- “Application Objectives Using Code Generation Advisor” on page 31-18
Use Configuration Reference to Select Code Generation Target

This example shows how to use a configuration reference to select a code generation target for a model reference hierarchy without modifying individual models.

Open Example Model

Open the example model `slexConfigSetRefExample`.

```matlab
open_system('slexConfigSetRefExample');
```

Sharing and Switching Configurations with Configuration Reference

This model and its referenced model use the same configuration set stored in data dictionary.

To open the active configuration set for the model `slexConfigSetRefExample`, from the model editor menu, select **Simulation > Model Configuration Parameters**.
The dialog box indicates that the model is using a referenced configuration set, Reference, located in the data dictionary, slexConfigSetRefData.sldd.

In the model editor, double-click the Model block, Amplifier.

open_system('slexConfigSetRefExample/Amplifier');
Sharing and Switching Configurations with Configuration Reference

This model and its parent model use the same configuration set stored in data dictionary.

Open the active configuration set for this model. The name and location for the referenced configuration is the same as in `slexConfigSetRefExample`.
Open the Referenced Configuration Set

To open the referenced configuration set, click the **Open** button in either of the Configuration Reference dialog boxes. The Model Explorer opens and displays the referenced configuration set.
In this example, the referenced configuration set is another configuration reference, Configuration_ERT. To open this referenced configuration, in the right panel, click the Open button. Model Explorer displays the configuration set Configuration_ERT.
Generate Code for ERT Target

The referenced configuration set is customized for ERT code generation. To generate code, press Ctrl+B.

rtwbuild('slexConfigSetRefExample');

### Starting build procedure for model: slexConfigSetRefMdlRef
### Successful completion of code generation for model: slexConfigSetRefMdlRef
### Starting build procedure for model: slexConfigSetRefExample
### Successful completion of code generation for model: slexConfigSetRefExample

The code generation report displays once code generation is complete.
Switch Targets and Generate Code for AUTOSAR Target

In the middle pane of the Model Explorer, there is another configuration set, Configuration_AUTOSAR, that is customized for AUTOSAR code generation. In the right panel, in the Name drop-down list, select Configuration_AUTOSAR. slexConfigSetRefExample and its referenced model, slexConfigSetMdlRef, now both use the configuration set, Configuration_AUTOSAR.

Because you edited the configuration reference, the data dictionary has unsaved changes. The configurations are stored outside of the models so the models do not have unsaved changes.
If you have downloaded the AUTOSAR package, you can now generate code for an AUTOSAR target. In the model editor window, press Ctrl+B.
Check Model and Configuration for Code Generation

You can use the Model Advisor checks to assess model readiness to generate code. To check and configure your model for code generation application objectives such as traceability or debugging, use the Code Generation Advisor.

Check Mode for Code Efficiency with Model Advisor

To check model rtwdemo_throttlecntrl for code efficiency, use the Model Advisor.

1. Open rtwdemo_throttlecntrl. Save a copy as throttlecntrl in a writable location on your MATLAB path.
2. To start the Model Advisor, select Analysis > Model Advisor > Model Advisor. A dialog box opens showing the model system hierarchy.
3. Click throttlecntrl and then click OK. The Model Advisor window opens.
4. Expand By Task > Code Generation Efficiency. To check your model for code generation efficiency, use the checks in the folder. By default, checks that do not trigger an Update Diagram are selected. The checks available for code generation efficiency depend on whether you have a Simulink Coder or Embedded Coder license.
5. In the left pane, select the remaining checks, and then select Code Generation Efficiency.
6. In the right pane, select Show report after run and click Run Selected Checks. The report shows a Run Summary that flags check warnings.
7. Review the report. The warnings highlight issues that impact code efficiency. For more information about the report, see “View Model Advisor Reports” (Simulink).
Check Model During Code Generation with Code Generation Advisor

To review a model as part of the code generation process, use the Code Generation Advisor:

1. To specify your code generation objectives, on the **Configuration Parameters > Code Generation** pane, choose a value for the **Select objective** parameter.

2. On the **Configuration Parameters > Code Generation > General** pane, select one of the following from **Check model before generating code**:
   - On (proceed with warnings)
   - On (stop for warnings)

3. If you want to only generate code, select **Generate code only**. Otherwise clear the check box to build an executable.

4. Apply your changes, and then click **Generate Code/Build**. The Code Generation Advisor starts and reviews the top model and subsystems.

   If the Code Generation Advisor issues failures or warnings, and you specified:
   - On (proceed with warnings) — The Code Generation Advisor window opens while the build process proceeds. After the build process is complete, you can review the results.
   - On (stop for warnings) — The build process halts and displays the Diagnostic Viewer. To continue, you must review and resolve the Code Generation Advisor results or clear the **Check model before generating code** parameter.

5. In the Code Generation Advisor window, review the results by selecting a check from the left pane. The results for that check display in the right pane.

6. After reviewing the check results, you can choose to fix warnings and failures as described in “Fix a Model Check Warning or Failure” (Simulink).

**Note** When you specify an efficiency or Safety precaution objective, the Code Generation Advisor includes additional checks. When you make changes to one of these additional checks, previous check results can potentially become invalid and need to be rerun.

For more information, see “Set Objectives — Code Generation Advisor Dialog Box” (Simulink Coder)

Application Objectives Using Code Generation Advisor

Consider how your application objectives, such as efficiency, traceability, and safety, map to code generation options in a model configuration set. Parameters that you set in the Solver, Data Import/Export, Diagnostics, and Code Generation panes in the Configuration Parameters dialog box specify the behavior of a model in simulation and the code generated for the model.

Before generating code, or as part of the code generation process, you can use the Code Generation Advisor to review a model. When you choose to review a model before generating code, you specify which model, subsystem, or referenced model the Code Generation Advisor reviews. When you choose to review a model as part of the code generation process, the Code Generation Advisor reviews the entire system. The Code Generation Advisor uses the information presented in “Recommended Settings Summary for Model Configuration Parameters” to determine the parameter values that meet your objectives. When there is a conflict between multiple objectives, the higher-priority objective takes precedence.

Setting code generation objectives, and then running the Code Generation Advisor provides information on how to meet code generation objectives for your model. The Code Generation Advisor does not alter the generated code. You can use the Code Generation Advisor to make the suggested changes to your model. The generated code is changed only after you modify your model and regenerate code. When you use the Code Generation Advisor to set code generation objectives and check your model, the generated code includes comments identifying which objectives you specified, the checks the Code Generation Advisor ran on the model, and the results of running the checks.

If a model uses a configuration reference (Simulink), you can run the Code Generation Advisor to review your configuration parameter settings. However, the Code Generation Advisor cannot modify the configuration parameter settings.
High-Level Code Generation Objectives

Depending on the type of application that your model represents, you are likely to have specific high-level code generation objectives. For example, safety and traceability might be more critical than efficient use of memory. If you have specific objectives, you can quickly configure your model to meet those objectives by selecting and prioritizing from these code generation objectives:

- **Execution efficiency (all targets)** — Configure code generation settings to achieve fast execution time.
- **ROM efficiency (ERT-based targets)** — Configure code generation settings to reduce ROM usage.
- **RAM efficiency (ERT-based targets)** — Configure code generation settings to reduce RAM usage.
- **Traceability (ERT-based targets)** — Configure code generation settings to provide mapping between model elements and code.
- **Safety precaution (ERT-based targets)** — Configure code generation settings to increase clarity, determinism, robustness, and verifiability of the code.
- **Debugging (all targets)** — Configure code generation settings to debug the code generation build process.
- **MISRA C:2012 guidelines (ERT-based targets)** — Configure code generation settings to increase compliance with MISRA C:2012 guidelines.
- **Polyspace (ERT-based targets)** — Configure code generation settings to prepare the code for Polyspace analysis.

If you select the MISRA C:2012 guidelines code generation objective, the Code Generation Advisor:

- Checks the model configuration settings for compliance with the MISRA C:2012 configuration setting recommendations.
- Checks for blocks that are not supported or recommended for MISRA C:2012 compliant code generation.

**Configure Model for Code Generation Objectives Using Code Generation Advisor**

This example shows how to use the Code Generation Advisor to check and configure your model to meet code generation objectives:
1. On the menu bar, select **Code > C/C++ Code > Code Generation Advisor**.

2. In the System Selector window, select the model or subsystem that you want to review, and then click **OK**.

3. In the Code Generation Advisor, on the **Code Generation Objectives** pane, select the code generation objectives from the drop-down list (GRT-based targets). As you select objectives, on the left pane, the Code Generation Advisor updates the list of checks it will run on your model. If your model is configured with an ERT-based target, more objectives are available.

4. Click **Run Selected Checks** to run the checks listed in the left pane of the Code Generation Advisor.

5. In the Code Generation Advisor window, review the results for **Check model configuration settings against code generation objectives** by selecting it from the left pane. The results for that check are displayed in the right pane.

**Check model configuration settings against code generation objectives** triggers a warning for these issues:

- Parameters are set to values other than the value recommended for the specified code generation objectives.
- Selected code generation objectives differ from the objectives set in the model.

Click **Modify Parameters** to set:

- Parameters to the value recommended for the specified code generation objectives.
- Code generation objectives in the model to the objectives specified in the Code Generation Advisor.

6. In the Code Generation Advisor window, review the results for the remaining checks by selecting them from the left pane. The results for the checks display in the right pane.

7. After reviewing the check results, you can choose to fix warnings and failures, as described in “Fix a Model Check Warning or Failure” (Simulink).

When you specify an efficiency or Safety precaution objective, the Code Generation Advisor includes additional checks. When you make changes to one of these additional checks, previous check results can potentially become invalid and need to be rerun.
Configure Model for Code Generation Objectives by Using Configuration Parameters Dialog Box

This example shows how to check and configure the code generation objectives in the Configuration Parameters dialog box:

1. Open the Configuration Parameters dialog box and select Code Generation.
2. Select or confirm selection of a System target file.
3. Specify the objectives using the Select objectives drop-down list (GRT-based targets) or clicking Set Objectives button (ERT-based targets). Clicking Set Objectives opens the “Set Objectives — Code Generation Advisor Dialog Box” (Simulink Coder) dialog box.
4. Click Check Model to run the model checks. The Code Generation Advisor dialog box opens. The Code Generation Advisor uses the code generation objectives to determine which model checks to run.
5. On the left pane, the Code Generation Advisor lists the checks run on the model and the results. Click each warning to see the suggestions for changes that you can make to your model to pass the check.
6. Determine which changes to make to your model. On the right pane of the Code Generation Advisor, follow the instructions listed for each check to modify the model.
Simulink Coder Model Advisor Checks for Standards and Code Efficiency

To check that your model meets standards and is ready to generate code, you can use the Model Advisor checks available with Simulink Coder.

- To start the Model Advisor, in the model window, select **Analysis > Model Advisor > Model Advisor**.
- In the Model Advisor window, expand the **By Task** folder. The folder contains Model Advisor checks that you can run to help accomplish the task.

For more information about the Model Advisor, see “Run Model Checks” (Simulink).

The table summarizes the Simulink Coder Model Advisor checks that are available in the **By Task** folders.

## Configure Code Comments

Configure how the code generator inserts comments into generated code by modifying parameters on the **Code Generation > Comments** pane.

<table>
<thead>
<tr>
<th>Goal</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Include comments in generated code</td>
<td><strong>Include comments</strong> (Simulink Coder). Selecting this parameter allows you to select one or more autogenerated comment types to be placed in the code.</td>
</tr>
<tr>
<td>Include comments that describe a Simulink block's code</td>
<td><strong>Simulink block comments</strong> (Simulink Coder). Selecting this parameter includes the comments before the Simulink block’s code in the generated code. In Embedded Coder, use <strong>Trace to model using</strong> (Simulink Coder) to select <strong>Block path</strong> or <strong>Simulink identifier</strong> as the comment format.</td>
</tr>
<tr>
<td>Include comments that describe Stateflow objects</td>
<td><strong>Stateflow object comments</strong> (Simulink Coder). Selecting this parameter includes the comments describing Stateflow objects in the generated code. In Embedded Coder, use <strong>Trace to model using</strong> (Simulink Coder) to select <strong>Block path</strong> or <strong>Simulink identifier</strong> as the comment format.</td>
</tr>
<tr>
<td>Include MATLAB source code as comments</td>
<td><strong>MATLAB source code as comments</strong> (Simulink Coder). Selecting this parameter inserts these comments preceding the associated generated code. The function signature is included in the function banner.</td>
</tr>
<tr>
<td>Include comments for eliminated blocks</td>
<td><strong>Show eliminated blocks</strong> (Simulink Coder). Selecting this parameter includes comments for blocks that were eliminated as the result of optimizations, such as inlining parameters.</td>
</tr>
<tr>
<td>Include parameter comments regardless of the number of parameters</td>
<td><strong>Verbose comments for SimulinkGlobal storage class</strong> (Simulink Coder). Selecting this parameter includes comments for parameter variable names and names of source blocks in the model parameter structure declaration in <code>model_prm.h</code>. If you do not select this parameter, parameter comments are generated if less than 1000 parameters are declared. This reduces the size of the generated file for models with a large number of parameters.</td>
</tr>
<tr>
<td>Include MATLAB user comments</td>
<td><strong>MATLAB user comments</strong> (Simulink Coder). Selecting this parameter includes function description comments and other user comments from MATLAB code as comments in the generated code.</td>
</tr>
<tr>
<td>Specify comment style</td>
<td><strong>Comment style</strong> (Simulink Coder). Select <strong>Auto</strong>, <strong>Multi-line</strong> or <strong>Single-line</strong> as the style of comments in the generated code.</td>
</tr>
</tbody>
</table>
**Note** When you configure the code generator to produce code that includes comments, the code generator includes text for model parameters, block names, signal names, and Stateflow object names in the generated code comments. If the text includes characters that are unrepresented in the character set encoding for the model, the code generator replaces the characters with XML escape sequences. For example, the code generator replaces the Japanese full-width Katakana letter .policy with the escape sequence `&#x30A2;`. For more information, see “Internationalization and Code Generation” (Simulink Coder).
Construction of Generated Identifiers

For GRT and RSim targets, the code generator automatically constructs identifiers for variables and functions in the generated code. These identifiers represent:

- Signals and parameters that have Auto storage class
- Subsystem function names that are not user-defined
- Stateflow names

The components of a generated identifier include:

- The root model name, followed by
- The name of the generating object (signal, parameter, state, and so on), followed by
- Unique name-mangling text

The code generator conditionally generates the name-mangling text to resolve potential conflicts with other generated identifiers.

To configure how the code generator names identifiers and objects, see:

- “Specify Identifier Length to Avoid Naming Collisions” on page 31-28
- “Specify Reserved Names for Generated Identifiers” on page 31-29

The code generator reserves certain words for its own use as keywords of the generated code language. For more information, see “Reserved Keywords” on page 31-30.

With an Embedded Coder license, you can specify parameters to control identifier formats, mangle length, scalar inlined parameters, and Simulink data object naming rules. For more information, see “Customize Generated Identifier Naming Rules” on page 39-14.
Identifier Name Collisions and Mangling

In identifier generation, a circumstance that would cause generation of two or more identical identifiers is called a name collision. When a potential name collision exists, unique name-mangling text is generated and inserted into each of the potentially conflicting identifiers. Each set of name-mangling characters is unique for each generated identifier.

Identifier Name Collisions with Referenced Models

Referenced models can introduce additional naming constraints. Within a model that uses referenced models, collisions between the names of the models cannot exist. When you generate code from a model that includes referenced models, the Maximum identifier length parameter must be large enough to accommodate the root model name and name-mangling text. A code generation error occurs if Maximum identifier length is too small.

When a name conflict occurs between an identifier within the scope of a higher-level model and an identifier within the scope of a referenced model, the identifier from the referenced model is preserved. Name mangling is performed on the identifier from the higher-level model.

For more information on referenced models, see “Parameterize Instances of a Reusable Referenced Model” (Simulink).
Specify Identifier Length to Avoid Naming Collisions

The length of a generated identifier is limited by the **Maximum identifier length** parameter specified on the **Symbols** pane of the Configuration Parameters dialog box. The **Maximum identifier length** field allows you to limit the number of characters in function, type definition, and variable names. The default is 31 characters. This is also the minimum length you can specify. The maximum is 256 characters.

When there is a potential name collision between two identifiers, name-mangling text is generated. The text has the minimum number of characters required to avoid the collision. The other symbol components are then inserted. If **Maximum identifier length** is not large enough to accommodate full expansions of the other components, they are truncated. To avoid this outcome, it is good practice to:

- Avoid name collisions by not using default block names (for example, Gain1, Gain2...) when the model includes multiple blocks of the same type.
- For subsystems, make them atomic and reusable.
- Increase the **Maximum identifier length** parameter to accommodate the length of the identifier you expect to generate.
Specify Reserved Names for Generated Identifiers

You can specify a set of reserved keywords that the code generation process should not use, facilitating code integration where functions and variables from external environments are unknown in the Simulink model. To create a list of reserved names, open the Configuration Parameters dialog box. On the Code Generation > Symbols pane, enter the keywords in the “Reserved names” (Simulink Coder) field.

If your model contains MATLAB Function or Stateflow blocks, the code generation process can use the reserved names specified for those blocks if you select Use the same reserved names as Simulation Target (Simulink Coder) on the Code Generation > Symbols pane.
Reserved Keywords

Generator keywords are reserved for internal use. Do not use them in models as identifiers or function names. Also avoid using C reserved keywords in models as identifiers or function names. If your model contains reserved keywords, code generation does not complete and an error message appears. To address the error, modify your model to use identifiers or names that are not reserved.

If you use the code generator to produce C++ code, your model must not contain the “Reserved Keywords for Code Generation” on page 31-31 nor the “C++ Reserved Keywords” on page 31-31.

Note You can register additional reserved identifiers in the Simulink environment. For more information, see “Specify Reserved Names for Generated Identifiers” on page 31-29.

### Code Generation Code Replacement Library Keywords

The list of code replacement library reserved keywords for your development environment varies depending on which libraries are registered. The list of available code replacement libraries varies depending on other installed products (for example, a target product), or if you used Embedded Coder to create and register custom code replacement libraries.

To generate a list of reserved keywords for libraries currently registered in your environment, use the following MATLAB function:

```matlab
lib_ids = RTW.TargetRegistry.getInstance.getTflReservedIdentifiers()
```

This function returns an array of library keywords. Specifying the input argument is optional.

**Note** To list the libraries currently registered in your environment, use the MATLAB command `crviewer`.

To generate a list of reserved keywords for a specific library that you are using to generate code, call the function passing the name of the library as displayed in the Code replacement library menu on the Code Generation > Interface pane of the Configuration Parameters dialog box. For example,

```matlab
lib_ids = RTW.TargetRegistry.getInstance.getTflReservedIdentifiers('GNU C99 Extensions')
```

Here is a partial example of the function output:

```matlab
>> lib_ids = ...
   RTW.TargetRegistry.getInstance.getTflReservedIdentifiers('GNU C99 Extensions')
lib_ids =
   'exp10'
   'exp10f'
```
Reserved Keywords

'acosf'
'acoshf'
'asinf'
'asinhf'
'atanf'
'atanhf'
...
'rt_lu_cplx'
'rt_lu_cplx_sgl'
'rt_lu_real'
'rt_lu_real_sgl'
'rt_mod_boolean'
'rt_rem_boolean'
'strcpy'
'utAssert'

Note Some of the returned keywords appear with the suffix $N$, for example, 'rt_atan2$N'. $N$ expands into the suffix _snf only if nonfinite numbers are supported. For example, 'rt_atan2$N' represents 'rt_atan2_snf' if nonfinite numbers are supported and 'rt_atan2' if nonfinite numbers are not supported. As a precaution, you should treat both forms of the keyword as reserved.
Debug

In the Configuration Parameters dialog box, use parameters on the **Diagnostics** pane and debugging parameters to configure a model such that the generated code and the build process are set for debugging. You can set parameters that apply to the model compilation phase, the target language code generation phase, or both.

Parameters in the following table will be helpful if you are writing TLC code for customizing targets, integrating legacy code, or developing new blocks.

<table>
<thead>
<tr>
<th>To...</th>
<th>Select...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Display progress information during code generation in the MATLAB Command Window</td>
<td>“Verbose build” (Simulink Coder). Compiler output also displays.</td>
</tr>
<tr>
<td>Prevent the build process from deleting the <code>model.rtw</code> file from the build folder at the end of the build</td>
<td>“Retain .rtw file” (Simulink Coder). This parameter is useful if you are modifying the target files, in which case you need to look at the <code>model.rtw</code> file.</td>
</tr>
<tr>
<td>Instruct the TLC profiler to analyze the performance of TLC code executed during code generation and generate a report</td>
<td>“Profile TLC” (Simulink Coder). The report is in HTML format and can be read in your web browser.</td>
</tr>
<tr>
<td>Start the TLC debugger during code generation</td>
<td>“Start TLC debugger when generating code” (Simulink Coder). Alternatively, enter the argument <code>-dc</code> for the “System target file” (Simulink Coder) parameter on the <strong>Code Generation</strong> pane. To start the debugger and run a debugger script, enter <code>-df filename</code> for <strong>System target file</strong>.</td>
</tr>
<tr>
<td><strong>To...</strong></td>
<td><strong>Select...</strong></td>
</tr>
<tr>
<td>---</td>
<td>---</td>
</tr>
<tr>
<td>Generate a report containing statistics indicating how many times the code generator reads each line of TLC code during code generation</td>
<td>“Start TLC coverage when generating code” (Simulink Coder). Alternatively, enter the argument -dg for the System Target File parameter on the Code Generation pane.</td>
</tr>
<tr>
<td>Halt a build if a user-supplied TLC file contains an <code>%assert</code> directive that evaluates to FALSE</td>
<td>“Enable TLC assertion” (Simulink Coder). Alternatively, you can use MATLAB commands to control TLC assertion handling. To set the flag on or off, use the <code>set_param</code> command. The default is off. ```matlab set_param(model, 'TLCAssertion', 'on</td>
</tr>
</tbody>
</table>
| Detect loss of tunability | “Detect loss of tunability” (Simulink) on the Diagnostics > Data Validity pane. You can use this parameter to report loss of tunability when an expression is reduced to a numeric expression. This can occur if a tunable workspace variable is modified by Mask Initialization code, or is used in an arithmetic expression with unsupported operators or functions. Possible values are:  
  • none — Loss of tunability can occur without notification.  
  • warning — Loss of tunability generates a warning (default).  
  • error — Loss of tunability generates an error. For a list of supported operators and functions, see “Tunable Expression Limitations” (Simulink Coder) |
<table>
<thead>
<tr>
<th>To...</th>
<th>Select...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable model verification (assertion) blocks</td>
<td>“Model Verification block enabling” (Simulink). Use this parameter to enable or disable model verification blocks such as Assert, Check Static Gap, and related range check blocks. The diagnostic applies to generated code and simulation behavior. For example, simulation and code generation ignore this parameter when model verification blocks are inside an S-function. Possible values are:</td>
</tr>
<tr>
<td></td>
<td>- User local settings</td>
</tr>
<tr>
<td></td>
<td>- Enable All</td>
</tr>
<tr>
<td></td>
<td>- Disable All</td>
</tr>
<tr>
<td></td>
<td>For Assertion blocks not disabled, generated code for a model includes one of the following statements, depending on the blocks input signal type (Boolean, real, or integer, respectively).</td>
</tr>
<tr>
<td></td>
<td>utAssert(input_signal);</td>
</tr>
<tr>
<td></td>
<td>utAssert(input_signal != 0.0);</td>
</tr>
<tr>
<td></td>
<td>utAssert(input_signal != 0);</td>
</tr>

| External Code by Using Model Configuration Parameters” (Simulink Coder).
When running a model in accelerator mode, the Simulink engine calls back to itself to execute assertion blocks instead of using generated code. Thus, user-defined callbacks are still called when assertions fail.

For more information about the TLC debugging options, see Debugging on “Target Language Compiler” (Simulink Coder). Also, consider using the Model Advisor as a tool for troubleshooting model builds.

Configure Model for Code Generation Objectives by Using Code Generation Advisor

In this section...

“High-Level Code Generation Objectives” on page 32-3
“Specify Objectives in Referenced Models” on page 32-3
“Configure Model Using Code Generation Advisor” on page 32-4
“Configure Model for Code Generation Objectives by Using Configuration Parameters Dialog Box” on page 32-6

Consider how your application objectives, such as efficiency, traceability, and safety, map to code generation parameters in a model configuration set. Parameters that you set in the Solver, Data Import/Export, Diagnostics, and Code Generation panes in the Configuration Parameters dialog box specify the behavior of a model in simulation and the code generated for the model.

Before generating code, or as part of the code generation process, you can use the Code Generation Advisor to review a model. When you choose to review a model before generating code, you specify which model, subsystem, or referenced model the Code Generation Advisor reviews. When you choose to review a model as part of the code generation process, the Code Generation Advisor reviews the entire system. The Code Generation Advisor uses the information presented in “Recommended Settings Summary for Model Configuration Parameters” to determine the parameter values that meet your objectives. When there is a conflict between multiple objectives, the higher-priority objective takes precedence.

Setting code generation objectives, and then running the Code Generation Advisor provides information on how to meet code generation objectives for your model. The Code Generation Advisor does not alter the generated code. You can use the Code Generation Advisor to make the suggested changes to your model. The generated code is changed only after you modify your model and regenerate code. When you use the Code Generation Advisor to set code generation objectives and check your model, the generated code includes comments identifying which objectives you specified, the checks that the Code Generation Advisor ran on the model, and the results of running the checks.

If a model uses a configuration reference (Simulink), you can run the Code Generation Advisor to review your configuration parameter settings. but the Code Generation Advisor cannot modify the configuration parameter settings.
High-Level Code Generation Objectives

Depending on the type of application that your model represents, you are likely to have specific high-level code generation objectives. For example, safety and traceability are more critical than efficient use of memory. If you have specific objectives, you can quickly configure your model to meet those objectives by selecting and prioritizing from these code generation objectives:

- Execution efficiency (all targets) — Configure code generation settings to achieve fast execution time.
- ROM efficiency (ERT-based targets) — Configure code generation settings to reduce ROM usage.
- RAM efficiency (ERT-based targets) — Configure code generation settings to reduce RAM usage.
- Traceability (ERT-based targets) — Configure code generation settings to provide mapping between model elements and code.
- Safety precaution (ERT-based targets) — Configure code generation settings to increase clarity, determinism, robustness, and verifiability of the code.
- Debugging (all targets) — Configure code generation settings to debug the code generation build process.
- MISRA C:2012 guidelines (ERT-based targets) — Configure code generation settings to increase compliance with MISRA C:2012 guidelines.
- Polyspace (ERT-based targets) — Configure code generation settings to prepare the code for Polyspace analysis.

If you select the MISRA C:2012 guidelines code generation objective, the Code Generation Advisor:

- Checks the model configuration settings for compliance with the MISRA C:2012 configuration setting recommendations.
- Checks for blocks that are not supported or recommended for MISRA C:2012 compliant code generation.

Specify Objectives in Referenced Models

When you check a model during the code generation process, you must specify the same objectives in the top model and referenced models. If you specify different objectives for the top model and referenced model, the build process generates an error.
To specify different objectives for the top model and each referenced model, review the models separately without generating code.

