, you must create a `my_ert_target_lcc.tmf` file.
Create ERT-Based TMF

If you are using the toolchain makefile approach with a toolchain compliant custom target, omit the steps that apply to the template makefile approach. (Skip this section.)

If you are using the templated makefile approach, follow the steps applying to TMF and omit calling the function enabling toolchain-compliance from your STF file, which is described in “Create ERT-Based, Toolchain Compliant STF” on page 84-52.

Create a TMF for your target by copying and modifying the standard ERT TMF for the LCC compiler:

1. Make sure that your working folder is still set to the target file folder you created previously in “Creating Target Folders” on page 84-51.
   
   c:/work/my_ert_target/my_ert_target

2. Place a copy of `matlabroot/rtw/c/ert/ert_lcc.tmf` in `c:/work/my_ert_target/my_ert_target` and rename it `my_ert_target_lcc.tmf`. The file `ert_lcc.tmf` is the ERT compiler-specific template makefile for the LCC compiler.

3. Open `my_ert_target_lcc.tmf` in a text editor.

4. Change the `SYS_TARGET_FILE` parameter so that the file reference for your `.tlc` file is generated in the make file. Change the line
   
   ```
   SYS_TARGET_FILE = any
   ```
   
   to
   
   ```
   SYS_TARGET_FILE = my_ert_target.tlc
   ```

5. Save changes to `my_ert_target_lcc.tmf` and close the file.

Your target can now generate code and build a host-based executable. In the next sections, you create a test model and test the build process using `my_ert_target`.

Create Test Model and S-Function

In this section, you build a simple test model for later use in code generation:

1. Set your working folder to `c:/work/my_targetmodel`.
   
   ```
   cd c:/work/my_targetmodel
   ```

   For the remainder of this tutorial, `my_targetmodel` is assumed to be the working folder. Your target writes the output files of the code generation process into a build
folder within the working folder. When inlined code is generated for the timestwo S-function, the build process looks for the TLC implementation of the S-function in the working folder.

2 Copy the following C and TLC files for the timestwo S-function to your working folder:

- `matlabroot/toolbox/simulink/simdemos/simfeatures/src/timestwo.c`
- `matlabroot/toolbox/simulink/simdemos/simfeatures/tlc_c/timestwo.tlc`

3 Build the timestwo MEX-file in `c:/work/my_targetmodel`.

```
mex timestwo.c
```

4 Create the following model, using an S-Function block from the Simulink User-Defined Functions library. Save the model in your working folder as `targetmodel`.

![Model Diagram](image)

5 Double-click the S-Function block to open the Block Parameters dialog box. Enter the S-function name `timestwo`. Click OK. The block is now bound to the `timestwo` MEX-file.

6 Open Model Explorer or the Configuration Parameters dialog box and select the Solver pane.

7 Set the solver Type to fixed-step and click Apply.

8 Save the model.

9 Open the scope and run a simulation. Verify that the timestwo S-function multiplies its input by 2.0.

Keep the `targetmodel` model open for use in the next section, in which you generate code using the test model.

**Verify Target Operation**

In this section you configure `targetmodel` for the `my_ert_target` custom target, and use the target to generate code and build an executable:
1. Open the Configuration Parameters dialog box and select the **Code Generation** pane.
2. Click **Browse** to open the System Target File Browser.
3. In the Browser, select **My ERT-based Target** and click **OK**.
4. The Configuration Parameters dialog box now displays the **Code Generation** pane for **my_ert_target**.
5. Select the **Code Generation > Report** pane and select the **Create code generation report** option.
6. Click **Apply** and save the model. The model is configured for **my_ert_target**.
7. Build the model. If the build succeeds, the MATLAB Command Window displays the message below.
   ```
   ### Created executable: ../targetmodel.exe
   ### Successful completion of build procedure for model: targetmodel
   ```
   Your working folder contains the **targetmodel.exe** file and the build folder, **targetmodel_my_ert_target_rtw**, which contains generated code and other files. The working folder also contains an **slprj** folder, used internally by the build process.

   The code generator also creates and displays a code generation report.

8. To view the generated model code, go to the code generation report window. In the **Contents** pane, click the **targetmodel.c** link.
9. In **targetmodel.c**, locate the model step function, **targetmodel_step**. Observe the following code.
   ```
   /* S-Function Block: <Root>/S-Function */
   /* Multiply input by two */
   targetmodel_B.SFunction = targetmodel_B.SineWave * 2.0;
   ```
   The presence of this code confirms that the **my_ert_target** custom target has generated an inlined output computation for the S-Function block in the model.

Customize Template Makefiles

To configure or customize a template makefile (TMF), you should be familiar with how the make command works and how it processes makefiles. You should also understand makefile build rules. For information on these topics, refer to the documentation provided with the make utility you use.

Template Makefiles and Tokens

TMFs are made up of statements containing tokens. The build process expands tokens and creates a makefile, *model.mk*. TMFs are designed to generate makefiles for specific compilers on specific platforms. The generated *model.mk* file is tailored to compile and link code generated from your model, using commands specific to your development system.

![Template Makefile](image)

Creation of *model.mk*

Template Makefile Tokens

The `make_rtw` command (or a different command provided with some targets) directs the process of generating *model.mk*. The `make_rtw` command processes the TMF specified on the Code Generation pane of the Configuration Parameters dialog box. `make_rtw` copies the TMF, line by line, expanding each token encountered. Template Makefile Tokens Expanded by `make_rtw` lists the tokens and their expansions.

These tokens are used in several ways by the expanded makefile:

- To control the conditional behavior in the makefile. The conditionals are used to control the source file lists, library names, target to be built, and other build-related information.
To provide the macro definitions for compiling the files, for example, `-DINTEGER_CODE=1`. 
### Template Makefile Tokens Expanded by `make_rtw`

</tr>
</tbody>
</table>
List of include paths for models referenced by the top model.

Folder for the library file built from the shared source files.

Library file built from the shared source files, including the path to the library folder.

Shared source files specification, including the path to the shared utilities folder.

Folder for shared source files.

These tokens are expanded by substitution of parameter values known to the build process. For example, if the source model contains blocks with two different sample times, the TMF statement

\[
\text{NUMST} = |\text{NUMST}| \\
\text{NUMST} = 2
\]

expands to the following in \textit{model.mk}.

\[
\text{NUMST} = 2
\]

In addition to the above, \texttt{make_rtw} expands tokens from other sources:

- Target-specific tokens defined in the target options of the Configuration Parameters dialog box
- Structures in the \texttt{rtwoptions} section of the system target file. Structures in the \texttt{rtwoptions} structure array that contain the field \texttt{makevariable} are expanded.

The following example is extracted from \texttt{matlabroot/rtw/c/grt/grt.tlc}. The section starting with \texttt{BEGIN_RTW_OPTIONS} contains MATLAB code that sets up \texttt{rtwoptions}. The following directive causes the |\texttt{EXT_MODE}| token to be expanded to 1 (on) or 0 (off), depending on how you set the external mode options.

\[
\texttt{rtwoptions(2).makevariable} = '\texttt{EXT_MODE}'
\]
Invoke the make Utility

- “make Command” on page 84-70
- “make Utility Versions” on page 84-70

make Command

After creating model.mk from your TMF, the build process invokes a make command. To invoke make, the build process issues this command.

```
makecommand -f model.mk
```

`makecommand` is defined by the MAKECMD macro in your target's TMF (see “Structure of the Template Makefile” on page 84-71). You can specify additional options to make in the `Make command` field of the Code Generation pane. (See the sections “Specify a Make Command” (Simulink Coder) and “Template Makefiles and Make Options” (Simulink Coder).)

For example, specifying `OPT_OPTS=-O2` in the `Make command` field causes `make_rtw` to generate the following `make` command.

```
makecommand -f model.mk OPT_OPTS=-O2
```

A comment at the top of the TMF specifies the available make command options. If these options do not provide you with enough flexibility, you can configure your own TMF.

make Utility Versions

The make utility lets you control nearly every aspect of building your real-time program. There are several different versions of make available. The code generator provides the Free Software Foundation GNU `make` for both UNIX\(^9\) and PC platforms in platform-specific subfolders under

```
matlabroot/bin
```

It is possible to use other versions of make with the code generator, although GNU Make is recommended. To be compatible with the code generator, verify that your version of make supports the following command format.

```
makecommand -f model.mk
```

---

9. UNIX is a registered trademark of The Open Group in the United States and other countries.
Structure of the Template Makefile

A TMF has multiple sections, including the following:

- **Abstract** — Describes what the makefile targets. Here is a representative abstract from the GRT TMFs in `matlabroot/rtw/c/grt` (open):

  ```
  # File    : grt_lcc.tmf
  #
  # Abstract:
  #    Template makefile for building a PC-based stand-alone generic real-time
  #    version of Simulink model using generated C code and LCC compiler
  #    Version 2.4.
  #
  # This makefile attempts to conform to the guidelines specified in the
  # IEEE Std 1003.2-1992 (POSIX) standard. It is designed to be used
  # with GNU Make (gmake) which is located in matlabroot/bin/win32.
  #
  # Note that this template is automatically customized by the build
  # procedure to create "<model>.mk"
  #
  # The following defines can be used to modify the behavior of the
  # build:
  #   OPT_OPTS       - Optimization options. Default is none. To enable
  #                    debugging specify as OPT_OPTS=-g4.
  #   OPTS           - User specific compile options.
  #   USER_SRCS      - Additional user sources, such as files needed by
  #                    S-functions.
  #   USER_INCLUDES  - Additional include paths
  #                   (i.e. USER_INCLUDES="-Iwhere-ever -Iwhere-ever2")
  #                   (For Lcc, have a '/'as file seperator before the
  #                    file name instead of a '\'.
  #                    i.e., d:\work\proj1/myfile.c - reqd for 'gmake')
  #
  # This template makefile is designed to be used with a system target
  # file that contains 'rtwgensettings.BuildDirSuffix'. See grt.tlc.
  ```

- **Macros read by make_rtw section** — Defines macros that tell make_rtw how to process the TMF. Here is a representative Macros read by make_rtw section from the GRT TMFs in `matlabroot/rtw/c/grt` (open):

  ```
  # --- Macros read by make_rtw ---
  #
  # The following macros are read by the build procedure:
  #
  #   MAKECMD       - The command that invokes the make utility
  #   HOST         - The platform (for example, PC) for which this TMF is written
  #   SHELL        - An operating system shell command
  #                 (for example, cmd) for the platform
  #   BUILD        - The flag that indicates whether to
  #                 invoke make from the build procedure
  ```
# SYS_TARGET_FILE - Name of system target file.

MAKECMD = "%MATLAB%\bin\win32\gmake"
HOST = PC
SHELL = cmd
BUILD = yes
SYS_TARGET_FILE = grt.tlc
BUILD_SUCCESS = ### Created
COMPILER_TOOL_CHAIN = lcc

MAKEFILE_FILESEP = /

The macros in this section might include:

- **MAKECMD** — Specifies the command used to invoke the make utility. For example, if MAKECMD = mymake, then the make command invoked is

  mymake -f model.mk

- **HOST** — Specifies the platform targeted by this TMF. This can be PC, UNIX, computer_name (see the MATLAB computer command), or ANY.

- **SHELL** — Specifies an operating system shell command for the platform. For Windows, this can be cmd.

- **BUILD** — Instructs make_rtw whether or not it should invoke make from the build procedure. Specify yes or no.

- **SYS_TARGET_FILE** — Specifies the name of the system target file or the value any. This is used for consistency checking by make_rtw to verify the system target file specified in the Target selection panel of the Code Generation pane of the Configuration Parameters dialog box. If you specify any, you can use the TMF with any system target file.

- **BUILD_SUCCESS** — Optional macro that specifies the build success message to be displayed for make completion on the PC. For example,

  BUILD_SUCCESS = ### Successful creation of

The BUILD_SUCCESS macro, if used, replaces the standard build success message found in the TMFs distributed with the bundled code generator targets (such as GRT):

  @echo ### Created executable $(MODEL).exe

Your TMF must include either the standard build success message, or use the BUILD_SUCCESS macro. For an example of the use of BUILD_SUCCESS, see matlabroot/rtw/c/grt/grt_lcc.tmf or the code example above this list of macros.
• **BUILD_ERROR** — Optional macro that specifies the build error message to be displayed when an error is encountered during the make procedure. For example,

```
BUILD_ERROR = ['Error while building ', modelName]
```

• **VERBOSE_BUILD_OFF_TREATMENT = PRINT_OUTPUT_ALWAYS** — Optional macro to include if you want the makefile output to be displayed regardless of the setting of the **Verbose build** option in the Code Generation > Debug pane.

• **COMPILER_TOOL_CHAIN** — For builds on Windows systems, specifies which compiler setup file — located in `matlabroot/toolbox/rtw/rtw` (open) — to use:

  - lcc selects `setup_for_lcc.m`
  - vc selects `setup_for_visual.m`
  - vcx64 selects `setup_for_visual_x64.m`
  - default selects `setup_for_default.m`

For builds on UNIX systems, specify `unix`. Other values are flagged as unknown and `make_rtw` uses `setup_for_default.m`.

**Note** Do not omit **COMPILER_TOOL_CHAIN** or leave it unspecified in your TMF. If your compiler is not the host compiler, specify `COMPILER_TOOL_CHAIN = default`.

• **DOWNLOAD** — An optional macro that you can specify as yes or no. If specified as yes (and BUILD=yes), then make is invoked a second time with the download target.

```
make -f model.mk download
```

• **DOWNLOAD_SUCCESS** — An optional macro that you can use to specify the download success message to be used when looking for a completed download. For example,

```
DOWNLOAD_SUCCESS = ### Downloaded
```

• **DOWNLOAD_ERROR** — An optional macro that you can use to specify the download error message to be displayed when an error is encountered during the download. For example,

```
DOWNLOAD_ERROR = ['Error while downloading ', modelName]
```
• **Tokens expanded by make_rtw section** — Defines the tokens that make_rtw expands. Here is a brief excerpt from a representative Tokens expanded by make_rtw section from the GRT TMFs in *matlabroot/rtw/c/grt* (open):

```bash
#---------------------- Tokens expanded by make_rtw ----------------------------
# The following tokens, when wrapped with "|>" and "<|" are expanded by the # build procedure.
#
# # MODEL_NAME          - Name of the Simulink block diagram
# # MODEL_MODULES       - Any additional generated source modules
# # MAKEFILE_NAME       - Name of makefile created from template makefile <model>.mk
# # MATLAB_ROOT         - Path to where MATLAB is installed.
...

MODEL                = |>MODEL_NAME<|
MODULES              = |>MODEL_MODULES<|
MAKEFILE             = |>MAKEFILE_NAME<|
MATLAB_ROOT          = |>MATLAB_ROOT<|
...
```

For more information about TMF tokens, see Template Makefile Tokens Expanded by make_rtw.

• Subsequent sections vary based on compiler, host, and target. Some common sections include Model and reference models, External mode, Tool Specifications or Tool Definitions, Include Path, C Flags, Additional Libraries, and Source Files.

• **Rules section** — Contains the make rules used in building an executable from the generated source code. The build rules are typically specific to your version of make. The Rules section might be followed by related sections such as Dependencies.

**Customize and Create Template Makefiles**

• “Supporting Continuous Time in Custom Targets” on page 84-78  
• “Model Reference Considerations” on page 84-79
Introduction

This section describes the mechanics of setting up a custom template makefile (TMF) and incorporating it into the build process. It also discusses techniques for modifying a TMF and MATLAB file mechanisms associated with the TMF.

Before creating a custom TMF, you should read “Folder and File Naming Conventions” on page 84-11 to understand the folder structure and MATLAB path requirements for custom targets.

Setting Up a Template Makefile

To customize or create a new TMF, you should copy an existing GRT or ERT TMF from one of the following locations:

matlabroot/rtw/c/grt (open)
matlabroot/rtw/c/ert (open)

Place the copy in the same folder as the associated system target file (STF). Usually, this is the mytarget/mytarget folder within the target folder structure. Then, rename your TMF (for example, mytarget.tmf) and modify it.

To allow the build process to locate and select your TMF, you must provide information in the STF file header (see “System Target File Structure” on page 84-29). For a target that implements a single TMF, the standard way to specify the TMF to be used in the build process is to use the TMF directive of the STF file header.

TMF: mytarget.tmf

Using Macros and Pattern Matching Expressions in a Template Makefile

This section shows, through an example, how to use macros and file-pattern-matching expressions in a TMF to generate commands in the model.mk file.

The make utility processes the model.mk makefile and generates a set of commands based upon dependency rules defined in model.mk. After make generates the set of commands for building or rebuilding test, make executes them.

For example, to build a program called test, make must link the object files. However, if the object files don't exist or are out of date, make must compile the source code. Thus there is a dependency between source and object files.
Each version of make differs slightly in its features and how rules are defined. For example, consider a program called test that gets created from two sources, file1.c and file2.c. Using most versions of make, the dependency rules would be

```
test: file1.o file2.o
    cc -o test file1.o file2.o

file1.o: file1.c
    cc -c file1.c

file2.o: file2.c
    cc -c file2.c
```

In this example, a UNIX\textsuperscript{10} environment is assumed. In a PC environment the file extensions and compile and link commands are different.

In processing the first rule
```
test: file1.o file2.o
```
make sees that to build test, it needs to build file1.o and file2.o. To build file1.o, make processes the rule
```
file1.o: file1.c
    cc -c file1.c
```
If file1.o doesn't exist, or if file1.o is older than file1.c, make compiles file1.c.

The format of TMFs follows the above example. Our TMFs use additional features of make such as macros and file-pattern-matching expressions. In most versions of make, a macro is defined with

```
MACRO_NAME = value
```
References to macros are made with \texttt{$(MACRO\_NAME)$}. When make sees this form of expression, it substitutes \texttt{value} for \texttt{$(MACRO\_NAME)$}.

You can use pattern matching expressions to make the dependency rules more general. For example, using GNU\textsuperscript{11} Make, you could replace the two “file1.o: file1.c” and “file2.o: file2.c” rules with the single rule

```
%.o : %.c
    cc -c $<
```

\textsuperscript{10} UNIX is a registered trademark of The Open Group in the United States and other countries.
\textsuperscript{11} GNU is a registered trademark of the Free Software Foundation.
Note that $<$ in the previous example is a special macro that equates to the dependency file (that is, file1.c or file2.c). Thus, using macros and the "%" pattern matching character, the previous example can be reduced to

```
SRCS = file1.c file2.c
OBJS = $(SRCS:.c=.o)

test: $(OBJJS)
    cc -o $@ $(OBJJS)

%.o : %.c
    cc -c $<
```

Note that the $@$ macro above is another special macro that equates to the name of the current dependency target, in this case test.

This example generates the list of objects (OBJJS) from the list of sources (SRCS) by using the text substitution feature for macro expansion. It replaces the source file extension (for example, .c) with the object file extension (.o). This example also generalized the build rule for the program, test, to use the special "$@$" macro.