**Configure Model Using Code Generation Advisor**

This example shows how to use the Code Generation Advisor to check and configure your model to meet code generation objectives:

1. On the menu bar, select **Code > C/C++ Code > Code Generation Advisor**.

2. In the System Selector window, select the model or subsystem that you want to review, and then click **OK**.

3. In the Code Generation Advisor, on the **Code Generation Objectives** pane, select the code generation objectives. As you select objectives, on the left pane, the Code Generation Advisor updates the list of checks it runs on your model. If your model is configured with an ERT-based target, more objectives are available. For this example, the model is configured with an ERT-based target. If your objectives are execution efficiency and traceability, in that priority, do the following:
   
   **a**  **In Available objectives**, double-click **Execution efficiency**. **Execution efficiency** is added to **Selected objectives - prioritized**.

   **b**  **In Available objectives**, double-click **Traceability**. **Traceability** is added to **Selected objectives - prioritized** under **Execution efficiency**.

4. To run the checks listed in the left pane of the Code Generation Advisor, click **Run Selected Checks**.

5. In the Code Generation Advisor window, review the results for **Check model configuration settings against code generation objectives** by selecting it from the left pane. The results for that check are displayed in the right pane.
Check model configuration settings against code generation objectives triggers a warning for these issues:

- Parameters are set to values other than the value recommended for the specified code generation objectives.
- Selected code generation objectives differ from the objectives set in the model.

Click **Modify Parameters** to set:

- Parameters to the value recommended for the specified code generation objectives.
- Code generation objectives in the model to the objectives specified in the Code Generation Advisor.

In the Code Generation Advisor window, review the results for the remaining checks by selecting them from the left pane. The results for the checks display in the right pane.

After reviewing the check results, you can choose to fix warnings and failures, as described in “Fix a Model Check Warning or Failure” (Simulink).
When you specify an efficiency or Safety precaution objective, the Code Generation Advisor includes additional checks. When you make changes to one of these additional checks, previous check results can potentially become invalid and need to be rerun.

**Configure Model for Code Generation Objectives by Using Configuration Parameters Dialog Box**

This example shows how to configure and check your model to meet code generation objectives via the Configuration Parameters dialog box:

1. Open the Configuration Parameters dialog box. Select **Code Generation**.
2. Specify a system target file. If you specify an ERT-based target, more objectives are available. For this example, choose an ERT-based target such as ert.tlc.
3. Click **Set Objectives**.
4. In the “Set Objectives — Code Generation Advisor Dialog Box” (Simulink Coder), specify your objectives. For example, if your objectives are execution efficiency and traceability, in that priority, do the following:
   a. In **Available objectives**, double-click **Execution efficiency**. Execution efficiency is added to **Selected objectives - prioritized**.
   b. In **Available objectives**, double-click **Traceability**. Traceability is added to **Selected objectives - prioritized** under **Execution efficiency**.

<table>
<thead>
<tr>
<th>Available objectives</th>
<th>Selected objectives - prioritized</th>
</tr>
</thead>
<tbody>
<tr>
<td>ROM efficiency</td>
<td>Execution efficiency</td>
</tr>
<tr>
<td>RAM efficiency</td>
<td>Traceability</td>
</tr>
<tr>
<td>Safety precaution</td>
<td></td>
</tr>
<tr>
<td>Debugging</td>
<td></td>
</tr>
<tr>
<td>MISRA C:2012 guidelines</td>
<td></td>
</tr>
<tr>
<td>Polyspace</td>
<td></td>
</tr>
</tbody>
</table>

5. To accept the objectives, click **OK**. In the Configuration Parameters dialog box, **Code Generation > General > Prioritized objectives** is updated.

5. On the **Configuration Parameters > Code Generation > General** pane, click **Check Model**.
6 In the System Selector window, select the model or subsystem that you want to review, and then click OK. The Code Generation Advisor opens and reviews the model or subsystem that you specified.

7 In the Code Generation Advisor window, review the results by selecting a check from the left pane. The results for that check display in the right pane.

8 After reviewing the check results, you can choose to fix warnings and failures, as described in “Fix a Model Check Warning or Failure” (Simulink).

When you specify an efficiency or Safety precaution objective, the Code Generation Advisor includes additional checks. When you make changes to one of these additional checks, previous check results can potentially become invalid and need to be rerun.

For more information, see “Set Objectives — Code Generation Advisor Dialog Box” (Simulink Coder)

Configure Code Generation Objectives Programmatically

This example shows how to configure code generation objectives by writing a MATLAB script or entering commands at the command line.

1 Specify a system target file. If you specify an ERT-based target, more objectives are available. For this example, specify ert.tlc. model_name is the name or handle to the model.

```matlab
set_param(model_name, 'SystemTargetFile', 'ert.tlc');
```

2 Specify your objectives. For example, if your objectives are execution efficiency and traceability, in that priority, enter:

```matlab
set_param(model_name, 'ObjectivePriorities',...
{'Execution efficiency', 'Traceability'});
```

3 Execute the Code Generation Advisor, by using either the Code Generation Advisor or in the Configuration Parameters dialog box. For more information, see “Configure Model for Code Generation Objectives by Using Code Generation Advisor” on page 32-2.

When you specify a GRT-based system target file, you can specify an objective at the command line. If you specify ROM efficiency, RAM efficiency, Traceability, MISRA C:2012 guidelines, Polyspace, or Safety precaution, the build process changes the objective to Unspecified because you have specified a value that is invalid when using a GRT-based target.

</table>

To check model rtwdemo_throttlecntrl for code efficiency, use the Model Advisor.

1. Open rtwdemo_throttlecntrl. Save a copy as throttlecntrl in a writable location on your MATLAB path.
2. To start the Model Advisor, select Analysis > Model Advisor > Model Advisor. A dialog box opens showing the model system hierarchy.
3. Click throttlecntrl and then click OK. The Model Advisor window opens.
4. Expand By Task > Code Generation Efficiency. To check your model for code generation efficiency, use the checks in the folder. By default, checks that do not trigger an Update Diagram are selected. The checks available for code generation efficiency depend on whether you have a Simulink Coder or Embedded Coder license.
5. In the left pane, select the remaining checks, and then select Code Generation Efficiency.
6. In the right pane, select Show report after run and click Run Selected Checks. The report shows a Run Summary that flags check warnings.
7. Review the report. The warnings highlight issues that impact code efficiency. For more information about the report, see “View Model Advisor Reports” (Simulink).

Check Model During Code Generation

To review a model as part of the code generation process, use the Code Generation Advisor.
1. To select and prioritize your code generation objectives, on the Configuration Parameters > Code Generation pane, click Set Objectives.

2. On the Configuration Parameters > Code Generation > General pane, select one of the following from Check model before generating code:
   - On (proceed with warnings)
   - On (stop for warnings)

3. If you want to only generate code, select Generate code only. Otherwise clear the check box to build an executable.

4. Apply your changes. In the model window, press Ctrl+B to generate code or build the model.

   If the Code Generation Advisor issues failures or warnings, and you specified:
   - On (proceed with warnings) — The Code Generation Advisor window opens while the build process proceeds. After the build process is complete, you can review the results.
   - On (stop for warnings) — The build process halts and displays the Diagnostic Viewer. To continue, you must review and resolve the Code Generation Advisor results or clear the Check model before generating code parameter.

5. In the Code Generation Advisor window, review the results by selecting a check from the left pane. The results for that check display in the right pane.

6. After reviewing the check results, you can choose to fix warnings and failures as described in “Fix a Model Check Warning or Failure” (Simulink).

**Note** When you specify an efficiency or Safety precaution objective, the Code Generation Advisor includes additional checks. When you make changes to one of these additional checks, previous check results can potentially become invalid and need to be rerun.

For more information, see “Set Objectives — Code Generation Advisor Dialog Box” (Simulink Coder)
Embedded Coder Model Advisor Checks for Standards, Guidelines, and Code Efficiency

To check that your model meets guidelines, standards, and is ready to generate code, you can use the Model Advisor checks available with Embedded Coder:

- To start the Model Advisor, in the model window, select **Analysis > Model Advisor > Model Advisor**.
- In the Model Advisor window, expand the **By Task** folder. The folder contains Model Advisor checks that you can run to help accomplish the task.

For more information about the Model Advisor, see “Run Model Checks” (Simulink).

The table summarizes the Embedded Coder Model Advisor checks that are available in the **By Task** folders.

Create Custom Code Generation Objectives

In this section...

“Specify Parameters in Custom Objectives” on page 32-16
“Specify Checks in Custom Objectives” on page 32-17
“Determine Checks and Parameters in Existing Objectives” on page 32-17
“Steps to Create Custom Objectives” on page 32-18

The Code Generation Advisor reviews your model based on objectives that you specify. If the predefined efficiency, traceability, Safety precaution, and debugging objectives do not meet your requirements, you can create custom objectives.

To create custom objectives:

• Create an objective and add parameters and checks to this new objective.
• Create an objective based on an existing objective, then add, modify, and remove the parameters and checks within that new objective.

Specify Parameters in Custom Objectives

When you create a custom objective, you specify the values of configuration parameters that the Code Generation Advisor reviews. You can use the following methods:

• addParam — Add parameters and specify the values that the Code Generation Advisor reviews in Check model configuration settings against code generation objectives.
• modifyInheritedParam — Modify inherited parameter values that the Code Generation Advisor reviews in Check model configuration settings against code generation objectives.
• removeInheritedParam — Remove inherited parameters from a new objective that is based on an existing objective. When you select multiple objectives, if another selected objective includes this parameter, the Code Generation Advisor reviews the parameter value in Check model configuration settings against code generation objectives.
Specify Checks in Custom Objectives

Objectives include the **Check model configuration settings against code generation objectives** check by default. When you create a custom objective, you specify the list of additional checks that are associated with the custom objective. You can use the following methods:

- **addCheck** — Add checks to the Code Generation Advisor. When you select the custom objective, the Code Generation Advisor displays the check, unless you specify an additional objective with a higher priority that excludes the check.

  For example, add a check to the Code Generation Advisor to include a custom check in the automatic model checking process.

- **excludeCheck** — Exclude checks from the Code Generation Advisor. When you select multiple objectives, if you specify an additional objective that includes this check as a higher priority objective, the Code Generation Advisor displays this check.

  For example, exclude a check from the Code Generation Advisor when a check takes a long time to process.

- **removeInheritedCheck** — Remove inherited checks from a new objective that is based on an existing objective. When you select multiple objectives, if another selected objective includes this check, the Code Generation Advisor displays the check.

  For example, remove an inherited check, rather than exclude the check, when the check takes a long time to process, but the check is important for another objective.

Determine Checks and Parameters in Existing Objectives

When you base a new objective on an existing objective, you can determine what checks and parameters the existing objective contains. The Code Generation Advisor contains the list of checks in each objective.

For example, the **Efficiency** objective includes checks that you can see in the Code Generation Advisor.

1. Open the *rtwdemo_rtwecintro* model.
2. Specify an ERT-based target.
3. On the model toolbar, select **Code > C/C++ Code > Code Generation Advisor**.
4. In the System Selector window, select the model or subsystem that you want to review, and then click **OK**.
In the Code Generation Advisor, on the Code Generation Objectives pane, select the code generation objectives. As you select objectives, on the left pane, the Code Generation Advisor updates the list of checks it runs on your model. For this example, select Execution efficiency. In Available objectives, double-click Execution efficiency. Execution efficiency is added to Selected objectives - prioritized.

In the left pane, the Code Generation Advisor lists the checks for the Execution efficiency objective. The first check, Check model configuration settings against code generation objectives, lists parameters and values specified by the objective. For example, the Code Generation Advisor displays the list of parameters and the recommended values in the Execution efficiency objective. To see the list of parameters and values:

1. Run Check model configuration settings against code generation objectives.
2. Click Modify Parameters.
3. Rerun the check.

In the check results, the Code Generation Advisor displays the list of parameters and recommended values for the Execution efficiency objective.

**Passed**

**Current Objectives:** Execution efficiency

The following parameters have been checked and confirmed with the recommended value.

**Steps to Create Custom Objectives**

To create a custom objective:

1. Create an sl_customization.m file.
   - Specify custom objectives in a single sl_customization.m file only or the software generates an error. This issue is true even if you have more than one sl_customization.m file on your MATLAB path.
• Except for the `matlabroot/work` folder, do not place an `sl_customization.m` file in your root MATLAB folder or its subfolders. Otherwise, the software ignores the customizations that the file specifies.

2 Create an `sl_customization` function that takes a single argument. When the software invokes the function, the value of this argument is the Simulink customization manager. In the function:

• To create a handle to the code generation objective, use the `ObjectiveCustomizer` constructor.
• To register a callback function for the custom objectives, use the `ObjectiveCustomizer.addCallbackObjFcn` method.
• To add a call to execute the callback function, use the `ObjectiveCustomizer.callbackFcn` method.

For example:

```matlab
function sl_customization(cm)
%SL_CUSTOMIZATION objective customization callback

objCustomizer = cm.ObjectiveCustomizer;
index = objCustomizer.addCallbackObjFcn(@addObjectives);
objCustomizer.callbackFcn{index}();
end
```

3 Create a MATLAB callback function that:

• Creates code generation objective objects by using the `rtw.codegenObjectives.Objective` constructor.
• Adds, modifies, and removes configuration parameters for each objective by using the `addParam`, `modifyInheritedParam`, and `removeInheritedParam` methods.
• Includes and excludes checks for each objective by using the `addCheck`, `excludeCheck`, and `removeInheritedCheck` methods.
• Registers objectives by using the `register` method.

The following example shows how to create an objective Reduce RAM Example. Reduce RAM Example includes five parameters and three checks that the Code Generation Advisor reviews.

```matlab
function addObjectives

% Create the custom objective
obj = rtw.codegenObjectives.Objective('ex_ram_1');
```
setObjectiveName(obj, 'Reduce RAM Example');
%
% Add parameters to the objective
addParam(obj, 'DefaultParameterBehavior', 'Inlined');
addParam(obj, 'BooleanDataType', 'on');
addParam(obj, 'OptimizeBlockIOStorage', 'on');
addParam(obj, 'EnhancedBackFolding', 'on');
addParam(obj, 'BooleansAsBitfields', 'on');
%
% Add additional checks to the objective
% The Code Generation Advisor automatically includes 'Check model
% configuration settings against code generation objectives' in every
% objective.
addCheck(obj, 'mathworks.design.UnconnectedLinesPorts');
addCheck(obj, 'mathworks.design.Update');
%
%Register the objective
register(obj);

end

The following example shows you how to create an objective My Traceability Example based on the existing Traceability objective. The custom objective modifies, removes, and adds parameters that the Code Generation Advisor reviews. It also adds and removes checks from the Code Generation Advisor.

function addObjectives
%
% Create the custom objective from an existing objective
obj = rtw.codegenObjectives.Objective('ex_my_trace_1', 'Traceability');
setObjectiveName(obj, 'My Traceability Example');
%
% Modify parameters in the objective
modifyInheritedParam(obj, 'GenerateTraceReportSf', 'Off');
removeInheritedParam(obj, 'ConditionallyExecuteInputs');
addParam(obj, 'MatFileLogging', 'On');
%
% Modify checks in the objective
addCheck(obj, 'mathworks.codegen.SWEnvironmentSpec');
removeInheritedCheck(obj, 'mathworks.codegen.CodeInstrumentation');
%
%Register the objective
register(obj);

end

4 If you previously opened the Code Generation Advisor, close the model from which you opened the Code Generation Advisor.

5 Refresh the customization manager. At the MATLAB command line, enter sl_refresh_customizations.

6 Open your model and review the new objectives.

Configuration Variations

Every model contains one or more named configuration sets that specify model parameters such as solver options, code generation options, and other choices. A model can contain multiple configuration sets, but only one configuration set is active at a time. For more information on configuration sets and how to view and edit them in the Configuration Parameters dialog box, see “About Model Configurations” (Simulink).

A configuration set includes parameters that specify code generation in general. For more information, see “Configure a Model for Code Generation” (Simulink Coder). With Embedded Coder and an ERT system target file, more parameters are available for fine-tuning to optimize and customize the appearance of the generated code.

Multiple configuration sets can be useful in embedded systems development. By defining multiple configuration sets in a model, you can easily retarget code generation from that model. For example, one configuration set can specify the default ERT target with external mode support enabled for rapid prototyping. Another configuration set can specify the ERT-based target for Visual C++® to generate production code for deployment of the application. Activation of either configuration set fully reconfigures the model for that type of code generation.

Configure and Optimize Model with Configuration Wizard Blocks

The Embedded Coder software provides a library of Configuration Wizard blocks and scripts to help you configure and optimize code generation from your models.

In this section...

“Configuration Wizard Block Library” on page 32-23
“Add a Configuration Wizard Block” on page 32-24
“Use Configuration Wizard Blocks to Configure Your Model” on page 32-25
“Create a Custom Configuration Wizard Block” on page 32-26

Configuration Wizard Block Library

The library provides a Configuration Wizard block that you can customize. It also provides four preset Configuration Wizard blocks that update the active configuration parameters for a specified goal.

<table>
<thead>
<tr>
<th>Block</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Custom MATLAB file</td>
<td>Update active configuration parameters of parent model by using a custom file</td>
</tr>
<tr>
<td>ERT (optimized for fixed-point)</td>
<td>Update active configuration parameters of parent model for ERT fixed-point code generation</td>
</tr>
<tr>
<td>ERT (optimized for floating-point)</td>
<td>Update active configuration parameters of parent model for ERT floating-point code generation</td>
</tr>
<tr>
<td>GRT (debug for fixed/floating-point)</td>
<td>Update active configuration parameters of parent model for GRT fixed- or floating-point code generation with debugging enabled</td>
</tr>
<tr>
<td>GRT (optimized for fixed/floating-point)</td>
<td>Update active configuration parameters of parent model for GRT fixed- or floating-point code generation</td>
</tr>
</tbody>
</table>
When you add one of the preset Configuration Wizard blocks to your model and double-click it, a predefined MATLAB file script configures parameters of the active configuration set without manual intervention. The preset blocks optimally configure the parameters for one of the following cases:

- Fixed-point code generation with the ERT target
- Floating-point code generation with the ERT target
- Fixed-point or floating-point code generation with TLC debugging parameters enabled, with the GRT target.
- Fixed-point or floating-point code generation with the GRT target

The Custom block provides an example MATLAB file script that you can adapt to your requirements.

You can also set up the Configuration Wizard blocks to invoke the build process after configuring the model.

**Add a Configuration Wizard Block**

The Configuration Wizard blocks are available in the Embedded Coder block library. To use a Configuration Wizard block:

1. Open the model that you want to configure.
2. Open the Embedded Coder block library by typing the command `rtweclib`.
4. Select the Configuration Wizard block that you want to use and drag it into your model. This model contains the ERT (optimized for fixed-point) Configuration Wizard block.

![Diagram](image.png)

5. If you want the Configuration Wizard block to invoke the build process after configuration, right-click the Configuration Wizard block in your model, and select **Mask > Mask Parameters** from the context menu. Then, select the **Invoke build process after configuration** parameter. Do not change the **Configure the model for** block parameter, unless you want to create a custom block and script. In that case, see “Create a Custom Configuration Wizard Block” on page 32-26.

6. Click **Apply** and close the Mask Parameters dialog box.
7. Save the model.

**Use Configuration Wizard Blocks to Configure Your Model**

After you add a Configuration Wizard block to your model, to configure your model, double-click the block. The script associated with the block sets parameters of the active configuration set that are relevant to code generation (including selection of the target). You can see that the parameters have changed by opening the Configuration Parameters dialog box and examining the parameter settings.
If you selected the **Invoke build process after configuration** block parameter, the script also initiates the code generation and build process.

**Note** To provide a quick way to switch between configurations, you can add more than one Configuration Wizard block to your model.

## Create a Custom Configuration Wizard Block

The Custom Configuration Wizard block and the associated MATLAB file script, `matlabroot/toolbox/rtw/rtw/rtwsampleconfig.m`, provide a starting point for customization.

### Set Up a Configuration Wizard Block

Set up a custom Configuration Wizard block and link it to a script. If you want to use the block in more than one mode, it is advisable to create a Simulink library to contain the block.

To begin, make a copy of the example script for later customization:

1. To store your custom script, create a folder. This folder must not be anywhere inside the MATLAB folder structure (that is, it must not be under `matlabroot`).

   The example refers to this folder as `/my_wizards`.

2. Add the folder to the MATLAB path. Save the path for future sessions.

3. Copy the example script `rtwsampleconfig.m` in the folder `matlabroot/toolbox/rtw/rtw` (open) to the `/my_wizards` folder that you created. Then, rename the script. This example uses the name `my_configscript.m`.

4. Open the example script into the MATLAB editor. Scroll to the end of the file and enter the following line of code:

```
    disp('Custom Configuration Wizard Script completed.');
```

   This statement is used later as a test to see that your custom block has executed the script.

5. Save your script and close the MATLAB editor.

The next task is to create a Simulink library and add a custom block to it.
1 Open the Embedded Coder block library and the Configuration Wizards sublibrary, as described in “Add a Configuration Wizard Block” on page 32-24.

2 Select New > Library from the File menu of the Configuration Wizards sublibrary window. An empty library window opens.

3 Select the Custom MATLAB file block from the Configuration Wizards sublibrary and drag it into the empty library window.

4 To distinguish your custom block from the original, edit the Custom MATLAB file label under the block.

5 Select Save as from the File menu of the new library window. Save the library to the /my_wizards folder, under your library name of choice. In this figure, the library is saved as ex_custom_button and the block is labeled my_wizard MATLAB-file.

The next task is to link the custom block to the custom script:

1 Right-click the block in your model and select Mask > Mask Parameters from the context menu. The Configure the model for menu is set to Custom. When Custom is selected, the Configuration function edit field is enabled so that you can enter the name of a custom script.

2 In the Configuration function field, enter the name of your custom script . (Do not enter the .m file name extension, which is implicit.)
By default, the **Invoke build process after configuration** parameter is cleared. You can change the default for your custom block by selecting this option. For now, leave this parameter cleared.

4. Click **Apply** and close the Mask Parameters dialog box.

5. Save the library.

6. Close the Embedded Coder block library and the Configuration Wizards sublibrary. Leave your custom library open for use in the next task.

Test your block and script in a model.

1. Open the `vdp` model by typing the command:

   ```matlab
   vdp
   ```

2. Open the Configuration Parameters dialog box and view the parameters by clicking **Code Generation** in the list in the left pane of the dialog box.

3. Observe that `vdp` is configured, by default, for the GRT target. Close the Configuration Parameters dialog box.

4. Select your custom block from your custom library. Drag the block into the `vdp` model.

5. In the `vdp` model, double-click your custom block.

6. In the MATLAB window, you see the test message that you previously added to your script:

   ```matlab
   Custom Configuration Wizard Script completed.
   ```

   The test message indicates that the custom block executed the script.

7. Reopen the Configuration Parameters dialog box and view the **Code Generation** pane again. The model is now configured for the ERT target.

Before applying further edits to your custom script, proceed to the next section to learn about the operation and conventions of Configuration Wizard scripts.

**Create a Configuration Wizard Script**

Create your custom Configuration Wizard script by copying and modifying the example script, `rtwsampleconfig.m`. 
The Configuration Function

The example script implements a single function without a return value. The function takes a single argument cs:

function rtwsampleconfig(cs)

The argument cs is a handle to a proprietary object that contains information about the active configuration set. The Simulink software obtains this handle and passes it in to the configuration function when you double-click a Configuration Wizard block.

Your custom script must conform to this prototype. Your code must use cs as a “black-box” object that transmits information to and from the active configuration set.

Access Configuration Set Parameters

To set parameters or obtain parameter values, use the Simulink set_param and get_param functions.

Option names are passed in to set_param and get_param as character vectors specifying an internal option name. The internal option name can be different from the option label on the UI (for example, the Configuration Parameters dialog box). The example configuration accompanies each set_param and get_param call with a comment that correlates internal option names to UI option labels. For example:

set_param(cs,'LifeSpan','1'); % Application lifespan (days)

To obtain the current setting of an option in the active configuration set, call get_param. Pass in the cs object as the first argument, followed by the internal option name. For example, the following code excerpt tests the setting of the Create code generation report option:

if strcmp(get_param(cs, 'GenerateReport'), 'on')
    ...

To set an option in the active configuration set, call set_param. Pass in the cs object as the first argument, followed by one or more parameter/value pairs that specify the internal option name and its value. For example, the following code excerpt turns off the Support absolute time option:

set_param(cs,'SupportAbsoluteTime','off');
Select a Target

A Configuration Wizard script must select a target configuration. The example script uses the ERT target as a default. The script first stores character vector variables that correspond to the required System target file, Template makefile, and Make command settings:

```matlab
stf = 'ert.tlc';
tmf = 'ert_default_tmf';
mc  = 'make_rtw';
```

You select the system target file by passing the cs object and the stf character vector to the switchTarget function:

```matlab
switchTarget(cs,stf,[]);
```

Set the template makefile and make command options by using set_param calls:

```matlab
set_param(cs,'TemplateMakefile',tmf);
set_param(cs,'MakeCommand',mc);
```

To select a target, your custom script must set up the character vector variables stf, tmf, and mc and pass them to the calls.

Obtain Target and Configuration Set Information

The following utility functions and properties are provided so that your code can obtain information about the current target and configuration set with the cs object:

- **isValidParam(cs, 'option')**: The option argument is an internal option name. isValidParam returns true if option is a valid option in the context of the active configuration set.
- **getPropEnabled(cs, 'option')**: The option argument is an internal option name. Returns true if this option is enabled (that is, writable).
- **IsERTTarget property**: Your code can detect whether the currently selected target is derived from the ERT target by checking the IsERTTarget property, as follows:

  ```matlab
  isERT = strcmp(get_param(cs,'IsERTTarget'),'on');
  ```

You can use this information to determine whether the script must configure ERT-specific parameters, for example:

```matlab
if isERT
    set_param(cs,'ZeroExternalMemoryAtStartup','off');
```
set_param(cs,'ZeroInternalMemoryAtStartup','off');
set_param(cs,'InitFltsAndDblsToZero','off');
set_param(cs,'InlinedParameterPlacement',...
    'NonHierarchical');
set_param(cs,'NoFixptDivByZeroProtection','on')
end

**Invoke a Configuration Wizard Script from the Command Line**

Configuration Wizard scripts can be run from the MATLAB command line.

Before invoking the script, you must open a model and instantiate a cs object to pass in as an argument to the script. After running the script, you can invoke the build process with the `rtwbuild` command. The following example opens, configures, and builds a model.

```matlab
open my_model;
cs = getActiveConfigSet ('my_model');
rtwsampleconfig(cs);
rtwbuild('my_model');
```

Create a Model Configured for Code Generation Using Model Templates

Model templates provide you with a starting point for quickly developing models for code generation. Embedded Coder templates provide starting models for the following applications:

- Code Generation System. Create a model to get started with code generation.
- Exported functions. Create a model for generating code from function-call subsystems.
- Fixed-step, multirate. Create a fixed-step model with multiple rates for production code generation.
- Fixed-step, single-rate. Create a fixed-step model with a single rate for production code generation.

In the templates, traceability and reporting are turned on so that you can easily evaluate your generated code. The model has System target file set to ert.tlc and is configured to meet code generation objectives prioritized in the following order:

1. Execution efficiency
2. Traceability

To create a model using a model template:

1. On the MATLAB home tab, click Simulink.
2. In the Simulink start page, expand Embedded Coder.
3. Select a template.
4. Click Create. A new model that uses the template contents and settings appears in the Simulink Editor window.

For more information, for example to create and use a template as a reference design, see “Create a Template from a Model” (Simulink).
System Target File Configuration

- “Configure a System Target File” on page 33-2
- “Configure STF-Related Code Generation Parameters” on page 33-7
- “Configure a Code Replacement Library” on page 33-17
- “Configure Standard Math Library for Target System” on page 33-18
- “Compare System Target File Support” on page 33-21
Configure a System Target File

To configure a model for code generation, follow the steps in “Select a Solver That Supports Code Generation” (Simulink Coder) and “Select a System Target File from STF Browser” (Simulink Coder). When you select a system target file, other model configuration parameters change to serve requirements of the execution environment. For example:

- Code interface parameters
- Build process parameters, such as the toolchain or template makefile
- Target hardware parameters, such as word size and byte ordering

After selecting a system target file, you can modify model configuration parameter settings.

You can switch between different system target files in a single workflow for different code generation purposes (for example, rapid prototyping versus production code deployment). To switch, set up different configuration sets for the same model and switch the active configuration set for the current operation. For more information on how to set up configuration sets and change the active configuration set, see “Manage a Configuration Set” (Simulink).

In this section...

“Select a Solver That Supports Code Generation” on page 33-2
“Select a System Target File from STF Browser” on page 33-3
“Select a System Target File Programmatically” on page 33-4
“Develop Custom System Target Files” on page 33-5

Select a Solver That Supports Code Generation

To build a model, the model configuration must select a solver that is compatible with code generation for the system target file. Few system target files support code generation with variable-step solvers or for models with a nonzero start time.

- Use Configuration Parameters > Solver > Type and select Fixed-step for GRT, ERT, and ERT-based system target files.
• Use **Configuration Parameters** > **Solver** > **Type** and select **Fixed-step** or **Variable-step** for Rapid Simulation (Rsim) or S-Function (rtwsfcn) system target files.

For more information about the requirement that you use a fixed-step solver to generate code for a realtime system target file, see “Time-Based Scheduling and Code Generation” on page 17-2.

When you try to build models with a nonzero start time using a system target file does not support a nonzero start time, the code generator does not produce code. The build process displays an error message. The Rapid Simulation (RSim) system target file supports a nonzero start time when **Configuration Parameters** > **RSim Target** > **Solver selection** is set to Use Simulink solver module. Other system target files do not support a nonzero start time.

### Select a System Target File from STF Browser

After you select a solver (see “Select a Solver That Supports Code Generation” (Simulink Coder)), use **Configuration Parameters** > **Code Generation** > **System target file** and click the **Browse** button to open the System Target File Browser. Select a system target file from the list. Your selection appears in the **System target file** field (`target.tlc`).

If you use a system target file that does not appear in the System Target File Browser, enter the name of your system target file in the **System target file** field.

You also can select a system target file programmatically from MATLAB code, as described in “Select a System Target File Programmatically” on page 33-4.

After selecting a system target file, you can modify model configuration parameter settings. Selecting a system target file for your model selects either the toolchain approach or template makefile approach for build process control. For more information about these approaches, see “Choose Build Approach and Configure Build Process” on page 43-14.

If you want to switch between different system target files in a single workflow for different code generation purposes, set up different configuration sets for the same model. Switch the active configuration set for the current operation. This approach is useful for switching between rapid prototyping and production code deployment. For more information on how to set up configuration sets and change the active configuration set, see “Manage a Configuration Set” (Simulink).
To select a system target file using the System Target File Browser,

1. Open the **Code Generation** pane of the Configuration Parameters dialog box.

2. Click the **Browse** button next to the **System target file** field. This button opens the System Target File Browser. The browser displays a list of currently available system target files, including customizations. When you select a system target file, the code generator automatically chooses the system target file, toolchain or template makefile, and/or make command for that configuration.

The next step shows the System Target File Browser with the GRT system target file selected.

3. Click the desired entry in the list of available configurations. The background of the list box turns yellow to indicate that an unapplied choice has been made. To apply it, click **Apply** or **OK**.

**System Target File Browser**

When you choose a system target file, the code generator selects the toolchain or template makefile and/or make command for that configuration and displays them in the **System target file** field. The description of the system target file from the browser is placed below its name in the **Code Generation** pane. For information each system target file, see “Compare System Target File Support” on page 33-21.

**Select a System Target File Programmatically**

Simulink models store model-wide parameters and system target file-specific data in **configuration sets**. Every configuration set contains a component that defines the
structure of a particular system target file and the current values of relevant options. Simulink loads some of this information from the system target file that you specify. You can configure models to generate alternative code by copying and modifying old or adding new configuration sets and browsing to select a new system target file. Then, you can interactively select an active configuration from among these sets (only one configuration set can be active at a given time).

Scripts that automate system target file selection must emulate this process.

To program system target file selection:

1. Obtain a handle to the active configuration set with a call to the `getActiveConfigSet` function.
2. Define character vector variables that correspond to the required system target file, toolchain or template makefile, and/or make command settings. For example, for the ERT system target file, you would define variables for the character vectors 'ert.tlc', 'ert_default_tmf', and 'make_rtw'.
3. Select the system target file with a call to the `switchTarget` function. In the function call, specify the handle for the active configuration set and the system target file.
4. Set the `TemplateMakefile` and `MakeCommand` configuration parameters to the corresponding variables created in step 2.

For example:

```matlab
cs = getActiveConfigSet(model);
stf = 'ert.tlc';
tmf = 'ert_default_tmf';
mc  = 'make_rtw';
switchTarget(cs,stf,[]);
set_param(cs,'TemplateMakefile',tmf);
set_param(cs,'MakeCommand',mc);
```

For more information about selecting system target files programmatically, see `switchTarget`.

**Develop Custom System Target Files**

You can create your own system target files that interface with external code or operating environments.
For more information on how to make custom system target files appear in the System Target File Browser and display relevant controls, see “About Embedded Target Development” (Simulink Coder) and the topics it references.

Configure STF-Related Code Generation Parameters

Many model configuration parameters for code generation are specific to GRT, ERT, or ERT-based system target files. For more information, see the following topics.

In this section...

“Specify Generated Code Interfaces” on page 33-7
“Configure Numeric Data Support” on page 33-12
“Configure Time Value Support” on page 33-12
“Configure Noninlined S-Function Support” on page 33-13
“Configure Model Function Generation and Argument Passing” on page 33-13
“Configure Code Reuse Support” on page 33-15

Specify Generated Code Interfaces

Use interface model configuration parameters to control which libraries to use when generating code, whether to include support for an API in generated code, and other interface options.

<table>
<thead>
<tr>
<th>To...</th>
<th>Select or Enter...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specify the standard math library that the code generator uses when generating code.</td>
<td>Select C89/C90 (ANSI), C99 (ISO), or C++03 (ISO) for the Standard math library parameter. Selecting C89/C90 (ANSI) provides the ANSI® C set of library functions. For example, selecting C89/C90 (ANSI) results in generated code that calls sin() whether the input argument is double precision or single precision. However, if you select C99 (ISO), the generated code calls the function sinf() when the input argument is single precision. If your compiler supports the ISO® C math extensions, selecting the ISO C library can result in more efficient code. For more information, see “Standard math library” (Simulink Coder). The options for this parameter have dependencies. See Interface Dependencies.</td>
</tr>
<tr>
<td>To...</td>
<td>Select or Enter...</td>
</tr>
<tr>
<td>-------</td>
<td>-------------------</td>
</tr>
<tr>
<td>Specify an application-specific library that the code generator uses when generating code.</td>
<td>If you generate application-specific C or C++ code for math functions or operations, select a value for <strong>Code replacement library</strong>. Otherwise, specify <strong>None</strong>. For more information about code replacement libraries, see “Choose a Code Replacement Library” on page 40-8 and “Code replacement library” (Simulink Coder). The options for this parameter have dependencies. See Interface Dependencies.</td>
</tr>
<tr>
<td>Direct where the code generator places fixed-point and other utility code.</td>
<td>Select <strong>Auto</strong> or <strong>Shared location</strong> for <strong>Shared code placement</strong>. The shared location directs code for utilities to be placed within the slprj folder in your working folder, which is used for building referenced models. If you select <strong>Auto</strong>,  - When the model contains Model blocks, places utility code within the slprj/target/_sharedutils folder.  - When the model does not contain Model blocks, places utility code in the build folder (generally, in model.c or model.cpp).</td>
</tr>
<tr>
<td>Specify text to be added to the variable names used when logging data to MAT-files and to distinguish logging data from code generation and simulation applications.</td>
<td>Enter a prefix or suffix, such as rt_ or _rt, for the <strong>MAT-file variable name modifier</strong> parameter. The code generator prefixes or appends the text to the variable names for system outputs, states, and simulation time specified in the <strong>Data Import/Export</strong> pane. See “Log Program Execution Results” on page 45-2 for information on MAT-file data logging.</td>
</tr>
</tbody>
</table>
To... | Select or Enter...
---|---
Specify data exchange APIs to be included in generated code. | Select one or more C API options, the ASAP2 interface option, or the External mode option. When you select External mode, other options appear. The data exchange APIs are independent, and you can select combinations of these APIs. For example, you could choose C API and external mode.

For more information on working with these interfaces, see “Exchange Data Between Generated and External Code Using C API” on page 46-2, “Export ASAP2 File for Data Measurement and Calibration” on page 47-2, and “Host-Target Communication with External Mode Simulation” (Simulink Coder).

The options for this parameter have dependencies. See Interface Dependencies.

---

Note Before setting Standard math library or Code replacement library, verify that your compiler supports the library you want to use. If you select a parameter value that your toolchain does not support, compiler errors can occur. For example, if you select standard math library C99 (ISO) and your compiler does not support the ISO C math extensions, compile-time errors could occur.

When the Embedded Coder product is installed on your system, the Code Generation > Interface pane expands to include several additional options. For descriptions of Code Generation > Interface pane parameters, see “Model Configuration Parameters: Code Generation Interface” (Simulink Coder).

Several interface parameters have dependencies on settings of other parameters. The following table summarizes the dependencies.

Configure Numeric Data Support

By default, ERT system target files support code generation for integer, floating-point, nonfinite, and complex numbers.

<table>
<thead>
<tr>
<th>To Generate Code That Supports...</th>
<th>Do...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Integer data only</td>
<td>Clear <strong>Support floating-point numbers</strong>. If noninteger data or expressions are encountered during code generation, an error message reports the offending blocks and parameters.</td>
</tr>
<tr>
<td>Floating-point data</td>
<td>Select <strong>Support floating-point numbers</strong>.</td>
</tr>
<tr>
<td>Nonfinite values (for example, NaN, Inf)</td>
<td>Select <strong>Support floating-point numbers</strong> and <strong>Support non-finite numbers</strong>.</td>
</tr>
<tr>
<td>Complex data</td>
<td>Select <strong>Support complex numbers</strong>.</td>
</tr>
</tbody>
</table>

For more information, see “Model Configuration Parameters: Code Generation Interface” (Simulink Coder).

Configure Time Value Support

Certain blocks require the value of absolute time, elapsed time, or continuous time. Absolute time is the time from the start of program execution to the present time. Elapsed time is the time elapsed between two trigger events. Depending on the blocks used, your model could require adjustment of the configuration settings for supported time values.

<table>
<thead>
<tr>
<th>To...</th>
<th>Select...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Generate code that creates and maintains integer counters for blocks that use absolute or elapsed time values (default).</td>
<td><strong>Support absolute time</strong>. For further information on the allocation and operation of absolute and elapsed timers, see “Absolute and Elapsed Time Computation” (Simulink Coder). If you do not select this parameter and the model includes a block that uses absolute or elapsed time values, the build process generates an error.</td>
</tr>
<tr>
<td>Generate code for blocks that rely on continuous time.</td>
<td><strong>Support continuous time</strong>. If you do not select this parameter and the model includes continuous-time blocks, the build process generates an error.</td>
</tr>
</tbody>
</table>

For more information, see “Model Configuration Parameters: Code Generation Interface” (Simulink Coder).
Configure Noninlined S-Function Support

To generate code for noninlined S-Functions in a model, select **Support noninlined S-functions**. The generation of noninlined S-functions requires floating-point and nonfinite numbers. Thus, when you select **Support non-inlined S-functions**, the ERT system target file selects **Support floating-point numbers** and **Support non-finite numbers**.

When you select **Support non-finite numbers** and the model includes a C MEX S-function that does not have a corresponding TLC implementation (for inlining code generation), the build process generates an error.

Inlining S-functions is highly advantageous in production code generation, for example in implementing device drivers. To enforce the use of inlined S-functions for code generation, clear **Support non-inlined S-functions**.

When generating code for a model that contains noninlined S-functions with an ERT system target file, there could be a mismatch between the simulation and code generation results when either of the following is true:

- Model configuration parameter GenCodeOnly is set to off or **Configuration Parameters > Code Generation > Generate code only** is cleared.
- Model configuration parameter ProdEqTarget is set to off.

To avoid such a mismatch, set ProdEqTarget to on or select **Configuration Parameters > Code Generation > Generate code only** (or set GenCodeOnly to on).

Configure Model Function Generation and Argument Passing

For ERT system target files, you can configure model for how functions are generated and how arguments are passed to the functions.

<table>
<thead>
<tr>
<th>To...</th>
<th>Do...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Generate model function calls that are compatible with the main</td>
<td>Select <strong>Classic call interface</strong> and <strong>MAT-file logging</strong>. In</td>
</tr>
<tr>
<td>program module of the pre-R2012a GRT system target file</td>
<td>addition, clearing <strong>Remove error status field in real-time model data structure</strong>. <strong>Classic call interface</strong> provides a quick way to use code generated in R2012a or higher with a pre-R2012a GRT-based custom system target file by generating wrapper function calls that interface to the generated code.</td>
</tr>
<tr>
<td>To...</td>
<td>Do...</td>
</tr>
<tr>
<td>-------</td>
<td>-------</td>
</tr>
<tr>
<td>Reduce overhead and use more local variables by combining the output and update functions in a single <code>model_step</code> function.</td>
<td>Select <strong>Single output/update function</strong>&lt;br&gt;Errors or unexpected behavior can occur if a Model block is part of a cycle and the model configuration enables “Single output/update function” (Simulink Coder) (the default). For more information about direct feed through, see “Algebraic Loops” (Simulink).</td>
</tr>
<tr>
<td>Generate a <code>model_terminate</code> function for a model not designed to run indefinitely.</td>
<td>Select <strong>Terminate function required</strong> (Simulink Coder). For more information, see the description of <code>model_terminate</code>.</td>
</tr>
<tr>
<td>Generate reusable, reentrant code from a model or subsystem.</td>
<td>Select <strong>Generate reusable code</strong>. See “Configure Code Reuse Support” on page 33-15 for details.</td>
</tr>
<tr>
<td>Statically allocate model data structures and access them directly in the model code.</td>
<td>Clear <strong>Generate reusable code</strong>. The generated code is not reusable or reentrant. See “Configure Code Generation for Model Entry-Point Functions” (Simulink Coder) for information on the calling interface generated for model functions in this case.</td>
</tr>
<tr>
<td>Suppress the generation of an error status field in the real-time model data structure, <code>rtModel</code>, for example, if you do not require to log or monitor error messages.</td>
<td>Select <strong>Remove error status field in real-time model data structure</strong>. Selecting this parameter can also cause the code generator to omit the <code>rtModel</code> structure from the generated code. When generating code for multiple integrated models, set this parameter the same for all of the models. Otherwise, the integrated application could exhibit unexpected behavior. For example, if you select the option in one model but not in another, it is possible that the integrated application could not register the error status. Do not select this parameter if you select the <strong>MAT-file logging</strong> option. The two options are incompatible.</td>
</tr>
<tr>
<td>To...</td>
<td>Do...</td>
</tr>
<tr>
<td>-------</td>
<td>-------</td>
</tr>
<tr>
<td>Open the Model Step Functions dialog box preview and modify the <em>model_step</em> function prototype (see “Configure Code Generation for Model Entry-Point Functions” (Simulink Coder)).</td>
<td>Click <strong>Configure Step Function</strong>. Based on the <strong>Function specification</strong> value you select for your <em>model_step</em> function (supported values include Default model-step function and Model specific C prototype), you can preview and modify the function prototype. Once you validate and apply your changes, you can generate code based on your function prototype modifications. For more information about using the <strong>Configure Step Function</strong> button and the Model Step Functions dialog box, see “Customize Generated C Function Interfaces” on page 29-2.</td>
</tr>
</tbody>
</table>

For more information, see “Model Configuration Parameters: Code Generation Interface” (Simulink Coder).

### Configure Code Reuse Support

For GRT, ERT, GRT-based, and ERT-based system target files, you can configure how a model reuses code by setting the **Configuration Parameters > Code Generation > Code interface packaging** parameter value to **Reusable function**.

The **Configuration Parameters > Code Generation > Pass root-level I/O as** parameter provides options that control how model inputs and outputs at the root level of the model are passed to the *model_step* function.

<table>
<thead>
<tr>
<th>To...</th>
<th>Select...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pass each root-level model input and output argument to the <em>model_step</em> function individually (the default)</td>
<td><strong>Code interface packaging</strong> &gt; Reusable function and <strong>Pass root-level I/O as</strong> &gt; Individual arguments.</td>
</tr>
<tr>
<td>Pack root-level input arguments and root-level output arguments into separate structures that are then passed to the <em>model_step</em> function</td>
<td><strong>Code interface packaging</strong> &gt; Reusable function and <strong>Pass root-level I/O as</strong> &gt; Structure reference.</td>
</tr>
<tr>
<td>Pack root-level input arguments and root-level output arguments into the model data structure to support reentrant multi-instance code from a model for ERT system target file</td>
<td><strong>Code interface packaging</strong> &gt; Reusable function and <strong>Pass root-level I/O as</strong> &gt; Part of model data structure.</td>
</tr>
</tbody>
</table>

If using the **Code interface packaging** > Reusable function selection, consider using the **Use dynamic memory allocation for model initialization** option to control...
whether an allocation function is generated. This option applies for ERT system target files.

Sometimes, selecting **Code interface packaging** as Reusable function can generate code that compiles but is not reentrant. For example, if a signal, DWork structure, or parameter data has a storage class other than Auto, global data structures are generated. To handle such cases, use the **Multi-instance code error diagnostic** parameter to choose the severity levels for diagnostics.

Sometimes, the code generator is unable to generate valid and compilable code. For example, if the model contains one of the following, the generated code is invalid.

- An S-function that is not code-reuse compliant
- A subsystem triggered by a wide function-call trigger

In these cases, the build terminates after reporting the problem.

For more information, see “Generate Reentrant Code from Top-Level Models” on page 37-21 and “Model Configuration Parameters: Code Generation Interface” (Simulink Coder).

Configure a Code Replacement Library

You can configure the code generator to change the code that it generates for functions and operators such that the code meets application requirements. Configure the code generator to apply a code replacement library (CRL) during code generation. If you have Embedded Coder, you can develop and apply custom code replacement libraries.

• “Compare System Target File Support” on page 33-21
• “Specify Generated Code Interfaces” on page 33-7
Configure Standard Math Library for Target System

Specify standard library extensions that the code generator uses for math operations. When you generate code for a new model or with a new configuration set object, the code generator uses the ISO®/IEC 9899:1999 C (C99 (ISO)) library by default. For preexisting models and configuration set objects, the code generator uses the library specified by the Standard math library parameter.

If your compiler supports the ISO®/IEC 9899:1990 (C89/C90 (ANSI)) or ISO/IEC 14882:2003 (C++03 (ISO)) math library extensions, you can change the standard math library setting. The C++03 (ISO) library is an option when you select C++ for the programming language.

The C99 library leverages the performance that a compiler offers over standard ANSI C. When using the C99 library, the code generator produces calls to ISO C functions when possible. For example, the generated code calls the function sqrtf(), which operates on single-precision data, instead of sqrt().

To change the library setting, use the Configuration Parameters>Standard math library parameter. The command-line equivalent is TargetLangStandard.

**Generate and Inspect ANSI C Code**

1. Open the example model rtwdemo_clibsup.
2. Generate code.

```matlab
if (rtb_Abs2 < 0.0F) {
    rtb_Abs2 = -(real32_T)sqrt((real32_T)fabs(rtb_Abs2));
} else {
    rtb_Abs2 = (real32_T)sqrt(rtb_Abs2);
}
```
Generate and Inspect ISO C Code

1. Change the setting of **Standard math library** to C99 (ISO). Alternatively, at the command line, set **TargetLangStandard** to C99 (ISO).

2. Regenerate the code.

```bash
### Starting build procedure for model: rtwdemo_clibsup
### Successful completion of code generation for model: rtwdemo_clibsup
```

3. Reexamine the code in the generated file `rtwdemo_clibsup.c`. Now the generated code calls the function `sqrtf` instead of `sqrt`.

```c
if (rtb_Abs2 < 0.0F) {
    rtb_Abs2 = -sqrtf(fabsf(rtb_Abs2));
} else {
    rtb_Abs2 = sqrtf(rtb_Abs2);
}
```

Compare System Target File Support

When you select a system target file (such as grt.tlc), the selection defines the run-time environment and the code generation features. To identify the system target file features that match your development process goals, see:

<table>
<thead>
<tr>
<th>In this section…</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Evaluate Product System Target Files” on page 33-23</td>
</tr>
<tr>
<td>“Compare Code Styles and STF Support” on page 33-25</td>
</tr>
<tr>
<td>“Compare Generated Code Features by Product” on page 33-26</td>
</tr>
<tr>
<td>“Compare Generated Code Features by STF” on page 33-29</td>
</tr>
</tbody>
</table>

The code generator uses the system target file to produce code intended for execution on certain target hardware or operating system. The system target file invokes other run-time environment-specific files. For more information on configuring model code generation parameters for target hardware, see “Configure Run-Time Environment Options” (Simulink Coder).

Different types of system target files support a selection of generated code features. In the system target file, the value of the CodeFormat TLC variable and corresponding rtwgensettings.DerivedFrom field value identify the system target file type and generated code features. These selections control decisions made at several points in the code generation process. These decisions include whether and how the model build generates:

- Certain data structures (for example, SimStruct or rtModel)
- Static or dynamic memory allocation code
- Calling interface for generated model functions

For custom system target file development, follow these guidelines:

- If the system target file does not include a value for the CodeFormat TLC variable, the default value is RealTime for generic real-time target (GRT). The corresponding rtwgensettings.DerivedFrom field value is grt.tlc (default value).
- If you are developing a custom system target file and you have a license for Embedded Coder software, consider setting the CodeFormat TLC variable value to Embedded-C for embedded real-time target (ERT). The corresponding rtwgensettings.DerivedFrom field value is ert.tlc. The ERT system target file supports more generated code features than the GRT system target file.
The following example shows how the value for the CodeFormat TLC variable and corresponding rtwgensettings.DerivedFrom field value are set in ert.tlc.

```%
%assign CodeFormat = "Embedded-C"

/%
   BEGIN_RTW_OPTIONS
   rtwgensettings.DerivedFrom = 'ert.tlc';
   END_RTW_OPTIONS
%/```

**Warning** You must use the value for the CodeFormat TLC variable with its corresponding rtwgensettings.DerivedFrom field value to generated code for the model. If none are explicitly selected, the default values correspond. For more information, see “System Target File Structure” (Simulink Coder).

For a description of the optimized call interface generated by default for both the GRT and ERT system target files, see “Configure Code Generation for Model Entry-Point Functions” (Simulink Coder).

The real-time model data structure (rtModel) encapsulates model-specific information in a much more compact form than the SimStruct. Many efficiencies related to generated code depend on generation of rtModel rather than SimStruct, including:

- Integer absolute and elapsed timing services
- Independent timers for asynchronous tasks
- Generation of improved C API code for signal, state, and parameter monitoring
- Pruning the data structure to minimize its size (ERT-derived system target files only)

For a description of the rtModel data structure, see “Use the Real-Time Model Data Structure” (Simulink Coder).

</tbody>
</table>
Evaluate Product System Target Files

The following table lists supported system target files.

Note You can select from a range of system target files by using the System Target File Browser. This selection lets you experiment with configuration options and save your model with different configurations. However, you cannot build or generate code for non-GRT system target files, unless you have the required license on your system. For example, you require Embedded Coder for ERT system target files, require Simulink Desktop Real-Time for SLDRT system target files, and so on.

Selecting a system target file for your model selects either the toolchain approach or template makefile approach for build process control. For more information about these approaches, see “Choose Build Approach and Configure Build Process” on page 43-14.

Third-party vendors supply additional system target files for the code generator. For more information about third-party products, see the MathWorks Connections program web page: [https://www.mathworks.com/products/connections](https://www.mathworks.com/products/connections).

**Compare Generated Code Features by Product**

The code generation process for real-time system target files (such as GRT) provides many embedded code optimizations. GRT and ERT system target files have many common features. But, selecting an ERT-based system target file offers more extensive features. The system target file selection determines the available features for the code generation product. The following table compares code features available with Simulink Coder and features available with Embedded Coder.
## Compare Code Generation Features for Simulink Coder Versus Embedded Coder

Internationalization Support in Simulink Coder
Internationalization and Code Generation

Internationalization support in software development tooling is vital for enabling efficient globalization. If there is any possibility of future collaboration with others across locales, consider internationalization from project inception. Internationalization can prevent rework or having to develop a new model design. The relevant requirement concerns locale settings.

<table>
<thead>
<tr>
<th>In this section...</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Locale Settings” on page 34-2</td>
</tr>
<tr>
<td>“Prepare to Generate Code for Mixed Languages and Locales” on page 34-2</td>

</tr>
<tr>
<td>“XML Escape Sequence Replacements” on page 34-3</td>
</tr>
<tr>
<td>“Generate and Review Code with Mixed Languages and Mixed Locales” on page 34-3</td>
</tr>
</tbody>
</table>

Locale Settings

On a computer, a locale setting defines the language (character set encoding) for the user interface and the display formats for information such as time, date, and currency. The encoding dictates the number of characters that a locale can render. For example, the US-ASCII coded character set (codeset) defines 128 characters. A Unicode® codeset, such as UTF-8, defines more than 1,100,000 characters.

For code generation, the locale setting determines the character set encoding of generated file content. To avoid garbled text or incorrectly displayed characters, the locale setting for your MATLAB session must be compatible with the setting for your compiler and operating system. For information on finding and changing the operating system setting, see “Internationalization” (MATLAB) or see the operating system documentation.

To check a model for characters that cannot be represented in the locale setting of your current MATLAB session, use the Simulink Model Advisor check “Check model for foreign characters” (Simulink).

Prepare to Generate Code for Mixed Languages and Locales

To prepare to generate code for a model, identify:
• The operating system locale.
• The locale of the MATLAB session.
• Code generation requirements for:
  • Target Language Compiler files
  • Code generation template files that include comments (requires Embedded Coder)

**Character Set Limitations**

Target language compiler files support user default encoding only. To produce international, custom generated code that is portable, use the 7-bit ASCII character set.

**XML Escape Sequence Replacements**

The code generator replaces characters that are not represented in the character set encoding of a model with XML escape sequences. Escape sequence replacements occur for block, signal, and Stateflow object names that appear in:

• Generated code comments
• Code generation reports
• Block paths logged to MAT-files
• Block paths logged to C API files `model_capi.c` (or `.cpp`) and `model_capi.h`

**Generate and Review Code with Mixed Languages and Mixed Locales**

This example shows how to use the code generator to generate and review code for use in mixed languages and mixed locales.

Before using this example, see “Internationalization and Code Generation” (Simulink Coder) or “Internationalization and Code Generation” on page 35-2.

The `rtwdemo_unicode` model configuration uses the Embedded Coder (R) `ert.tlc` system target file. To see internationalization and localization support with Simulink Coder®, configure the model to use the `grt.tlc` system target file. The example indicates the support that is specific to Embedded Coder® (for example, code generation templates).
The model configuration specifies files and settings that control how the code generator handles localization for:

- C and C++ API interfaces
- Code generation template (CGT) files (requires Embedded Coder®)
- Target Language Compiler (TLC) files that apply code customizations (requires Embedded Coder®)

**Open the example model `rtwdemo_unicode`**.

Labels in the model appear in multiple languages (Arabic, Chinese, English, German, and Japanese) and various Unicode symbols.