**Customizing Generated Makefiles with rtwmakecfg**

TMFs provide tokens that let you add the following items to generated makefiles:

- Source folders
- Include folders
- Run-time library names
- Run-time module objects

S-functions can add this information to the makefile by using an rtwmakecfg.m file function. This function is particularly useful when building a model that contains one or more of your S-Function blocks, such as device driver blocks.

To add information pertaining to an S-function to the makefile,

1. Create the function rtwmakecfg in file rtwmakecfg.m. The code generator associates this file with your S-function based on its folder location.
2. Modify your target's TMF such that it supports macro expansion for the information returned by rtwmakecfg functions.

After the TLC phase of the build process, when generating a makefile from the TMF, the build process searches for an rtwmakecfg.m file in the folder that contains the S-
function component. If it finds the file, the build process calls the `rtwmakecfg` function. For more information, see “Use `rtwmakecfg.m` API to Customize Generated Makefiles” (Simulink Coder).

**Supporting Continuous Time in Custom Targets**

If you want your custom ERT-based target to support continuous time, you must update your template makefile (TMF) and the static main program module (for example, `mytarget_main.c`) for your target.

**Template Makefile Modifications**

Add the `NCSTATES` token expansion after the `NUMST` token expansion, as follows:

```
NUMST = |>NUMST<|
NCSTATES = |>NCSTATES<|
```

In addition, add `NCSTATES` to the `CPP_REQ_DEFINES` macro, as in the following example:

```
CPP_REQ_DEFINES = -DMODEL=$(MODEL) -DNUMST=$(NUMST) -DNCSTATES=$(NCSTATES) \
                 -DMAT_FILE=$(MAT_FILE) \
                 -DINTEGER_CODE=$(INTEGER_CODE) \
                 -DONESTEPFCN=$(ONESTEPFCN) -DTERMFCN=$(TERMFCN) \
                 -DHAVESTDIO \
                 -DMULTI_INSTANCE_CODE=$(MULTI_INSTANCE_CODE) \
```

**Modifications to Main Program Module**

The main program module defines a static main function that manages task scheduling for the supported tasking modes of single- and multiple-rate models. `NUMST` (the number of sample times in the model) determines whether the main function calls multirate or single-rate code. However, when a model uses continuous time, do not rely on `NUMST` directly.

When the model has continuous time and the flag `TID01EQ` is true, both continuous time and the fastest discrete time are treated as one rate in generated code. The code associated with the fastest discrete rate is guarded by a major time step check. When the model has only two rates, and `TID01EQ` is true, the generated code has a single-rate call interface.

To support models that have continuous time, update the static main module to take `TID01EQ` into account, as follows:

```
1 Before NUMST is referenced in the file, add the following code:
```
#if defined(TID01EQ) && TID01EQ == 1 && NCSTATES == 0
#define DISC_NUMST (NUMST - 1)
#else
#define DISC_NUMST NUMST
#endif

2 Replace instances of NUMST in the file by DISC_NUMST.

**Model Reference Considerations**

See “Support Model Referencing” on page 84-84 for important information on TMF modifications you may need to make to support the code generator model referencing features.

**Note** If you are using a TMF without the variables SHARED_SRC or MODELREFS, the file might have been used with a previous release of Simulink software. If you want your TMF to support model referencing, add either variable SHARED_SRC or MODELREFS to the make file.

</tr>
</tbody>
</table>

The required configuration changes are modifications to your system target file (STF), and in some cases also modifications to your template makefile (TMF) or your custom static main program.
The API for STF callbacks provides a function `SelectCallback` for use in STFs. `SelectCallback` is associated with the target rather than with its individual options. If you implement a `SelectCallback` function for a target, it is triggered whenever the user selects the target in the System Target File Browser.

The API provides the functions `slConfigUIGetVal`, `slConfigUISetEnabled`, and `slConfigUISetVal` for controlling custom target configuration options from a user-written `SelectCallback` function. (For function descriptions and examples, see the function reference pages.)

The general requirements for supporting one of the optional features include:

- To support model referencing or compiler optimization level control, the target must be derived from the GRT or the ERT target. To support C function prototype control or C++ class interface control, the target must be derived from the ERT target.
- The system target file (STF) must declare feature compliance by including one of the target configuration parameters listed above in a `SelectCallback` function call.
- Additional changes such as TMF modifications or static main program modifications may be required, depending on the feature. See the detailed steps in the subsections for individual features.

For an example that shows how to configure custom target optional features, see “Customize System Target Files” (Simulink Coder).

Support Toolchain Approach with Custom Target

This section describes how to configure a custom system target file to support builds with the toolchain approach.

In the Configuration Parameters dialog box, on the Code Generation pane of, you can present either the build controls for the toolchain approach or the template makefile approach. The model parameters that contribute to determining which build controls appear include these parameters.

<table>
<thead>
<tr>
<th>Model Parameter</th>
<th>Value</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>UseToolchainInfoCompliant</td>
<td>on</td>
<td>For toolchain approach, set this parameter to 'on'. For TMF approach, set this parameter to 'off'.</td>
</tr>
<tr>
<td>GenerateMakefile</td>
<td>on</td>
<td>For toolchain approach, set this parameter to 'on'.</td>
</tr>
</tbody>
</table>

When the dialog box detects that the selected target has these properties, the dialog box recognizes the target as toolchain-compliant and displays the build controls for the toolchain approach.

Because the custom target file cannot set these properties directly, use a SelectCallback function in the custom target file to set the properties. The SelectCallback function call in the RTW_OPTION section of the TLC file can take the form:

```matlab
rtwgensettings.SelectCallback = 'enableToolchainCompliant(hSrc, hDlg)';
```

A corresponding callback function can contain:

```matlab
function enableToolchainCompliant(hSrc, hDlg)
    hCS = hSrc.getConfigSet();
    
    % The following parameters enable toolchain compliance.
    slConfigUISetVal(hDlg, hSrc, 'UseToolchainInfoCompliant', 'on');
    hCS.setProp('GenerateMakefile','on');
    
    % The following parameters are not required for toolchain compliance.
    % But, it is recommended practice to set these default values and
    % disable the parameters (as shown).
    hCS.setProp('RTWCompilerOptimization','off');
    hCS.setProp('MakeCommand','make_rtw');
    hCS.setPropEnabled('RTWCompilerOptimization',false);
```
When you select your custom target, the configuration parameters dialog box displays the toolchain approach build controls. For an example, see “Create a Custom Target Configuration” on page 84-48.

For an example that shows how to configure custom target optional features, see “Customize System Target Files” (Simulink Coder).

Support Model Referencing

This section describes how to configure a custom embedded target to support model referencing. Without the described modifications, you will not be able to use the custom target when building a model that includes referenced models. If you do not intend to use referenced models with your target, you can skip this section. If you later find that you need to use referenced models, you can upgrade your target then.

About Model Referencing with a Custom Target

The requirements for supporting model referencing are as follows:

- The target must be derived from the GRT target or the ERT target.
- The system target file (STF) must declare model reference compliance, as described in “Declaring Model Referencing Compliance” on page 84-85.
- The template makefile (TMF) must define some entities that support model referencing, as described in “Providing Model Referencing Support in the TMF” on page 84-85.
- The TMF must support using the Shared Utilities folder, as described in “Supporting the Shared Utilities Folder” on page 84-89.

Optionally, you can provide additional capabilities that support model referencing:

- You can configure a target to support parallel builds for large model reference hierarchies (see “Reduce Build Time for Referenced Models” (Simulink Coder)). To do this, you must modify the STF and TMF for parallel builds as described in “Declaring Model Referencing Compliance” on page 84-85 and “Providing Model Referencing Support in the TMF” on page 84-85.
- If your target supports parallel builds for large model reference hierarchies, you can additionally set up automatic verification of MATLAB Distributed Computing Server workers, as described in “Verifying Worker Configuration for Parallel Builds of Model Reference Hierarchies (Optional)” on page 84-93.
- You can modify hook files to handle referenced models differently than top models to prevent resource conflicts, as described in “Preventing Resource Conflicts (Optional)” on page 84-95.

See “Model Reference Basics” (Simulink) for information about model referencing in Simulink models, and “Generate Code for Referenced Models” (Simulink Coder) for information about model referencing in generated code.
For an example that shows how to configure custom target optional features, see “Customize System Target Files” (Simulink Coder).

**Declaring Model Referencing Compliance**

To declare model reference compliance for your target, you must implement a callback function that sets the `ModelReferenceCompliant` flag, and then install the callback function in the `SelectCallback` field of the `rtwgensettings` structure in your STF. The callback function is triggered whenever the user selects the target in the System Target File Browser. For example, the following STF code installs a `SelectCallback` function named `custom_select_callback_handler`:

```matlab
rtwgensettings.SelectCallback = 'custom_select_callback_handler(hDlg,hSrc)';
```

The arguments to the `SelectCallback` function (hDlg, hSrc) are handles to private data used by the callback API functions. These handles are restricted to use in STF callback functions. They should be passed in without alteration.

Your callback function should set the `ModelReferenceCompliant` flag as follows:

```matlab
slConfigUISetVal(hDlg,hSrc,'ModelReferenceCompliant','on');
slConfigUISetEnabled(hDlg,hSrc,'ModelReferenceCompliant',false);
```

If you might use the target to build models containing large model reference hierarchies, consider configuring the target to support parallel builds, as discussed in “Reduce Build Time for Referenced Models” (Simulink Coder).

To configure a target for parallel builds, your callback function must also set the `ParMdlRefBuildCompliant` flag as follows:

```matlab
slConfigUISetVal(hDlg,hSrc,'ParMdlRefBuildCompliant','on');
slConfigUISetEnabled(hDlg,hSrc,'ParMdlRefBuildCompliant',false);
```

For more information about the STF callback API, see the `slConfigUIGetVal`, `slConfigUISetEnabled`, and `slConfigUISetVal` function reference pages.

**Providing Model Referencing Support in the TMF**

Do the following to configure the template makefile (TMF) to support model referencing:

1. Add the following make variables and tokens to be expanded when the makefile is generated:

   ```makefile
   MODELREFS     = |>|MODELREFS<|
   MODELLIB      = |>|MODELLIB<|
   ```
The following code excerpt shows how makefile tokens are expanded for a referenced model.

```makefile
MODELREFS                 =
MODELLIB                  = engine3200cc_rtwlib.a
MODELREF_Link_Libs        =
MODELREF_Link_RSPFile     =
MODELREF_INC_PATH         =
RELATIVE_PATH_TO_ANCHOR   = ../../..
MODELREF_Target_Type      = RTW
```

The following code excerpt shows how makefile tokens are expanded for the top model that references the referenced model.

```makefile
MODELREFS = engine3200cc transmission
MODELLIB = archlib.a
MODELREF_Link_Libs = engine3200cc_rtwlib.a transmission_rtwlib.a
MODELREF_Link_RSPFile =
MODELREF_INC_PATH = -I../slprj/ert/engine3200cc -I../slprj/ert/transmission
RELATIVE_PATH_TO_ANCHOR = ..
MODELREF_Target_Type = NONE
```

<table>
<thead>
<tr>
<th>Token</th>
<th>Expands to</th>
</tr>
</thead>
<tbody>
<tr>
<td>MODELREFS for the top model</td>
<td>List of referenced model names.</td>
</tr>
<tr>
<td>MODELLIB</td>
<td>Name of the library generated for the model.</td>
</tr>
<tr>
<td>MODELREF_Link_Libs token for the top model</td>
<td>List of referenced model libraries that the top model links against.</td>
</tr>
<tr>
<td>MODELREF_Link_RSPFile token for the top model</td>
<td>Name of a response file that the top model links against. This token is valid only for build environments that support linker response files. For an example of its use, see <code>matlabroot/rtw/c/grt/grt_vc.tmf</code>.</td>
</tr>
<tr>
<td>MODELREF_INC_PATH token for the top model</td>
<td>Include path to the referenced models.</td>
</tr>
</tbody>
</table>
### Token Definitions

<table>
<thead>
<tr>
<th>Token</th>
<th>Expands to</th>
</tr>
</thead>
<tbody>
<tr>
<td>RELATIVE_PATH_TO_ANCHOR</td>
<td>Relative path, from the location of the generated makefile, to the MATLAB working folder.</td>
</tr>
<tr>
<td>MODELREF_TARGET_TYPE</td>
<td>Signifies the type of target being built. Possible values are</td>
</tr>
<tr>
<td></td>
<td>• <strong>NONE</strong>: Standalone model or top model referencing other models</td>
</tr>
<tr>
<td></td>
<td>• <strong>RTW</strong>: Model reference target build</td>
</tr>
<tr>
<td></td>
<td>• <strong>SIM</strong>: Model reference simulation target build</td>
</tr>
</tbody>
</table>

If you are configuring your target to support parallel builds, as discussed in “Reduce Build Time for Referenced Models” (Simulink Coder), you must also add the following token definitions to your TMF:

```plaintext
START_DIR = |>START_DIR<|
MASTER_ANCHOR_DIR = |>MASTER_ANCHOR_DIR<|
```

<table>
<thead>
<tr>
<th>Token</th>
<th>Expands to</th>
</tr>
</thead>
<tbody>
<tr>
<td>START_DIR</td>
<td>Current work folder (pwd) at the time the build started.</td>
</tr>
<tr>
<td>MASTER_ANCHOR_DIR</td>
<td>Current work folder (pwd) at the time the build started.</td>
</tr>
</tbody>
</table>

2. Add `RELATIVE_PATH_TO_ANCHOR` and `MODELREF_INC_PATH` include paths to the overall INCLUDES variable.

```plaintext
INCLUDES = -I -I$(RELATIVE_PATH_TO_ANCHOR) $(ADD_INCLUDES) $(USER_INCLUDES) $(MODELREF_INC_PATH) $(SHARED_INCLUDES)
```

3. Change the SRCS variable in your TMF so that it initially lists only common modules. Additional modules are then appended conditionally, as described in the next step. For example, change

```plaintext
SRCS = $(MODEL).c $(MODULES) ert_main.c $(ADD_SRCS) $(EXT_SRC)
```

To

```plaintext
SRCS = $(MODULES) $(S_FUNCTIONS)
```
Create variables to define the final target of the makefile. You can remove variables that may have existed for defining the final target. For example, remove

\[
\text{PROGRAM} = ../\$(MODEL)
\]

and replace it with

\[
\text{ifeq (}$\$(\text{MODELREF\_TARGET\_TYPE)$, \text{NONE})}
\text{# Top model for RTW}
\text{PRODUCT} = $(\text{RELATIVE\_PATH\_TO\_ANCHOR})/$(MODEL)
\text{BIN\_SETTING} = $(\text{LD}) $(\text{LDFLAGS}) -o $(PRODUCT) $(SYSLIBS)
\text{BUILD\_PRODUCT\_TYPE} = "executable"
\text{# ERT based targets}
\text{SRCS} += $(MODEL).c ert\_main.c $(EXT\_SRC)
\text{# GRT based targets}
\text{SRCS} += $(MODEL).c grt\_main.c rt\_sim.c $(EXT\_SRC) $(SOLVER)
\text{else}
\text{# sub-model for RTW}
\text{PRODUCT} = $(\text{MODELLIB})
\text{BUILD\_PRODUCT\_TYPE} = "library"
\text{endif}
\]

Create rules for the final target of the makefile (replace existing final target rules). For example:

\[
\text{ifeq (}$\$(\text{MODELREF\_TARGET\_TYPE)$, \text{NONE})}
\text{# Top model for RTW}
$(PRODUCT) : $(OBJS) $(SHARED\_LIB) $(LIBS) $(MODELREF\_LINK\_LIBS)
$(BIN\_SETTING) $(LINK\_OBJS) $(MODELREF\_LINK\_LIBS)
$(SHARED\_LIB) $(LIBS)
@echo "### Created $(BUILD\_PRODUCT\_TYPE): $@"
\text{else}
\text{# sub-model for RTW}
$(PRODUCT) : $(OBJS) $(SHARED\_LIB) $(LIBS)
@\text{rm -f $(MODELLIB)}
$(ar) ruvs $(MODELLIB) $(LINK\_OBJS)
@echo "### Created $(MODELLIB)"
@echo "### Created $(BUILD\_PRODUCT\_TYPE): $@"
\text{endif}
\]

Create a rule to allow referenced models to compile files that reside in the MATLAB working folder (pwd).

\[
$.o : $(\text{RELATIVE\_PATH\_TO\_ANCHOR})/%.c
$$(\text{CC}) -c $(\text{CFLAGS}) $<$
\]

**Note** If you are using a TMF without the variables \text{SHARED\_SRC} or \text{MODELREFS}, the file might have been used with a previous release of Simulink software. If you want your TMF to support model referencing, add either variable \text{SHARED\_SRC} or \text{MODELREFS} to the make file.
Controlling Configuration Option Value Agreement