```plaintext
model = 'rtwdemo_unicode';
open_system(model);
```

**Verify Locale Settings**

Verify that the locale setting for your MATLAB® software is compatible with your compiler. See the documentation for your operating system or the following MATLAB documentation:

- “Set Locale on Windows Platforms” (MATLAB)
- “Set Locale on Linux Platforms” (MATLAB)
- “Set Locale on Mac Platforms” (MATLAB)
Verify Model for Use of Foreign Characters

to verify the model for characters that the code generator cannot represent in the model’s current character set encoding, use the Simulink® Model Advisor check **Check model for foreign characters**.

1. Open the Model Advisor in Simulink®. Select **Analysis > Model Advisor > Model Advisor**. Or, in the Command Window, type:

   ```matlab
   modeladvisor('rtwdemo_unicode')
   ```

2. Expand **By Product**.

3. Expand **Simulink**.

4. Select **Check model for foreign characters**

5. Click **Run This Check**.

6. Review the results. Several warnings appear. Verify that the characters in the model can be represented in the current character set encoding.

7. Close the Model Advisor.

**Code Generation Template Files**

To use a code generation template file with unicode characters when generating code, complete these steps (requires Embedded Coder®). Otherwise, go to the next section.

1. Open the Configuration Parameters dialog box.

2. Navigate to the **Code Generation > Template** pane. The model is configured to use the code generation template file `rtwdemo_unicode.cgt`. That file adds comments to the top of generated code files. For the code generator to apply escape sequence replacements for the character set encoding `UTF-8`, enable replacements by specifying:

   ```xml
   <encodingIn = "encoding-name">
   ```

3. Open the file `/toolbox/rtw/rtwdemos/rtwdemo_unicode.cgt`.

   ```bash
   edit rtwdemo_unicode.cgt
   ```

4. Find the line of code that enables escape sequence replacements for the character set encoding `UTF-8`. 

**Generated File Customization Template**

To use file customization templates with unicode characters when generating code, complete these steps (requires Embedded Coder®). Otherwise, go to the next section.

You can specify customizations to generated code files by using TLC code. TLC files support user default encoding only. To produce international custom generated code that is portable, use the 7-bit ASCII character set.

1. Open the Configuration Parameters dialog box.

2. Navigate to the **Code Generation > Template** pane. The model is configured to use the code customization file example_file_process.tlc. That file customizes the generated code just before the code generator writes the code files. For example, the file adds a C source file, corresponding include file, and `#define` and `#include` statements.

3. Open the file /toolbox/rtw/rtwdemos/example_file_process.tlc.

```matlab
edit example_file_process.tlc
```

4. Before generating code, uncomment the following line of code:

```matlab
%% %assign ERTCustomFileTest = TLC_TRUE
```

5. Close the file /toolbox/rtw/rtwdemos/example_file_process.tlc.

**Generate C Code**

Generate C code and a code generation report.

```matlab
evalc('rtwbuild(''rtwdemo_unicode'')');
```

**Review the Generated Code**

For characters that are not in the current MATLAB® character set encoding, the code generator uses escape sequence replacements to render characters correctly in the code generation report.

1. If the code generation report for model `rtwdemo_unicode` is not open, in the Command Window, type:
coder.report.open('rtwdemo_unicode')

2. Review the generated code in rtwdemo_unicode.c and rtwdemo_unicode.h. Names of model elements appear in code comments as replacement names in the local language.

3. Open the Traceability Report. The report maintains traceability information, even when the name contains characters that are not represented in the current encoding. Names of model elements appear in the report as replacement names in the local language.

4. Scroll down to and click the code location link for the first Chart (State 'Selection' <S2>:23). The report view changes to show the corresponding code in rtwdemo_unicode.c.

5. In the code comment, click the <S2>:23 link. The model window shows the chart in a new tab.

6. In the model window, right-click that chart. Select C/C++ Code > Navigate to C/C++ Code. The report view changes to show the named constant section of code for that chart.

7. Close the code generation report, Model Advisor, and model. In the Command Window, type:

   coder.report.close();
   bdclose('all');

**Generate C++ Code**

Generate C++ code and a code generation report.

1. Open the model.

   model = 'rtwdemo_unicode';
   open_system(model);
2. Change **Configuration Parameters > Code Generation > Language** to C++. Or, in the Command Window, type:

```matlab
set_param('rtwdemo_unicode','TargetLang','C++');
```

3. Change **Configuration Parameters > Code Generation > Interface > Code interface packaging** to C++ class. Or, in the Command Window, type:

```matlab
set_param('rtwdemo_unicode','CodeInterfacePackaging','C++ class');
```

4. Generate C++ code and a code generation report.

```matlab
evalc('rtwrebuild(''rtwdemo_unicode'')');
```

5. To see internationalization and localization support, review the generated code. See **Review the Generated Code**.

6. Close the code generation report and model. In the Command Window, type:

```matlab
coder.report.close();
bdclose('all');
```

**More About**

- “Locale Settings for MATLAB Process” (MATLAB)
Internationalization Support in Embedded Coder
Internationalization and Code Generation

Internationalization support in software development tooling is vital to enabling efficient globalization. If there is a remote possibility that you could collaborate in the future with others across locales, consider internationalization from project inception. Internationalization can prevent rework or having to develop a new model design. The relevant requirement concerns locale settings.

In this section...

“Locale Settings” on page 35-2
“Prepare to Generate Code for Mixed Languages and Locales” on page 35-3
“Character Set Limitations” on page 35-3
“XML Escape Sequence Replacements” on page 35-3
“CGT Files and XML Escape Sequence Replacements” on page 35-3
“Generate and Review Code with Mixed Languages and Mixed Locales” on page 35-4

Locale Settings

On a computer, a locale setting defines the language (character set encoding) for the user interface and the display formats for information such as time, date, and currency. The encoding dictates the number of characters that a locale can render. For example, the US-ASCII coded character set (codeset) defines 128 characters. A Unicode codeset, such as UTF-8, defines more than 1,100,000 characters.

For code generation, the locale setting determines the character set encoding of generated file content. To avoid garbled text or incorrectly displayed characters, the locale setting for your MATLAB session must be compatible with the setting for your compiler and operating system. For information on finding and changing the operating system setting, see “Internationalization” (MATLAB) or see the operating system documentation.

To check a model for characters that cannot be represented in the locale setting of your current MATLAB session, use the Simulink Model Advisor check “Check model for foreign characters” (Simulink).
Prepare to Generate Code for Mixed Languages and Locales

To prepare to generate code for a model, identify:

- The operating system locale.
- The locale of the MATLAB session.
- Code generation requirements for:
  - Target Language Compiler files
  - Code generation template files that include comments (requires Embedded Coder)

Character Set Limitations

Target language compiler files support user default encoding only. To produce international, custom generated code that is portable, use the 7-bit ASCII character set.

XML Escape Sequence Replacements

The code generator replaces characters that are not represented in the character set encoding of a model with XML escape sequences. Escape sequence replacements occur for block, signal, and Stateflow object names that appear in:

- Generated code comments
- Code generation reports
- Block paths logged to MAT-files
- Block paths logged to C API files `model_capi.c` (or `.cpp`) and `model_capi.h`

CGT Files and XML Escape Sequence Replacements

The code generator replaces characters that are not represented in the character set encoding for a model with XML escape sequences. Escape sequence replacements occur for block, signal, and Stateflow object names that appear in Comments in code generation template (CGT) files.

By default, code generation template files do not contain character set encoding information. The operating system reads the files, using its current encoding, regardless of the encoding that you use to write the file. You can enable escape sequence replacements by adding the following token at the top of the template file:
<encodingIn = "encoding">

Replace encoding with a string that names a standard character encoding scheme, such as UTF-8, ISO-8859–1, or windows-1251.

This example shows content from the file rtwdemo_unicode.cgt in a MATLAB session for windows-1251. The example uses the encodingIn token to set the encoding to UTF–8, which is the correct value for code generation.

```matlab
<encodingIn = "UTF-8">
<FileBanner style = "box">
File: %<FileName>

Code generated for Simulink model '%<ModelName>'.

Model version : %<ModelVersion>
Simulink Coder version : %<RTWFileVersion>
TLC version : %<TLCVersion>
C/C++ source code generated on : %<SourceGeneratedOn>

You can customize this banner by specifying a different template.
Unicode characters written in cct file:

Greek Symbols: â™ƒ â™„ â™… â™† â™‡ â™— â™‰ â™Œ â™Ž â™® â™ â™ â™¥ â™¶
```

**Generate and Review Code with Mixed Languages and Mixed Locales**

This example shows how to use the code generator to generate and review code for use in mixed languages and mixed locales.

Before using this example, see “Internationalization and Code Generation” (Simulink Coder) or “Internationalization and Code Generation” on page 35-2.

The rtwdemo_unicode model configuration uses the Embedded Coder (R) ert.tlc system target file. To see internationalization and localization support with Simulink Coder®, configure the model to use the grt.tlc system target file. The example indicates the support that is specific to Embedded Coder® (for example, code generation templates).

The model configuration specifies files and settings that control how the code generator handles localization for:
• C and C++ API interfaces
• Code generation template (CGT) files (requires Embedded Coder®)
• Target Language Compiler (TLC) files that apply code customizations (requires Embedded Coder®)

Open the example model `rtwdemo_unicode`.

Labels in the model appear in multiple languages (Arabic, Chinese, English, German, and Japanese) and various Unicode symbols.

```matlab
model = 'rtwdemo_unicode';
open_system(model);
```

Verify Locale Settings

Verify that the locale setting for your MATLAB® software is compatible with your compiler. See the documentation for your operating system or the following MATLAB documentation:

• “Set Locale on Windows Platforms” (MATLAB)
• “Set Locale on Linux Platforms” (MATLAB)
• “Set Locale on Mac Platforms” (MATLAB)
Verify Model for Use of Foreign Characters

to verify the model for characters that the code generator cannot represent in the model's current character set encoding, use the Simulink® Model Advisor check **Check model for foreign characters.**

1. Open the Model Advisor in Simulink®. Select **Analysis > Model Advisor > Model Advisor.** Or, in the Command Window, type:

   ```matlab
   modeladvisor('rtwdemo_unicode')
   ```

2. Expand **By Product.**

3. Expand **Simulink.**

4. Select **Check model for foreign characters**

5. Click **Run This Check.**

6. Review the results. Several warnings appear. Verify that the characters in the model can be represented in the current character set encoding.

7. Close the Model Advisor.

**Code Generation Template Files**

To use a code generation template file with unicode characters when generating code, complete these steps (requires Embedded Coder®). Otherwise, go to the next section.

1. Open the Configuration Parameters dialog box.

2. Navigate to the **Code Generation > Template** pane. The model is configured to use the code generation template file `rtwdemo_unicode.cgt`. That file adds comments to the top of generated code files. For the code generator to apply escape sequence replacements for the character set encoding UTF-8, enable replacements by specifying:

   ```xml
   <encodingIn = "encoding-name">
   ```

3. Open the file `/toolbox/rtw/rtwdemos/rtwdemo_unicode.cgt`

   ```matlab
   edit rtwdemo_unicode.cgt
   ```

4. Find the line of code that enables escape sequence replacements for the character set encoding UTF-8.

**Generated File Customization Template**

To use file customization templates with unicode characters when generating code, complete these steps (requires Embedded Coder®). Otherwise, go to the next section.

You can specify customizations to generated code files by using TLC code. TLC files support user default encoding only. To produce international custom generated code that is portable, use the 7-bit ASCII character set.

1. Open the Configuration Parameters dialog box.

2. Navigate to the **Code Generation > Template** pane. The model is configured to use the code customization file example_file_process.tlc. That file customizes the generated code just before the code generator writes the code files. For example, the file adds a C source file, corresponding include file, and `#define` and `#include` statements.

3. Open the file /toolbox/rtw/rtwdemos/example_file_process.tlc.

   edit example_file_process.tlc

4. Before generating code, uncomment the following line of code:

   `%% %assign ERTCustomFileTest = TLC_TRUE%`

5. Close the file /toolbox/rtw/rtwdemos/example_file_process.tlc.

**Generate C Code**

Generate C code and a code generation report.

`evalc('rtwbuild(''rtwdemo_unicode''))';`

**Review the Generated Code**

For characters that are not in the current MATLAB® character set encoding, the code generator uses escape sequence replacements to render characters correctly in the code generation report.

1. If the code generation report for model `rtwdemo_unicode` is not open, in the Command Window, type:
coder.report.open('rtwdemo_unicode')

2. Review the generated code in rtwdemo_unicode.c and rtwdemo_unicode.h. Names of model elements appear in code comments as replacement names in the local language.

3. Open the Traceability Report. The report maintains traceability information, even when the name contains characters that are not represented in the current encoding. Names of model elements appear in the report as replacement names in the local language.

4. Scroll down to and click the code location link for the first Chart (State 'Selection' <S2>:23). The report view changes to show the corresponding code in rtwdemo_unicode.c.

5. In the code comment, click the <S2>:23 link. The model window shows the chart in a new tab.

6. In the model window, right-click that chart. Select C/C++ Code > Navigate to C/C++ Code. The report view changes to show the named constant section of code for that chart.

7. Close the code generation report, Model Advisor, and model. In the Command Window, type:
   
   ```
   coder.report.close();
   bdclose('all');
   ```

   **Generate C++ Code**

   Generate C++ code and a code generation report.

   1. Open the model.

   ```
   model = 'rtwdemo_unicode';
   open_system(model);
   ```
2. Change **Configuration Parameters > Code Generation > Language** to C++. Or, in the Command Window, type:

```matlab
set_param('rtwdemo_unicode','TargetLang','C++');
```

3. Change **Configuration Parameters > Code Generation > Interface > Code interface packaging** to C++ class. Or, in the Command Window, type:

```matlab
set_param('rtwdemo_unicode','CodeInterfacePackaging','C++ class');
```

4. Generate C++ code and a code generation report.

```matlab
evalc('rtwrebuild(''rtwdemo_unicode'')');
```

5. To see internationalization and localization support, review the generated code. See **Review the Generated Code**.

6. Close the code generation report and model. In the Command Window, type:

```matlab
coder.report.close();
bdclose('all');
```

About This Example

Learning Objectives

• Learn about the functional behavior of the example model.
• Learn about the role of the example test harness and its components.
• Run simulation tests on a model.

Prerequisites

• Ability to open and modify Simulink models and subsystems.
• Understand subsystems and how to view subsystem details.
• Understand referenced models and how to view referenced model details.
• Ability to set model configuration parameters.

Required Files

Before you use each example model file, place a copy in a writable location and add it to your MATLAB path.

• rtwdemo_throttlecntrl model file
• rtwdemo_throttlecntrl_testharness model file
**Functional Design of the Model**

This example uses a simple, but functionally complete, example model of a throttle controller. The model features redundant control algorithms. The model highlights a standard model structure and a set of basic blocks in algorithm design.

**View the Top Model**

Open `rtwdemo_throttlecntrl` and save a copy as `throttlecntrl` in a writable location on your MATLAB path.

**Note** This model uses Stateflow software.

The top level of the model consists of the following elements:

<table>
<thead>
<tr>
<th>Subsystems</th>
<th>PI_ctrl_1</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>PI_ctrl_2</td>
</tr>
<tr>
<td></td>
<td>Define_Throt_Param</td>
</tr>
<tr>
<td></td>
<td>Pos_Command_Arbitration</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Top-level input</th>
<th>pos_rqst</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>fbk_1</td>
</tr>
<tr>
<td></td>
<td>fbk_2</td>
</tr>
</tbody>
</table>
The layout uses a basic architectural style for models:

- Separation of calculations from signal routing (lines and buses)
- Partitioning into subsystems

You can apply this style to a wide range of models.

**View the Subsystems**

Explore two of the subsystems in the top model.

1. If not already open, open `throttlecntrl`.

Two subsystems in the top model represent proportional-integral (PI) controllers, `PI_ctrl_1` and `PI_ctrl_2`. At this stage, these identical subsystems, use identical data. If you have Embedded Coder, you can use these subsystems in an example that shows how to “Partition and Modularize Generated Code”.

2. Open the `PI_ctrl_1` subsystem.
The PI controllers in the model are from a *library*, a group of related blocks or models for reuse. Libraries provide one of two methods for including and reusing models. The second method, model referencing, is described in “Simulation Test Environment” on page 36-5. You cannot edit a block that you add to a model from a library. Edit the block in the library so that instances of the block in different models remain consistent.

3 Open the *Pos_Command_Arbitration* subsystem. This Stateflow chart performs basic error checking on the two command signals. If the command signals are too far apart, the Stateflow diagram sets the output to a *fail_safe* position.

4 Close *throttlecntrl*.

**Simulation Test Environment**

To test the throttle controller algorithm, incorporate it into a test harness. A test harness is a model that evaluates the control algorithm and offers the following benefits:

- Separates test data from the control algorithm.
- Separates the plant or feedback model from the control algorithm.
- Provides a reusable environment for multiple versions of the control algorithm.

The test harness model for this example implements a common simulation testing environment consisting of the following parts:

- Unit under test
• Test vector source  
• Evaluation and logging  
• Plant or feedback system  
• Input and output scaling

Explore the simulation testing environment.

1. Open the test harness model `rtwdemo_throttlecntrl_testharness` and save a copy as `throttlecntrl_testharness` in a writable location on your MATLAB path.

2. Set up your `throttlecntrl` model as the control algorithm of the test harness.  
   a. Open the `Unit_Under_Test` block and view the control algorithm.  
   b. View the model reference parameters by right-clicking the `Unit_Under_Test` block and selecting **Block Parameters (ModelReference)**.
rtwdemo_throttlecntrl appears as the name of the referenced model.

**c** Change the value of **Model name** to **throttlecntrl**.

**d** Update the test harness model diagram by clicking **Simulation > Update Diagram**.

The control algorithm is the unit under test, as indicated by the name of the Model block, **Unit_Under_Test**.

The Model block provides a method for reusing components. From the top model, it allows you to reference other models (directly or indirectly) as compiled functions. By default, Simulink software recompiles the model when the referenced models change. Compiled functions have the following advantages over libraries:

- Simulation time is faster for large models.
• You can directly simulate compiled functions.
• Simulation requires less memory. Only one copy of the compiled model is in memory, even when the model is referenced multiple times.

3 Open the test vector source, implemented in this test harness as the Test_Vectors subsystem.

The subsystem uses a Signal Builder block for the test vector source. The block has data that drives the simulation (PosRequest) and provides the expected results used by the Verification subsystem. This example test harness uses only one set of test data. Typically, create a test suite that fully exercises the system.

4 Open the evaluation and logging subsystem, implemented in this test harness as subsystem Verification.

A test harness compares control algorithm simulation results against golden data — test results that exhibit the desired behavior for the control algorithm as certified by an expert. In the Verification subsystem, an Assertion block compares the simulated throttle value position from the plant against the golden value from the test harness. If the difference between the two signals is greater than 5%, the test fails and the Assertion block stops the simulation.
Alternatively, you can evaluate the simulation data after the simulation completes execution. Perform the evaluation with either MATLAB scripts or third-party tools. Post-execution evaluation provides greater flexibility in the analysis of data. However, it requires waiting until execution is complete. Combining the two methods can provide a highly flexible and efficient test environment.

5 Open the plant or feedback system, implemented in this test harness as the Plant subsystem.

The Plant subsystem models the throttle dynamics with a transfer function in canonical form. You can create plant models to varying levels of fidelity. It is common to use different plant models at different stages of testing.

6 Open the input and output scaling subsystems, implemented in this test harness as Input_Signal_Scaling and Output_Signal_Scaling.
The subsystems that scale input and output perform the following primary functions:

- Select input signals to route to the unit under test.
- Select output signals to route to the plant.
- Rescale signals between engineering units and units that are writable for the unit under test.
- Handle rate transitions between the plant and the unit under test.

7 Save and close `throttlecntrl_testharness`.

**Run Simulation Tests**

1 Check that your working folder is set to a writable folder, such as the folder into which you placed copies of the example model files.
2 Open your copy of the test harness model, `throttlecntrl_testharness`.
3 Start a test harness model simulation. When the simulation is complete, the following results appear.
The lower-right hand plot shows the difference between the expected (golden) throttle position and the throttle position that the plant calculates. If the difference between the two values is greater than ±0.05, the simulation stops.

4 Save and close throttle controller and test harness models.

**Key Points**

- A basic model architecture separates calculations from signal routing and partitions the model into subsystems.
- Two options for model reuse include block libraries and model referencing.
- If you represent your control algorithm in a test harness as a Model block, specify the name of the control algorithm model in the Model Reference Parameters dialog box.
A test harness is a model that evaluates a control algorithm. Typically, a harness consists of a unit under test, a test vector source, evaluation and logging, a plant or feedback system, and input and output scaling components.

The unit under test is the control algorithm being tested.

The test vector source provides the data that drives the simulation which generates results used for verification.

During verification, the test harness compares control algorithm simulation results against golden data and logs the results.

The plant or feedback component of a test harness models the environment that is being controlled.

When developing a test harness,

- Scale input and output components.
- Select input signals to route to the unit under test.
- Select output signals to route to the plant.
- Rescale signals between engineering units and units that are writable for the unit under test.
- Handle rate transitions between the plant and the unit under test.

Before running simulation or completing verification, consider checking a model with the Model Advisor.

Configure Model and Generate Code

In this section...

“About This Example” on page 36-13
“Configure the Model for Code Generation” on page 36-14
“Save Your Model Configuration as a MATLAB Function” on page 36-15
“Check Model Conditions and Configuration Settings” on page 36-16
“Generate Code for the Model” on page 36-16
“Review the Generated Code” on page 36-17
“Generate an Executable” on page 36-18
“Key Points” on page 36-18

About This Example

Learning Objectives

• Configure a model for code generation.
• Apply model checking tools to discover conditions and configuration settings resulting in generation of inaccurate or inefficient code.
• Generate code from a model.
• Locate and identify generated code files.
• Review generated code.

Prerequisites

• Ability to open and modify Simulink models and subsystems.
• Ability to set model configuration parameters.
• Ability to use the Simulink Model Advisor.
• Ability to read C code.
• An installed, supported C compiler.

Required Files

rtwdemo_throttlecntrl model file
Configure the Model for Code Generation

Model configuration parameters determine the method for generating the code and the resulting format.

1. Open `rtwdemo_throttlecntrl` and save a copy as `throttlecntrl` in a writable location on your MATLAB path.

2. Open the Configuration Parameters dialog box, **Solver** pane. To generate code for a model, you must configure the model to use a fixed-step solver. The following table shows the solver configuration for this example.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Setting</th>
<th>Effect on Generated Code</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type</strong></td>
<td>Fixed-step</td>
<td>Maintains a constant (fixed) step size, which is required for code generation</td>
</tr>
<tr>
<td><strong>Solver</strong></td>
<td>discrete (no continuous states)</td>
<td>Applies a fixed-step integration technique for computing the state derivative of the model</td>
</tr>
<tr>
<td><strong>Fixed-step size</strong></td>
<td>.001</td>
<td>Sets the base rate; must be the lowest common multiple of the rates in the system</td>
</tr>
</tbody>
</table>

3. Open the **Code Generation > General** pane and note that the **System target file** is set to `grt.tlc`.

**Note** The GRT (Generic Real-Time Target) configuration requires a fixed-step solver. However, the `rsim.tlc` system target file supports variable step code generation.
The system target file (STF) defines an environment for generating and building code for execution on a certain hardware or operating system platform. For example, one property of a system target file is the value for the CodeFormat TLC variable. The GRT configuration requires a fixed step solver and the rsim.tlc supports variable step code generation.

4 Open the Code Generation > Custom Code pane and under Include list of additional, select Include directories. The following path appears in the text field:

"$matlabroot\toolbox\rtw\rtwdemos\EmbeddedCoderOverview\"

This folder includes files that are required to build an executable for the model.

5 Close the dialog box.

Save Your Model Configuration as a MATLAB Function

You can save the settings of model configuration parameters as a MATLAB function by using the getActiveConfigSet function. In the MATLAB Command Window, enter:

```matlab
thcntrlAcs = getActiveConfigSet('throttlecntrl');
thcntrlAcs.saveAs('throttlecntrlModelConfig');
```

You can then use the resulting function (for example, throttlecntrlModelConfig) to:

- Archive the model configuration.
- Compare different model configurations by using differencing tools.
- Set the configuration of other models.

For example, you can set the configuration of model myModel to match the configuration of the throttle controller model by opening myModel and entering:

```matlab
myModelAcs = throttlecntrlModelConfig;
attachConfigSet('myModel', myModelAcs, true);
setActiveConfigSet('myModel', myModelAcs.Name);
```

For more information, see “Save a Configuration Set” (Simulink) and “Load a Saved Configuration Set” (Simulink).
Check Model Conditions and Configuration Settings

Before generating code for a model, use the Simulink Model Advisor to check the model for conditions and configuration settings. This check finds issues that can result in inaccurate or inefficient code.

1. Open `throttlecntrl`.
2. Start the Model Advisor by selecting **Analysis > Model Advisor > Model Advisor**. A dialog box opens showing the model system hierarchy.
3. Click `throttlecntrl` and then click **OK**. The Model Advisor window opens.
4. Expand **By Product** and **Embedded Coder**. By default, checks that do not trigger an Update Diagram, with one exception, are selected.
5. In the left pane, select the remaining checks and select **Embedded Coder**.
6. In the right pane, select **Show report after run** and click **Run Selected Checks**. The report shows a **Run Summary** that flags check warnings.
7. Review the report. The warnings highlight issues for embedded systems. At this point, you can ignore them. For more information about reports, see “View Model Advisor Reports” (Simulink).

Generate Code for the Model

1. Open `throttlecntrl`.
2. In the Configuration Parameters dialog box, select **Code Generation > Generate code only** and click **Apply**.
3. On the **Code Generation > Report** pane, select **Create code generation report** and click **Apply**.
4. With the model open, initiate code generation and the build process for the model by using any of the following options:

   - Click the **Build Model** button.
   - Press **Ctrl+B**.
   - Select **Code > C/C++ Code > Build Model**.
   - Invoke the `rtwbuild` command from the MATLAB command line.
   - Invoke the `slbuild` command from the MATLAB command line.

Watch the messages that appear in the MATLAB Command Window. The code generator produces standard C and header files, and an HTML code generation
Review the Generated Code

1. Open Model Explorer, and in the Model Hierarchy pane, expand the node for the throttlecntrl model, and select the Code for node.
2. In the Contents pane, select HTML Report. Model Explorer displays the HTML code generation report for the throttle controller model.
3. In the HTML report, click the link for the generated C model file and review the generated code. Look for these items in the report:
   - Identification, version, timestamp, and configuration comments.
   - Links to help you navigate within and between files
   - Data definitions
   - Scheduler code
   - Controller code
   - Model initialization and termination functions
   - Call interface for the GRT system target file — output, update, initialization, start, and terminate
4. Save and close throttlecntrl.

Consider examining the following files. In the HTML report Contents pane, click the links. Or, in your working folder, explore the generated code subfolder:

<table>
<thead>
<tr>
<th>File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>throttlecntrl.c</td>
<td>C file that contains the scheduler, controller, initialization, and interface code</td>
</tr>
<tr>
<td>throttlecntrl_data.c</td>
<td>C file that assigns values to generated data structures</td>
</tr>
<tr>
<td>throttlecntrl.h</td>
<td>Header file that defines data structures</td>
</tr>
<tr>
<td>throttlecntrl_private.h</td>
<td>Header file that defines data used only by the generated code</td>
</tr>
<tr>
<td>throttlecntrl_types.h</td>
<td>Header file that defines the model data structure</td>
</tr>
</tbody>
</table>
For more information, see “Manage Build Process File Dependencies” (Simulink Coder).

At this point, consider logging data to a MAT-file. For an example, see “Log Data for Analysis” (Simulink Coder).

**Generate an Executable**

1. Open throttlecntrl.
2. In the Configuration Parameters dialog box, clear the **Code Generation > Generate code only** check box and click **Apply**.
3. Press **Ctrl+B**. Watch the messages in the MATLAB Command Window. The code generator uses a template make file associated with your system target file selection to create an executable file. You can run this program on your workstation, independent of external timing and events.
4. Check your working folder for the file throttlecntrl.exe.
5. Run the executable. In the Command Window, enter `!throttlecntrl`. The ! character passes the command that follows it to the operating system, which runs the standalone program.

The program produces one line of output in the Command Window:

```
** starting the model **
```

At this point, consider logging data to a MAT-file. For an example, see “Log Data for Analysis” (Simulink Coder).

**Tip** For UNIX platforms, run the executable in the Command Window with the syntax `!/executable_name`. If preferred, run the executable from an OS shell with the syntax `./executable_name`. For more information, see “Run External Commands, Scripts, and Programs” (MATLAB).

**Key Points**

- To generate code, change the model configuration to specify a fixed-step solver then select a system target file. Using the `grt.tlc` file requires a fixed-step solver. If the model contains continuous time blocks, you can use a variable-step solver with the `rsim.tlc` system target file.
• After debugging a model, consider configuring a model with parameter inlining enabled.
• Use the getActiveConfigSet function to save a model configuration for future use or to apply it to another model.
• Before generating code, consider checking a model with the Model Advisor.
• The code generator places generated files in a subfolder (model_grt_rtw) of your working folder.

Configure Data Interface

About This Example

Learning Objectives

- Configure the data interface for code generated for a model.
- Control the name, data type, and data storage class of signals and parameters in generated code.

Prerequisites

- Understanding ways to represent and use data and signals in models.
- Familiarity with representing data constructs as data objects.
- Ability to read C code.

Required File

rtwdemo_throttlecntrl_datainterface model file

Declare Data

Most programming languages require that you declare data before using it. The declaration specifies the following information:

<table>
<thead>
<tr>
<th>Data Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>The region of the program that has access to the data</td>
</tr>
<tr>
<td>Duration</td>
<td>The period during which the data is resident in memory</td>
</tr>
<tr>
<td>Data type</td>
<td>The amount of memory allocated for the data</td>
</tr>
<tr>
<td>Initialization</td>
<td>An initial value, a pointer to memory, or NULL. If you do not provide an initial value, most compilers assign a zero value or a null pointer.</td>
</tr>
</tbody>
</table>

The following data types are supported for code generation.
### Supported Data Types

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>double</td>
<td>Double-precision floating point</td>
</tr>
<tr>
<td>single</td>
<td>Single-precision floating point</td>
</tr>
<tr>
<td>int8</td>
<td>Signed 8-bit integer</td>
</tr>
<tr>
<td>uint8</td>
<td>Unsigned 8-bit integer</td>
</tr>
<tr>
<td>int16</td>
<td>Signed 16-bit integer</td>
</tr>
<tr>
<td>uint16</td>
<td>Unsigned 16-bit integer</td>
</tr>
<tr>
<td>int32</td>
<td>Signed 32-bit integer</td>
</tr>
<tr>
<td>uint32</td>
<td>Unsigned 32-bit integer</td>
</tr>
<tr>
<td>Fixed-point data types</td>
<td>8-, 16-, 32-bit word lengths</td>
</tr>
</tbody>
</table>

A storage class is the scope and duration of a data item. For more information about storage classes, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 22-81.

### Use Data Objects

In Simulink models and Stateflow charts, the following methods are available for declaring data: data objects and direct specification. This example uses the data object method. Both methods allow full control over the data type and storage class. You can mix the two methods in a single model.

In the MATLAB and Simulink environment, you can use data objects in various ways. This example focuses on the following types of data objects:

- Signal
- Parameter
- Bus

To configure the data interface for your model using the data object method, in the MATLAB base workspace, you define data objects. Then, associate them with your Simulink model or embedded Stateflow chart. When you build your model, the build process uses the associated base workspace data objects in the generated code.

You can set the values of the data object properties, which include:
You can create and inspect base workspace data objects by entering commands in the MATLAB Command Window or by using Model Explorer. To explore base workspace signal data objects, use these steps:

1. Open `rtwdemo_throttlecntrl_datainterface` and save a copy as `throttlecntrl_datainterface` in a writable location on your MATLAB path.
2. Open Model Explorer.
3. Select **Base Workspace**.
4. Select the `pos_cmd_one` signal object for viewing.
You can also view the definition of a signal object. In the MATLAB Command Window, enter `pos_cmd_one`:

```matlab
pos_cmd_one =

Signal with properties:

    CoderInfo: [1x1 Simulink.CoderInfo]
    Description: 'Throttle position command from the first PI controller'
    DataType: 'double'
    Min: -1
    Max: 1
    Unit: '
    Dimensions: [-1]
    DimensionsMode: 'auto'
    Complexity: 'auto'
    SampleTime: -1
    InitialValue: '0'
```

To view other signal objects, in Model Explorer, click the object name or in the MATLAB Command Window, enter the object name. The following table summarizes object characteristics for some of the data objects in this model.
<table>
<thead>
<tr>
<th><strong>Object Characteristics</strong></th>
<th><strong>pos_cmd_one</strong></th>
<th><strong>pos_rqst</strong></th>
<th><strong>P_InErrMap</strong></th>
<th><strong>ThrotComm</strong></th>
<th><strong>ThrottleCommands</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Description</td>
<td>Top-level output</td>
<td>Top-level input</td>
<td>Calibration parameter</td>
<td>Top-level output structure</td>
<td>Bus definition</td>
</tr>
<tr>
<td>Data type</td>
<td>Double</td>
<td>Double</td>
<td>Auto</td>
<td>Auto</td>
<td>Structure</td>
</tr>
<tr>
<td>Storage class</td>
<td>Exported global</td>
<td>Imported extern pointer</td>
<td>Constant</td>
<td>Exported global</td>
<td>None</td>
</tr>
</tbody>
</table>

*ThrottleCommands* defines a Bus object; ThrotComm is an instantiation of the bus. If the bus is a nonvirtual bus, the signal generates a structure in the C code.

You can use a bus definition (*ThrottleCommands*) to instantiate multiple instances of the structure. In a model diagram, a bus object appears as a wide line with central dashes, as shown.

![Diagram of a bus object](image)

### Add New Data Objects

You can create data objects for named signals, states, and parameters. To associate a data object with a construct, the construct must have a name.

To find constructs for which you can create data objects, use the Data Object Wizard. This tool finds the constructs and then creates the objects for you. The model includes two signals that are not associated with data objects: `fbk_1` and `pos_cmd_two`.

To find the signals and create data objects for them:

1. In the model window, select **Code > Data Objects > Data Object Wizard**. The Data Object Wizard dialog box opens.
2. To find candidate constructs, click **Find**. Constructs `fbk_1` and `pos_cmd_two` appear in the dialog box.
3 To select both constructs, click **Select All**.

4 In the table, under **Class**, make sure that each proposed data object uses the class `Simulink.Signal`. To change the class of the objects, click **Change Class**.

5 To create the data objects, click **Create**. Constructs `fbk_1` and `pos_cmd_two` are removed from the dialog box.

6 Close the Data Object Wizard.

7 In the **Contents** pane of the Model Explorer, find the newly created objects `fbk_1` and `pos_cmd_two`.

**Enable Data Objects for Generated Code**

1 Enable a signal to appear in generated code.

   a In the model window, right-click the `pos_cmd_one` signal line and select **Properties**. A Signal Properties dialog box opens.

   b Make sure that you select the **Signal name must resolve to Simulink signal object** parameter.

![Signal Properties: pos_cmd_one](image)

2 Enable signal object resolution for the signals in the model. In the MATLAB Command Window, enter:

   ```matlab
disableimplicitsignalresolution('throttlecntrl_datainterface')
```

3 Save and close `throttlecntrl_datainterface`.

**Effects of Simulation on Data Typing**

In the throttle controller model, the data types are set to `double`. Because Simulink software uses the `double` data type for simulation, do not expect changes in the model behavior when you run the generated code. You verify this effect by running the test harness.
Before you run your test harness, update it to include the 
throttlecntrl_datainterface model.

**Note** The following procedure requires a Stateflow license.

1. Open throttlecntrl_datainterface.
2. Open your copy of test harness, throttlecntrl_testharness.
3. Right-click the Unit_Under_Test Model block and select Block Parameters (ModelReference).
4. Set Model name to throttlecntrl_datainterface. Click OK.
5. Update the test harness model diagram.
6. Simulate the test harness.

The resulting plot shows that the difference between the golden and simulated versions of the model remains zero.
7 Save and close `throttlecntrl_testharness`.

**Manage Data**

Data objects exist in a separate file from the model in the base workspace. To save the data manually, in the MATLAB Command Window, enter `save`.

The separation of data from the model provides the following benefits:

- One model, multiple data sets:
• Use of different parameter values to change the behavior of the control algorithm (for example, for reusable components with different calibration values)

• Use of different data types to change targeted hardware (for example, for floating-point and fixed-point targeted hardware)

• Multiple models, one data set:
  • Sharing data between models in a system
  • Sharing data between projects (for example, transmission, engine, and wheel controllers can use the same CAN message data set)

Key Points

• You can declare data in Simulink models and Stateflow charts by using data objects or direct specification.

• From the Model Explorer or from the command line in the MATLAB Command Window, manage (create, view, configure, and so on) base workspace data.

• The Data Object Wizard provides a quick way to create data objects for constructs such as signals, buses, and parameters.

• Configure data objects explicitly to appear by name in generated code.

• Separation of data from model provides several benefits.

“Key Points” on page 36-35

About This Example

Learning Objectives

• Evaluate a C function as part of a model simulation.
• Call an external C function from generated code.

Prerequisites

• Ability to open and modify Simulink models and subsystems.
• Ability to set model configuration parameters.
• Ability to read C code.
• An installed, supported C compiler.

Required Files

• rtwdemo_throttlecntrl_extfunccall model file
• rtwdemo_ValidateLegacyCodeVrsSim model file
• /toolbox/rtw/rtwdemos/EmbeddedCoderOverview/stage_4_files/SimpleTable.c
• /toolbox/rtw/rtwdemos/EmbeddedCoderOverview/stage_4_files/SimpleTable.h
Include External C Functions in a Model

Simulink models are one part of Model-Based Design. For many applications, a design also includes a set of pre-existing C functions created, tested (verified), and validated outside of a MATLAB and Simulink environment. You can integrate these functions easily into a model and the generated code. You can use external C code in the generated code to access hardware devices and external data files during rapid simulation runs.

This example shows you how to create a custom block that calls an external C function. When the block is part of the model, you can take advantage of the simulation environment to test the system further.

Create a Block That Calls a C Function

To specify a call to an external C function, use an S-Function block. You can automate the process of creating the S-Function block by using the Simulink Legacy Code Tool. Using this tool, specify an interface for your external C function. The tool then uses that interface to automate creation of an S-Function block.

1 Make copies of the files SimpleTable.c and SimpleTable.h, located in the folder matlabroot/toolbox/rtw/rtwdemos/EmbeddedCoderOverview/stage_4_files (open). Put the copies in your working folder.

2 Create an S-Function block that calls the specified function at each time step during simulation:

   a In the MATLAB Command Window, create a function interface definition structure:

   ```matlab
   def=legacy_code('initialize')
   ```

   The data structure `def` defines the function interface to the external C code.

   ```matlab
   def =
   ```

   ```matlab
   SFunctionName: ''
   InitializeConditionsFcnSpec: ''
   OutputFcnSpec: ''
   StartFcnSpec: ''
   TerminateFcnSpec: ''
   HeaderFiles: {}
   SourceFiles: {}
   HostLibFiles: {}
   ```
Populate the function interface definition structure by entering the following commands:

```plaintext
def.OutputFcnSpec=['double y1 = SimpleTable(double u1,',...
  'double p1[], double p2[], int16 p3)'];
def.HeaderFiles = {'SimpleTable.h'};
def.SourceFiles = {'SimpleTable.c'};
def.SFunctionName = 'SimpTableWrap';
```

Create the S-function:

```plaintext
legacy_code('sfcn_cmex_generate', def)
```

Compile the S-function:

```plaintext
legacy_code('compile', def)
```

Create the S-Function block:

```plaintext
legacy_code('slblock_generate', def)
```

A new model window opens that contains the SimpTableWrap block.

**Tip** Creating the S-Function block is a one-time task. Once the block exists, you can reuse it in multiple models.

3. Save the model to your working folder as: `s_func_simptablewrap`.

4. Create a Target Language Compiler (TLC) file for the S-Function block:

   ```plaintext
   legacy_code('sfcn_tlc_generate', def)
   ```

   The TLC file is the component of an S-function that specifies how the code generator produces the code for a block.

For more information on using the Legacy Code Tool, see:

- “Integrate C Functions Using Legacy Code Tool” (Simulink)
- “Import Calls to External Code into Generated Code with Legacy Code Tool” (Simulink Coder)
Validate External Code in the Simulink Environment

When you integrate external C code with a Simulink model, before using the code, validate the functionality of the external C function code as a standalone component.

1. Open the model `rtwdemo.ValidateLegacyCodeVrsSim`. This model validates the S-function block that you created.

   - The Sine Wave block produces output values from [-2 : 2].
   - The input range of the lookup table is from [-1 : 1].
   - The output from the lookup table is the absolute value of the input.
   - The lookup table output clips the output at the input limits.

2. Simulate the model.

3. View the validation results by opening the Validation subsystem and, in that subsystem, clicking the Scope block.

   The following figure shows the validation results. The external C code and the Simulink Lookup table block provide the same output values.
Close the validation model.

**Validate C Code as Part of a Model**

After you validate the functionality of the external C function code as a standalone component, validate the S-function in the model. Use the test harness model to complete the validation.

*Note* The following procedure requires a Stateflow license.

1. Open `rtwdemo_throttlecntrl_extfuncall` and save a copy to `throttlecntrl_extfuncall` in a writable folder on your MATLAB path.
2. Examine the `PI_ctrl_1` and `PI_ctrl_2` subsystems.
   a. Lookup blocks have been replaced with the block you created using the Legacy Code Tool.
b  Note the block parameter settings for SimpTableWrap and SimpTableWrap1.
c  Close the Block Parameter dialog boxes and the PI subsystem windows.

3  Open the test harness model, right-click the Unit_Under_Test Model block, and select Block Parameters (ModelReference).

4  Set Model name to throttlecntrl_extfuncall. Click OK.

5  Update the test harness model diagram.

6  Simulate the test harness.

The simulation results match the expected golden values.

7  Save and close throttlecntrl_extfuncall and throttlecntrl_testharness.
Call a C Function from Generated Code

The code generator uses a TLC file to process the S-Function block. Calls to C code embedded in an S-Function block:

- Can use data objects.
- Are subject to expression folding, an operation that combines multiple computations into a single output calculation.

1. Open throttlecntrl_extfunccall.
2. Generate code for the model.
3. Examine the generated code in the file throttlecntrl_extfunccall.c.

Key Points

- You can easily integrate external functions into a model and generated code by using the Legacy Code Tool.
- Validate the functionality of external C function code which you integrate into a model as a standalone component.
- After you validate the functionality of external C function code as a standalone component, validate the S-function in the model.

Reload Generated Code

You can reload the code generated for a model from the Model Explorer.

1. Click the Code for model node in the Model Hierarchy pane.
2. In the Code pane, click the Refresh link.

The code generator reloads the code for the model from the build folder.

- “Rebuild a Model” (Simulink Coder)
- “Control Regeneration of Top Model Code” (Simulink Coder)
Manage Build Process Folders

The build process places generated files from Simulink diagram updates and model builds into a hierarchy of folders that is specified by default. You can change the default specification for build process folders, if, for example:

- Your company does not use the current working folder as the location for the code generation folder or the simulation cache folder.
- You place the code generation folder under version control, but do not place the simulation cache folder under version control.

The MATLAB session parameters `CacheFolder`, `CodeGenFolder`, and `CodeGenFolderStructure` are file generation control parameters that specify the folder locations for the build process. At the start of a MATLAB session, these Simulink preferences determine the values of the parameters:

**Simulation cache folder** (Simulink) – `CacheFolder`

**Code generation folder** (Simulink) – `CodeGenFolder`

**Code generation folder structure** (Simulink) – `CodeGenFolderStructure`

To modify the parameters during a MATLAB session, use `Simulink.fileGenControl`. The parameter values that you set expire at the end of the MATLAB session.

**File Generation Control Parameters**

This table provides information about how you can use the parameters to manage build process folders.
<table>
<thead>
<tr>
<th>MATLAB Session Parameter</th>
<th>Simulink Preference</th>
<th>Description</th>
</tr>
</thead>
</table>
| CacheFolder              | **Simulation cache folder** (Simulink) | The build process places generated files from Simulink diagram updates and model build artifacts for simulation in the simulation cache folder `simulationCacheFolder`. The folder is a root folder. By default (`CacheFolder = ''`), `simulationCacheFolder` is the current working folder, `pwd`. You can use the parameter to specify another folder. For example, if you want to:  
  - Separate generated files from the models and other source material.  
  - Reuse or share previously built simulation targets without having to set the current working folder back to a previous working folder. |
<table>
<thead>
<tr>
<th>MATLAB Session Parameter</th>
<th>Simulink Preference</th>
<th>Description</th>
</tr>
</thead>
</table>
| CodeGenFolder            | Code generation folder (Simulink) | The build process, which uses system target files to generate production code from a Simulink model, places the production code in the code generation folder `codegenFolder`. The folder is a root folder.  
If you choose to generate an executable program file, the build process writes the file `model.exe` (Windows) or `model` (UNIX) to the folder.  
By default (`CodeGenFolder = ''`), `codegenFolder` is the current working folder, `pwd`.  
You can use the parameter to specify another folder. For example, if you want to separate generated production code from:  
• Models and other source material.  
• Generated simulation artifacts.  
If you specify the root folder of a drive as the code generation folder, the build process cannot generate code for your model. For example, `C:\`. |
| CodeGenFolderS structure | Code generation folder structure (Simulink) | To specify the folder structure within the code generation folder, use the parameter. For example, if you configure models for different target environments, you can specify a separate subfolder for the generated code from each model. |
## Build Process Folders

This table provides information about how `CodeGenFolderStructure` controls the folder structure within the simulation cache folder and the code generation folder.

<table>
<thead>
<tr>
<th>Folder Name when <code>CodeGenFolderStructure</code> = 'ModelSpecific'</th>
<th>Folder Name when <code>CodeGenFolderStructure</code> = 'TargetEnvironmentSubfolder'</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>codeGenerationFolder/model_target_rtw</code></td>
<td><code>codeGenerationFolder/targetSpecific/model</code></td>
<td>Build folder, which stores generated source code and other files created by the build process. Contains the generated code modules, <code>model.c</code> and <code>model.h</code>, and the generated makefile, <code>model.mk</code>. <code>model</code> is the name of the source model.</td>
</tr>
<tr>
<td><code>codeGenerationFolder/slprj/target/model</code></td>
<td><code>codeGenerationFolder/targetSpecific/_ref/model</code></td>
<td>Model reference target files.</td>
</tr>
<tr>
<td><code>codeGenerationFolder/slprj/target/model/referenced_model_includes</code></td>
<td><code>codeGenerationFolder/targetSpecific/_ref/model/referenced_model_includes</code></td>
<td>Header files from models referenced by <code>model</code>.</td>
</tr>
<tr>
<td><code>codeGenerationFolder/slprj/target/model/tmwinternal</code></td>
<td><code>codeGenerationFolder/targetSpecific/_ref/model/tmwinternal</code></td>
<td>MAT-files used during code generation.</td>
</tr>
</tbody>
</table>
If the system target file is ERT-based, then these configuration parameters also control the location of shared utility code:

- Shared code placement (Simulink Coder) (UtilityFuncGeneration)
- Existing shared code (ExistingSharedCode)

You can use `RTW.getBuildDir` to display build folder information for the model.

Manage Build Process Files

To apply generated code source and header files from the build process, it is helpful to understand the files that the build process generates and the conditions that control file generation. This information provides access to generated code resources, such as:

- Public interface to the model entry points
- Enumerated types corresponding to built-in data types
- Data structures that describe the model signals, states, and parameters

The code generator creates `model.*` files during the code generation and build process. You can customize the file names for generated header, source, and data files. For more information, see “Customize Generated File Names” on page 39-70. The code generator creates additional folders and dependency files to support shared utilities and model references. For more information about the folders that the build process creates, see “Manage Build Process Folders” (Simulink Coder). For an example that shows how to use Simulink project to manage build process folders, see “Generate Code and Simulate Models in a Simulink Project” (Simulink Coder).

Depending on model architectures and code generation options, the build process for a GRT-based system target file can produce files that the build process does not generate for an ERT-based system target file. Also, for ERT-based system target files, the build process packages generated files differently than for GRT-based system target files. See “Manage File Packaging of Generated Code Modules” on page 37-14.

**Note**  By default, the build process deletes foreign (not generated) source files in the build folder. It is possible to preserve foreign source files in the build folder by following the guidelines in “Preserve External Code Files in Build Folder” (Simulink Coder).

The table describes the principal generated files. Within the generated file names shown in the table, the `model` represents the name of the model for which you are generating code. The `subsystem` represents the name of a subsystem within the model. When you select the **Create code generation report** parameter, the code generator produces a set of HTML files. There is one HTML file for each source file plus a `model_contents.html` index file in the `html` subfolder within your build folder. The source and header files in the table have dependency relationships. For descriptions of other file dependencies, see “Manage Build Process File Dependencies” (Simulink Coder) and “Add Build Process Dependencies” (Simulink Coder).
<table>
<thead>
<tr>
<th>File</th>

</tr>
</tbody>
</table>
model.bat

This file contains Windows batch file commands that set the compiler environment and invoke the make utility.

If you are using the toolchain approach for the build process, you also can use this batch file to extract information from the generated makefile, model.mk. The information includes macro definitions and values that appear in the makefile, such as CFLAGS (C compiler flags) and CPP_FLAGS (C++ compiler flags). With the folder containing model.bat selected as the current working folder, in the Command Window, type:

```bash
>> system('model.bat info')
```

On UNIX and Macintosh platforms, the code generator does not create the model.bat file. To extract information for toolchain approach builds from the generated makefile on these systems, in the Command Window, type:

```bash
>> system('gmake -f model.mk info')
```

model.h

The header file model.h declares model data structures and a public interface to the model entry points and data structures. This header file also provides an interface to the real-time model data structure (model_M) by using access macros. If your code interfaces to model functions or model data structures, include model.h:

- Exported global signals

  ```c
  extern int32_T INPUT;    /* '<Root>/In' */
  ```

- Global structure definitions

  ```c
  /* Block parameters (auto storage) */
  extern Parameters_mymodel mymodel_P;
  ```

- Real-time model (RTM) macro definitions

  ```c
  #ifndef rtmGetSampleTime
  # define rtmGetSampleTime(rtm, idx)
  ((rtm)->Timing.sampleTimes[idx])
  #endif
  ```

- Model entry point functions (ERT example)
extern void mymodel_initialize(void);
extern void mymodel_step(void);
extern void mymodel_terminate(void);

The main.c (or .cpp) file includes model.h. If the model build generates the main.c (or .cpp) file from a TLC script, the TLC source can include model.h.

#include "%<CompiledModel.Name>.h"

If main.c is a static source file, you can use the fixed header file name rtmodel.h. This file includes the model.h header file:

#include "model.h"  /* If main.c is generated */

or

#include "rtmodel.h"  /* If static main.c is used */

Other external source files can require to include model.h to interface to model data, for example exported global parameters or signals. The model.h file itself can have additional header dependencies due to requirements of generated code. See “System Header Files” (Simulink Coder) and “Code Generator Header Files” (Simulink Coder).

To reduce dependencies and reduce the number of included header files, see “Manage Build Process File Dependencies” (Simulink Coder).

**rtwtypes.h**

The header file rtwtypes.h defines data types, structures, and macros required by the generated code. You include rtwtypes.h for GRT and ERT system target files, instead of including tmwtypes.h or simstruc_types.h.

Often, the generated code requires that integer operations overflow or underflow at specific values. For example, when the code expects a 16-bit integer, the code does not accept an 8-bit or a 32-bit integer type. The C language does not set a standard for the number of bits in types such as char, int, and others. So, there is no universally accepted data type in C to use for sized-integers.

To accommodate this feature of the C language, the generated code uses sized integer types, such as int8_T, uint32_T, and others, which are not standard C types. In rtwtypes.h, the generated code maps these sized-integer types to the corresponding C keyword base type using information in the **Hardware Implementation** pane of the configuration parameters.
The code generator produces the optimized version of `rtwtypes.h` for ERT-based system target files when these conditions exist:

- The model has cleared the **Configuration Parameters > Code Generation > Interface > Advanced parameters > Classic call interface** option.
- The model does not contain noninlined S-functions.

Include `rtwtypes.h`. If you include it for GRT system target files, for example, it is easier to use your code with ERT-based system target files.

For GRT and ERT system target files, the location of `rtwtypes.h` depends on whether the build process uses the *shared utilities* location. If it uses a shared location, the code generator places `rtwtypes.h` in `slprj/target/_sharedutils`; otherwise, it places `rtwtypes.h` in the build folder (`model_target_rtw`). See “Specify Generated Code Interfaces” (Simulink Coder).

Source files include the `rtwtypes.h` header file when the source files use code generator type names or other code generator definitions. A typical example is for files that declare variables by using a code generator data type, for example, `uint32_T myvar`.

A source file that the code generator and an S-function use can use the preprocessor macro `MATLAB_MEX_FILE`. The macro definition comes from the `mex` function:

```c
#ifdef MATLAB_MEX_FILE
#include "tmwtypes.h"
#else
#include "rtwtypes.h"
#endif
```

A source file for the code generator `main.c` (or `.cpp`) file includes `rtwtypes.h` without preprocessor checks.