By default, the value of a configuration option defined in the system target file for a TLC-based custom target must be the same in any referenced model and its parent model. To relax this requirement, include the `modelReferenceParameterCheck` field in the `rtwoptions` structure element that defines the configuration option, and set the value of the field to 'off'. For example:

```plaintext
rtwoptions(2).prompt         = 'My Custom Parameter';
rtwoptions(2).type           = 'Checkbox';
rtwoptions(2).default        = 'on';
rtwoptions(2).modelReferenceParameterCheck  = 'on';
rtwoptions(2).tlcvariable    = 'mytlcvariable';
...```

The configuration option **My Custom Parameter** can differ in a referenced model and its parent model. See “Customize System Target Files” on page 84-28 for information about TLC-based system target files, and `rtwoptions` Structure Fields Summary for a list of `rtwoptions` fields.

Supporting the Shared Utilities Folder

- “Overview” on page 84-89
- “Implementing Shared Utilities Folder Support” on page 84-91

**Overview**

The makefile used by the build process must support compiling and creating libraries, and so on, from the locations in which the code is generated. Therefore, you need to update your makefile and the model reference build process to support the shared utilities location. The **Shared code placement** options have the following requirements:

- **Auto**
  - Standalone model build — Build files go to the build folder; makefile is not updated.
  - Referenced model or top model build — Use shared utilities folder; makefile requires full model reference support.

- **Shared location**
  - Standalone model build — Use shared utilities folder; makefile requires shared location support.
• Referenced model or top model build — Use shared utilities folder; makefile requires full model reference support.

The shared utilities folder (slprj/target/_sharedutils) typically stores generated utility code that is common between a top model and the models it references. You can also force the build process to use a shared utilities folder for a standalone model. See “Manage Build Process Folders” (Simulink Coder) for details.

If you want your target to support compilation of code generated in the shared utilities folder, several updates to your template makefile (TMF) are required. Support for Model Reference builds requires the shared utilities folder. See the preceding sections to learn about additional updates for supporting Model Reference builds.

The exact syntax of the changes can vary due to differences in the make utility and compiler/archiver tools used by your target. The examples below are based on the GNU make utility. You can find the following updated TMF examples for GNU and Microsoft Visual C++ make utilities in the GRT and ERT target folders:

• GRT: matlabroot/rtw/c/grt (open)
  - grt_lcc.tmf
  - grt_vc.tmf
  - grt_unix.tmf
• ERT: matlabroot/rtw/c/ert (open)
  - ert_lcc.tmf
  - ert_vc64.tmf
  - ert_unix.tmf

Use the GRT or ERT examples as a guide to the location, within the TMF, of the changes and additions described below.

**Note** The ERT-based TMFs contain extra code to handle generation of ERT S-functions and Model Reference simulation targets. Your target does not need to handle these cases.

---

12. GNU is a registered trademark of the Free Software Foundation.
Implementing Shared Utilities Folder Support

Make the following changes to your TMF to support the shared utilities folder:

1. Add the following make variables and tokens to be expanded when the makefile is generated:

   \[
   \begin{align*}
   \text{SHARED\_SRC} & = \text{\texttt{\textbackslash |\texttt{SHARED\_SRC}\textbackslash |}} \\
   \text{SHARED\_SRC\_DIR} & = \text{\texttt{\textbackslash |\texttt{SHARED\_SRC\_DIR}\textbackslash |}} \\
   \text{SHARED\_BIN\_DIR} & = \text{\texttt{\textbackslash |\texttt{SHARED\_BIN\_DIR}\textbackslash |}} \\
   \text{SHARED\_LIB} & = \text{\texttt{\textbackslash |\texttt{SHARED\_LIB}\textbackslash |}} \\
   \end{align*}
   \]

   \text{SHARED\_SRC} specifies the shared utilities folder location and the source files in it. A typical expansion in a makefile is

   \[
   \text{SHARED\_SRC} = \text{\texttt{../slprj/ert/_sharedutils/\textasterright\textbackslash c}}
   \]

   \text{SHARED\_LIB} specifies the library file built from the shared source files, as in the following expansion.

   \[
   \text{SHARED\_LIB} = \text{\texttt{../slprj/ert/_sharedutils/rtwshared.lib}}
   \]

   \text{SHARED\_SRC\_DIR} and \text{SHARED\_BIN\_DIR} allow specification of separate folders for shared source files and the library compiled from the source files. In the current release, the TMFs use the same path, as in the following expansions.

   \[
   \begin{align*}
   \text{SHARED\_SRC\_DIR} & = \text{\texttt{../slprj/ert/_sharedutils}} \\
   \text{SHARED\_BIN\_DIR} & = \text{\texttt{../slprj/ert/_sharedutils}}
   \end{align*}
   \]

2. Set the \text{SHARED\_INCLUDES} variable according to whether shared utilities are in use. Then append it to the overall \text{INCLUDES} variable.

   \[
   \text{SHARED\_INCLUDES} = \\
   \text{\texttt{\textbackslash ifndef (\texttt{\textbackslash $(SHARED\_SRC\_DIR)\textbackslash ,)\textbackslash }}} \\
   \text{\texttt{\textbackslash $(SHARED\_SRC\_DIR)\end{align*}}
   \text{\textbackslash endif\textbackslash }}}
   \]

   \[
   \text{INCLUDES} = -I, \text{\texttt{\textbackslash $(ADD\_INCLUDES) \textbackslash \textbackslash \textbackslash $(USER\_INCLUDES) \textbackslash $(SHARED\_INCLUDES)\textbackslash }}}
   \]

3. Update the \text{SHARED\_SRC} variable to list shared files explicitly.

   \[
   \text{SHARED\_SRC} := \text{\texttt{\textbackslash $(\text{\textbackslash wildcard \textbackslash $(SHARED\_SRC)\textbackslash ))}}
   \]

4. Create a \text{SHARED\_OBJJS} variable based on \text{SHARED\_SRC}.

   \[
   \text{SHARED\_OBJJS} = \text{\texttt{\textbackslash $(\text{\textbackslash addsuffix \textbackslash .o, \textbackslash $(\text{\textbackslash basename \textbackslash $(SHARED\_SRC)\textbackslash ))}}}
   \]
Create an **OPTS** (options) variable for compilation of shared utilities.

```
SHARED_OUTPUT_OPTS = -o $@
```

Provide a rule to compile the shared utility source files.

```
$(SHARED_OBJS) : $(SHARED_BIN_DIR)/%.o : $(SHARED_SRC_DIR)/%.c
  $(CC) -c $(CFLAGS) $(SHARED_OUTPUT_OPTS) $<
```

Provide a rule to create a library of the shared utilities. The following example is based on UNIX\(^\text{13}\).

```
$(SHARED_LIB) : $(SHARED_OBJS)
  @echo "### Creating $@"
  ar r $@ $(SHARED_OBJS)
  @echo "### Created $@"
```

**Note** Depending on your make utility, you may be able to combine Steps 6 and 7 into one rule. For example, `gmake` (used with `ert_unix.tmf`) uses:

```
$(SHARED_LIB) : $(SHARED_SRC)
  @echo "### Creating $@"
  cd $(SHARED_BIN_DIR); $(CC) -c $(CFLAGS) $(GCC_WALL_FLAG_MAX) $(notdir $?)
  ar ruvs $@ $(SHARED_OBJS)
  @echo "### $@ Created"
```

See this and other examples in the files `ert_vcx64.tmf`, `ert_lcc.tmf`, and `ert_unix.tmf` located at `matlabroot/rtw/c/ert` (open).

Add **SHARED_LIB** to the rule that creates the final executable.

```
$(PROGRAM) : $(OBJS) $(LIBS) $(SHARED_LIB)
  $(LD) $(LDFLAGS) -o $@ $(LINK_OBJ) $(LIBS)
$(SHARED_LIB) $(SYSLIBS)
  @echo "### Created executable: $(MODEL)"
```

Remove explicit references to `rt_nonfinite.c` from your TMF. For example, change

```
ADD_SRCS = $(RTWLOG) rt_nonfinite.c
```

```
ADD_SRCS = $(RTWLOG)
```

---

13. UNIX is a registered trademark of The Open Group in the United States and other countries.
Note If your target interfaces to a development environment that is not makefile based, you must make equivalent changes to provide information to your target compilation environment.

Verifying Worker Configuration for Parallel Builds of Model Reference Hierarchies (Optional)

If your target supports parallel builds for large model reference hierarchies, you can additionally set up automatic verification of MATLAB Distributed Computing Server workers. This addresses the possibility that parallel workers might have different configurations, some of which might not be compatible with a specific target build. For example, the required compiler might not be installed on a worker system.

The code generator provides a programming interface that you can use to automatically check the configuration of parallel workers. If parallel workers are not set up as expected, take action, such as reverting to sequential builds or throwing an error.

To set up automatic verification of workers, you must define a parallel configuration check function named `STF_par_cfg_chk`, where `STF` designates your system target file name. For example, the parallel configuration check function for `ert.tlc` is `ert_par_cfg_chk`.

The general syntax for the function is:

```
function varargout = STF_par_cfg_chk(action,varargin)
```

The number of output and input arguments vary according to the `action` specified, and according to the types of information you choose to coordinate between the client and the workers. The function should support the following general sequence of parallel configuration setup calls, differentiated by the first argument passed in:

<table>
<thead>
<tr>
<th>Call Syntax</th>
<th>Called on:</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>cfg = STF_par_cfg_chk('getPreferredCfg');</code></td>
<td>Client</td>
<td>Return a structure representing the preferred configuration for MATLAB Distributed Computing Server workers.</td>
</tr>
<tr>
<td>Call Syntax</td>
<td>Called on:</td>
<td>Action</td>
</tr>
<tr>
<td>------------------------------------------------</td>
<td>------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>[tf, cfg] = STF_par_cfg_chk ('getWorkerCfg', cfg);</code></td>
<td>Workers</td>
<td>Each worker is passed the MATLAB Distributed Computing Server client’s preferred configuration. Return true if the worker can support the preferred configuration; otherwise return false along with a structure representing a configuration the worker can support. Information returned by each worker is added to a cell array of configurations.</td>
</tr>
<tr>
<td><code>[tf, cfg] = STF_par_cfg_chk ('getCommonCfg', cfgs);</code></td>
<td>Client</td>
<td>The client is passed the cell array of worker configurations. If a usable common configuration exists, return true, and return the common configuration to set for all systems. If a common configuration cannot be established, return false or take some action, such as reverting to sequential builds or throwing an error.</td>
</tr>
<tr>
<td><code>tf = STF_par_cfg_chk ('setCommonCfg', cfg);</code></td>
<td>Workers and client</td>
<td>Each system is passed the common configuration to use. Set up the common configuration and, if successful, return true. If errors or issues occur, return false or take some action, such as reverting to sequential builds or throwing an error.</td>
</tr>
<tr>
<td><code>STF_par_cfg_chk ('clearCfg');</code></td>
<td>Workers and client</td>
<td>Clean up after completion of the parallel build.</td>
</tr>
</tbody>
</table>

The parallel configuration check functions for MathWorks provided targets are implemented as wrapper functions that call a function named `parallelMdlRefHostConfigCheckFcn`. For example, see the ERT parallel configuration check function in the file `matlabroot/toolbox/rtw/rtw/ert_par_cfg_chk.m`, and the function it calls in the file `matlabroot/toolbox/simulink/simulink/+Simulink/parallelMdlRefHostConfigCheckFcn.m`. The `parallelMdlRefHostConfigCheckFcn` function tries to establish a common compiler across the MATLAB Distributed Computing Server client and workers.

For more information about parallel builds, see “Reduce Build Time for Referenced Models” (Simulink Coder).
Preventing Resource Conflicts (Optional)

Hook files are optional TLC and MATLAB program files that are invoked at well-defined stages of the build process. Hook files let you customize the build process and communicate information between various phases of the process.

If you are adapting your custom target for code generation compatibility with model reference features, consider adding checks to your hook files for handling referenced models differently than top models to prevent resource conflicts.

For example, consider adding the following check to your `STF_make_rtw_hook.m` file:

```matlab
% Check if this is a referenced model
mdlRefTargetType = get_param(codeGenModelName, 'ModelReferenceTargetType');
isNotModelRefTarget = strcmp(mdlRefTargetType, 'NONE'); % NONE, SIM, or RTW
if isNotModelRefTarget
    % code that is specific to the top model
else
    % code that is specific to the referenced model
end
```

You may need to do a similar check in your TLC code.

```matlab
%if !IsModelReferenceTarget()
    % code that is specific to the top model
%else
    % code that is specific to the referenced model
%endif
```

Support Compiler Optimization Level Control

This section describes how to configure a custom embedded target to support compiler optimization level control. Without the described modifications, you cannot use the Configuration Parameters > Code Generation > Build process > Compiler optimization level parameter to control the compiler optimization level for building generated code. For more information about compiler optimization level control, see “Compiler optimization level” (Simulink Coder).

About Compiler Optimization Level Control and Custom Targets

The requirements for supporting compiler optimization level control are as follows:

- The target must be derived from the GRT target or the ERT target.
- The system target file (STF) must declare compiler optimization level control compliance, as described in “Declaring Compiler Optimization Level Control Compliance” on page 84-96.
- The target makefile must honor the setting for Compiler optimization level, as described in “Providing Compiler Optimization Level Control Support in the Target Makefile” on page 84-97.

For an example that shows how to configure custom target optional features, see “Customize System Target Files” (Simulink Coder).

Declaring Compiler Optimization Level Control Compliance

To declare compiler optimization level control compliance for your target, you must implement a callback function that sets the CompOptLevelCompliant flag, and then install the callback function in the SelectCallback field of the rtwgensettings structure in your STF. The callback function is triggered whenever the user selects the target in the System Target File Browser. For example, the following STF code installs a SelectCallback function named custom_select_callback_handler:

```
rtwgensettings.SelectCallback = 'custom_select_callback_handler(hDlg,hSrc)';
```

The arguments to the SelectCallback function (hDlg, hSrc) are handles to private data used by the callback API functions. These handles are restricted to use in STF callback functions. They should be passed in without alteration.
Your callback function should set the `CompOptLevelCompliant` flag as follows:

```matlab
slConfigUISetVal(hDlg,hSrc,'CompOptLevelCompliant','on');
slConfigUISetEnabled(hDlg,hSrc,'CompOptLevelCompliant',false);
```

For more information about the STF callback API, see the `slConfigUIGetVal`, `slConfigUISetEnabled`, and `slConfigUISetVal` function reference pages.

When the `CompOptLevelCompliant` target configuration parameter is set to `on`, the Compiler optimization level parameter is displayed in the Code Generation pane of the Configuration Parameters dialog box for your model.

**Providing Compiler Optimization Level Control Support in the Target Makefile**

As part of supporting compiler optimization level control for your target, you must modify the target makefile to honor the setting for Compiler optimization level. Use a GRT or ERT target provided by MathWorks as a model for making the modifications.

Support C Function Prototype Control

This section describes how to configure a custom embedded target to support function prototype control. Without the described modifications, you will not be able to use available interfaces for customizing entry-point function interfaces. For more information, see “Customize Generated C Function Interfaces” on page 38-2.

About C Function Prototype Control and Custom Targets

The requirements for supporting C function prototype control are as follows:

- The target must be derived from the ERT target.
- The system target file (STF) must declare C function prototype control compliance, as described in “Declaring C Function Prototype Control Compliance” on page 84-98.
- If your target uses a custom static main program, and if a nondefault function prototype control configuration is associated with a model, the static main program must call the function prototype controlled initialize and step functions, as described in “Providing C Function Prototype Control Support in the Custom Static Main Program” on page 84-99.

For an example that shows how to configure custom target optional features, see “Customize System Target Files” (Simulink Coder).

Declaring C Function Prototype Control Compliance

To declare C function prototype control compliance for your target, you must implement a callback function that sets the ModelStepFunctionPrototypeControlCompliant flag, and then install the callback function in the SelectCallback field of the rtwgensettings structure in your STF. The callback function is triggered whenever the user selects the target in the System Target File Browser. For example, the following STF code installs a SelectCallback function named custom_select_callback_handler:

```matlab
rtwgensettings.SelectCallback = 'custom_select_callback_handler(hDlg,hSrc)';
```

The arguments to the SelectCallback function (hDlg, hSrc) are handles to private data used by the callback API functions. These handles are restricted to use in STF callback functions. They should be passed in without alteration.

Your callback function should set the ModelStepFunctionPrototypeControlCompliant flag as follows:
For more information about the STF callback API, see the `slConfigUIGetVal`, `slConfigUISetEnabled`, and `slConfigUISetVal` function reference pages.

When the `ModelStepFunctionPrototypeControlCompliant` target configuration parameter is set to `on`, you can use the Configure C Step Function Interface dialog box to control the function prototype of the base-rate step function generated for a rate-based model.

### Providing C Function Prototype Control Support in the Custom Static Main Program

If your target uses a custom static main program, and if a nondefault function prototype control configuration is associated with a model, you must update the static main program to call the function prototype controlled initialize and step functions. You can do this in either of the following ways:

1. Manually adapt your static main program to declare model data and call the function prototype controlled initialize and step functions.
2. Generate your main program using **Generate an example main program** on the Templates pane of the Configuration Parameters dialog box. The generated main program declares model data and calls the function prototype controlled initialize and step function.

Support C++ Class Interface Control

This section describes how to configure a custom embedded target to support C++ class interface control. Without the described modifications, you will not be able to use C++ class code interface packaging and the Configure C++ Class Interface button on the Interface pane of the Configuration Parameters dialog box to generate and configure C++ class interfaces to model code. For more information about C++ class interface control, see “Customize Generated C++ Class Interfaces” on page 38-36.

About C++ Class Interface Control and Custom Targets

The requirements for supporting C++ class interface control are as follows:

• The target must be derived from the ERT target.
• The system target file (STF) must declare C++ class interface control compliance, as described in “Declaring C++ Class Interface Control Compliance” on page 84-100.

For an example that shows how to configure custom target optional features, see “Customize System Target Files” (Simulink Coder).

Declaring C++ Class Interface Control Compliance

To declare C++ class interface control compliance for your target, you must implement a callback function that sets the CPPClassGenCompliant flag, and then install the callback function in the SelectCallback field of the rtwgensettings structure in your STF. The callback function is triggered whenever the user selects the target in the System Target File Browser. For example, the following STF code installs a SelectCallback function named custom_select_callback_handler:

```matlab
rtwgensettings.SelectCallback = 'custom_select_callback_handler(hDlg,hSrc)';
```

The arguments to the SelectCallback function (hDlg, hSrc) are handles to private data used by the callback API functions. These handles are restricted to use in STF callback functions. They should be passed in without alteration.

Your callback function should set the CPPClassGenCompliant flag as follows:

```matlab
slConfigUISetVal(hDlg,hSrc,'CPPClassGenCompliant','on');
slConfigUISetEnabled(hDlg,hSrc,'CPPClassGenCompliant',false);
```

For more information about the STF callback API, see the slConfigUIGetVal, slConfigUISetEnabled, and slConfigUISetVal function reference pages.
When the `CPPClassGenCompliant` target configuration parameter is set to `on`, you can use the C++ class code interface packaging and the **Configure C++ Class Interface** button on the Interface pane of the Configuration Parameters dialog box to generate and configure C++ class interfaces to model code.

### Providing C++ Class Interface Control Support in the Custom Static Main Program

Selecting C++ class code interface packaging for your model turns on the model option **Generate an example main program**. With this option on, code generation generates an example main program, `ert_main.cpp`. The generated example main program declares model data and calls the C++ class interface configured model step method, and illustrates how the generated code can be deployed.

To customize the build process and disable generation and inclusion of an example main program, see the `setTargetProvidesMain` function. Disabling example main generation permits including a custom main program.

- “Customize System Target Files” (Simulink Coder)
Support Concurrent Execution of Multiple Tasks

If a custom embedded target must support concurrent execution of multiple tasks on a multicore platform, the target must declare support for concurrent execution by setting the target configuration option `ConcurrentExecutionCompliant`. Otherwise, you will not be able to configure a multicore target model for concurrent execution.

If `ConcurrentExecutionCompliant` is not already configured for your custom target, you can set the option in the following ways:

- Include the following code directly in your system target file (`mytarget.tlc`):
  ```
  rtwgensettings.SelectCallback = 'slConfigUISetVal(hDlg,hSrc,...
  'ConcurrentExecutionCompliant',''on'');';
  rtwgensettings.ActivateCallback = 'slConfigUISetVal(hDlg,hSrc,...
  'ConcurrentExecutionCompliant',''on'');';
  ```

- Implement a callback function that sets the `ConcurrentExecutionCompliant` option, and then install the callback function in the `SelectCallback` field of the `rtwgensettings` structure in your STF. The callback function is triggered whenever the user selects the target in the System Target File Browser. For example, the following STF code installs a `SelectCallback` function named `custom_select_callback_handler`:
  ```
  rtwgensettings.SelectCallback = 'custom_select_callback_handler(hDlg,hSrc)';
  ```

  The arguments to the `SelectCallback` function (`hDlg`, `hSrc`) are handles to private data used by the callback API functions. These handles are restricted to use in STF callback functions. They should be passed in without alteration.

  Your callback function should set the `ConcurrentExecutionCompliant` option as follows:
  ```
  slConfigUISetVal(hDlg,hSrc,'ConcurrentExecutionCompliant','on');
  slConfigUISetEnabled(hDlg,hSrc,'ConcurrentExecutionCompliant',false);
  ```

  For more information about the STF callback API, see the `slConfigUIGetVal`, `slConfigUISetEnabled`, and `slConfigUISetVal` function reference pages.

  When the `ConcurrentExecutionCompliant` target configuration option is set to `on`, you can select the custom target and configure your multicore target model for concurrent execution.

  For an example that shows how to configure custom target optional features, see “Customize System Target Files” (Simulink Coder).

- “Sample Custom Targets” (Simulink Coder)
- “Customize System Target Files” (Simulink Coder)
Interface to Development Tools

Unless you are developing a target purely for code generation purposes, you will want your embedded target to support a complete build process. A full post-code generation build process includes

- Compilation of generated code
- Linking of compiled code and runtime libraries into an executable program module (or some intermediate representation of the executable code, such as S-Rec format)
- Downloading the executable to target hardware with a debugger or other utility
- Initiating execution of the downloaded program

Supporting a complete build process is inherently a complex task, because it involves interfacing to cross-development tools and utilities that are external to the code generator.

If your development tools can be controlled with traditional makefiles and a make utility such as gmake, it may be relatively simple for you to adapt existing target files (such as the ert.tlc and ert.tmf files provided by the Embedded Coder software) to your requirements. This approach is discussed in “Template Makefile Approach” on page 84-104.

About Interfacing to Development Tools

Automating your build process through a modern integrated development environment (IDE) presents a different set of challenges. Each IDE has its own way of representing the set of source files and libraries for a project and for specifying build arguments. Interfacing to an IDE may require generation of specialized file formats required by the IDE (for example, project files) and, and also may require the use of inter-application communication (IAC) techniques to run the IDE. One such approach to build automation is discussed in “Interface to an Integrated Development Environment” on page 84-105.

Template Makefile Approach

A template makefile provides information about your model and your development system. The build process uses this information to create a makefile (.mk file) to build an executable program. The code generator provides a number of template makefiles suitable for development computer compilers, such as LCC (ert_lcc.tmf) and Microsoft Visual C++ (ert_vcx64.tmf).
Adapting one of the existing template makefiles to your cross-compiler's make utility may require little more than copying and renaming the template makefile in accordance with the conventions of your project.

If you need to make more extensive modifications, you need to understand template makefiles in detail. For a detailed description of the structure of template makefiles and of the tokens used in template makefiles, see “Customize Template Makefiles” on page 84-62.

The following topics supplement the basic template makefile information:

- “Supporting Multiple Development Environments” on page 84-48
- “Suppling Development Environment Information to Your Template Makefile” on page 84-25

Interface to an Integrated Development Environment

This section describes techniques that have been used to integrate embedded targets with integrated development environment (IDEs), including

- How to generate a header file containing directives to define variables (and their values) required by a non-makefile based build.
- Some problems and solutions specific to interfacing embedded targets with the Freescale Semiconductor CodeWarrior IDE. The examples provided should help you to deal with similar interfacing problems with your particular IDE.

- “Generating a CPP_REQ_DEFINES Header File” on page 84-105
- “Interfacing to the Freescale CodeWarrior IDE” on page 84-106

Generating a CPP_REQ_DEFINES Header File

In template makefiles, the token CPP_REQ_DEFINES is expanded and replaced with a list of parameter settings entered with various dialog boxes. This variable often contains information such as MODEL (name of generating model), NUMST (number of sample times in the model), MT (model is multitasking or not), and numerous other parameters (see “Template Makefiles and Tokens” on page 84-62).

The makefile mechanism handles the CPP_REQ_DEFINES token automatically. If your target requires use of a project file, rather than the traditional makefile approach, you can generate a header file containing directives to define these variables and provide their values.
The following TLC file, `gen_rtw_req_defines.tlc`, provides an example. The code generates a C header file, `cpp_req_defines.h`. The information required to generate each `#define` directive is derived either from information in the `model.rtw` file (e.g., `CompiledModel.NumSynchronousSampleTimes`), or from make variables from the `rtwoptions` structure (for example, `PurelyIntegerCode`).

```tlc
%% File: gen_rtw_req_defines_h.tlc
%openfile CPP_DEFINES = "cpp_req_defines.h"
#ifndef _CPP_REQ_DEFINES_
#define _CPP_REQ_DEFINES_
#define MODEL %<CompiledModel.Name>
#define ERT 1
#define NUMST %<CompiledModel.NumSynchronousSampleTimes>
#define TID01EQ %<CompiledModel.FixedStepOpts.TID01EQ>
%%
%if CompiledModel.FixedStepOpts.SolverMode == "MultiTasking"
#define MT 1
#define MULTITASKING 1
#else
#define MT 0
#define MULTITASKING 0
%endif
%%
#define MAT_FILE 0
#define INTEGER_CODE %<PurelyIntegerCode>
#define ONESTEPFCN %<CombineOutputUpdateFcns>
#define TERMFCN %<IncludeMdlTerminateFcn>
%%
#define MULTI_INSTANCE_CODE 0
#define HAVESTDIO 0
%endif
%closefile CPP_DEFINES
```

**Interfacing to the Freescale CodeWarrior IDE**

Interfacing an embedded target's build process to the CodeWarrior IDE requires that two problems must be dealt with:

- The build process must generate a CodeWarrior compatible project file. This problem, and a solution, is discussed in “XML Project Import” on page 84-107. The solution described is applicable to ASCII project file formats.
- During code generation, the target must automate a CodeWarrior session that opens a project file and builds an executable. This task is described in “Custom Target Development in Simulink Coder.”
Automation” on page 84-110. The solution described is applicable to IDEs that can be controlled with Microsoft Component Object Model (COM) automation.

XML Project Import

This section illustrates how to use the Target Language Compiler (TLC) to generate an eXtensible Markup Language (XML) file, suitable for import into the CodeWarrior IDE, that contains information about the source code generated by an embedded target.

The choice of XML format is dictated by the fact that the CodeWarrior IDE supports project export and import with XML files. As of this writing, native CodeWarrior project files are in a proprietary binary format.

Note that if your target needs to support some other compiler's project file format, you can apply the techniques shown here to other ASCII file formats (see “Generating a CPP_REQ_DEFINES Header File” on page 84-105).

To illustrate the basic concept, consider a hypothetical XML file exported from a CodeWarrior stationery project. The following is a partial listing:

```xml
<target>
    <settings>
        ...
    </settings>
    <file><name>foo.c</name>
    </file>
        ...
    <file><name>foobar.c</name>
    </file>
    <fileref><name>foo.c</name>
    </fileref>
        ...
    <fileref><name>foobar.c</name>
    </fileref>
</target>
```

Insert this XML code into an %openfile/%closefile block within a TLC file, test.tlc, as shown below.

```tcl
%% test.tlc
%% This code will generate a file model_project.xml,
%% where model is the generating model name specified in
%% the CompiledModel.Name field of the model.rtw file.
%openfile XMLFileContents = %<CompiledModel.Name>_project.xml
```
Note the use of the TLC token CompiledModel.Name. The token is resolved and the resulting filename is included in the output stream. You can specify other information, such as paths and libraries, in the output stream by specifying other tokens defined in model.rtw. For example, System.Name may be defined as <Root>/Subsystem1.

Now suppose that test.tlc is invoked during a target's build process, where the generating model is mymodel. This should be done after the codegenentry statement. For example, test.tlc could be included directly in the system target file:

%include "codegenentry.tlc"
%include "test.tlc"

Alternatively, the %include "test.tlc" directive could be inserted into the mytarget_genfiles.tlc hook file, if present.

TLC tokens such as

<file><name>%<CompiledModel.Name>.c</name>

are expanded, with the CompiledModel record in the mymodel.rtw file, as in

<file><name>mymodel.c</name>

test.tlc generates an XML file, file model_project.xml, from a model. model_project.xml contains references to generated code files. model_project.xml can be imported into the CodeWarrior IDE as a project.
The following flowchart summarizes this process.

proj.mcp: CodeWarrior project binary stationery file

*Code Warrior (manual): Export to XML.*

proj.xml: XML project file

*Text editor (manual): Add TLC tokens to
genenerate references to model files, MATLAB
and other paths, and other settings. Embed
the XML code marked with tokens in
openfile/closefile block. Save as
proj_gen.tlc.*

proj_gen.tlc: TLC file for
generating XML file

*TLC: During code generation, expand TLC
tokens and generate XML project file,
model_project.xml.*

model_project.xml:
Generated XML project file
with generated file references
and target-specific
information

*Code Warrior (manual or with script): Import from XML.*

model_project.mcp: CodeWarrior project binary file

*Code Warrior (manual or with script): Build project as indicated in "Build Process Automation".*
This process has drawbacks. First, manually editing an XML file exported from a CodeWarrior stationery project can be a laborious task, involving modification of a few dozen lines embedded within several thousand lines of XML code. Second, if you make changes to the CodeWarrior project after importing the generated XML file, the XML file must be exported and manually edited once again.

Build Process Automation

An application that supports COM automation can control other applications that include a COM interface. Using MATLAB COM automation functions, a MATLAB file can command a COM-compatible development system to execute tasks required by the build process.

The MATLAB COM automation functions described in this section are documented in “Call COM Objects” (MATLAB).

For information about automation commands supported by the CodeWarrior IDE, see your CodeWarrior documentation.

COM automation is used by some embedded targets to automate the CodeWarrior IDE to execute tasks such as:

- Opening a new CodeWarrior session
- Configure a project
- Loading a CodeWarrior project file
- Removing object code from the project
- Building or rebuilding the project
- Debug an application

COM technology automates certain repetitive tasks and allows the user to interact directly with the external application. For example, when the end user of the embedded targets capability initiates a build, the target quickly invokes CodeWarrior actions and leaves a project built and ready to run with the IDE.

Example COM Automation Functions

The functions below use the MATLAB actxserver command to invoke COM functions for controlling the CodeWarrior IDE from a MATLAB file:
• **CreateCWComObject**: Create a COM connection to the CodeWarrior IDE.
• **OpenCW**: Open the CodeWarrior IDE without opening a project.
• **OpenMCP**: Open the CodeWarrior project file (.mcp file) specified by the input argument.
• **BuildCW**: Open the specified .mcp file, remove object code, and build project.

These functions are examples; they do not constitute a full implementation of a COM automation interface. If your target creates the project file during code generation, the top-level BuildCW function should be called after the code generation process is completed. Normally BuildCW would be called from the exit method of your `STF_make_rtw_hook.m` file (see “STF_make_rtw_hook.m” on page 84-20).

In the code examples, the variable `in_qualifiedMCP` is assumed to store a fully qualified path to a CodeWarrior project file (for example, path, filename, and extension). For example:

```matlab
ing_qualifiedMCP = 'd:\work\myproject.mcp';
```

In actual practice, your code is responsible for determining the conventions used for the project filename and location. One simple convention would be to default to a project file `model.mcp`, located in your target's build folder.

```matlab
% Function: CreateCWComObject
% Abstract: Creates the COM connection to CodeWarrior

function ICodeWarriorApp = CreateCWComObject
vprint([mfilename ': creating CW com object']);
try
    ICodeWarriorApp = actxserver('CodeWarrior.CodeWarriorApp');
catch
    error(["Error creating COM connection to ' ComObj ...
         '. Verify that CodeWarrior is installed. Verify COM access to
         CodeWarrior outside of MATLAB."]);
end
return;
```

```matlab
% Function: OpenCW
% Abstract: Opens CodeWarrior without opening a project. Returns the
% handle ICodeWarriorApp.

function ICodeWarriorApp = OpenCW()
    ICodeWarriorApp = CreateCWComObject;
    CloseAll;
    OpenMCP(in_qualifiedMCP);
```
%=====================================================================  
% Function: OpenMCP  
% Abstract: open an MCP project file  
%  
function OpenMCP(in_qualifiedMCP)  
   % Argument checking. This method requires valid project file.  
   if ~exist(in_qualifiedMCP)  
      error([mfilename ': Missing or empty project file argument']);  
   end  
   if isempty(in_qualifiedMCP)  
      error([mfilename ': Missing or empty project file argument']);  
   end  
   ICodeWarriorApp = CreateCWComObject;  
   vprint([mfilename ': Importing']);  
   try  
      ICodeWarriorProject = ...  
         invoke(ICodeWarriorApp.Application,...  
                 'OpenProject', in_qualifiedMCP,...  
                 1,0,0);  
      catch  
         error([{'Error using COM connection to import project. ' ...  
                 'Verify that CodeWarrior is installed. Verify COM access to  
                 CodeWarrior outside of MATLAB.'}]);  
   end  
%=====================================================================  
% Function: BuildCW  
% Abstract: Opens CodeWarrior.  
%            Opens the specified CodeWarrior project.  
%            Deletes objects.  
%            Builds.  
%  
function ICodeWarriorApp = BuildCW(in_qualifiedMCP)  
   % ICodeWarriorApp = BuildCW:  
   ICodeWarriorApp = CreateCWComObject;  
   CloseAll;  
   OpenMCP(in_qualifiedMCP);  
   try  
      invoke(ICodeWarriorApp.DefaultProject,'RemoveObjectCode', 0, 1);  
      catch  
         error([{'Error using COM connection to remove objects of current project. ' ...  
                 'Verify that CodeWarrior is installed. Verify COM access to  
                 CodeWarrior outside of MATLAB.'}]);  
   end  
   try  
      invoke(ICodeWarriorApp.DefaultProject,'BuildAndWaitToComplete');  
      catch  
         error([{'Error using COM connection to build current project. ' ...  
                 'Verify that CodeWarrior is installed. Verify COM access to  
                 CodeWarrior outside of MATLAB.'}]);  
   end  
%======================================================================

Device Drivers

Device drivers that communicate with target hardware are essential to many real-time development projects.

You can integrate existing C (or C++) device driver functions into Simulink models by using the Legacy Code Tool. When you use the code generator to generate code from a model, the Legacy Code Tool can insert a call to your C function into the generated code. For details, see “Import Calls to External Code into Generated Code with Legacy Code Tool” (Simulink Coder) and “Integrate C Functions into Simulink Models with Legacy Code Tool” (Simulink).

Block Selection

You can create models for targeting the same way you create other Simulink models—by combining standard blocks and C-MEX S-functions.

You can use blocks from the following sources:

- The Embedded Coder Support Packages.
- The Embedded Targets library (embeddedtargetslib) in the Embedded Coder product.
- Blocks from the System Toolboxes products
- Custom blocks

Avoid using blocks that do not generate code, including the following blocks.

<table>
<thead>
<tr>
<th>Block Name/Category</th>
<th>Library</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Simulink, DSP System Toolbox software</td>
<td>Provides oscilloscope view of your output. Do not use the Save data to workspace option on the Data history pane in the Scope Parameters dialog.</td>
</tr>
<tr>
<td>To Workspace</td>
<td>Simulink</td>
<td>Return data to your MATLAB workspace.</td>
</tr>
<tr>
<td>From Workspace</td>
<td>Simulink</td>
<td>Send data to your model from your MATLAB workspace.</td>
</tr>
</tbody>
</table>
### Block Name/Category | Library | Description
--- | --- | ---
Spectrum Scope | DSP System Toolbox | Compute and display the short-time FFT of a signal. It has internal buffering that can slow your process without adding value.
To File | Simulink | Send data to a file on your host machine.
From File | Simulink | Get data from a file on your host machine.
Triggered to Workspace | DSP System Toolbox | Send data to your MATLAB workspace.
Signal To Workspace | DSP System Toolbox | Send a signal to your MATLAB workspace.
Signal From Workspace | DSP System Toolbox | Get a signal from your MATLAB workspace.
Triggered Signal From Workspace | DSP System Toolbox | Get a signal from your MATLAB workspace.
To Wave device | DSP System Toolbox | Send data to a .wav device.
From Wave device | DSP System Toolbox | Get data from a .wav device.

### Configure Target Hardware Resources

#### Configure Parameters Under the Hardware Implementation Tab

Configure the parameters under the **Hardware Implementation** tab of your Simulink model for a specific target hardware and tool chain. Doing so updates other parameters in the Configuration Parameters dialog to the default values for the software build tool chain and target hardware you are using.

**Note** The Target Preferences (Removed) block has been removed from the Simulink block libraries for the Embedded Coder and Simulink Coder products.

Parameters in the Target Preferences block have been moved to the Target Hardware Resources tab.
To configure your Simulink model for a specific target hardware and tool chain:

1. In a Simulink model, open the model Configuration Parameters by:
   - Clicking the gear icon,
   - Pressing Ctrl+E on your keyboard
   - Selecting the Simulation > Model Configuration Parameters menu items

2. In the Configuration Parameters dialog, click Hardware Implementation, and then select the Hardware board you are using.

   **Note** Selecting a Hardware board automatically populates many parameters in the Code Generation appropriate for the hardware.

3. Review the other parameters under the Target Hardware Resources tab.

4. (Optional) In the Configuration Parameters dialog, click Code Generation to review and modify other code generation features for your model.

5. Click Apply, and save the changes to your model.

### Configuration Parameters

- “What are Configuration Parameters?” on page 85-4
- “Setting Model Configuration Parameters” on page 85-4

#### What are Configuration Parameters?

To see the model Configuration Parameters, open the Configuration Parameters dialog. You can do this in the model editor by selecting Simulation > Model Configuration Parameters, or by pressing Ctrl+E on your keyboard.

The Configuration Parameters dialog specifies the values for a model's active configuration set. These parameters determine the type of solver used, the import and export settings, and other values that determine how the model runs.

#### Setting Model Configuration Parameters

To set the Configuration Parameters to the right values for you to generate code from your model, see “Configure Parameters Under the Hardware Implementation Tab” on
page 85-3. This action initializes the model Configuration Parameters to the right default values for you to generate code. You can then use the Configuration Parameters dialog to make further modifications to the values. You can generate buildable code using these default values.

Processor-Specific Optimizations for Embedded Targets in Embedded Coder
Replace Code for Embedded Targets

<table>
<thead>
<tr>
<th>In this section...</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Using a Processor-Specific Code Replacement Library to Optimize Code” on page 86-2</td>
</tr>
</tbody>
</table>

Using a Processor-Specific Code Replacement Library to Optimize Code

You can optimize the code the code generator produces for a specific processor by configuring the code generator to use a code replacement library (CRL) during code generation. If you have an Embedded Coder license, you can develop and apply custom code replacement libraries.

For more information about replacing code, using code replacement libraries that MathWorks provides, see “What Is Code Replacement?” on page 51-2 and “Replace Code Generated from Simulink Models” on page 51-10. For information about developing code replacement libraries, see “What Is Code Replacement Customization?” on page 64-3 and “Develop a Code Replacement Library” on page 64-27.

Process of Determining Optimization Effects Using Real-Time Profiling Capability

You can use the real-time profiling capability to examine the results of applying the processor-specific library functions and operators to your generated code. After you select a processor-specific code replacement library, use the real-time execution profiling capability to examine the change in program execution time.

Use the following process to evaluate the effects of applying a processor-specific code replacement library when you generate code:

1. Enable real-time profiling in your model. Refer to “Code Execution Profiling”.
2. Generate code for your project without specifying a code replacement library (the default Code replacement library setting is None).
3. Profile the code, and save the report.
4 Rebuild your project using a processor-specific code replacement library.
5 Profile the code, and save the second report.
6 Compare the profile report from running your application with the processor-specific library selected to the profile results in the first report with no code replacement library selected.

For an example of verifying the code optimization, search help for "Optimizing Embedded Code via Code Replacement Library" and select the example that matches your IDE.

- “Control Data Type Casts in Generated Code” on page 87-26
- “Simplify Multiply Operations for Array Indexing in Loops” on page 87-30
- “Increase Likelihood of Generating MISRA C Compliant Code from MATLAB Code” on page 87-31
Specify Comment Style for C/C++ Code

In this section...

“Specify Comment Style Using the MATLAB Coder App” on page 87-2
“Specify Comment Style Using the Command-Line Interface” on page 87-3

If you have an Embedded Coder, you can specify the comment style for C/C++ code generated from MATLAB code. Specify single-line style to generate single-line comments preceded by //. Specify multiline style to generate single-line or multiline comments delimited by /* and */. Single-line style is the default for C++ code generation. Multiline style is the default for C code generation. For C code generation, select single-line comment style only if your compiler supports it.

Specify Comment Style Using the MATLAB Coder App

1. On the Generate Code page, to open the Generate dialog box, click the Generate arrow.
2. Set Build type to one of the following:
   - Source Code
   - Static Library (.lib)
   - Dynamic Library (.dll)
   - Executable (.exe)
3. Click More Settings.
4. On the Code Appearance tab, select the Include comments check box if it is not already selected. By default, the Include comments check box is selected.
5. Set Comment Style to one of the following options.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Auto (Use standard comment style of the target language)</td>
<td>For C, generate multiline comments. For C++, generate single-line comments. (default)</td>
</tr>
<tr>
<td>Single-line (Use C++-style comments)</td>
<td>Generate single-line comments preceded by //.</td>
</tr>
<tr>
<td>Multi-line (Use C-style comments)</td>
<td>Generate single-line or multiline comments delimited by /* and */.</td>
</tr>
</tbody>
</table>
Specify Comment Style Using the Command-Line Interface

1. Create a code configuration object for C/C++ code generation. For example, create a configuration object for C/C++ static library generation:

   ```
   cfg = coder.config('lib','ecoder',true);
   ```

2. Set the `CommentStyle` property to one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'Auto'</td>
<td>For C, generate multiline comments. For C++, generate single-line comments. (default)</td>
</tr>
<tr>
<td>'Single-line'</td>
<td>Generate single-line comments preceded by //.</td>
</tr>
<tr>
<td>'Multi-line'</td>
<td>Generate single-line or multiline comments delimited by /* and */.</td>
</tr>
</tbody>
</table>

   For example, this code sets the comment style to single-line style:

   ```
   cfg.CommentStyle='Single-line';
   ```

More About

- “Configure Build Settings” (MATLAB Coder)
Specify Indent Style for C/C++ Code

**In this section...**

| “Specify Indent Style Using the MATLAB Coder App” on page 87-5 |
| “Specify Indent Style Using the Command-Line Interface” on page 87-5 |

If you have an Embedded Coder license, you can control the indent style and indent size in C/C++ code generated from MATLAB code. Indent style controls the placement of braces. Indent size controls the number of characters per indentation level.

You can specify the K&R indent style or the Allman indent style. Both styles:

- Place the function opening and closing braces on their own lines at the same indentation level as the function header.
- Indent code within the function according to the indent size.
- For blocks within a function, place closing braces on a new line at the same indentation level as the control statement.
- Indent code within a block according to the indent size.

The K&R style and the Allman style differ in their placement of the opening brace for a control statement. If you want the opening brace on the same line as its control statement, select the K&R style. Here is code that has the K&R indent style:

```c
void addone(const double x[6], double z[6])
{
    int i0;
    for (i0 = 0; i0 < 6; i0++) {
        z[i0] = x[i0] + 1.0;
    }
}
```

If you want the opening brace on its own line, select the Allman style. Here is code that has the Allman indent style:

```c
void addone(const double x[6], double z[6])
{
    int i0;
    for (i0 = 0; i0 < 6; i0++)
    {
        z[i0] = x[i0] + 1.0;
    }
}
Specify Indent Style Using the MATLAB Coder App

1. On the Generate Code page, to open the Generate dialog box, click the Generate arrow.
2. Set Build type to one of the following:
   - Source Code
   - Static Library (.lib)
   - Dynamic Library (.dll)
   - Executable (.exe)
3. Click More Settings.
4. On the All Settings tab, under Advanced, set Indent style to K&R or Allman.
5. On the All Settings tab, under Advanced, set Indent size to an integer from 2 to 8.

Specify Indent Style Using the Command-Line Interface

1. Create a code configuration object for 'lib', 'dll', or 'exe'. For example:
   ```matlab
cfg = coder.config('lib','ecoder',true); % or dll or exe
```
2. Set the IndentStyle property to 'K&R' or 'Allman'. For example:
   ```matlab
cfg.IndentStyle = 'Allman';
```
3. Set the IndentSize property to an integer from 2 to 8. For example:
   ```matlab
cfg.IndentSize = 4;
```

• “Configure Build Settings” (MATLAB Coder)
Generate Custom File and Function Banners for C/C++ Code

When you generate C and C++ code from MATLAB code, you can use a code generation template (CGT) file to specify custom:

- File banners
- Function Banners
- File trailers
- Comments before code sections

This example shows how you can create your own CGT file and customize it to generate your own file and function banners.

1. Create a local copy of the default CGT file for MATLAB Coder and rename it. The default CGT file is `matlabcoder_default_template.cgt` in the `matlabroot/toolbox/coder/matlabcoder/templates/` folder.

2. Store the copy in a folder that is outside of the MATLAB folder structure, but on the MATLAB path. If necessary, add the folder to the MATLAB path. If you intend to use the CGT file with a custom target, locate the CGT file in a folder under your target root folder. If the file is not on the MATLAB path, specify a full path to the file when adding the file to your configuration.

3. View the default template and generated output. For example, here is the default File Banner section:

```markdown
%% Custom File Banner section (optional)
%% Customize File banners by using either custom tokens or the following
%% predefined tokens:
%% %<FileName>, %<MATLABCoderVersion>, %<EmbeddedCoderVersion>
%% %<SourceGeneratedOn>, %<HardwareSelection>, %<OutputType>
%%
%% You can also use "custom tokens" in all of the sections below. See the
%% documentation center for more details.
%%
<<FileBanner style="classic">
File: %<FileName>
MATLAB Coder version : %<MATLABCoderVersion>
C/C++ source code generated on : %<SourceGeneratedOn>
</FileBanner>
```

When you generate code using this default, the file banner looks similar to this file banner:
/*
 * File: coderand.c
 *
 * MATLAB Coder version            : 2.7
 * C/C++ source code generated on  : 06-Apr-2014 14:34:15
 */

4 Edit your local copy of the CGT file. You can change the default values and add your own custom tokens. For example, here is the File Banner section with the style changed to box and a custom token myCustomToken:

```plaintext
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
%% Custom File Banner section (optional)
%% Customize File banners by using either custom tokens or the following
%% predefined tokens:
%% %<FileName>, %<MATLABCoderVersion>, %<EmbeddedCoderVersion>
%% %<SourceGeneratedOn>, %<HardwareSelection>, %<OutputType>
%%
%% You can also use "custom tokens" in all of the sections below. See the
%% documentation center for more details.
%%
%% <FileBanner style="box">
File: %<FileName>
My custom token                : %<myCustomToken>
MATLAB Coder version           : %<MATLABCoderVersion>
C/C++ source code generated on : %<SourceGeneratedOn>
</FileBanner>
```

For more information, see “Code Generation Template Files for MATLAB Code” on page 87-9.

5 Create a configuration object for generation of a C static library for an embedded target.

```matlab
% Create configuration object for an embedded target
cfgObj = coder.config('lib','ecoder',true);
```

6 Create a `MATLABCodeTemplate` object from your CGT file and add it to the configuration object.

```matlab
% Specify the custom CGT file
CGTFile = 'myCGTFile.cgt';
% Use custom template
cfgObj.CodeTemplate = coder.MATLABCodeTemplate(CGTFile);
```

7 Assign values for custom tokens that you added to the template. For example, assign the value 'myValue' to the myCustomToken token that you added in a previous step.

```matlab
cfgObj.CodeTemplate.setTokenValue('myCustomToken','myValue');
```
8 Make sure that generation of comments is enabled. Otherwise, the code generator does not produce file or function banners.

cfgObj.GenerateComments=true;

9 Generate code using the configuration object that you created.

codegen -config cfgObj coderand

10 View the changes to the generated file banner. For example, here is the file banner for coderand.c using the customized CGT file:

```c
/******************************************************************************/
/* File: coderand.c                                                        */
/*                                                                            */
/* My custom token : myValue                                                 */
/*                                                                            */
/* MATLAB Coder version : 2.7                                                */
/* C/C++ source code generated on : 06-Apr-2014 14:42:55                      */
/******************************************************************************/
```

Changes to a CGT file do not affect the generated code unless you create a MATLABCodeTemplate object from the modified CGT file, and then add it to the configuration object. If you modify the CGT File, myCGTFile.cgt, used in the previous example, you must repeat these steps:

1 Create a MATLABCodeTemplate object from myCGTFile.cgt and add it to the configuration object.

   CGTFile = 'myCGTFile.cgt';
   cfgObj.CodeTemplate = coder.MATLABCodeTemplate(CGTFile);

2 Assign the value 'myValue' to the myCustomToken token.

   cfgObj.CodeTemplate.setTokenValue('myCustomToken','myValue');

3 Generate code.

   codegen -config cfgObj coderand

coder.MATLABCodeTemplate

More About
• “Code Generation Template Files for MATLAB Code” on page 87-9
A code generation template (CGT) file defines the sections in generated code that you can customize using comments and tokens. Using a code generation template (CGT) file for the generation of C and C++ code from MATLAB code, you can specify custom file banners and function banners for generated code. File banners are comment sections in the header and trailer sections of a generated file. Function banners are comment sections for each function in the generated code. You can also customize comments before code sections. Use these banners to:

- Add a company copyright statement.
- Specify a special version symbol for your configuration management system.
- Remove timestamps.
- Add other custom information to your generated files.

For information on creating, customizing, and using a CGT file, see “Generate Custom File and Function Banners for C/C++ Code” on page 87-6.

**Default CGT File**

You can base your custom template on the default CGT file, `matlabcoder_default_template.cgt`, in the `matlabroot/toolbox/coder/matlabcoder/templates/` folder.

**Note** If you choose not to customize banners for your generated code, the default template is used for code generation.

**CGT File Structure**

A CGT file consists of 13 optional sections.
**File Banner Section**
Contains comments and tokens for use in generating a custom file banner.

**Function Banner Section**
Contains comments and tokens for use in generating a custom function banner.

**Shared Utility Function Banner**
Contains comments and tokens for use in generating custom banners for shared utility functions.

**File Trailer Section**
Contains comments for use in generating a custom trailer banner.

**Include Files Banner**
Contains comments for use in generating a custom banner for the include files section.

**Type Definitions**
Contains comments for use in generating a custom banner for the type definitions section.

**Named Constants**
Contains comments for use in generating a custom banner for the named constants section.

**Variable Declarations**
Contains comments for use in generating a custom banner for the variable declarations section.

**Variable Definitions**
Contains comments for use in generating a custom banner for the variable definitions section.

**Function Declarations**
Contains comments for use in generating a custom banner for the function declarations section.
**Function Definitions**

Contains comments for use in generating a custom banner for the function definitions section.

**Custom Source Code**

Contains comments for use in generating a custom banner for the custom source code section.

**Custom Header Code**

Contains comments for use in generating a custom banner for the custom header code section.

**Components of the CGT File Sections**

Each CGT file section is defined by open and close tags.

<table>
<thead>
<tr>
<th>CGT File Section</th>
<th>Open Tag</th>
<th>Close Tag</th>
</tr>
</thead>
<tbody>
<tr>
<td>“File Banner” on page 87-14</td>
<td><code>&lt;FileBanner&gt;</code></td>
<td><code>&lt;/FileBanner&gt;</code></td>
</tr>
<tr>
<td>“Function Banner Section” on page 87-10</td>
<td><code>&lt;FunctionBanner&gt;</code></td>
<td><code>&lt;/FunctionBanner&gt;</code></td>
</tr>
<tr>
<td>“Shared Utility Function Banner” on page 87-10</td>
<td><code>&lt;SharedUtilityBanner&gt;</code></td>
<td><code>&lt;/SharedUtilityBanner&gt;</code></td>
</tr>
<tr>
<td>“File Trailer Section” on page 87-10</td>
<td><code>&lt;FileTrailer&gt;</code></td>
<td><code>&lt;/FileTrailer&gt;</code></td>
</tr>
<tr>
<td>“Include Files Banner” on page 87-10</td>
<td><code>&lt;IncludeFilesBanner&gt;</code></td>
<td><code>&lt;/IncludeFilesBanner&gt;</code></td>
</tr>
<tr>
<td>“Type Definitions” on page 87-10</td>
<td><code>&lt;TypeDefinitionsBanner&gt;</code></td>
<td><code>&lt;/TypeDefinitionsBanner&gt;</code></td>
</tr>
<tr>
<td>“Named Constants” on page 87-10</td>
<td><code>&lt;NamedConstantsBanner&gt;</code></td>
<td><code>&lt;/NamedConstantsBanner&gt;</code></td>
</tr>
<tr>
<td>“Variable Declarations” on page 87-10</td>
<td><code>&lt;VariableDeclarationsBanner&gt;</code></td>
<td><code>&lt;/VariableDeclarationsBanner&gt;</code></td>
</tr>
</tbody>
</table>
You can customize your banners by including tokens and comments between the open and close tags for each section. Tokens are replaced with values in the generated code. The following rules apply to tokens in your CGT file:

- You can have only one token per line.
- Token values must not contain a ‘\t’ for formatting.

**Note** In the contents of your banner, C comment indicators, '/\*' or '*/', can introduce an error in the generated code.

An open tag includes tag attributes. Enclose the value of the attribute in double quotes. The attributes available for an open tag are:

- **width**: specifies the width of the file or function banner comments in the generated code. The default value is 80.
- **style**: specifies the boundary for the file or function banner comments in the generated code.

The open tag syntax is:

```
<OpenTag style = "style_value" width = "num_width">
```

There are five options for the banner style. The `CommentStyle` and `TargetLang` configuration object properties determine the use of C or C++ comment style. The built-in style options for the style attribute are:

<table>
<thead>
<tr>
<th>CGT File Section</th>
<th>Open Tag</th>
<th>Close Tag</th>
</tr>
</thead>
<tbody>
<tr>

File Banner

This section contains comments and tokens for use in generating a custom file banner that precedes the generated C and C++ code. If you omit the file banner section from the CGT file, the code generator does not generate a file banner in the generated code. The file banner section provided in the default CGT file is:
Summary of Tokens for File Banner Generation

<table>
<thead>
<tr>
<th>Token</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FileName</td>
<td>Name of the generated file (for example, &quot;kalman.c&quot;)</td>
</tr>

<td>Type of output (for example, lib, exe, or dll)</td>
</tr>
</tbody>
</table>

**Function Banner**

This section contains comments and tokens for use in generating a custom function banner that precedes a generated C or C++ function. If you omit the function banner section from the CGT file, the code generator does not generate function banners. The function banner section provided in the default CGT file is:

```plaintext
%% Custom Function Banner section (optional)
%% Customize function banners by using the following predefined tokens:
%% %<FunctionName>, %<FunctionDescription>, %<FunctionPrototype>
%% %<Arguments>, %<ReturnType>
%%
<FunctionBanner style="classic">
%<FunctionPrototype>
%<FunctionDescription>
Arguments    : %<Arguments>
Return Type  : %<ReturnType>
</FunctionBanner>
```
Summary of Tokens for Function Banner Generation

<table>
<thead>
<tr>
<th>FunctionName</th>
<th>Name of function</th>
</tr>
</thead>
<tbody>
<tr>
<td>FunctionDescription</td>
<td>Short abstract about the function</td>
</tr>
<tr>
<td></td>
<td>If the configuration parameter MATLABFcnDesc is true, the function description appears in the function banner. Otherwise, the code generator treats the function description as user comments.</td>
</tr>
<tr>
<td>FunctionPrototype</td>
<td>MATLAB function prototype</td>
</tr>
<tr>
<td></td>
<td>The function prototype appears in the function banner only if the MATLABSourceComments configuration parameter is true.</td>
</tr>
<tr>
<td>Arguments</td>
<td>List of function arguments</td>
</tr>
<tr>
<td>ReturnType</td>
<td>Return type of function</td>
</tr>
</tbody>
</table>

Shared Utility Banner

This section contains comments and tokens for use in generating a custom shared utility function banner that precedes a generated C or C++ shared utility function. If you omit the shared utility function banner section from the CGT file, the code generator does not generate shared utility function banners. The shared utility function banner section provided in the default CGT file is:

```matlab
%% Custom Shared Utility Function Banner section (optional)
%% Customize shared utility function banners by using the following
%% predefined tokens:
%% %<FunctionName>, %<FunctionDescription>
%% %<Arguments>, %<ReturnType>
%%
%% <SharedUtilityBanner style="classic">
Arguments    : %<Arguments>
Return Type  : %<ReturnType>
</SharedUtilityBanner>
```
Summary of Tokens for Shared Utility Function Banner Generation

<table>
<thead>
<tr>
<th>FunctionName</th>
<th>Name of function</th>
</tr>
</thead>
<tbody>
<tr>
<td>FunctionDescription</td>
<td>Short abstract about the function</td>
</tr>
<tr>
<td>Arguments</td>
<td>List of function arguments</td>
</tr>
<tr>
<td>ReturnType</td>
<td>Return type of function</td>
</tr>
</tbody>
</table>

**File Trailer**

The file trailer section contains comments for generating a custom file trailer that follows the generated C or C++ code. If you omit the file trailer section from the CGT file, the code generator does not generate a file trailer. The file trailer section provided in the default CGT file is:

```plaintext
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
%% Custom file trailer section (optional)
%% You can use any of the predefined tokens used for File Banner
%%
<FileTrailer style="classic">
File trailer for %<FileName>

[EOF]
</FileTrailer>
```

Tokens for the file banner are available for the file trailer. See Summary of Tokens for File Banner Generation.