```c
#include "rtwtypes.h"
```

Custom source files that the Target Language Compiler generates can also emit these `include` statements into their generated file.

See “Control Placement of rtwtypes.h for Shared Utility Code” (Simulink Coder).

Manage Build Process File Dependencies

An important control of the size of generated code is managing the number and size of included files (dependencies). To reduce the number of system header files and generated header files that generated code requires, it is helpful to understand the dependencies that the build process generates and the conditions that lead to dependencies.

The dependency relationships among generated source and header files appear in the figure. Arrows coming from a file point to files it includes. Other dependencies exist, for example, on Simulink header files `tmwtypes.h` and `simstruc_types.h`, plus C or C++ library files. The figure maps inclusion relations between only those files that are generated in the build folder. These files can reference utility and model reference code located in a code generation folder. For more information about the folders and files that the build process creates, see “Manage Build Process Folders” (Simulink Coder) and “Manage Build Process Files” (Simulink Coder).

The two tables identify the conditions that control creation of dependency files for GRT and ERT targets. To manage build-related dependencies, consider how these conditions apply to your model and code generation process. Then, configure model parameters and code generation options to manage build process file dependencies.

Due to differences in file packaging options for code generated with ERT-based system target files, the file dependencies differ slightly from file packaging for code generated with GRT-based system target files. See “Manage File Packaging of Generated Code Modules” on page 37-14.

The parent system header files (`model.h`) include child subsystem header files (`subsystem.h`). In more layered models, subsystems similarly include their children's header files in the model hierarchy. As a consequence, subsystems are able to view recursively into their descendant subsystems and view into the root system because every `subsystem.c` or `subsystem.cpp` includes `model.h` and `model_private.h`.

In the figure, files `model.h`, `model_private.h`, and `subsystem.h` depend on the header file `rtwtypes.h`. If you use system target files that are not based on the ERT system target file, the source files that you generate can have additional dependencies on `tmwtypes.h` and `simstruc_types.h`. 
rtmodel.h is a placeholder include file for code generated with the GRT system target file.

For information about file dependencies in header files, see the following:

<table>

<td>“Code Generator Header Files” on page 36-57</td>
</tr>
</tbody>
</table>

**System Header Files**

The system header files make function declarations, type definitions, and macro definitions available to the legacy or external code. Some code generation scenarios require including header files that are specific to the code generator product.

The code generator includes some system header files for broadly defined cases. For example, generated code includes `<stddef.h>` when the model contains a utility function that requires this header file. This approach helps identify header file dependencies.
1. Set the Shared code placement parameter to 'Shared location' and build the model. The code generator places the utility functions in __sharedutils folder.

2. Use a find-in-file utility (for example, grep utility) to search the .c and .h files in the __sharedutils folder for #include. The search results list the utilities with header file dependencies.

3. Use this information to identify utilities to remove from the model and reduce header file dependencies in the generated code.

For more information, see “Generate Shared Utility Code for Fixed-Point Functions” (Simulink Coder).

</tbody>
</table>

**Code Generator Header Files**

Dependencies in the table for generated header files apply to the system target files `grt.tlc` and `ert.tlc`. System target files derived from these base system target files can have additional header dependencies. Code generation for blocks from blocksets, embedded targets, and custom S-functions can introduce additional header dependencies.

Add Build Process Dependencies

When you specify a system target file for code generation, the code generator can build a standalone executable program that can run on the development computer. To build the executable program, the code generator uses the selected compiler and the generated makefile for a toolchain approach or for a template makefile (TMF) approach build processes. Part of the makefile generation process is to add source file, header file, and library file information (the dependencies) in the generated makefile for a compilation. Or, for a specific application, you can add the generated files and file dependencies through a configuration management system.

The generated code for a model consists of a small set of files. (See “Manage Build Process Files” (Simulink Coder).) These files have dependencies on other files, which occur due to:

- Header file inclusions
- Macro declarations
- Function calls
- Variable declarations

The model or external code introduces dependencies for various reasons:

- Blocks in a model generate code that makes function calls. These calls can occur in several forms:
  - Included source files (not generated) declare the called functions. In cases such as a blockset, manage these source file dependencies by compiling them into a library file.
  - The generated code makes calls to functions in the run-time library provided by the compiler.
  - Some function dependencies also are generated files, which are referred to as shared utilities. Some examples are fixed-point utilities and non-finite support functions. These dependencies are referred to as shared utilities. The generated functions can appear in files in the build folder for standalone models or in the _sharedutils folder under the slprj folder for builds that involve model reference.
- Models with continuous time require solver source code files.
- Code generator options such as external mode, C API, and MAT-file logging.
• External code specifies dependencies.

For information about adding file dependencies in information for the build process, see the following:

<table>

</tr>
</tbody>
</table>

**File Dependency Information for the Build Process**

The code generator provides several mechanisms to input file dependency information into the build process. The mechanisms depend on whether your dependencies are block-based or are model- or system target file-based.

For block dependencies, consider using:

• S-functions and blocksets
  • Add folders that contain S-function MEX-files that the model uses to the header include path.
  • Create makefile rules for these folders to allow for finding source code.
  • Specify additional source file names with the S-Function block parameter `SFunctionModules`.
  • Specify additional dependencies with the `rtwmakecfg.m` mechanism. See “Use `rtwmakecfg.m` API to Customize Generated Makefiles” (Simulink Coder).

For more information on applying these approaches to legacy or external code integration, see “Import Calls to External Code into Generated Code with Legacy Code Tool” (Simulink Coder).

• S-Function Builder block, which provides its own UI for specifying dependency information

For model- or system target file-based dependencies, such as external header files, consider using:

• The **Code Generation > Custom Code** pane in the Configuration Parameters dialog box. You can specify additional libraries, source files, and include folders.
• TLC functions `LibAddToCommonIncludes()` and `LibAddToModelSources()`. You can specify dependencies during the TLC phase. See “LibAddToCommonIncludes(incFileName)” (Simulink Coder) and “LibAddSourceFileCustomSection(file, builtInSection, newSection)” (Simulink Coder). The Embedded Coder product also provides a TLC-based customization template for generating additional source files.

**Generated Makefile Dependencies**

For toolchain approach or template makefile (TMF) approach build processes, the code generator generates a makefile. For TMFs, the generated makefile provides token expansion in which the build process expands different tokens in the makefile to include the additional dependency information. The resulting makefile contains the complete dependency information. See “Customize Template Makefiles” (Simulink Coder).

The generated makefile contains:

• Names of the source file dependencies
• Folders where source files are located
• Location of the header files
• Precompiled library dependencies
• Libraries that the make utility compiles and creates

A property of make utilities is that you do not have to specify the specific location for a given source C or C++ file. If a rule exists for that folder and the source file name is a prerequisite in the makefile, the make utility can find the source file and compile it. The C or C++ compiler (preprocessor) does not require absolute paths to the headers. The compiler finds header file with the name of the header file by using an `#include` directive and an include path. The generated C or C++ source code depends on this standard compiler capability.

Libraries are created and linked against, but occlude the specific functions that the program calls.

These properties can make it difficult to determine the minimum list of file dependencies manually. You can use the makefile as a starting point to determine the dependencies in the generated code. For an example that shows how to identify dependencies, see “Relocate Code to Another Development Environment with packNGo” (Simulink Coder).

Another approach to determining the dependencies is using linker information, such as a linker map file, to determine the symbol dependencies. The map file provides the location
of code generator and blockset source and header files to help in locating the dependencies.

**Code Generator Static File Dependencies**

Several locations in the MATLAB folder tree contain static file dependencies specific to the code generator:

- `matlabroot/rtw/c/src` (open)

  This folder has subfolders and contains additional files must be compiled. Examples include solver functions (for continuous time support), external mode support files, C API support files, and S-function support files. Include source files in this folder into the build process with the SRC variables of the makefile.

- Header files in the folder `matlabroot/rtw/extern/include`
- Header files in the folder `matlabroot/simulink/include`

  These folders contain additional header file dependencies such as `tmwtypes.h`, `simstruc_types.h`, and `simstruc.h`.

**Note** For ERT-based system target files, you can avoid several header dependencies. ERT-based system target files generate the minimum set of type definitions, macros, and so on, in the file `rtwtypes.h`.

**Blockset Static File Dependencies**

Blockset products with S-function code apply the `rtwmakecfg.m` mechanism to provide the code generator with dependency information. The `rtwmakecfg.m` file from the blockset contains the list of include path and source path dependencies for the blockset. Typically, blocksets create a library from the source files to which the generated model code can link. The libraries are created and identified when you use the `rtwmakecfg.m` mechanism.

To locate the `rtwmakecfg.m` files for blocksets in your MATLAB installed tree, use the following command:

```bash
>> which -all rtwmakecfg.m
```

If the model that you are compiling uses one or more of the blocksets listed by the `which` command, you can determine folder and file dependency information from the respective `rtwmakecfg.m` file.
Folder Dependency Information for the Build Process

You can add `#include` statements to generated code. Such references can come from several sources, including TLC scripts for inlining S-functions, custom storage classes, bus objects, and data type objects. The included files consist of header files for external code or other customizations. You can specify compiler include paths with the `-I` compiler option. The build process uses the specified paths to search for included header files.

Usage scenarios for the generated code include, but are not limited to, the following:

- A custom build process compiles generated code that requires an environment-specific set of `#include` statements.

  In this scenario, the build process invokes the code generator when you select the **Generate code only** check box. Consider using fully qualified paths, relative paths, or just the header file names in the `#include` statements. Use include paths.

- The build process compiles the generated code.

  In this case, you can specify compiler include paths (`-I`) for the build process in several ways:

  - Specify additional include paths on the **Code Generation > Custom Code** pane in the Configuration Parameters dialog box. The code generator propagates the include paths into the generated makefile.

  - The `rtwmakecfg.m` mechanism allows S-functions to introduce additional include paths into the build process. The code generator propagates the include paths into the generated makefile.

  - When building a model that uses a custom system target file and is makefile-based, you can directly add the include paths into the template makefile that the system target file uses.

  - Use the `make` command to specify a `USER_INCLUDES` make variable that defines a folder in which the build process searches for included files. For example:

    ```
    make_rtw USER_INCLUDES=-Id:\work\feature1
    ```

    The build process passes the custom includes to the command-line invocation of the `make` utility, which adds them to the overall flags passed to the compiler.
Use #include Statements and Include Paths

Consider the following approaches for using #include statements and include paths with the build process to generate code that remains portable and minimizes compatibility problems with future versions.

Assume that additional header files are:

c:\work\feature1\foo.h
c:\work\feature2\bar.h

- An approach is to include in the #include statements only the file name, such as:

  #include "foo.h"
  #include "bar.h"

  Then, the include path passed to the compiler contains folders in which the headers files exist:

  cc -Ic:\work\feature1 -Ic:\work\feature2 ... 

- Another approach is to use relative paths in #include statements and provide an anchor folder for these relative paths using an include path, for example:

  #include "feature1\foo.h"
  #include "feature2\bar.h"

  Then, specify the anchor folder (for example \work) to the compiler:

  cc -Ic:\work ... 

Avoid These Folder Dependencies

When using the build process, avoid dependencies on folders in the build process “Code generation folder” (Simulink), such as the model_ert_rtw folder or the slprj folder. Do not use paths in #include statements that are relative to the location of the generated source file. For example, if your MATLAB code generation folder is c:\work, the build process generates the model.c source file into a subfolder such as:

c:\work\model_ert_rtw\model.c

The model.c file has #include statements of the form:

  #include "..\feature1\foo.h"
  #include "..\feature2\bar.h"

  It is preferable to use one of the other suggested approaches because the relative path creates a dependency on the code generator folder structure.

Enable Build Process for Folder Names with Spaces

The code generator uses alternate folder name support, which is specific to your Windows or UNIX operating system, to process folder names that include spaces. On Windows systems, the code generator maps a drive corresponding to the MATLAB installation folder for either of these conditions:

- The `matlabroot` folder is a UNC location.
- The path the `matlabroot` folder contains spaces, and the system has no alternate name support.

The build process provides similar support for other build-related folders. For a summary of support and limitations, see “Build Process Folder Support on Windows” (Simulink Coder).

Spaces in folder names can appear in the paths to build-related locations:

- `matlabroot`—path to your MATLAB installation folder.
  
  An example is a `matlabroot` similar to `C:\Program Files\MATLAB\R2015b`.

- `pwd`—current working folder from which you start the build.

  An example is a `pwd` at the start of a build similar to `C:\Users\username\Documents\My Work`.

- The installation folder for a compiler that the build process uses.

If your work environment includes one or more of the preceding scenarios, use the following support mechanisms for the build process:

- If you are using the toolchain approach to build generated code, the system support for spaces in folder names influences toolchain operation:

  - For UNIX systems and Windows systems with 8.3 name creation enabled, the toolchain manages spaces in folder names by using alternate names from the platform. The toolchain uses the `TransformPathsWithSpaces` attribute to manage these names.

    ```
    addAttribute(toolchainObject, 'TransformPathsWithSpaces', true);
    ```

    - For Windows systems with 8.3 name creation disabled, the toolchain manages spaces in folder names by mapping a network drive using a batch file (.bat). This
operation requires adding the RequiresBatchFile attribute to the toolchain definition.

    addAttribute(toolchainObject, 'RequiresBatchFile', true);

When developing a toolchain for a Windows system, set both attributes. For more information about the toolchain attributes, see addAttribute.

- If you are using the template makefile approach to build generated code, the template makefile (.tmf) requires code to manage spaces in folder names. When the alternate folder names (Windows short names) differ from the file system folder names (Windows long names), add this code to the makefile.

    ALT_MATLAB_ROOT        = |>ALT_MATLAB_ROOT<|
    ALT_MATLAB_BIN         = |>ALT_MATLAB_BIN<|
    !if "$(MATLAB_ROOT)" != "$(ALT_MATLAB_ROOT)"
        MATLAB_ROOT = $(ALT_MATLAB_ROOT)
    !endif
    !if "$(MATLAB_BIN)" != "$(ALT_MATLAB_BIN)"
        MATLAB_BIN = $(ALT_MATLAB_BIN)
    !endif

When the values of the location tokens are not equal, this code replaces MATLAB_ROOT with ALT_MATLAB_ROOT. The replacement indicates that the path to your MATLAB installation folder includes spaces. This code applies the same type of replacement for MATLAB_BIN with ALT_MATLAB_BIN. The preceding code is specific to nmake. For platform-specific examples, see the supplied template makefiles.

With either build approach, when there is an issue with support for creation of alternate names (short names), build errors can occur on Windows. If a build generates an error message similar to the following message, see “Troubleshooting Errors When Folder Names Have Spaces” (Simulink Coder).

    NMAKE : fatal error U1073: don't know how to make ' ... 

When using operating system commands, such as system or dos, enclose paths that specify executable files or command parameters in double quotes (" "). For example:

    system('dir "D:\Applications\Common Files"')

</tbody>
</table>
### Troubleshooting Errors When Folder Names Have Spaces

On Windows, when there is an issue with support for creation of short file names, build process errors can occur. When this issue affects a build, you see an error message similar to:

```
NMAKE : fatal error U1073: don't know how to make 'C:\Work\My'
```

This message can occur if a space in the folder name (C:\Work\My Models) prevents the build process from finding the model or a file to build. For descriptions of the build-related folders that are sensitive to a space in the folder name or path, see “Build Process Folder Support on Windows” (Simulink Coder).

To avoid issues from folder names with spaces when Windows short file name support for file names is disabled, do not use paths with spaces. For example, install third-party software to paths without spaces. Do not use paths with spaces for folders containing your models, source files, or libraries.
An issue can occur with builds that use folder names with spaces, because it is possible to disable Windows alternate name support. The build process uses this alternate name support on Windows systems. There are many terms for this file, folder, and path alternate name support:

- 8.3 name
- DOS path
- short file name (SFN, ShortFileName)
- long name alias
- Windows path alias

Verify the type of file system that the drive uses. In Windows Explorer, right-click the drive icon and select properties.

- If the file system is ReFS (Resilient File System), it is an issue. The ReFS does not provide short file name support. Except for the MATLAB installation folder, the build process does not support folder names with spaces for the ReFS file system. If your work environment requires short file name support for the build folder or for additional external code folders, do not use ReFS.
- If the file system is NTFS (New Technology File System), it is possible that the build error is related to a registry setting incompatibility. Continue with troubleshooting steps.

The error could stem from an issue with short file name support on a system using NTFS. Check the Windows registry setting that enables the creation of short names for files, folders, and paths.

1. Open the Windows command prompt, running as administrator. For example, from the Windows Start menu, type cmd, right-click the cmd.exe icon, and select Run as administrator.

2. Change to the windows\system32 folder and query the NtfsDisable8dot3NameCreation status by typing:
   
   ```
   > fsutil 8dot3name query
   ```

3. If the registry state of NtfsDisable8dot3NameCreation is not 2, the default (Volume level setting), change the value to 2 by typing:
   
   ```
   > fsutil 8dot3name set 2
   ```

Changing the registry setting enables creation of short names only for files and folders that are created after the change.

4. To create short names for files created while short name creation was disabled, at the Windows command line, use the fsutil utility.

To set the short name, the syntax is:

```bash
> fsutil file setshortname <FileName> <ShortName>
```

For example, to create the short name PROGRA~1 for the long name C:\Program Files, type:

```bash
> fsutil file setshortname "C:\Program Files" PROGRA~1
```

The C:\Program Files folder name is in quotations because it has spaces.

5. To verify that the short name was created, use the dir command with /x option to show short names.

```bash
> dir C:\ /x
```

- MATLAB Answers: “Why is the build process failing ...?”
MATLAB, Simulink, and the code generator store matrix data and arrays (1-D, 2-D, ...) in column-major format as a vector. Column-major format orders elements in a matrix starting from the first column, top to bottom, and then moving on to the next column. For example, the following 3x3 matrix:

\[
A =
\begin{bmatrix}
1 & 2 & 3 \\
4 & 5 & 6 \\
7 & 8 & 9 \\
\end{bmatrix}
\]

translates to an array of length 9 in the following order:

\[
A(1) = A(1,1) = 1; \\
A(2) = A(2,1) = 4; \\
A(3) = A(3,1) = 7; \\
A(4) = A(1,2) = 2; \\
A(5) = A(2,2) = 5; \\
\]

and so on.

In column-major format, the next element of an array in memory is accessed by incrementing the first index of the array. For example, these element pairs are stored sequentially in memory:

- \(A(i)\) and \(A(i+1)\)
- \(B(i,j)\) and \(B(i+1,j)\)
- \(C(i,j,k)\) and \(C(i+1,j,k)\)

For more information on the internal representation of MATLAB data, see “MATLAB Data” (MATLAB) in the MATLAB External Interfaces document.

Code generation software uses column-major format for several reasons:

- The world of signal and array processing is largely column major: MATLAB, LA Pack, Fortran90, DSP libraries.
• A column is equivalent to a channel in frame-based processing. In this case, column-major storage is more efficient.

• A column-major array is self-consistent with its component submatrices:
  • A column-major 2-D array is a simple concatenation of 1-D arrays.
  • A column-major 3-D array is a simple concatenation of 2-D arrays.
  • The stride is the number of memory locations to index to the next element in the same dimension. The stride of the first dimension is one element. The stride of the nth dimension element is the product of sizes of the lower dimensions.
  • Row-major n-D arrays have their stride of 1 for the highest dimension. Submatrix manipulations are typically accessing a scattered data set in memory, which does not allow for efficient indexing.

C typically uses row-major format. MATLAB and Simulink use column-major format. You cannot configure the code generation software to generate code with row-major ordering. If you are integrating external C code with the generated code, consider the following:

<table>
<thead>
<tr>
<th>To</th>
<th>Consider</th>
</tr>
</thead>
</table>
| Integrate row-major data in external C code with Simulink generated functions. | • Transposing the row-major data in your external C code into column-major format as a 1-D array.  
• Using “Access Data Through Functions with Custom Storage Class GetSet” on page 26-42. The GetSet custom storage class replaces get (read from) and set (write to) with user-specified GetSet functions. The user-specified GetSet function has a single index argument, requiring the function to process the argument and access the targeted row and column data element. Using the GetSet function impacts code efficiency. |
| Integrate external C code functions requiring row-major data with Simulink generated data. | Using the Legacy Code Tool option `convert2DMatrixToRowMajor` to create an S-function that integrates external code functions with Simulink generated data. See `legacy_code`. The generated code stores the data as a 1-D array. Using `convert2DMatrixToRowMajor` impacts code efficiency. |
Code Generator Matrix Parameters

The compiled model file, `model.rtw`, represents matrices as character vectors in MATLAB syntax, without an implied storage format. This format allows you to copy the character vector out of an `.rtw` file, paste it into a MATLAB file, and have it recognized by MATLAB.

The code generator declares Simulink block matrix parameters as scalar or 1-D array variables

```c
real_T scalar;
real_T mat[ nRows * nCols ];
```

`real_T` can be a data type supported by Simulink. It matches the variable type given in the model file.

For example, the 3-by-3 matrix in the 2-D Look-Up Table block

```
1   2   3
4   5   6
7   8   9
```

is stored in `model.rtw` as

Parameter {
    Name      "OutputValues"
    Value     Matrix(3,3)
    
[[1.0, 2.0, 3.0]; [4.0, 5.0, 6.0]; [7.0, 8.0, 9.0];]
    String   "t"
    StringType   "Variable"
    ASTNode {
        IsNonTerminal  0
        Op   SL_NOT_INLINED
        ModelParameterIdx 3
    }
}

and results in this definition in `model.h`.

```c
typedef struct Parameters_tag {
    real_T s1_Look_Up_Table_2_D_Table[9];
    