**Include Files Banner**

The include files banner section contains comments for generating a custom banner that precedes the include files section in the generated code. If you omit the include files banner section from the CGT file, the code generator does not generate a banner for this section. The include files banner section provided in the default CGT file is:

```plaintext
<?IncludeFilesBanner  style="classic">
Include Files
</IncludeFilesBanner>
```

**Type Definitions Banner**

The type definitions banner section contains comments for generating a custom banner that precedes the type definitions section in the generated code. If you omit the type definitions banner section from the CGT file, the code generator does not generate a
banner for this section. The type definitions banner section provided in the default CGT file is:

<TypeDefinitionsBanner style="classic">
Type Definitions
</TypeDefinitionsBanner>

**Named Constants Banner**

The named constants banner section contains comments for generating a custom banner that precedes the named constants section in the generated code. If you omit the named constants banner section from the CGT file, the code generator does not generate a banner for this section. The named constants banner section provided in the default CGT file is:

<NamedConstantsBanner style="classic">
Named Constants
</NamedConstantsBanner>

**Variable Declarations**

The variable declarations banner section contains comments for generating a custom banner that precedes the variable declarations section in the generated code. If you omit the variable declarations banner section from the CGT file, the code generator does not generate a banner for this section. The variable declarations banner section provided in the default CGT file is:

<VariableDeclarationsBanner style="classic">
Variable Declarations
</VariableDeclarationsBanner>

**Variable Definitions**

The variable definitions banner section contains comments for generating a custom banner that precedes the variable definitions section in the generated code. If you omit the variable definitions banner section from the CGT file, the code generator does not generate a banner for this section. The variable definitions banner section provided in the default CGT file is:

<VariableDefinitionsBanner style="classic">
Variable Definitions
</VariableDefinitionsBanner>
**Function Declarations**

The function declarations banner section contains comments for generating a custom banner that precedes the function declarations section in the generated code. If you omit the function declarations banner section from the CGT file, the code generator does not generate a banner for this section. The function declarations banner section provided in the default CGT file is:

```html
<functionDeclarationsBanner style="classic">
Function Declarations
</functionDeclarationsBanner>
```

**Function Definitions**

The function definitions banner section contains comments for generating a custom banner that precedes the function definitions section in the generated code. If you omit the function definitions banner section from the CGT file, the code generator does not generate a banner for this section. The function definitions banner section provided in the default CGT file is:

```html
<FunctionDefinitionsBanner style="classic">
Function Definitions
</FunctionDefinitionsBanner>
```

**Custom Source Code**

The custom source code banner section contains comments for generating a custom banner that precedes the custom source code section in the generated code. If you omit the custom source code banner section from the CGT file, the code generator does not generate a banner for this section. The custom source code banner section provided in the default CGT file is:

```html
<CustomSourceCodeBanner style="classic">
Custom Source Code
</CustomSourceCodeBanner>
```

**Custom Header Code**

The custom header code banner section contains comments for generating a custom banner that precedes the custom header code section in the generated code. If you omit the custom header code banner section from the CGT file, the code generator does not generate a banner for this section. The custom header code banner section provided in the default CGT file is:
<CustomHeaderCodeBanner style="classic">
Custom Header Code
</CustomHeaderCodeBanner>

Customize Generated Identifiers

In this section...

“Customize Identifiers by Using the MATLAB Coder App” on page 87-21
“Customize Generated Identifiers by Using the Command-Line Interface” on page 87-22

If you have Embedded Coder, you can customize the identifiers in C/C++ code generated from MATLAB code. For each kind of identifier that you want to customize, set the appropriate identifier format parameter to a macro that specifies the format of the generated identifiers. The macro can include:

- Valid C or C++ language identifiers (a-z, A-Z, _, 0-9).
- The tokens listed in the following table. $M$ is required.

<table>
<thead>
<tr>
<th>Token</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$M$</td>
<td>Code generator inserts name mangling text to avoid naming collisions. Required.</td>
</tr>
<tr>
<td>$N$</td>
<td>Code generator inserts the name of the object (global variable, global type, local function, local temporary variable, or constant macro) for which the identifier is generated. Improves readability of generated code.</td>
</tr>
<tr>
<td>$R$</td>
<td>Code generator inserts the root project name into identifier, replacing unsupported characters with the underscore (_) character.</td>
</tr>
</tbody>
</table>

Customize Identifiers by Using the MATLAB Coder App

1. On the Generate Code page, to open the Generate dialog box, click the Generate arrow ▼.
2. Set Build type to one of the following:
   - Source Code
   - Static Library
• Dynamic Library
• Executable

3 Click More Settings.

4 On the Code Appearance tab, under Identifier Format, for each kind of identifier that you want to customize, enter the macro.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default Macro</th>
</tr>
</thead>
<tbody>
<tr>
<td>Global variables</td>
<td>$M$N</td>
</tr>
<tr>
<td>Global types</td>
<td>$M$N</td>
</tr>
<tr>
<td>Field name of global types</td>
<td>$M$N</td>
</tr>
<tr>
<td>Local functions</td>
<td>$M$N</td>
</tr>
<tr>
<td>Local temporary variables</td>
<td>$M$N</td>
</tr>
<tr>
<td>Constant macros</td>
<td>$M$N</td>
</tr>
<tr>
<td>EMX Array Types</td>
<td>emxArray_$M$N</td>
</tr>
<tr>
<td>EMX Array Utility Functions</td>
<td>emx$M$N</td>
</tr>
</tbody>
</table>

For example, suppose that Global variables has the value glob_$M$N. For a global variable named g, when name mangling is not required, the generated identifier is glob_g. If name mangling is required, the generated identifier includes the name mangling text.

### Customize Generated Identifiers by Using the Command-Line Interface

1 Create a code configuration object for a library or executable program. For example:

```matlab
cfg = coder.config('lib','ecoder',true);
```

2 For each kind of identifier that you want to customize, specify the macro as a character vector.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Default Macro</th>
</tr>
</thead>
<tbody>
<tr>
<td>CustomSymbolStrGlobalVar</td>
<td>Global variables</td>
<td>'$M$N'</td>
</tr>
<tr>
<td>CustomSymbolStrType</td>
<td>Global types</td>
<td>'$M$N'</td>
</tr>
<tr>
<td>CustomSymbolStrField</td>
<td>Field name of global types</td>
<td>'$M$N'</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Default Macro</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>---------------------------</td>
<td>---------------</td>
</tr>
<tr>
<td>CustomSymbolStrFcn</td>
<td>Local functions</td>
<td>'$M$N'</td>
</tr>
<tr>
<td>CustomSymbolStrTmpVar</td>
<td>Local temporary variables</td>
<td>'$M$N'</td>
</tr>
<tr>
<td>CustomSymbolStrMacro</td>
<td>Constant macros</td>
<td>'$M$N'</td>
</tr>
<tr>
<td>CustomSymbolStrEMXArray</td>
<td>EMX Array Types</td>
<td>'emxArray_$M$N'</td>
</tr>
<tr>
<td>CustomSymbolStrEMXArrayFcn</td>
<td>EMX Array Utility Functions</td>
<td>'emx$M$N'</td>
</tr>
</tbody>
</table>

For example:

```matlab
cfg.CustomSymbolStrGlobalVar = 'glob_$M$N';
```

For a global variable named `g`, when name mangling is not required, the generated identifier is `glob_g`. If name mangling is required, the generated identifier includes the name mangling text.

- “Configure Build Settings” (MATLAB Coder)
Control Signed Left Shifts in Generated Code

If you have an Embedded Coder license, you can control whether MATLAB Coder replaces multiplications by powers of two with signed left bitwise shifts. Some coding standards, such as MISRA, do not allow bitwise operations on signed integers.

By default, MATLAB Coder replaces multiplication by powers of two with signed left shifts. Here is an example of generated C code that uses a signed left shift for multiplication by eight.

\[ i \ll= 3; \]

To increase the likelihood of generating MISRA C:2012 compliant code, disable the replacement of multiplication by powers of two with signed left shifts. Here is an example of generated C code that does not use a signed left shift for multiplication by eight:

\[ i = i \ast 8; \]

**Control Signed Left Shifts Using the MATLAB Coder App**

1. On the **Generate Code** page, to open the **Generate** dialog box, click the **Generate** arrow.
2. Set **Build type** to one of the following:
   - Source Code
   - Static Library (.lib)
   - Dynamic Library (.dll)
   - Executable (.exe)
3. Click **More Settings**.
4. On the **Code Appearance** tab, select or clear the **Use signed shift left for fixed-point operations and multiplication by powers of 2** check box.
Control Signed Left Shifts Using the Command-Line Interface

1. Create a code configuration object for 'lib', 'dll', or 'exe'. For example:
   ```matlab
cfg = coder.config('lib','ecoder',true); % or dll or exe
```
2. Set the EnableSignedLeftShifts property to true or false. For example:
   ```matlab
cfg.EnableSignedLeftShifts = false;
```

- “Configure Build Settings” (MATLAB Coder)
Control Data Type Casts in Generated Code

In this section...

“Specify Casting Mode Using the MATLAB Coder App” on page 87-28
“Specify Casting Mode Using the Command-Line Interface” on page 87-28

If you have an Embedded Coder license, you can control data type casts in C/C++ code generated from MATLAB code. You can specify one of the following casting modes.

<table>
<thead>
<tr>
<th>Casting Mode</th>
<th>Description</th>
</tr>
</thead>
</table>
| Nominal      | Nominal casting mode is the default casting mode. Generated C/C++ code uses the default C compiler data type casting. When you do not have special data type information requirements, choose this option. Here is an example of code generated using nominal casting mode:

```c
short addone(short x)
{
    int i0;
    i0 = x + 1;
    if (i0 > 32767) {
        i0 = 32767;
    }

    return (short)i0;
}
``` |
<table>
<thead>
<tr>
<th>Casting Mode</th>
<th>Description</th>
</tr>
</thead>
</table>
| Standards Compliant | Generated C/C++ code has data type casts that conform to MISRA standards. The MISRA data type casting eliminates common MISRA standard violations, including address arithmetic and assignment. It reduces 10.1, 10.2, 10.3, and 10.4 violations. Here is an example of code generated using standards-compliant casting mode:  
short addone(short x)  
{  
    int i0;  
    i0 = (int)x + (int)1;  
    if (i0 > (int)32767) {  
        i0 = (int)32767;  
    }  
    return (short)i0;  
}                                                                                                                                                                                                                       |
| Explicit          | Generated C/C++ code has explicit data type casts. Explicit data type casts provide information about the amount of memory that the variable uses and the level of precision for calculations using the variable. Here is an example of code generated using explicit casting mode:  
short addone(short x)  
{  
    int i0;  
    i0 = (int)x + 1;  
    if (i0 > 32767) {  
        i0 = 32767;  
    }  
    return (short)i0;  
}                                                                                                                                                                                                                       |
Specify Casting Mode Using the MATLAB Coder App

1. On the Generate Code page, to open the Generate dialog box, click the Generate arrow.
2. Set Build type to one of the following:
   - Source Code
   - Static Library (.lib)
   - Dynamic Library (.dll)
   - Executable (.exe)
3. Click More Settings.
4. On the All Settings tab, under Advanced, set Casting mode to one of the following values:
   - Nominal
   - Standards Compliant
   - Explicit

Specify Casting Mode Using the Command-Line Interface

1. Create a code configuration object for 'lib', 'dll', or 'exe'. For example:
   ```
   cfg = coder.config('lib','ecoder',true); % or dll or exe
   ```
2. Set the CastingMode property to one of the following values:
   - 'Nominal'
   - 'Standards'
   - 'Explicit'
   For example:
   ```
   cfg.CastingMode = 'Standards';
   ```

- “Configure Build Settings” (MATLAB Coder)
Simplify Multiply Operations for Array Indexing in Loops

If you use Embedded Coder to generate C/C++ code from MATLAB code, you can enable an optimization that simplifies array indexing in loops in the generated code. When possible, for array indices in loops, this optimization replaces multiply operations with add operations. Multiply operations can be expensive. This optimization, referred to as strength reduction, is useful when the C/C++ compiler on the target platform does not optimize the array indexing.

Here is code generated without the optimization:

```
for (i = 0; i < 10; i++) {
    z[5 * (1 + i) - 1] = x[5 * (1 + i)];
}
```

Here is code generated with the optimization:

```
for (b_i = 0; b_i < 10; b_i++) {
    z[i + 4] = x[i + 5];
    i += 5;
}
```

By default, the strength reduction optimization is disabled. To enable it:

- At the command line, set the configuration object parameter EnableStrengthReduction to true.
- In the MATLAB Coder app, project build settings, on the All Settings tab, set Simplify array indexing to Yes.

Even when the optimization replaces the multiply operations in the generated code, it is possible that the C/C++ compiler can generate multiply instructions.

Increase Likelihood of Generating MISRA C Compliant Code from MATLAB Code

The Motor Industry Software Reliability Association (MISRA)\(^\text{14}\) has established “Guidelines for the Use of the C Language in Critical Systems” (MISRA C). When you generate code from MATLAB code, if you have Embedded Coder, you can configure certain code generation parameters to increase the likelihood of generating code that complies with the MISRA C:2012 guidelines.

**Configure Code Generation Configuration Object Properties to Increase Likelihood of MISRA C Compliant Code**

1. Create an Embedded Coder code generation configuration object.
   
   \[
   \text{cfg} = \text{coder.config('lib', 'ecoder', true)};
   \]

2. Set the properties listed in the table to the values for increased MISRA C compliance.

<table>
<thead>
<tr>
<th>Property</th>
<th>Value for Increased MISRA C Compliance</th>
</tr>
</thead>
<tbody>
<tr>
<td>CastingMode</td>
<td>'Standards'</td>
</tr>
<tr>
<td>DataTypeReplacement</td>
<td>'CoderTypedefs'</td>
</tr>
<tr>
<td>DynamicMemoryAllocation</td>
<td>'Off'</td>
</tr>
<tr>
<td>EnableRuntimeRecursion</td>
<td>false</td>
</tr>
<tr>
<td>EnableSignedLeftShifts</td>
<td>false</td>
</tr>
<tr>
<td>EnableSignedRightShifts</td>
<td>false</td>
</tr>
<tr>
<td>GenerateDefaultInSwitch</td>
<td>true</td>
</tr>
<tr>
<td>ParenthesesLevel</td>
<td>'Maximum'</td>
</tr>
<tr>
<td>TargetLangStandard</td>
<td>'C99 (ISO)' for C, 'C++03 (ISO)' for C++</td>
</tr>
</tbody>
</table>

To set these properties in one step, use `coder.setupMISRACConfig`.

\[
\text{coder.setupMISRACConfig(cfg)};
\]

---

\(^{14}\) MISRA and MISRA C are registered trademarks of MIRA Ltd., held on behalf of the MISRA Consortium.
Alternatively, set properties individually. For example:

cfg.CastingMode = 'Standards';

codegen myFunction -config cfg ...

Configure MATLAB Coder App Settings to Increase Likelihood of MISRA C Compliant Code

1 On the Generate Code page, set Build type to Source Code, Static Library, Dynamic Library, or Executable.
2 Click More Settings.
3 Click MISRA Compliance.

The app displays the settings that might impact MISRA C compliance.

Use the following settings to improve MISRA compliance of generated code.

<table>
<thead>
<tr>
<th>Setting</th>
<th>Current Value</th>
<th>Recommended Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic memory allocation</td>
<td>For arrays with max size at or above thres...</td>
<td>Never</td>
</tr>
<tr>
<td>Enable run-time recursion</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Use signed shift left for fixed-point ...</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Allow right shifts on signed integers</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Casting mode</td>
<td>Nominal</td>
<td>Standards Compliant</td>
</tr>
<tr>
<td>Data Type Replacement</td>
<td>Use built-in C data types in the generated ...</td>
<td>Use MathWorks typedefs in the generated</td>
</tr>
<tr>
<td>Parentheses</td>
<td>Nominal (Optimize for readability)</td>
<td>Maximum (Specify precedence with paren...</td>
</tr>
<tr>
<td>Always generate a default case for s...</td>
<td>No</td>
<td>Yes</td>
</tr>
</tbody>
</table>

To set all of these settings to the recommended values, click Set to Recommended Values.

To modify an individual setting, click All Settings, and then search for the setting.

Code Replacement for MATLAB Code

• “What Is Code Replacement?” on page 88-2
• “Choose a Code Replacement Library” on page 88-8
• “Replace Code Generated from MATLAB Code” on page 88-10
What Is Code Replacement?

Code replacement is a technique to change the code that the code generator produces for functions and operators to meet application code requirements. For example, you can replace generated code to meet requirements such as:

- Optimization for a specific run-time environment, including, but not limited to, specific target hardware.
- Integration with existing application code.
- Compliance with a standard, such as AUTOSAR.
- Modification of code behavior, such as enabling or disabling nonfinite or inline support.
- Application- or project-specific code requirements, such as:
  - Elimination of `math.h`.
  - Elimination of system header files.
  - Elimination of calls to `memcpy` or `memset`.
  - Use of BLAS.
  - Use of a specific BLAS.

To apply this technique, configure the code generator to apply a code replacement library (CRL) during code generation. By default, the code generator does not apply a code replacement library. You can choose from libraries that MathWorks provides and that you create and register by using the Embedded Coder product. The list of available libraries depends on:

- Installed support packages.
- System target file, language, standard math library, and device vendor configuration.
- Whether you have created and registered libraries, using the Embedded Coder product.

Libraries that include GNU99 extensions are intended for use with the GCC compiler. If you use one of those libraries with another compiler, generated code might not compile.

Code Replacement Libraries

A code replacement library consists of one or more code replacement tables that specify application-specific implementations of functions and operators. For example, a library for
a specific embedded processor specifies function and operator replacements that optimize generated code for that processor.

A code replacement table contains one or more code replacement entries, with each entry representing a potential replacement for a function or operator. Each entry maps a conceptual representation of a function or operator to an implementation representation and priority.

<table>
<thead>
<tr>
<th>Table Entry Component</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Conceptual representation</td>
<td>Identifies the table entry and contains match criteria for the code generator. Consists of:</td>
</tr>
<tr>
<td></td>
<td>• Function name or a key. The function name identifies most functions. For operators and some functions, a series of characters, called a key identifies a function or operator. For example, function name <em>'cos'</em> and operator key <em>'RTW_OP_ADD'</em>.</td>
</tr>
<tr>
<td></td>
<td>• Conceptual arguments that observe code generator naming (<em>'y1', 'u1', 'u2', ...</em>), with corresponding I/O types (output or input) and data types.</td>
</tr>
<tr>
<td></td>
<td>• Other attributes, such as an algorithm, fixed-point saturation, and rounding modes, which identify matching criteria for the function or operator.</td>
</tr>
<tr>
<td>Table Entry Component</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| Implementation representation | Specifies replacement code. Consists of:  
- Function name. For example, 'cos_dbl' or 'u8_add_u8_u8'.  
- Implementation arguments, with corresponding I/O types (output or input) and data types.  
- Parameters that provide additional implementation details, such as header and source file names and paths of build resources. |
| Priority | Defines the entry priority relative to other entries in the table. The value can range from 0 to 100, with 0 being the highest priority. If multiple entries have the same priority, the code generator uses the first match with that priority. |

When the code generator looks for a match in a code replacement library, it creates and populates a call site object with the function or operator conceptual representation. If a match exists, the code generator uses the matched code replacement entry populated with the implementation representation and uses it to generate code.

The code generator searches the tables in a code replacement library for a match in the order that the tables appear in the library. If the code generator finds multiple matches within a table, the priority determines the match. The code generator uses a higher-priority entry over a similar entry with a lower priority.

**Code Replacement Terminology**

<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cache hit</td>
<td>A code replacement entry for a function or operator, defined in the specified code replacement library, for which the code generator finds a match.</td>
</tr>
<tr>
<td>Cache miss</td>
<td>A conceptual representation of a function or operator for which the code generator does not find a match.</td>
</tr>
<tr>
<td><strong>Term</strong></td>
<td><strong>Definition</strong></td>
</tr>
<tr>
<td>-----------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Call site object</td>
<td>Conceptual representation of a function or operator that the code generator uses when it encounters a call site for a function or operator. The code generator uses the object to query the code replacement library for a conceptual representation match. If a match exists, the code generator returns a code replacement object, fully populated with the conceptual representation, implementation representation, and priority, and uses that object to generate replacement code.</td>
</tr>
<tr>
<td>Code replacement library</td>
<td>One or more code replacement tables that specify application-specific implementations of functions and operators. When configured to use a code replacement library, the code generator uses criteria defined in the library to search for matches. If a match is found, the code generator replaces code that it generates by default with application-specific code defined in the library.</td>
</tr>
<tr>
<td>Code replacement table</td>
<td>One or more code replacement table entries. Provides a way to group related or shared entries for use in different libraries.</td>
</tr>
<tr>
<td>Code replacement entry</td>
<td>Represents a potential replacement for a function or operator. Maps a conceptual representation of a function or operator to an implementation representation and priority.</td>
</tr>
<tr>
<td>Conceptual argument</td>
<td>Represents an input or output argument for a function or operator being replaced. Conceptual arguments observe naming conventions (‘y1’, ‘u1’, ‘u2’, ...) and data types familiar to the code generator.</td>
</tr>
<tr>
<td>Term</td>
<td>Definition</td>
</tr>
<tr>
<td>----------------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Conceptual representation</td>
<td>Represents match criteria that the code generator uses to qualify functions and operators for replacement. Consists of:</td>
</tr>
<tr>
<td></td>
<td>• Function or operator name or key</td>
</tr>
<tr>
<td></td>
<td>• Conceptual arguments with type, dimension, and complexity specification for inputs and output</td>
</tr>
<tr>
<td></td>
<td>• Attributes, such as an algorithm and fixed-point saturation and rounding modes</td>
</tr>
<tr>
<td>Implementation argument</td>
<td>Represents an input or output argument for a C or C++ replacement function. Implementation arguments observe C/C++ name and data type specifications.</td>
</tr>
<tr>
<td>Implementation representation</td>
<td>Specifies C or C++ replacement function prototype. Consists of:</td>
</tr>
<tr>
<td></td>
<td>• Function name (for example, 'cos_dbl' or 'u8_add_u8_u8')</td>
</tr>
<tr>
<td></td>
<td>• Implementation arguments specifying type, type qualifiers, and complexity for the function inputs and output</td>
</tr>
<tr>
<td></td>
<td>• Parameters that provide build information, such as header and source file names and paths of build resources and compile and link flags</td>
</tr>
<tr>
<td>Key</td>
<td>Identifies a function or operator that is being replaced. A function name or key appears in the conceptual representation of a code replacement entry. The key RTW_OP_ADD identifies the addition operator.</td>
</tr>
<tr>
<td>Term</td>
<td>Definition</td>
</tr>
<tr>
<td>-------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Priority</td>
<td>Defines the match priority for a code replacement entry relative to other entries, which have the same name and conceptual argument list, within a code replacement library. The priority can range from 0 to 100, with 0 being the highest priority. The default is 100. If a library provides two implementations for a function or operator, the implementation with the higher priority shadows the one with the lower priority.</td>
</tr>
</tbody>
</table>

**Code Replacement Limitations**

Code replacement verification — It is possible that code replacement behaves differently than you expect. For example, data types that you observe in code generator input might not match what the code generator uses as intermediate data types during an operation. Verify code replacements by examining generated code.

**See Also**

**Related Examples**

- “Replace Code Generated from MATLAB Code” on page 88-10
- “Choose a Code Replacement Library” on page 88-8
Choose a Code Replacement Library

About Choosing a Code Replacement Library

By default, the code generator does not use a code replacement library.

If you are considering using a code replacement library:

1. Explore available libraries. Identify one that best meets your application needs.

   - Consider the lists of application code replacement requirements and libraries that MathWorks provides in “What Is Code Replacement?” on page 88-2.

If you do not find a suitable library and you have an Embedded Coder license, you can create a custom code replacement library.

Explore Available Code Replacement Libraries

You can select the code replacement library to use for code generation in a project, on the Custom Code tab, by setting the Code replacement library parameter. Alternatively, in a code configuration object, set the CodeReplacementLibrary parameter.

Explore Code Replacement Library Contents

Use the Code Replacement Viewer to explore the content of a code replacement library.

1. At the command prompt, type crviewer.

   >> crviewer
The viewer opens. To view the content of a specific library, specify the name of the library as an argument in single quotes. For example:

```
crviewer('GNU C99 extensions')
```

2 In the left pane, select the name of a library. The viewer displays information about the library in the right pane.

3 In the left pane, expand the library, explore the list of tables it contains, and select a table from the list. In the middle pane, the viewer displays the function and operator entries that are in that table, along with abbreviated information for each entry.

4 In the middle pane, select a function or operator. The viewer displays information from the table entry in the right pane.

If you select an operator entry that specifies net slope fixed-point parameters (instantiated from entry class `RTW.TflCOperationEntryGenerator` or `RTW.TflCOperationEntryGenerator_NetSlope`), the viewer displays an additional tab that shows fixed-point settings.

See Code Replacement Viewer for details on what the viewer displays.

**Related Examples**

- “Replace Code Generated from MATLAB Code” on page 88-10
Replace Code Generated from MATLAB Code

This example shows how to replace generated code using a code replacement library. Code replacement is a technique for changing the code that the code generator produces for functions and operators to meet application code requirements.

Prepare for Code Replacement

1. Make sure that you have installed required software. Required software is:
   - MATLAB
   - MATLAB Coder
   - C compiler

   Some code replacement libraries available in your development environment require Embedded Coder.

   For instructions on installing MathWorks products, see the MATLAB installation documentation. If you have installed MATLAB and want to see which other MathWorks products are installed, in the MATLAB Command Window, enter `ver`.

2. Identify an existing MATLAB function or create a new MATLAB function for which you want the code generator to replace code.

Choose a Code Replacement Library

If you are not sure which library to use, explore available libraries.

Configure Code Generator To Use Code Replacement Library

1. Configure the code generator to apply a code replacement library during code generation for the MATLAB function. Do one of the following:
   - In a project, on the Custom Code tab, set the Code replacement library parameter.
   - In a code configuration object, set the CodeReplacementLibrary parameter.

2. Configure the code generator to produce only code. Before you build an executable, verify your code replacements. Do one of the following:
   - In a project, in the Generate dialog box, select the Generate code only check box.
In a code configuration object, set the `GenCodeOnly` parameter.

**Include Code Replacement Information In Code Generation Report**

If you have an Embedded Coder license, you can configure the code generator to include a code replacement section in the code generation report. The additional information helps you verify code replacements.

1. Configure the code generator to generate a report.
   - In a project, on the **Debugging** tab, set the **Always create a code generation report** parameter.
   - In a code configuration object, set the `GenerateReport` parameter.

2. Include the code replacement section in the report.
   - In a project, on the **Debugging** tab, select the **Code replacements** check box.
   - In a code configuration object, set the `GenerateCodeReplacementReport` parameter.

**Generate Replacement Code**

Generate C/C++ code from the MATLAB code. If you configured the code generator to produce a report, generate a code generation report. For example, in the MATLAB Coder app, on the **Generate Code** page, click **Generate**. Or, at the command prompt, enter:

```
codegen -report myFunction -args {5} -config cfg
```

The code generator produces the code and displays the report.

**Verify Code Replacements**

Verify code replacements by examining the generated code. Code replacement can sometimes behave differently than you expect. For example, data types that you observe
in the code generator input might not match what the code generator uses as intermediate data types during an operation.

Storage Classes for Code Generation from MATLAB Code

- “Storage Classes for Code Generation from MATLAB Code” on page 89-2
- “Control Declarations and Definitions of Global Variables in Code Generated from MATLAB Code” on page 89-5
Storage Classes for Code Generation from MATLAB Code

If you have an Embedded Coder license, you can use storage classes to control the declaration and definition of a global variable in the generated C/C++ code.

In the context of code generation, a storage class is a specification that determines the declaration and definition of a variable in the generated code. For code generation, the term storage class is not the same as the C language term storage class specifier.

Storage classes help you to integrate generated code with external code. You can make a generated variable visible to external code. You can also make variables declared in the external code visible to the generated code. For code generation from MATLAB code, you can use storage classes with global variables only. The storage class determines:

- The file placement of a global variable declaration and definition.
- Whether the global variable is imported from external code or exported for use by external code.

To assign a storage class to a global variable, in your MATLAB code, use the `coder.storageClass` function. Only when you use an Embedded Coder project or configuration object for generation of C/C++ libraries or executables does the code generator recognize `coder.storageClass` calls.

The syntax for `coder.storageClass` is:

```matlab
coder.storageClass(global_name, storage_class)
```

`global_name` is the name of a global variable, specified as a character vector. `global_name` must be a compile-time constant.

`storage_class` can be one of the following values.
### Storage Classes for Code Generation from MATLAB Code

<table>
<thead>
<tr>
<th>Storage Class</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'ExportedGlobal'</td>
<td>• Defines the variable in the Variable Definitions section of the C file entry_point_name.c.</td>
</tr>
<tr>
<td></td>
<td>• Declares the variable as an extern in the Variable Declarations section of the header file entry_point_name.h.</td>
</tr>
<tr>
<td></td>
<td>• Initializes the variable in the function entry_point_name_initialize.h.</td>
</tr>
<tr>
<td>'ExportedDefine'</td>
<td>Declares the variable with a #define directive in the Exported data define section of the header file entry_point_name.h.</td>
</tr>
<tr>
<td>'ImportedExtern'</td>
<td>Declares the variable as an extern in the Variable Declarations section of the header file entry_point_name_data.h. The external code must supply the variable definition.</td>
</tr>
<tr>
<td>'ImportedExternPointer'</td>
<td>Declares the variable as an extern pointer in the Variable Declarations section of the header file entry_point_name_data.h. The external code must define a valid pointer variable.</td>
</tr>
</tbody>
</table>

Storage classes have these requirements and limitations:

- Assign the storage class to a global variable in a function that declares the global variable. You do not have to assign the storage class in more than one function.
- After you assign a storage class to a global variable, you cannot assign a different storage class to that global variable.
- You cannot assign a storage class to a constant global variable.
- A global variable with an ExportedDefine storage class must be a scalar but not a complex or multi-word scalar. The global variable must only be read and not written to in the code.
If you do not assign a storage class to a global variable, except for the declaration location, the variable behaves like it has an 'ExportedGlobal' storage class. For an 'ExportedGlobal' storage class, the global variable is declared in the file `entry_point_name.h`. When the global variable does not have a storage class, the variable is declared in the file `entry_point_name_data.h`.

- “Generate Code for Global Data” (MATLAB Coder)
Control Declarations and Definitions of Global Variables in Code Generated from MATLAB Code

This example uses storage classes to control the declarations and definitions of global variables in C/C++ code generated from MATLAB code. Using storage classes helps you to interface generated code with external code.

This example requires an Embedded Coder license.

Write a function addglobals that adds four global variables. Declare the global variables in the function.

```matlab
function y = addglobals
  % Define the global variables.
  global u;
  global v;
  global x;
  global z;
  % Assign the storage classes.
  coder.storageClass('u','ExportedGlobal');
  coder.storageClass('v','ImportedExtern');
  coder.storageClass('x','ImportedExternPointer');
  coder.storageClass('z','ExportedDefine');
  y = u + v + x + z;
end
```

Create a file `c:\myfiles\myfile.c` that defines and initializes the imported global variables `u` and `v`.

```c
#include <stdio.h>

/* Variable definitions for imported variables */
double v = 1.0;
double *x = &v;
```

Create a code configuration object. Configure the code generation parameters to include `myfile.c`. For output type 'lib', or if you generate source code only, you can generate code without providing this file. Otherwise, you must provide this file.
cfg = coder.config('dll','ecoder', true);
cfg.CustomSource = 'myfile.c';
cfg.CustomInclude = 'c:\myfiles';

Generate the code. This example uses the -globals argument to specify the types and initial values of the global variables u, v, x, and z. Alternatively, you can define global variables in the MATLAB global workspace. For the imported global variables v and x, the code generator uses the initial values only to determine the type.

codegen -config cfg -globals {'u', 1, 'v', 2, 'x', 3, 'z', 4} addglobals -report

From the initial values 1, 2, 3, and 4 codegen determines that u, v, x and z have type double. codegen defines and declares the exported global variables u and z. It generates code that initializes u to 1.0 and z to 4.0. codegen declares the imported global variables v and x. It does not define these variables or generate code that initializes them. myfile.c provides the code that defines and initializes v and x.

To view the code generated for the global variables, open the report. Click the View report link.

View the definition for the exported global z in the Exported data define section in addglobals.h.

/* Definition for custom storage class: ExportedDefine */
#define z

View the definition and declaration for the exported global u.

• u is defined in the Variable Definitions section in addglobals.c.

    /* Variable Definitions */
    /* Definition for custom storage class: ExportedGlobal */
    double u;

• u is declared as extern in the Variable Declarations section in addglobals.h.

    /* Variable Declarations */
    /* Declaration for custom storage class: ExportedGlobal */
    extern double u;

• u is initialized in addglobals_initialize.c.

    /* Include Files */
    #include "rt_nonfinite.h"
    #include "addglobals.h"
#include "addglobals_initialize.h"

/* Named Constants */
#define b_u (1.0)

/* Function Definitions */

/*
 * Arguments    : void
 * Return Type  : void
 */
void addglobals_initialize(void)
{
    rt_InitInfAndNaN(8U);
    u = b_u;
}

View the definition and declaration for the imported external global v and the imported external global pointer x.

v and x are declared as extern in the Variable Declarations section in addglobals_data.h.

/* Variable Declarations */
/* Declaration for custom storage class: ImportedExtern */
extern double v;

/* Declaration for custom storage class: ImportedExternPointer */
extern double *x;

Highlight Potential Data Type Issues in a Report

In this section...

“Enable Highlight Option Using the MATLAB Coder App” on page 90-2
“Enable Highlight Option Using the Command Line Interface” on page 90-3

If you have Embedded Coder, you have the option to highlight potential data types issues in the code generation report for standalone code generated from MATLAB code. If you enable this option, on the Code Insights tab, the report identifies single-precision and double-precision operations in the generated C/C++ code. If you have Fixed-Point Designer, the report also identifies expensive fixed-point operations.

To view potential data type issues in a code generation report:

1. Click the Code Insights tab.
2. Expand the Potential data type issues section.
3. Expand the data type issues section that you want to see.

For example, this report identifies MATLAB code that results in double-precision operations in the generated code.

The option to highlight potential data type issues is disabled by default.

Enable Highlight Option Using the MATLAB Coder App

1. On the Generate Code page, to open the Generate dialog box, click the Generate arrow.
2. Set Build type to one of the following:
   - Source Code
   - Static Library (.lib)
• Dynamic Library (.dll)
• Executable (.exe)

3  Click More Settings.
4  On the Debugging tab, select the Always create a code generation report and Highlight potential data type issues check boxes.

Enable Highlight Option Using the Command Line Interface

1  Create an embedded code configuration object for 'lib', 'dll', or 'exe':

```matlab
cfg = coder.config('lib','ecoder',true); % or dll or exe
```

2  Set the GenerateReport and HighlightPotentialDataTypeIssues configuration object properties to true:

```matlab
cfg.GenerateReport = true;
cfg.HighlightPotentialDataTypeIssues = true;
```

Find Potential Data Type Issues in Generated Code

Data Type Issues Overview

When you generate C code from MATLAB code, you can highlight potential data type issues in the C code generation report. The report highlights MATLAB code that requires single-precision, double-precision, or expensive fixed-point operations. The expensive fixed-point operations checks require a Fixed-Point Designer.

- The double-precision check highlights expressions that result in a double-precision operation. When trying to achieve a strict-single or fixed-point design, manual inspection of code can be time-consuming and error prone.

For a strict-single precision design, specify a standard math library that supports single-precision implementations. To change the library for a project, during the Generate Code step, in the project settings dialog box, on the Custom Code tab, set the Standard math library to C99 (ISO).

- The single-precision check highlights expressions that result in a single operation.

- The expensive fixed-point operations check identifies optimization opportunities for fixed-point code. It highlights expressions in the MATLAB code that require cumbersome multiplication or division, expensive rounding, expensive comparison, or multiword operations. For more information on optimizing generated fixed-point code, see “Tips for Making Generated Code More Efficient” (Fixed-Point Designer).
Enable Highlighting of Potential Data Type Issues

Enable the highlight option using the MATLAB Coder app

1. On the **Generate Code** page, to open the **Generate** dialog box, click the **Generate** arrow.
2. Set **Build type** to one of the following:
   - Source Code
   - Static Library (.lib)
   - Dynamic Library (.dll)
   - Executable (.exe)
3. Click **More Settings**.
4. On the **Debugging** tab, select the **Always create a code generation report** and **Highlight potential data type issues** check boxes.

Enable the highlight option using the command-line interface

1. Create an embedded code configuration object for 'lib', 'dll', or 'exe':
   ```
   cfg = coder.config('lib','ecoder',true); % or dll or exe
   ```
2. Set the **GenerateReport** and **HighlightPotentialDataTypeIssues** configuration object properties to true:
   ```
   cfg.GenerateReport = true;
   cfg.HighlightPotentialDataTypeIssues = true;
   ```

Find and Address Cumbersome Operations

Cumbersome operations usually occur due to an insufficient range of output. Avoid inputs to a multiply or divide operation that have word lengths larger than the base integer type of your processor. Software can process operations with larger word lengths, but this approach requires more code and runs slower.

This example requires Embedded Coder and Fixed-Point Designer. The target word length for the processor in this example is 64.