/* Variable:s1_Look_Up_Table_2_D_Table */
/* External Mode Tunable:yes */
/* Referenced by block: */
```
Parameters model_P = {
    /* 3 x 3 matrix s1_Look_Up_Table_2_D_Table */
    { 1.0, 4.0, 7.0, 2.0, 5.0, 8.0, 3.0, 6.0, 9.0 },
    [ ... other parameter declarations ...]
};

### Internal Data Storage for Complex Number Arrays

Simulink and code generator internal data storage formatting differs from MATLAB internal data storage formatting only in the storage of complex number arrays. In MATLAB, the real and imaginary parts are stored in separate arrays. In Simulink and the code generator, the parts are stored in an "interleaved" format. The numbers in memory alternate real, imaginary, real, imaginary, and so forth. This convention allows efficient implementations of small signals on Simulink lines, for Mux blocks, and other "virtual" signal manipulation blocks. For example, the signals do not actively copy their inputs, just the references.

Cross-Release Shared Utility Code Reuse

When you generate code for a model, the code generator by default creates shared utility files that the model requires. When you generate code with different releases, the code generators can produce functionally identical shared files that contain some nonfunctional differences. For example, different comments and different coding style. When you use the same release to generate code for different models in different folders, you can also produce shared files with nonfunctional differences. For example, if you specify different ParenthesesLevel or ExpressionFolding values for the models, the code generator can produce shared files that contain different comments or different coding styles.

Integrated code that includes functionally identical shared files:

- Is more expensive to verify because each shared file requires verification.
- Produces compilation errors if the shared files define duplicate symbols.

If you have an Embedded Coder license, you can avoid these issues by specifying the reuse of shared code from an existing folder, for example, a read-only library of verified code. In this case, the code generator does not create new shared utility files. The build process uses external code or previously generated shared utility code from the folder. An administrator maintains and updates the read-only library.

Workflow to Reuse Shared Utility Code

1. In the Configuration Parameters > Code Generation > Interface > Advanced parameters > Existing shared code field, enter the full path to your shared code folder.
2. Verify that the Configuration Parameters > Diagnostics > Advanced parameters > Use only existing shared code diagnostic is set to error (default).
3. Remove the slprj folder or move to a new working folder.
4. Build your model. If you do not see an error, your shared code folder contains the required shared utility files.
If files are missing from the existing shared code folder, you see an error. To continue code generation with a locally generated version of the missing shared utility files:

a. Set Configuration Parameters > Diagnostics > Advanced parameters > Use only existing shared code to warning.

b. Rebuild your model. The code generation process uses a locally generated version of the missing shared utility files.

c. Provide the administrator of the verified code library with your model and information about missing shared utility files. With the model, the administrator generates the required shared utility files. Using sharedCodeUpdate, the administrator adds the files to the existing shared code folder.

If you require reuse of shared code for a component exported from a previous release, provide the administrator with information about the exported artifacts location. The administrator can use sharedCodeUpdate to copy the shared code for your component to the existing shared code folder.

d. When the files are available in the existing shared code folder, repeat steps 1–4.

If the shared utility code is generated from library subsystems that are shared across models (Simulink Coder), you cannot reuse the code across releases because the code is release-specific—the symbol name and file name mangling includes the release number. The administrator must add the shared utility code generated for each release to the shared code folder.

The sharedCodeUpdate function can add files to the shared code folder that have identical content but different file and function names. This behavior is useful when you have different model components that require their own shared utility functions. Although some code is duplicated, the different model components can access the shared utility functions with which they were verified. To force model components to have their own versions of shared utility functions, configure naming rules to insert the model name into shared utility identifiers (Simulink Coder).

**Required Edits to Reuse Shared Utility Code**

For most shared utility code files, you can specify master copies that you can reuse across releases without modifying the files. With some files, for example, rtwtypes.h, and zero_crossing_types.h, there are situations where manual editing is required to produce master copies that you can use with generated code from different releases. For example:
• The rtwtypes.h file generated by R2010a contains a checksum.

    /* This ID is used to detect inclusion
       of an incompatible rtwtypes.h */
    #define RTWTYPES_ID_C08S16I32L64N64F0

    For each R2010a version of rtwtypes.h that you want to include in your integration,
    copy the corresponding #define statement into your master copy of rtwtypes.h.

• In R2015a, the zero-crossing definitions moved from rtwtypes.h into
  zero_crossing_types.h. To create an rtwtypes.h file that is compatible with
  generated model code from different releases, in your master copy of rtwtypes.h,
  insert this statement.

    #include "zero_crossing_types.h"

    Remove definitions from rtwtypes.h that zero_crossing_types.h provides.

“Import AUTOSAR Code from Previous Releases” on page 36-100

If you have an Embedded Coder license, you can integrate generated C code from previous releases (R2010a and later) with generated code from the current release when the source models are single-rate and the generated C code is from:

- Top-model or subsystem build processes that use the nonreusable function code interface.
- Single or multiple instance model reference build processes that suppress error status monitoring (SuppressErrorStatus is on).

If you can reuse existing code without modification, you can reduce the cost of reverification.

**Workflow**

Consider this control system model.
The Controller Model block references a model that consists of three components:

- **P1** is a Model block, which references a model developed with a previous release, for example, R2015b. The generated model code, with the standalone code interface, is in the folder `P1_ert_rtw`.
- **C1** is a Model block, which references a model that you are developing in the current release.
- **P2** is a subsystem block developed with a previous release, for example, R2016a. The generated subsystem code is in the folder `P2_ert_rtw`. 
• P3 is a Model block, which references a model developed with a previous release, for example, R2016b. The generated model code, with the model reference code interface, is in the folder slprj/ert/P3.

To integrate code from previous releases with generated code from the current release, use this workflow:

1  **Register previous releases with sharedCodeMATLABVersions**

   Use sharedCodeMATLABVersions to specify locations of the previous MATLAB releases, R2015b, R2016a, and R2016b.

2  **Export components from previous releases**

   In the current release, enter the commands:

   ```matlab
   P1ArtifactsLocation = crossReleaseExport(folderPathForP1_ert_rtw);
   P2ArtifactsLocation = crossReleaseExport(folderPathForP2_ert_rtw);
   P3ArtifactsLocation = crossReleaseExport(folderPathForP3);
   ```

   The crossReleaseExport function starts the required previous release and creates a folder that contains export artifacts, for example, P1_R2015b.

3  **Specify an existing shared code folder**

   You can specify the reuse of shared code (Simulink Coder) from an existing folder, for example, a library of verified code that an administrator maintains and updates. Specify the shared code folder for model components that require code generation in the current release, for example, Controller and C1.

   In the **Configuration Parameters > Code Generation > Interface > Advanced parameters > Existing shared code** field, enter the full path to the shared code folder.

4  **Import components into current release**

   From the current release, using export artifacts created in step 2, import generated component code from previous releases as software-in-the-loop (SIL) blocks or processor-in-the-loop (PIL) blocks. For example:

   ```matlab
   crossReleaseImport(P1ArtifactsLocation,'Controller', ... 'SimulationMode','SIL');
   crossReleaseImport(P2ArtifactsLocation,'Controller', ... 'SimulationMode','SIL');
   crossReleaseImport(P3ArtifactsLocation,'Controller', ... 'SimulationMode','SIL');
   ```
P1ArtifactsLocation, P2ArtifactsLocation, and P3ArtifactsLocation are paths to the export artifact folders, P1_R2015b, P2_R2016a, and P3_R2016b, which are created in step 2.

In the current working folder, the crossReleaseImport function creates the xrel subfolder that contains software-in-the-loop (SIL) blocks and subfolders:

- P1_R2015b_sil and P1_R2015b_sil_resources
- P2_R2016a_sil and P2_R2016a_sil_resources
- P3_R2016b_sil and P3_R2016b_sil_resources

### 5 Incorporate components into current release model

To replace components with SIL or PIL blocks, use the Simulink Editor or the pil_block_replace command. For example, replace:

- P1 with P1_R2015b_sil.
- P2 with P2_R2016a_sil.
- P3 with P3_R2016b_sil.

When you run a model simulation, the simulation runs the previous release code through the SIL or PIL blocks.

When you build the Controller model (rtwbuild('Controller')), the code generator does not generate new code for the components represented by the SIL or PIL blocks. The model code calls code generated by previous releases.

The Simulink Code Inspector supports call-site validation for a cross-release SIL or PIL block. The block provides a specification of the expected function call, which is derived from the exported generated code and associated artifacts. During analysis, the Simulink Code Inspector compares the expected function call with the block behavior. For information about analysis limitations, see “S-Function” (Simulink Code Inspector).

### Limitations

The cross-release code integration workflow does not support:

- Export-function models for ERT code.
- Simulink Function and Function Caller blocks across the boundaries of ERT code generated by different releases.
• The integration of generated code from releases before R2010a.
• The import of generated code from the current release into a previous release (forward compatibility).
• The export of files located in the MATLAB root folder of the previous release, for example, blockset library files.
• The export and import of generated code from models with non-inlined S-functions.
• C-API on page 46-2.

At the end of the model build process, the code generation report displays shared files that are directly used by the integration model, for example, Controller. The report does not display shared files used by the components of the model, for example, P1 and P2.

If your model has:

• A cross-release SIL or PIL block, you cannot run rapid accelerator mode simulations.
• A Model block that references a model containing a cross-release SIL or PIL block, you cannot run accelerator mode or rapid accelerator mode simulations.

You can run:

• Top-model SIL simulations of models that contain cross-release SIL or PIL blocks. The models must not contain cross-release AUTOSAR Model blocks.
• Model block SIL simulations of referenced models that contain cross-release SIL or PIL blocks. The referenced models must not contain cross-release AUTOSAR Model blocks.

For information about other cross-release AUTOSAR code integration limitations, see “Import AUTOSAR Code from Previous Releases” on page 36-100.

**Simulink.Bus Support**

To use a bus object as a data type in cross-release ERT code integration, use one of these approaches.
<table>
<thead>
<tr>
<th>Approach</th>
<th>Code Export</th>
<th>Code Import</th>
</tr>
</thead>
<tbody>
<tr>
<td>Automatic</td>
<td>In the previous release, before generating code, set the <code>DataScope</code> property of the <code>Simulink.Bus</code> object to <code>Auto</code>. Do not assign a value to the <code>HeaderFile</code> property. The code generator creates the <code>Simulink.Bus</code> data type definition in the default header file on page 37-18, which is located in the code generation folder for the model.</td>
<td>In the current release, before running <code>crossReleaseImport</code>, set the <code>DataScope</code> property of the <code>Simulink.Bus</code> object to <code>Auto</code>. When you build the integration model, the build process uses the <code>Simulink.Bus</code> data type from the header file in the imported code.</td>
</tr>
</tbody>
</table>
In the previous release, before generating code, specify these properties of the Simulink.Bus object:

- **DataScope** — Set to **Exported**.
- **HeaderFile** — Specify a file name, for example, `prevRelBusType`.

The code generator creates `prevRelBusType.h` in the shared utility code folder. This header file contains the definition for the Simulink.Bus data type. Use `sharedCodeUpdate` to add `prevRelBusType.h` to the shared code folder that `ExistingSharedCode` specifies.

For R2010a and R2010b, the **DataScope** property is not available. Do not assign a value to the **HeaderFile** property. The code generator creates the Simulink.Bus data type definition in `modelName_types.h`, which is located in the code generation folder for the model.

In the current release, before running `crossReleaseImport`, set the **DataScope** property of the Simulink.Bus object to **Imported**.

When you build the integration model that incorporates the imported SIL or PIL block, the build process uses the Simulink.Bus data type definition in `prevRelBusType.h`.

If the imported code is from R2010a or R2010b, specify these properties of the Simulink.Bus object:

- **DataScope** — Set to **Imported**.
- **HeaderFile** — Set to file path for `modelName_types.h`, which is in the imported code folder.

When you build the integration model, the build process uses the Simulink.Bus data type definition in `modelName_types.h`.

<table>
<thead>
<tr>
<th><strong>Approach</strong></th>
<th><strong>Code Export</strong></th>
<th><strong>Code Import</strong></th>
</tr>
</thead>
</table>
| **Exported bus** | In the previous release, before generating code, specify these properties of the Simulink.Bus object:  
- **DataScope** — Set to **Exported**.  
- **HeaderFile** — Specify a file name, for example, `prevRelBusType`.  

The code generator creates `prevRelBusType.h` in the shared utility code folder. This header file contains the definition for the Simulink.Bus data type. Use `sharedCodeUpdate` to add `prevRelBusType.h` to the shared code folder that `ExistingSharedCode` specifies.  

For R2010a and R2010b, the **DataScope** property is not available. Do not assign a value to the **HeaderFile** property. The code generator creates the Simulink.Bus data type definition in `modelName_types.h`, which is located in the code generation folder for the model. | In the current release, before running `crossReleaseImport`, set the **DataScope** property of the Simulink.Bus object to **Imported**.  

When you build the integration model that incorporates the imported SIL or PIL block, the build process uses the Simulink.Bus data type definition in `prevRelBusType.h`.  

If the imported code is from R2010a or R2010b, specify these properties of the Simulink.Bus object:  
- **DataScope** — Set to **Imported**.  
- **HeaderFile** — Set to file path for `modelName_types.h`, which is in the imported code folder.  

When you build the integration model, the build process uses the Simulink.Bus data type definition in `modelName_types.h`. |
In the previous release, before generating code, specify these properties of the Simulink.Bus object:

- **DataScope** — Set to Imported.
- **HeaderFile** — Specify a path to a file that contains the Simulink.Bus data type definition, for example, aBusType.h.

For R2010a and R2010b, the DataScope property is not available. For the HeaderFile property, specify a path to a file that contains the Simulink.Bus data type definition, for example, aBusType.h.

In the current release, after importing generated code, you do not have to change the Simulink.Bus.

When you build the integration model that incorporates the imported SIL or PIL block, the build process uses the Simulink.Bus data type definition from aBusType.h.

If the imported code is from R2010a or R2010b, specify these properties of the Simulink.Bus object:

- **DataScope** — Set to Imported.
- **HeaderFile** — Set to aBusType.h.

When you build the integration model, the build process uses the Simulink.Bus data type definition in aBusType.h.

### Root-Level I/O Through Global Variables in Generated Code

When imported ERT code from a previous release implements an input or output port through a global variable, the code that is generated from the integration model depends on the properties of the signal connected to the port in the integration model.

If the integration model signal does not map to a generated code variable that has the same name as the signal in the imported code, the generated code:

- Defines the variable if it is declared but undefined in the imported code.
- Creates additional code to copy data between the variable generated from the integration model and the variable in the imported code.

If the integration model signal maps to a variable with the same name as the signal in the imported code, the variable used by the imported code is also used by the code generated from the integration model. You must use a compatible storage class for the signal.
<table>
<thead>
<tr>
<th>Storage Class Property</th>
<th>Property Value Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Unstructured only</td>
</tr>
<tr>
<td>Data access</td>
<td>Cannot connect a port implemented as a Pointer variable in the imported code to a signal of the same name that is implemented through a Direct storage class in the integration model. Cannot connect a port implemented as a Direct variable in the imported code to a signal of the same name that is implemented as a Pointer in the integration model.</td>
</tr>
</tbody>
</table>
### Storage Class Property | Property Value Support
--- | ---
**Data scope** | If the imported code declares but does not define the variable (i.e. code is generated from a signal that uses the *Imported* value), then one of the following is required:

- The integration model uses the *Exported* value.
- External code defines the variable.

If the imported code defines the variable (i.e. code is generated from a signal that uses the *Exported* value):

- For signals in the integration model that are connected to root-level I/O ports:
  
  - Set the `EnableDataOwnership` configuration parameter to *on*.
  
  - Use a custom storage class with these properties:
    
    - **Type** - Unstructured
    - **Data access** - Direct
    - **Data scope** - Exported
    - **Owner** - Non-empty value that is not the name of the integration model. For example, the value can be the name of the imported component.

- For signals in the integration model that are not connected to root-level I/O ports, use a custom storage class with these property values:
  
  - **Data scope** - Imported
  
  - **Data access** - Direct
Communicate Between Current and Previous Release Components Through Global Data Stores

Current and previous release components can communicate through global data stores associated with Simulink.Signal objects in the MATLAB base workspace or a Simulink data dictionary. The workflow described here applies to cross-release ERT code integration.

Export Configuration

Before generating code in the old release, for the model component that you want to export, configure data store memory to use a storage class that imports external code.

If a top-model or subsystem build process generates the code, set the Storage class property of the Simulink.Signal objects to one of these classes:

- ImportedExtern
- ImportedExternPointer
- ImportFromFile custom storage class

If a model reference build process generates the code, you can also use these classes:

- ExportedGlobal
- ExportToFile custom storage class

When you run crossReleaseExport, the function identifies data store memories in the codeInfo.mat file and places required information in the crossReleaseInfo.m artifact.

Import Configuration

In the current release, before you run crossReleaseImport, define a Simulink.Signal object in the MATLAB base workspace or a Simulink data dictionary for each global data store of the component that you want to import:

1. For the object name and the Data type, Complexity, and Dimensions object properties, specify values that match values of the corresponding object in the component that you want to import.

2. For the Storage class property, specify a value that is compatible. If the previous release value is ImportedExtern, specify one of these values for the current release:
- ImportedExtern
- ExportedGlobal
- ImportFromFile or ExportToFile custom storage class.

If the previous release value is ImportedExternPointer, then specify ImportedExternPointer for the current release.

3 For the **Alias** property, specify a matching value only if the property is specified for the object in the component that you want to import.

4 Save the Simulink.Signal objects. The objects are required each time you simulate or build the imported SIL or PIL block.

For more information, see “Data Stores in Generated Code” (Simulink Coder).

**Parameter Tuning**

The cross-release ERT code integration workflow supports parameter tuning in an integration model that contains component code with tunable parameters from previous releases.

In the current release, before you run `crossReleaseImport`, for each tunable parameter of the component that you want to import:

1 Define a Simulink.Parameter object in the MATLAB base workspace or a Simulink data dictionary.

2 For the object name and the **Data type, Complexity**, and **Dimensions** object properties, specify values that match the exported object values. If the variable in the imported source code does not have the same name as the object, for the **Alias** property, specify a value that matches the variable name.

3 If the exported object uses the GetSet custom storage class, specify:

   - A matching value for the **Storage class** object property.
   - The header file that defines the get and set access functions. For details, see “Control Data Representation by Configuring Custom Storage Class Properties” on page 26-31 and “Access Data Through Functions with Custom Storage Class GetSet” on page 26-42.

Support of the GetSet custom storage class from a previous release applies only for R2011a and later releases.
For code generated by a top-model or subsystem build process in a previous release, these limitations apply:

- If a tunable parameter specified by a `Simulink.Parameter` object is exported from the previous release with storage class set to `ExportedGlobal` and the storage class of the `Simulink.Parameter` object in the current release is also `ExportedGlobal`, an error occurs when you build the integration model.

- On a Mac operating system, if a tunable parameter specified by a `Simulink.Parameter` object is exported from a previous release with storage class set to `ExportedGlobal`, you cannot build the integration model if the storage class of the `Simulink.Parameter` object in the current release (with the same name or alias) is `ImportedExtern`. To work around this limitation, modify the default settings:

1. Get the build tool from the default toolchain.
   ```matlab
tc = coder.make.getDefaultToolchain;
cComp = tc.getBuildTool('C Compiler');
```

2. Extract the C compiler standard options.
   ```matlab
stdMaps = cComp.SupportedStandard.getLangStandardMaps;
optionValues = stdMaps.getCompilerOptions('*');
```

3. Remove `-fno-common` from the standard options for the C and C++ compilers.
   ```matlab
optionToRemove = '-fno-common';
optionsToKeep = strrep(optionValues, optionToRemove, '');
c_standard_opts_id = '$(C_STANDARD_OPTS)';

custToolChainOpts = get_param(model,'CustomToolchainOptions');
custToolChainOpts{2} = ...
   strrep(custToolChainOpts{2}, c_standard_opts_id, optionsToKeep);
set_param(model, 'CustomToolchainOptions',custToolChainOpts);
```

**Use Multiple Instances of Code Generated from Reusable Referenced Model**

Using a reusable referenced model, you can specify unique model argument values (Simulink) for each instance of the referenced model in a parent model. You can export previously generated code for the reusable referenced model, import the code into the current release as a parameterized cross-release SIL or PIL block, and then insert multiple instances of the block into an integration model. For each block instance, you can specify unique model argument values.

1. Export generated code for the reusable referenced model.
artifactLocation = crossReleaseExport(reusableReferencedModelcodeLocation)

2 Update existing shared code folder.

sharedCodeUpdate(sourceFolder,destinationFolder)

3 Import the code into the current release as a parameterized cross-release block, for example, a SIL block.

handleSILBlock = crossReleaseImport(artifactLocation, ... 
        configSetIntegrationModel, 'SimulationMode', 'SIL');

4 In the integration model, replace, for example, two instances of the referenced model with instances of the cross-release SIL block.

open_system(integrationModel);

blockInstanceName1 = 'refModelInstanceName1';
blockinstanceName2 = 'refModelInstanceName2';

SILBlockFullName = getfullname(handleSILBlock);
replace_block(integrationModel, 'Name', blockInstanceName1, ... 
        SILBlockFullName, 'noprompt');
replace_block(integrationModel, 'Name', blockInstanceName2, ... 
        SILBlockFullName, 'noprompt');

5 Suppose the reusable referenced model has model arguments paramA and paramB, and the values for the referenced model instances, refModelInstanceName1 and refModelInstanceName2, are workspace variables. In this case, you can specify argument values for the cross-release block instances that are workspace variables.

pathToBlockInstanceName1 = [integrationModel, '/', blockInstanceName1];
pathToBlockInstanceName2 = [integrationModel, '/', blockInstanceName2];

set_param(pathToBlockInstanceName1, 'paramA', 'paramA_instName1');
set_param(pathToBlockInstanceName1, 'paramB', 'paramB_instName1');

set_param(pathToBlockInstanceName2, 'paramA', 'paramA_instName2');
set_param(pathToBlockInstanceName2, 'paramB', 'paramB_instName2');

6 To specify unique model argument values for the block instances in the integration model, assign values to the workspace variables, paramA_instName1, paramB_instName1, paramA_instName2, and paramB_instName2.
Compare Simulation Behavior of Model Component in Current Release and Generated Code from Previous Release

In a previous release, suppose that you developed a model component, generated code for the component, and tested and deployed the generated code. Now, in the current release, you want to add features to the model component and use the model component in system development and code generation. Before you proceed, you can compare the functional behavior of the model component and the generated code from the previous release.

To test the numerical equivalence between the model component and the generated code from the previous release, use Simulink Test. With the Test Manager (Simulink Test), you can perform back-to-back tests and output comparisons:

1. Bring the model component into the current release as a Model block with the **Simulation mode** block parameter set to **Normal**.
2. With the Model block, create a top model that specifies test input data.
3. Import the code generated in the previous release into the current release as a SIL block.
4. With the SIL block, create another top model that specifies the same the test input data.
5. In the Test Manager, create an equivalence test case that runs simulations of the top models and compares outputs.
6. Run the test case and review results.

For more information, see Test Manager examples in “Simulink Test Examples” (Simulink Test).

**Note** If you want to compare the behavior of generated code from the current and previous release, in step 1, specify these Model block parameters:

- Set **Simulation mode** to **Software-in-the-loop (SIL)** or **Processor-in-the-loop (PIL)**.
- Set **Code interface** to **Top model**.
Import AUTOSAR Code from Previous Releases

If you install the Embedded Coder Support Package for AUTOSAR Standard, you can import into the current release AUTOSAR component code that you generated in a previous release.

When you run `crossReleaseImport`, the function imports the AUTOSAR code as a cross-release Model block instead of a SIL or PIL block. The Simulation mode parameter of the Model block is set to Software-in-the-loop (SIL) or Processor-in-the-loop (PIL). Incorporate the Model block into the current release model.

These limitations apply:

- The cross-release workflow does not support per-instance memory that accesses NVRAM.
- Tunable parameters must use AUTOSAR `CalPrm` or `InternalCalPrm` custom storage classes.
- If the original model uses variants or symbolic dimensions (dimension variants), the imported model can use only the same variant and symbolic dimension configuration that was used when generating the code in the previous release.

Generate Code Using Simulink® Coder™

This example shows how to select a system target file for a Simulink® model, generate C code for real-time simulation, and view generated files.

The model represents an 8-bit counter that feeds a triggered subsystem that is parameterized by constant blocks INC, LIMIT, and RESET. Input and Output represent I/O for the model. The Amplifier subsystem amplifies the input signal by gain factor \( K \), which updates when signal equal_to_count is true.

1. Open the model. For example, type the following commands at the MATLAB® command prompt.

```matlab
model='rtwdemo_rtwintro';
open_system(model)
```

Algorithm Description

An 8-bit counter feeds a triggered subsystem parameterized by constants INC, LIMIT, and RESET. The I/O for the model is Input and Output. The Amplifier subsystem amplifies the input signal by gain factor \( K \), which is updated whenever signal equal_to_count is true.
2. Open the Configuration Parameters dialog box from the model editor by clicking Simulation > Configuration Parameters.

Alternately, type the following commands at the MATLAB® command prompt.

cs = getActiveConfigSet(model);
openDialog(cs);

3. Select the Code Generation node.

4. In the Target Selection pane, click Browse to select a target.

You can generate code for a particular target environment or purpose. Some built-in targeting options are provided using system target files, which control the code generation process for a target.
5. Select the **Generic Real-Time (GRT)** target and click **Apply**.

Optionally, in the **Code Generation Advisor** pane set the **Select objective** field to **Execution efficiency** or **Debugging**. Then click **Check model...** to identify and systematically change parameters to meet your objectives.

6. In the model window, initiate code generation and the build process for the model by using any of the following options:
• Click the Build Model button.
• Press Ctrl+B.
• Select Code > C/C++ Code > Build Model.
• Invoke the rtwbuild command from the MATLAB command line.
• Invoke the slbuild command from the MATLAB command line.

7. View the code generation report that appears.

   The report includes links to model files such as rtwdemo_rtwintro.c and associated utility and header files.
The figure below contains a portion of `rtwdemo_rtwintro.c`
Source Code Generation in Simulink Coder

    */
    rtb_equal_to_count = (rtb_sum_out != 16);

    /* Outputs for Triggered SubSystem: '<Root>/Amplifier' incorporates:
    * TriggerPort: '<S1>/Trigger'
    */
    if (rtb_equal_to_count && (rtwdemo_rtwintro_Prev2CSigState Amplier_Trig_ZCE
                             != POS_ZCSIG)) {
        /* Output: '<Root>/Output' incorporates:
        * Gain: '<S1>/Gain'
        * Input: '<Root>/Input'
        */
        rtwdemo_rtwintro_Y.Output = rtwdemo_rtwintro_U.Input << 1;
    }

    rtwdemo_rtwintro_Prev2CSigState.Amplier_Trig_ZCE = (uint8_T)
        (rtb_equal_to_count ? (int32_T)POS_ZCSIG : (int32_T)ZERO_ZCSIG);

    /* End of Outputs for SubSystem: '<Root>/Amplifier' */

    /* Switch: '<Root>/Switch' */
    if (rtb_equal_to_count) {
        /* Update for UnitDelay: '<Root>/X' */
        rtwdemo_rtwintro_DWork.X = rtb_sum_out;
    } else {
        /* Update for UnitDelay: '<Root>/X' incorporates:
        * Constant: '<Root>/RESET'
        */
        rtwdemo_rtwintro_DWork.X = 0U;
    }

    /* End of Switch: '<Root>/Switch' */

}
8. Close the model.

bdclose(model)
rtwdemoclean;

Generate Code Using Embedded Coder®

This example shows how to select a target for a Simulink® model, configure options, generate C code for embedded systems, and view generated files.

The model represents an 8-bit counter that feeds a triggered subsystem that is parameterized by constant blocks INC, LIMIT, and RESET. Input and Output represent I/O for the model. The Amplifier subsystem amplifies the input signal by gain factor K, which updates when signal equal_to_count is true.

1. Open the model.

```matlab
model='rtwdemo_rtwecintro';
open_system(model)
```

2. Open the Configuration Parameters dialog box from the model editor by clicking Simulation > Model Configuration Parameters.
Alternately, type the following commands at the MATLAB® command prompt.

```matlab
cs = getActiveConfigSet(model);
openDialog(cs);
```

3. Select the **Code Generation** node.

![Configuration Parameters](image)

4. In the **Target Selection** pane, click **Browse** to select a target.

You can generate code for a particular target environment or purpose. Some built-in targeting options are provided using system target files, which control the code generation process for a target.
Source Code Generation in Embedded Coder

Target selection

System target file:  ert.tlc
Language:  C
Description:  Embedded Coder
5. Select the **Embedded Real-Time (ERT)** target and click **Apply**.

The ERT target includes a utility to specify and prioritize code generation settings based on your application objectives.

6. In the **Code Generation Advisor** pane, click **Set Objectives**.
You can set and prioritize objectives for the generated code. For example, while code traceability might be a very important criterion for your application, you might not want to prioritize it at the cost of code execution efficiency.

7. In the Set Objectives pane, select Execution efficiency and Traceability. Click OK.

You can select and prioritize a combination of objectives before generating code.

8. In the model window, initiate code generation and the build process for the model by using any of the following options:

- Click the Build Model button.
- Press Ctrl+B.
- Select Code > C/C++ Code > Build Model.
- Invoke the rtwbuild command from the MATLAB command line.
- Invoke the slbuild command from the MATLAB command line.

9. View the code generation report that appears.

The report includes rtwdemo_rtwecintro.c, associated utility and header files, and traceability and validation reports.
The figure below contains a portion of `rtwdemo_rtwecintro.c`
File: rtwdemo_rtwecintro.c

1 /* Model step function */
2 void rtwdemo_rtwecintro_step(void)
3 {
4     boolean_T rtb_equal_to_count;
5
6     /* Sum: '<Root>/Sum' incorporates:
7        * Constant: '<Root>/INC'
8        * UnitDelay: '<Root>/X'
9        */
10    rtDWork.X = (uint8_T)(1U + (uint32_T)rtDWork.X);
11
12    /* RelationalOperator: '<Root>/RelOpt' incorporates:
13       * Constant: '<Root>/LIMIT'
14       */
15    rtb_equal_to_count = (rtDWork.X != 16);
16
17    /* Outputs for Triggered SubSystem: '<Root>/Amplifier' incorporates:
18       * TriggerPort: '<s1>/Trigger'
19       */
20    if (rtb_equal_to_count && (rtPrevZCSigState.Amplifier_Trig_ZCE != POS_ZCSIG))
21    {
22        /* Output: '<Root>/Output' incorporates:
23           * Gain: '<s1>/Gain'
24           * Import: '<Root>/Input'
25           */
26        rtY.Output = rtU.Input << 1;
27    }
28
29    rtPrevZCSigState.Amplifier_Trig_ZCE = (uint8_T)(rtb_equal_to_count ? (int32_T)
30    POS_ZCSIG : (int32_T)ZERO_ZCSIG);
31
32    /* End of Outputs for SubSystem: '<Root>/Amplifier' */
33
34    /* Switch: '<Root>/Switch' */
35    if (!rtb_equal_to_count) {
36        /* Update for UnitDelay: '<Root>/X' incorporates:
37           * Constant: '<Root>/RESET'
38           */
39        rtDWork.X = 0U;
40    }
41    /* End of Switch: '<Root>/Switch' */
42}
10. Close the model.