1. Create the function `myMul`.
function out = myMul(in1, in2)
    out = fi(in1*in2, 1, 64, 0);
end

Generate code for myMul.

cfg = coder.config('lib');
cfg.GenerateReport = true;
cfg.HighlightPotentialDataTypeIssues = true;
fm = fimath('ProductMode', 'SpecifyPrecision', 'ProductWordLength', 64);
codegen -config cfg myMul -args {fi(1, 1, 64, 4, fm), fi(1, 1, 64, 4, fm)}

Click View report.

In the code generation report, click the Code Insights tab.

Expand the Potential data type issues section. Then, expand the Expensive fixed-point operations section.

The report flags the expression in1 * in2. To resolve the issue, modify the data types of in1 and in2 so that the word length of the product does not exceed the target word length of 64.

Find and Address Expensive Rounding

Traditional handwritten code, especially for control applications, almost always uses "no effort" rounding. For example, for unsigned integers and two's complement signed integers, shifting right and dropping the bits is equivalent to rounding to floor. To get results comparable to, or better than, what you expect from traditional handwritten code, use the floor rounding method.

This example requires Embedded Coder and Fixed-Point Designer.

1 Create the function myRounding.

    function [quot] = myRounding(in1, in2)
        quot = in1 / in2;
    end

2 Generate code for myRounding.

    cfg = coder.config('lib');
    cfg.GenerateReport = true;
cfg.HighlightPotentialDataTypeIssues = true;
codegen -config cfg myRounding -args {fi(1, 1, 16, 2), fi(1, 1, 16, 4)}

3 Click **View report**.

4 In the code generation report, click the **Code Insights** tab.

5 Expand the **Potential data type issues** section. Then, expand the **Expensive fixed-point operations** section.

The division operation \( \frac{\text{in1}}{\text{in2}} \) uses the default rounding method, **nearest**. Changing the rounding method to **Floor** provides a more efficient implementation.

---

**Find and Address Expensive Comparison Operations**

Comparison operations generate extra code when a casting operation is required to do the comparison. For example, before comparing an unsigned integer to a signed integer, one of the inputs must be cast to the signedness of the other. Consider optimizing the data types of the input arguments so that a cast is not required in the generated code.

This example requires Embedded Coder and Fixed-Point Designer.

1 Create the function **myRelop**.

   ```matlab
   function out = myRelop(in1, in2)
       out = in1 > in2;
   end
   ```

2 Generate code for **myRelop**.

   ```matlab
   cfg = coder.config('lib');
   cfg.GenerateReport = true;
   cfg.HighlightPotentialDataTypeIssues = true;
   codegen -config cfg myRelop -args {fi(1, 1, 14, 3, 1), fi(1, 0, 14, 3, 1)}
   ```

3 Click **View report**.

4 In the code generation report, click the **Code Insights** tab.

5 Expand the **Potential data type issues** section. Then, expand the **Expensive fixed-point operations** section.
The first input argument, in1, is signed, while in2 is unsigned. Extra code is generated because a cast must occur before the two inputs can be compared.

Change the signedness and scaling of one of the inputs to generate more efficient code.

Find and Address Multiword Operations

Multiword operations can be inefficient on hardware. When an operation has an input or output data type larger than the largest word size of your processor, the generated code contains multiword operations. You can avoid multiword operations in the generated code by specifying local fimath properties for variables. You can also manually specify input and output word lengths of operations that generate multiword code.

This example requires Embedded Coder and Fixed-Point Designer. In this example, the target word length is 64.

1. Create the function myMul.

   ```matlab
   function out = myMul(in1, in2)
       out = in1 * in2;
   end
   ```

2. Generate code for myMul.

   ```bash
   cfg = coder.config('lib');
   cfg.GenerateReport = true;
   cfg.HighlightPotentialDataTypeIssues = true;
   codegen -config cfg myMul -args {fi(1, 1, 33, 4), fi(1, 1, 32, 4)}
   ```

3. Click View report.

4. In the code generation report, click the Code Insights tab.

5. Expand the Potential data type issues section. Then, expand the Expensive fixed-point operations section.
The report flags the `in1 * in2` operation in line 2 of `myMul`.

6 In the code pane, pause over `in1`, `in2`, and the expression `in1 * in2`. You see that:

- The word length of `in1` is 33 bits and the word length of `in2` is 32 bits.
- The word length of the expression `in1 * in2` is 65 bits.

The software detects a multiword operation because the word length 65 is larger than the target word length of 64.

7 To resolve this issue, modify the data types of `in1` and `in2` so that the word length of the product does not exceed the target word length. Alternatively, specify the `ProductMode` property of the local `fimath` object.

- “Code Generation Reports” (MATLAB Coder)
PIL Execution with ARM Cortex-A at the Command Line

This example shows how to set up a PIL execution to verify generated code at the command line.

You can use processor-in-the-loop (PIL) executions to verify generated code that you deploy to target hardware by using a MATLAB Coder procedure. You can profile algorithm performance and speed for your generated code. To verify generated code with the MATLAB Coder app, you must have an Embedded Coder license.

This PIL execution is available with these hardware support packages. To use the PIL execution, install one of these support packages.

• Embedded Coder Support Package for BeagleBone® Black Hardware
• Embedded Coder Support Package for ARM Cortex-A Processors

In the Command Window, select the hardware for PIL execution.

```matlab
hw = coder.hardware('ARM Cortex-A9 (QEMU)')

hw =

Hardware with properties:

    Name: 'ARM Cortex-A9 (QEMU)'
    CPUClockRate: 1000

When using the BeagleBone hardware, more hardware properties are supported (Username, Password, and DeviceAddress). Set these properties based on your specific hardware or application.

```matlab
hw = coder.hardware('BeagleBone Black')

hw =

Hardware with properties:

    Name: 'BeagleBone Black'
    CPUClockRate: 1000
    Password: 'root'
    Username: 'admin'
    DeviceAddress: '192.168.1.10'
```

Add the hardware to the MATLAB Coder configuration object.
cfg = coder.config('lib','ecoder',true);
cfg.VerificationMode = 'PIL';
cfg.Hardware = hw;

Generate PIL code for a function, averaging_filter.

codegen -config cfg averaging_filter -args {zeros(1,16)}

For more information on the averaging_filter function, see “Averaging Filter” (MATLAB Coder).

For another example of PIL verification, see the "Processor-in-the-Loop Verification of MATLAB Functions" page in the documentation of the Embedded Coder Support Package for ARM Cortex-A Processors. To install the Embedded Coder Support Package for ARM Cortex-A Processors, see “Supported Hardware”.
PIL Execution with ARM Cortex-A by Using the MATLAB Coder App

You can use processor-in-the-loop (PIL) executions to verify generated code that you deploy to target hardware by using a MATLAB Coder procedure. You can profile algorithm performance and speed for your generated code. To verify generated code with the MATLAB Coder app, you must have an Embedded Coder license.

This PIL execution is available with these hardware support packages. To use the PIL execution, install one of these support packages.

- Embedded Coder Support Package for BeagleBone Black Hardware
- Embedded Coder Support Package for ARM Cortex-A Processors

You can set up PIL execution with the MATLAB Coder app.

To configure the build type and hardware board:

1. On the Generate Code page, in the Generate dialog box:
   - Set the Build type to Static Library.
   - Clear the Generate code only check box.
   - Set the Hardware Board to BeagleBone Black or ARM Cortex-A9 (QEMU).
2. If necessary, modify the settings for your board. To modify the settings, click More Settings, and then click Hardware.
3. To generate the library, click Generate.
4. Set up your PIL execution. Click Verify Code to open the Verify Code dialog box.

   Because the hardware board is not MATLAB Host Computer, the Verify Code dialog box is configured for PIL execution.

   In the Verify Code dialog box:
   - Enter the name of the test file to use for PIL execution.
   - Select Generated code.
5. To start the PIL execution, click Run Generated Code.
6. To stop the PIL execution, click Stop.
For another example of PIL verification, see the "Processor-in-the-Loop Verification of MATLAB Functions" page in the documentation of the Embedded Coder Support Package for ARM Cortex-A Processors. Install the support package to view the documentation.
Interactively Trace Between MATLAB Code and Generated C/C++ Code

This example shows how to trace between MATLAB source code and the generated C/C++ code. Tracing between source code and generated code helps you to:

- Understand how the code generator implemented your algorithm.
- Debug issues in the generated code.
- Evaluate the quality of the generated code.

If you have Embedded Coder and enable production of a code generation report with traceability, you can view MATLAB source code and generated C/C++ code next to each other. As you move your pointer over code, you can follow highlighted traces to the corresponding generated code or source MATLAB code.

Create the MATLAB Source Code

To illustrate interactive traceability, this example produces a report for generation of a C static library for a MATLAB function `lpsolve` that solves the linear program:

- maximize \( y = c^*x \)
- subject to \( A^*x \leq b \)
- where \( x \geq 0 \) and \( b \geq 0 \)

\[ \text{lpsolve} \]

\[
\begin{verbatim}
%Attempts to solve the linear program:
% maximize y = c^*x
% subject to: A^*x <= b,
% where x >= 0 and b >= 0
%
% using the dictionary form of the simplex algorithm.
%
% c must be a double, real row vector.
% b must be a double, real column vector.
% A must be a double, real, non-empty matrix with
% size(A) = [length(b),length(c)].
%
% Compare to
\end{verbatim}
\]
% x = linprog(-c(:),A,b,[],[],zeros(length(c),1))
% y = c*x
%
% Copyright 2011-2018 The MathWorks, Inc.

function [x,y] = lpsolve(c,A,b)
%#codegen
narginchk(3,3);
m = int32(size(A,1));
n = int32(size(A,2));
if ~validInputs(c,A,b)
    % Something is wrong with the inputs. Return NaNs.
    x = nan(n,1);
    y = nan;
    return
end

cn = c;
nIdx = 1:n; % indices of non-basic variables
bIdx = n + (1:m); % indices of basic variables
% Perform iterations.
j = findPivotColumn(cn,nIdx);
unbounded = false;
while j > 0 && ~unbounded
    [i,r] = findPivotRow(j,A,b);
    if i == 0 || isinf(r)
        unbounded = true;
    else
        b(i) = r;
        % Take account of the variables entering and leaving the basis.
        entering = nIdx(j);
        leaving = bIdx(i);
        bIdx(i) = entering;
        nIdx(j) = leaving;
        [cn,A,b] = pivot(cn,A,b,i,j);
        j = findPivotColumn(cn,nIdx);
    end
end
% Construct the solution.
if unbounded
    x = nan(n,1);
    y = inf;
else
    x = zeros(n,1);
    y = 0;
end
for k = 1:m
    j = bIdx(k);
    if j <= n
        x(j) = b(k);
        y = y + c(j)*x(j);
    end
end

function p = validInputs(c,A,b)
coder.inline('never');
% All inputs must be double.
p = isa(c,'double') && isa(A,'double') && isa(b,'double');
% All inputs must be real.
p = p && isreal(c) && isreal(A) && isreal(b);
% A must be a non-empty matrix.
p = p && ismatrix(A) && ~isempty(A);
% c must be a row-vector with length = size(A,2).
p = p && isrow(c) && size(c,2) == size(A,2);
% b must be a column-vector with length = size(A,1).
p = p && iscolumn(b) && size(b,1) == size(A,1);
% The elements of b must be non-negative.
p = p && all(b(:) >= 0);

function [c,A,b] = pivot(c,A,b,i,j)
% Pivot on element i,j.
coder.inline('never');

x % display x
y % display y

Copy lpsole.m and lpsole_test.m to a writable folder.
copyfile(fullfile(docroot, 'toolbox', 'ecoder', 'examples', 'lpsole.m'))
copyfile(fullfile(docroot, 'toolbox', 'ecoder', 'examples', 'lpsole_test.m'))

Prepare for Code Generation

Before you generate C/C++ code, it is a best practice to screen your MATLAB code for
code generation readiness.
coder.screener('lpsole')

The code generation readiness report indicates that lpsole is suitable for code
generation.

It is also a best practice to check for run-time issues by generating and testing a MEX
function.

• To specify the types of the inputs arguments, pass representative input values to the
codegen -args option. Alternatively, because you have a test function, you can use
coder.getArgTypes to determine the types.
• To generate and test a MEX function, use the -test option.

c = [2 3 1 1];
A = [2 3 1 -1;1 0 2 1;0 2 1 1];
b = [27;9;18];
codegen lpsole -args {c A b} -test lpsole_test

Running test file: 'lpsole_test' with MEX function 'lpsole_mex'.

90-18
x =
  5
  7
  0
  4

y =
  35

codegen successfully generates and runs the MEX function.

**Produce a Code Generation Report with Traceability**

To generate a report that has interactive traceability:

- Create a `coder.EmbeddedCodeConfig` object. The `EnableTraceability` property controls traceability. By default, the `EnableTraceability` property is `true`.
- Specify the types of the input arguments by passing representative input values to the `-args` option.
- Enable production of a code generation report by using the `-report` option.

```matlab
cfg = coder.config('lib', 'ecoder', true);
codegen -config cfg lpsolve -args {c A b} -report
```

**Access Trace Mode in the Report**

To open the code generation report, click **View report**.

In the code pane, you see `lpsolve.m`.

To enable tracing, on the **Report** tab, click **Trace Code**.
You see the MATLAB source code and the generated C code next to each other.

**Trace Code**

You can trace from the MATLAB code to the C code or from the C code to the MATLAB code. Traceable code is marked with blue on the side that you are tracing from and with orange on the side that you are tracing to. As you move your pointer over traceable code, the code is highlighted in purple and you see the traces to the corresponding code on the
other side. When you select highlighted code by clicking it, the code becomes yellow and you can see the traces even when you move your pointer away from the selection. The code remains selected until you press Esc or select different code. To change the side that you are tracing from, select code on the other side.

Explore tracing in the example report.

1 In the MATLAB code, point to the while-loop that starts at line 38 and scroll down until the entire while-loop is in view.

You see this symbol that tells you that the highlighted MATLAB code has one trace that is not in view.

You see the corresponding C code in a separate window in the C code pane.

2 In the C code pane, scroll down until you see the C code that corresponds to the while loop.
3 In the MATLAB code, move your pointer over different syntax elements in the while loop. Highlight variables, expressions, and code blocks. When you move your pointer over expressions that are part of larger expressions, different shades of purple help you to find the relevant expression in the corresponding C code. For example, at line 43, pause over i.

4 In the MATLAB code, move your pointer back to the while-loop that starts at line 38. When the entire loop is highlighted in purple, select it by clicking. When you move your pointer outside of the trace, the yellow highlighting identifies the selected trace.

To clear the selection, press Esc or select different code.
View Multiple Traces

When code traces to more than one place in the corresponding source or generated code:

- If you pause over the code that you are tracing, at the top of the code pane, you see the number of traces.
- If some traces are not in view, you see a symbol that tells you how many traces are out of view.

- In the code pane, if you select the code that you want to trace, at the top of the code pane, you can select the trace that you want to see.

In the report for `lpsolve`, view multiple traces.

1. Pause over line 36.
   
   At the top of the code pane, you see that line 36 has two traces.

2. Select line 36.
   
   At the top of the code pane, you see the location of the first trace.

3. To list all traces, click the arrow to the right of the traces.

View Traces to Different Files

In the code generation report for `lpsolve`, all traces from the MATLAB code go to one C file `lpsolve.c`. If MATLAB code traces to multiple C files, above the C code, you see a symbol such as that provides the number of additional files in which you can find a trace. If you click the symbol, you can select the file that you want to see. If you select the MATLAB code, then you can select the trace that you want to see.
Likewise, above the MATLAB source code, a symbol such as ☐ indicates that the highlighted C code traces to multiple MATLAB files.

**Switch the Locations of the Source and Generated Code**

1. To view lpsolve.c on the left side of the code pane, in the list of generated files, click lpsolve.c.

2. To view the MATLAB code on the left side of the code pane, click a MATLAB function, for example, lpsolve.

**Enable Code Tooltips and Links**

When you are not in trace mode:

- In the MATLAB code, if you point to a variable or expression, a tooltip provides information such as the type.
- In the C code, links go to other parts of the code such as type or function definitions.

When you are in trace mode, to enable MATLAB code tooltips and C code links, hold down Ctrl. MATLAB code tooltips are available only for a selected MATLAB function.

In the report for lpsolve, view type information for a variable.

1. In the MATLAB Source pane, select pivot.
2 In the code pane, hold down **Ctrl** and pause over the input argument `i`.

![Variable Info](image)

**Note** On a Macintosh platform, use the **Command** key instead of **Ctrl**.

### Disable Traceability

To produce a code generation report that does not include traceability:

- In a `coder.EmbeddedCodeConfig` object, set the `EnableTraceability` property to `false`.
- In the MATLAB Coder app, set **Enable code traceability** to No.

Polyspace Verification of C/C++ Code Generated by MATLAB Coder

To check for run-time errors in C/C++ code generated from MATLAB code, you can use Polyspace Code Prover. To check for defects, you can use Polyspace Bug Finder. If you have Polyspace and Embedded Coder, Polyspace is integrated into the MATLAB Coder workflow.

• In the MATLAB Coder app, you can run Polyspace analysis without additional setup.
• At the command line, after code generation with codegen, you can run Polyspace analysis on the generated code by providing the code generation output folder to pslinkrun.

Run Polyspace Analysis in the MATLAB Coder App

1 Generate standalone C/C++ code (a static library, dynamically linked library, or executable program).
2 On the Generate Code page, click Polyspace.
3 Select the options. See “Configure Advanced Polyspace Options in MATLAB Coder App” (Polyspace Code Prover).
4 Click Run.

The app logs the analysis output on the Polyspace Log tab and opens the Polyspace user interface.

Run Polyspace Analysis on Code Generated by codegen

1 Create a pslinkoptions object for verification of code generated by MATLAB Coder.
2 As needed, change object properties:
   • In the ResultDir property, specify the name of the folder for the Polyspace results.
   • In the VerificationMode property, specify the Polyspace verification product.
3 Run the verification by using pslinkrun. Provide the pslinkoptions object and the folder that contains the generated code.
4 To view verification results, open the Polyspace user interface.
For example, suppose that you generated a static library for the MATLAB function `myFunction` and that the code generation output folder is `codegen/lib/myFunction`. To run Polyspace Code Prover on the generated code, use this code:

```matlab
opts = pslinkoptions('codegen');
opts.ResultDir = 'polyspace';
opts.VerificationMode = 'CodeProver';
pslinkrun('-codegenfolder', 'codegen/lib/myFunction', opts);
polyspaceCodeProver('polyspace/myFunction.psprj');
```

You can also set the `VerificationMode` property to 'BugFinder' and view verification results by using `polyspaceBugFinder`.

### Review Analysis Results

In the **Results List** pane of the Polyspace user interface, review the run-time checks. See whether you can trace the issues back to the original MATLAB code. See “Interactively Trace Between MATLAB Code and Generated C/C++ Code” on page 90-14.

For example, an operation in the C code might overflow because Polyspace assumes an unbounded range for a function input. Consider specifying a constraint on the input and reanalyzing the code with Polyspace. See “Run Polyspace on C/C++ Code Generated from MATLAB Code” (Polyspace Code Prover).