```matlab
bdclose(model)
rtwdemoclean;
```

Generate Code by Using the Quick Start Tool

The Quick Start tool helps you prepare a model for generating readable, efficient code. To start the tool, from the model window, select Code > C/C++ > Embedded Coder Quick Start.

After you start the tool, you must answer these questions about the code that you want to generate:

- What is the model or subsystem for code generation?
- What is the type of code output for your generated code?
- Does your application require reentrant, multi-instance code?
- What is the target hardware processor type?
- What is your primary code generation objective?

The tool validates your choices against the model and presents the parameter changes required to generate code. If you choose to generate code, the tool applies the changes to your configuration set and generates the code. After code generation, you can view the code generation report and find information on building, customizing, optimizing, and packaging the code. To further customize your generated code, click Finish and you are immediately brought into the Code Perspective environment in the editor window. The Code Perspective provides the tools to control the names and representation of the model data and functions in the generated code. For more information, see “Environment for Configuring Model Data and Functions for Code Generation” on page 21-2.

Quick Start Model Analysis

At each step of the quick start process, the tool validates your model against your selections. The tool determines if there are model conditions that prevent you from proceeding with code generation. During the analysis step, the tool must also examine your model or subsystem for answers to the following questions. The answers help determine the best configuration for the deployment of your code.

How many sample rates are in your system?

The Quick Start tool evaluates your model to determine the number of periodic sample rates in your system.
Single rate | Your model has only one periodic sample rate. The generated code has a single-entry point function that runs at the time interval of the sample rate.

Multirate | Your model has more than one periodic sample rate. It is possible that the generated code does not execute at the same time intervals. After the analysis step, you can choose to generate a single-entry point function for each of the sample rates or generate a different entry point function for each sample rate.

If you choose to generate multitasking code, the code generator produces multiple entry-point functions. These functions run as multiple tasks. Each entry-point function is called at an interval defined by the sample rate that is configured in the model.

**Note** If your model contains an asynchronous rate, an additional entry-point function is generated to run at the specific interrupt time.

For more information about sample rates, see “Time-Based Scheduling and Code Generation” (Simulink Coder).

**Does your system contain continuous states?**

The Quick Start tool evaluates your model for continuous blocks to determine the correct solver to use.

| No | If your system does not contain continuous states, the Quick Start tool configures your model to use a fixed-step discrete solver for code generation if you have not selected one. |
| Yes | If your system does contain continuous states, the Quick Start tool configures your model to use a fixed-step continuous solver for code generation if you have not selected one. The tool also selects the SupportContinuous configuration parameter. |

For more information on solvers, see “Solver Types” (Simulink).

**Did you configure your system for export function calls?**

The Quick Start tool evaluates your model to see if scheduler code must be generated.
**No** | If you did not configure your system for export function calls, the generated code includes code for the system algorithm and the scheduler code.
---|---
**Yes** | If you configured your system for export function calls, the generated code includes code for the system algorithm. You can manually write the scheduler code or generate it from other models.

For more information, see “Export-Function Models” (Simulink).

**Does your system contain referenced models?**

The Quick Start tool evaluates your model to see if it depends on code from other models.

<table>
<thead>
<tr>
<th>No</th>
<th>If your system does not contain referenced models, the generated code does not depend on code from other models.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Yes</td>
<td>If your system contains referenced models, the generated code for your model depends on other modules generated from referenced models. The code generator can optimize the generated code because it is aware of the relationship between your model and the referenced models.</td>
</tr>
</tbody>
</table>

For more information, see “Code Generation of Referenced Models” (Simulink Coder).

**Configuration Parameter Changes for Models with a Configuration Reference**

To apply configuration parameter changes to a model with an active configuration reference, the Quick Start tool:

- Creates a `Simulink.ConfigSet` object, `QuickStart_timestamp`, in the workspace or data dictionary that contains the original configuration set. The new object is a copy of the original configuration set that has the parameter changes applied.
- Creates a `Simulink.ConfigSetRef` object that points to the new configuration set object.
- Attaches the new configuration reference to the model and makes it the active configuration.

To restore the original configuration set, activate the original `Simulink.ConfigSetRef` object.
Note If the Quick Start tool creates the configuration set object in the MATLAB workspace, you must save it to preserve the configuration set after the MATLAB session ends. For more information, see “Save a Configuration Set” (Simulink).

Next Steps

After you have generated code by using Quick Start, possible next steps are:

- “Open Code Generation Report” on page 38-8
- “Code Appearance”
- “Build Process”
- “Application Objectives Using Code Generation Advisor” (Simulink Coder)
- “Manage a Configuration Set” (Simulink)
- “Configure Model and Generate Code” (Simulink Coder)
- “Relocate Code to Another Development Environment” (Simulink Coder)

To control the names and representation of the model data and functions in the generated code, use the Code Perspective in the Simulink Editor. When you are done with Quick Start and you click Finish, you are immediately brought into the Code Perspective environment in the editor window. To enter the perspective from outside of the Quick Start tool, in the model window, select **Code > C/C++ Code > Configure Model in Code Perspective**. For more information, see “Environment for Configuring Model Data and Functions for Code Generation” on page 21-2.
Manage File Packaging of Generated Code Modules

The code generator produces code modules. The file packaging configuration controls where the code generator places code into code modules and header files.

To locate and examine the generated code files, use the HTML code generation report. The code generation report provides hyperlinks in the comments that you click to view the generated code in the MATLAB Help browser. For more information, see “Traceability in Code Generation Report” on page 64-3.

<table>

</tr>
<tr>
<td>“Customize Generated Code Modules” on page 37-18</td>
</tr>
</tbody>
</table>

Generated Code Modules

The code generator creates a build folder in your working folder to store generated source code. The build folder contains object files, a makefile, and other files created during the code generation process. The default name of the build folder is `model_ert_rtw`.

Code Modules and Header Files Affected by File Packaging summarizes the structure of source code that the code generator produces.

You can customize the generated set of files in several ways:

- File packaging formats: Manage the number of source files generated for your model. In the Configuration Parameter dialog box, on the Code Generation > Code Placement pane, specify the File packaging format parameter. For more information, see “Customize Generated Code Modules” on page 37-18.

- Nonvirtual subsystem code generation: Instruct the code generation software to generate separate functions within separate code files for nonvirtual subsystems. You can control the names of the functions and of the code files. For further information, see “Control Generation of Subsystem Functions” (Simulink Coder).

- Custom storage classes: Use custom storage classes to partition generated data structures into different files based on file names that you specify. For further
information, see “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 26-19.

- Module Packaging Features (MPF): Direct the generated code into a required set of .c or .cpp and .h files, and control the internal organization of the generated files. For details, see “Data, Function, and File Definition”.
## Code Modules and Header Files Affected by File Packaging

<table>
<thead>
<tr>
<th>File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>model.c</code> or <code>.cpp</code></td>
<td>Contains entry points for code implementing the model algorithm (for example, <code>model_step</code>, <code>model_initialize</code>, and <code>model_terminate</code>).</td>
</tr>
<tr>
<td><code>model_private.h</code></td>
<td>Contains local macros and local data that the model and subsystems require. This file is included in the <code>model.c</code> file as a <code>#include</code> statement. You do not need to include <code>model_private.h</code> when interfacing handwritten code to the generated code of a model.</td>
</tr>
<tr>
<td><code>model.h</code></td>
<td>Declares model data structures and a public interface to the model entry-points and data structures. Provides an interface to the real-time model data structure (<code>model_M</code>) with accessor macros.</td>
</tr>
<tr>
<td></td>
<td>The code generator:</td>
</tr>
<tr>
<td></td>
<td>• Produces a separate header file for each Simulink Function block in a model.</td>
</tr>
<tr>
<td></td>
<td>• Includes <code>model.h</code> in the subsystem <code>.c</code> or <code>.cpp</code> files of a model.</td>
</tr>
<tr>
<td></td>
<td>If you interface handwritten code to generated code for one or more models, include <code>model.h</code> for each of those models.</td>
</tr>
<tr>
<td><code>model_data.c</code> or <code>.cpp</code></td>
<td>Contains (if conditionally generated) the declarations for the parameters data structure, the constant block I/O data structure, and any zero representations for the model structure data types. If the model does not use these data structures and zero representations, <code>model_data.c</code> or <code>.cpp</code> is not generated. These structures and zero representations are declared <code>extern</code> in <code>model.h</code>.</td>
</tr>
<tr>
<td><code>model_types.h</code></td>
<td>Provides forward declarations for the real-time model data structure and the parameters data structure. Function declarations of reusable functions can require these declarations. Provides type definitions for user-defined types that the model uses.</td>
</tr>
<tr>
<td><code>rtwtypes.h</code></td>
<td>Defines data types, structures, and macros required by generated code. For more information, see “Control Placement of rtwtypes.h for Shared Utility Code” (Simulink Coder).</td>
</tr>
<tr>
<td>File</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>multiword_types.h</td>
<td>Contains type definitions for wide data types and their chunks. File is generated when multiword data types are used or when you select one or more of these configuration parameters:</td>
</tr>
<tr>
<td></td>
<td>• <strong>MAT-file logging</strong></td>
</tr>
<tr>
<td></td>
<td>• <strong>Code Generation &gt; Interface &gt; External mode</strong></td>
</tr>
<tr>
<td>model_reference_types.h</td>
<td>Contains type definitions for timing bridges. File is generated for a model reference target or a model containing model reference blocks.</td>
</tr>
<tr>
<td>builtin_typeid_types.h</td>
<td>Defines an enumerated type corresponding to built-in data types. File is generated when your model contains a Stateflow chart that uses messages or when you select one or more of these configuration parameters:</td>
</tr>
<tr>
<td></td>
<td>• <strong>MAT-file logging</strong></td>
</tr>
<tr>
<td></td>
<td>• Any C API option at Code Generation &gt; Interface</td>
</tr>
<tr>
<td>zero_crossing_types.h</td>
<td>Contains zero-crossing definitions for models with triggered subsystems where the trigger is rising, falling, or either. File is generated only if required by the model.</td>
</tr>
<tr>
<td>ert_main.c or.cpp</td>
<td>(optional file) If the <strong>Generate an example main program</strong> option is on (default), this file is generated. For more information, see “Generate an example main program”.</td>
</tr>
<tr>
<td>rtmodel.h</td>
<td>(optional file) If the <strong>Generate an example main program</strong> option is off, this file is generated. For more information, see “Generate an example main program”.</td>
</tr>
<tr>
<td></td>
<td>Contains #include directives required by the rt_main.c or rt_cppclass_main.cpp static main program module. Includes rtmodel.h to access model-specific data structures and entry points, because the static main program module is not created at code generation time.</td>
</tr>
<tr>
<td></td>
<td>For more information, see “Static Main Program Module” on page 52-11.</td>
</tr>
</tbody>
</table>
### User-Written Code Modules

Code that you write to interface with generated model code usually includes a customized main module. Base this module on a main program provided by the code generation software. This customized main module can also include interrupt handlers, device driver blocks and other S-functions, and other supervisory or supporting code. Steps to set up the development environment to support a customized main module include:

1. Establish a working folder for your own code modules.
2. Put your working folder on the MATLAB path.
3. At minimum, inform the build process about the location of your source and object files with **Additional build information** in the **Code Generation > Custom Code** pane.
4. Your development process could require generating code for a particular microprocessor or development board and deploying the code on target hardware with a cross-development system. To accomplish these goals, make more extensive modifications to the ERT-based system target file.

For information on how to customize your ERT-based system target file for your production requirements, see “Target Development” (Simulink Coder).

### Customize Generated Code Modules

A configuration parameter is available to specify how the code generator packages generated source code into files. The configuration parameter **File packaging format** options are located in the Configuration Parameter dialog box, on the **Code Generation > Code Placement** pane, in the **Code packaging** section. The options are Modular, Compact (with separate data file), and Compact. The table describes the generated files and the removed files for each file packaging format.

<table>
<thead>
<tr>
<th>File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>model_capi.c</code></td>
<td>(optional file) Provides data structures that enable a running program to access model signals, states, and parameters without external mode. To learn how to generate and use the <code>model_capi.c</code> or <code>.cpp</code> and <code>.h</code> files, see “Exchange Data Between Generated and External Code Using C API” (Simulink Coder).</td>
</tr>
</tbody>
</table>
Generated Files According to File Packaging Format

<table>

<td>(conditional, see Removed Files According to File Packaging Format)</td>
</tr>
</tbody>
</table>

The table describes content placement from the removed files.

Removed Files According to File Packaging Format

<table>
<thead>
<tr>
<th>Removed File</th>
<th>Generated Content In File</th>
</tr>
</thead>
<tbody>
<tr>
<td>model_private.h</td>
<td>model.c and model.h</td>
</tr>
<tr>
<td>model_types.h</td>
<td>model.h</td>
</tr>
<tr>
<td>model_data.c</td>
<td>model.c</td>
</tr>
</tbody>
</table>

You can specify a different file packaging format for each referenced model.
The **Configuration Parameter > Code Generation > Interface > Shared code placement** selection interacts with file packaging operations. If you specify **Shared code placement** as Shared location, the code generator generates separate files for utility code in a shared location, regardless of the file packaging format. If you specify the **Shared code placement** as Auto, the code generator generates code for utilities according to the file packaging format selection.

- **Modular**: Some shared utility files are in the build folder.
- **Compact (with separate data file)**: Utility code is generated in `model.c`.
- **Compact**: Utility code is generated in `model.c`.

File packaging formats Compact and Compact (with separate data file) generate `model_types.h` for models containing:

- A Model Variants block or a Variant Subsystem block. The `model_types.h` file includes preprocessor directives defining the variant objects associated with a variant block.
- Custom storage classes generating a separate header file.

File packaging formats Compact and Compact (with separate data file) are not compatible with:

- A model containing a subsystem, which is configured to generate separate source files
- A model containing a noninlined S-function
- A model for which **Shared code placement** is set to Auto, which uses data objects for which **Data scope** is set to Exported

Generate Reentrant Code from Top-Level Models

<table>
<thead>
<tr>
<th>In this section…</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Configure Model” on page 37-21</td>
</tr>
<tr>
<td>“Share Data Between Instances” on page 37-22</td>
</tr>
</tbody>
</table>

To generate reentrant multi-instance code from a model, select Reusable function code interface packaging. When you select the Reusable function code interface for an ERT-based model:

- By default, the generated model.c source file does not contain an allocation function that dynamically allocates model data for each instance of the model. Use the Use dynamic memory allocation for model initialization option to control whether an allocation function is generated.
- The generated code passes the real-time model data structure in, by reference, as an argument to model.Step and the other model entry point functions.
- The real-time model data structure is exported with the model.h header file.
- By default, root-level input and output arguments are passed to the reusable model entry-point functions as individual arguments. Use the Pass root-level I/O as parameter to control whether root-level input and output arguments are passed. This selection chooses whether this I/O is included in the real-time model data structure that is passed to the functions, passed as individual arguments, or passed as references to an input structure and an output structure.

Configure Model

To configure an ERT-based model to generate reusable, reentrant code:

1. In the Code Generation > Interface pane of the Configuration Parameters dialog box, set Code interface packaging (Simulink Coder) to the value Reusable function. This action enables the parameters Multi-instance code error diagnostic, Pass root-level I/O as, and Use dynamic memory allocation for model initialization.

2. Examine the setting of Multi-instance code error diagnostic (Simulink Coder). Leave the parameter at its default value Error unless you have a specific need to alter the severity level for diagnostics displayed when a model violates requirements for generating multi-instance code.
3 Configure **Pass root-level I/O as** (Simulink Coder) to control how root-level model input and output are passed to `model_step` and the other generated model entry-point functions.

When you set **Code interface packaging** to **Reusable function**, model data (such as block I/O, DWork, and parameters) is packaged into the real-time model data structure, and the model structure is passed to the model entry-point functions. If you set **Pass root-level I/O as** to **Part of model data structure**, the root-level model input and output also are packaged into the real-time model data structure.

4 If you want the generated model code to contain a function that dynamically allocates memory for model instance data, select the option **Use dynamic memory allocation for model initialization** (Simulink Coder). If you do not select this option, the generated code statically allocates memory for model data structures.

5 Generate model code.

6 Examine the model entry-point function interfaces in the generated files and the HTML code generation report. For more information about generating and calling model entry-point functions, see “Configure Code Generation for Model Entry-Point Functions” (Simulink Coder).

For an example of a model configured to generate reusable, reentrant code, open the example model `rtwdemo_reusable`. Click the button **View Interface Configuration** and examine the **Code interface** parameters on the **Code Generation > Interface** pane.

---

**Share Data Between Instances**

When your code calls a reentrant model entry-point function multiple times, each call represents an instance of the model. By default, Embedded Coder generates code that assumes each instance reads from and writes to a separate copy of the signals, block states, and parameters in the model.
• To share a piece of parameter data between the instances (for example, to share a setpoint for a reusable PID control algorithm), use a parameter object, such as `Simulink.Parameter`, and apply a storage class other than `Auto` or, if you set the default storage class for the corresponding category of parameter data to `Default` (the default setting) in the Code Mapping Editor, `Model default`. The parameter object appears in the code as a global symbol, such as a global variable, that the function accesses directly. For more information, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 22-81.

• To share a piece of nonparameter data between the instances (for example, to share a fault indication or an accumulator), use a data store. You can configure the data store to appear in the code as a global symbol, such as a global variable, that the function accesses directly. Create a global data store by using a `Simulink.Signal` object or use a `Data Store Memory` block and select the `Share across model instances` parameter. For more information, see “Model Global Data by Creating Data Stores” (Simulink) and `Data Store Memory`.

- “Web View of Model in Code Generation Report” on page 38-15
- “Analyze the Generated Code Interface” on page 38-19
- “Static Code Metrics” on page 38-33
- “Generate Static Code Metrics Report for Simulink Model” on page 38-37
- “Generate a Static Code Metrics Report for MATLAB Code” on page 38-42
- “Analyze Code Replacements in Generated Code” on page 38-48
- “Document Generated Code with Simulink Report Generator” on page 38-50
- “Get Code Description of Generated Code” on page 38-57
The code generator software produces an HTML code generation report so that you can view and analyze the generated code. When your model is built, the code generation process produces an HTML file that is displayed in an HTML browser or in the Model Explorer. The code generation report includes:

- The **Summary** section that contains model and code information, including **Author**, **Tasking Mode**, **System Target File**, **Hardware Device Type**, and code generation objectives information. The **Configuration settings at the time of code generation** link opens a noneditable view of the Configuration Parameters dialog box. The dialog box shows the Simulink model settings at the time of code generation, including TLC options.

- The **Subsystem Report** section that contains information on nonvirtual subsystems in the model.

- In the **Generated Files** section on the **Contents** pane, you can click the names of source code files generated from your model to view their contents in a MATLAB Web browser window. In the displayed source code, global variables are hypertext that links to their definitions.

For an example, see “Generate a Code Generation Report” on page 38-5.

If you have a Simulink Report Generator license, you can document your code generation project in multiple formats, including HTML, PDF, RTF, Microsoft Word, and XML. For an example of how to create a Microsoft Word report, see “Document Generated Code with Simulink Report Generator” on page 38-50.

### HTML Code Generation Report Location

The default location for the code generation report files is in the `html` subfolder of the build folder, `model_target_rtw/html/`. `target` is the name of the **System target file** specified on the **Code Generation** pane. The default name for the top-level HTML report file is `model_codegen_rpt.html` or `subsystem_codegen_rpt.html`. For more
information on the location of the build folder; see “Manage Build Process Folders” (Simulink Coder).

**HTML Code Generation Report for Referenced Models**

To generate a code generation report for a top model and code generation reports for each referenced model, you need to specify the Create code generation report on the Code Generation > Report pane for the top model and each referenced model. You can open the code generation report of a referenced model in one of two ways:

- From the top-model code generation report, you can access the referenced model code generation report by clicking a link under Referenced Models in the left navigation pane. Clicking a link opens the code generation report for the referenced model in the browser. To navigate back to the top model code generation report, use the Back button at the top of the left navigation pane.

For more information, see “Generate Code for Referenced Models” (Simulink Coder)

**HTML Code Generation Report Extensions**

If you have an Embedded Coder license, the code generator enhances the HTML code generation report. Configure your model to include the following sections in the report:

- The Code Interface Report section provides information about the generated code interface, including model entry-point functions and input/output data. For more information, see “Analyze the Generated Code Interface” on page 38-19.
- The Traceability Report section allows you to account for Eliminated / Virtual Blocks that are untraceable versus the listed Traceable Simulink Blocks / Stateflow Objects / MATLAB Scripts. This provides a complete mapping between model elements and code. For more information, see “Customize Traceability Reports” on page 64-36.
- The Static Code Metrics Report section provides statistics of the generated code. Metrics are estimated from static analysis of the generated code. For more information, see “Static Code Metrics” on page 38-33.
- The Code Replacements Report section allows you to account for code replacement library (CRL) functions that were used during code generation, providing a mapping between each replacement instance and the Simulink block that triggered the
replacement. For more information, see “Analyze Code Replacements in Generated Code” on page 38-48.

- The model Web view displays an interactive model diagram within the code generation report and supports traceability between the source code and the model. Therefore, you can share your model and generated code outside of the MATLAB environment. For more information, see “Web View of Model in Code Generation Report” on page 38-15.

On the Contents pane, in the Generated Files section, you can click the names of source code files generated from your model to view their contents in a MATLAB Web browser window. In the displayed source code:

- If you enable code-to-model traceability, hyperlinks within the displayed source code navigate to the blocks or subsystems from which the code is generated. For more information, see “Code-to-Model Traceability” on page 64-8.
- If you enable model-to-code traceability, you can navigate to the generated code for a block in the model. For more information, see “Model-to-Code Traceability” on page 64-10.
- If you set the Code coverage tool parameter on the Code Generation > Verification pane, you can view the code coverage data and annotations. For more information, see “Configure Code Coverage with Third-Party Tools” on page 70-11.
- If you select the Static code metrics check box on the Code Generation > Report pane, you can view code metrics information and navigate to code definitions and declarations in the generated code. For more information, see “View Static Code Metrics and Definitions Within the Generated Code” on page 38-35.

Related Examples

- “Verify Generated Code by Using Code Tracing” on page 64-2
Generate a Code Generation Report

To generate a code generation report when the model is built:

2. Select the Create code generation report (Simulink Coder) parameter.
3. If you want the code generation report to automatically open after generating code, select the Open report automatically (Simulink Coder) parameter (which is enabled by selecting Create code generation report).
4. Generate code.

The build process writes the code generation report files to the html subfolder of the build folder (see “HTML Code Generation Report Location” on page 38-2). Next, the build process automatically opens a MATLAB Web browser window and displays the code generation report.

To open an HTML code generation report at any time after a build, see “Open Code Generation Report” on page 38-8 and “Generate Code Generation Report After Build Process” on page 38-6.
Generate Code Generation Report After Build Process

After generating code, if you did not configure your model to create a code generation report, you can generate a code generation report without rebuilding your model.

1 In the model diagram window, select Code > C/C++ Code > Code Generation Report > Open Model Report.
2 If your current working folder contains the code generation files the following dialog opens.

   ![Generate Report Dialog]

   Code generation report is not found. To generate and open the report, click "Generate Report".

   Click Generate Report.
3 If the code generation files are not in your current working directory, the following dialog opens.

   ![Open Code Generation Report Dialog]

   The build folder cannot be determined. If the build folder is not in the current working folder, or not in the code generation folder specified in "Simulink Preferences > File generation control", then specify the location of the build folder.

   Enter the full path of the build folder for your model, ..\model_target_rtw and click Open Report.
The software generates a report, `model_codgen_rpt.html`, from the code generation files in the build folder you specified.

**Note** An alternative method for generating the report after the build process is complete is to configure your model to generate a report and build your model. In this case, the software generates the report without regenerating the code.
Open Code Generation Report

You can refer to existing code generation reports at any time. If you generated a code generation report, in the Simulink Editor, you can open the report by selecting the menu option **Code > C/C++ Code > Code Generation Report > Open Model Report**. If you are opening a report for a subsystem, select **Open Subsystem Report**. A Simulink Coder license is required to view the code generation report. An Embedded Coder license is required to view a code generation report enhanced with Embedded Coder features.

If your current working folder does not contain the code generation files and the code generation report, the following dialog box opens:

![Open Code Generation Report dialog box](image)

Enter the full path of the build folder for your model, `../model_target_rtw` and click **Open Report**.

Alternatively, you can open the code generation report (`model_codegen_rpt.html` or `subsystem_codegen_rpt.html`) manually into a MATLAB Web browser window, or in another Web browser. For the location of the generated report files, see “HTML Code Generation Report Location” on page 38-2.

**Limitation**

After building your model or generating the code generation report, if you modify legacy or custom code, you must rebuild your model or regenerate the report for the code generation report to include the updated legacy source files. For example, if you modify your legacy code, and then use the **Code > C/C++ Code > Code Generation Report >**
Open Model Report menu to open an existing report, the software does not check if the legacy source file is out of date compared to the generated code. Therefore, the code generation report is not regenerated and the report includes the out-of-date legacy code. This issue also occurs if you open a code generation report using the `coder.report.open` function.

To regenerate the code generation report, do one of the following:

- Rebuild your model.
- Generate the report using the `coder.report.generate` function.
Generate Code Generation Report Programmatically

At the MATLAB command line, you can generate, open, and close an HTML Code Generation Report with the following functions:

- `coder.report.generate` generates the code generation report for the specified model.
- `coder.report.open` opens an existing code generation report.
- `coder.report.close` closes the code generation report.
View Code Generation Report in Model Explorer

After generating an HTML code generation report, you can view the report in the right pane of the Model Explorer. You can also browse the generated files directly in the Model Explorer.

When you generate code, or open a model that has generated code for its current target configuration in your working folder, the Hierarchy (left) pane of Model Explorer contains a node named Code for model. Under that node are other nodes, typically called This Model and Shared Code. Clicking This Model displays in the Contents (middle) pane a list of generated source code files in the build folder of that model. The next figure shows code for the rtwdemo_counter model.

In this example, the file S:/rtwdemo_counter_grt_rtw/rtwdemo_counter.c is being displayed. To view a file in the Contents pane, click it once.

The views in the Document (right) pane are read only. The code listings there contain hyperlinks to functions and macros in the generated code. Clicking the file hyperlink opens that source file in a text editing window where you can modify its contents.

If an open model contains Model blocks, and if generated code for these models exists in the current slprj folder, nodes for the referenced models appear in the Hierarchy pane.
one level below the node for the top model. Such referenced models do not need to be open for you to browse and read their generated source files.

If the code generator produces shared utility code for a model, a node named Shared Code appears directly under the This Model node. It collects source files that exist in the ./slprj/target/_sharedutils subfolder.

**Note** You cannot use the Search tool built into Model Explorer toolbar to search generated code displayed in the Code Viewer. On PCs, typing Ctrl+F when focused on the Document pane opens a Find dialog box that you can use to search for text in the currently displayed file. You can also search for text in the HTML report window, and you can open the files in the editor.
Package and Share the Code Generation Report

In this section...

“Package the Code Generation Report” on page 38-13
“View the Code Generation Report” on page 38-14

Package the Code Generation Report

To share the code generation report, you can package the code generation report files and supporting files into a zip file for transfer. The default location for the code generation report files is in two folders:

- /slprj
- html subfolder of the build folder, model_target_rtw, for example
  rtwdemo_counter_grt_rtw/html

To create a zip file from the MATLAB command window:

1. In the Current Folder browser, select the two folders:
   - /slprj
   - Build folder: model_target_rtw

2. Right-click to open the context menu.

3. In the context menu, select Create Zip File. A file appears in the Current Folder browser.

4. Name the zip file.

Alternatively, you can use the MATLAB zip command to zip the code generation report files:

```matlab
zip('myzip',{''slprj','rtwdemo_counter_grt_rtw'})
```

Note: If you need to relocate the static and generated code files for a model to another development environment, such as a system or an integrated development environment (IDE) that does not include MATLAB and Simulink products, use the code generator pack-and-go utility. For more information, see “Relocate Code to Another Development Environment” (Simulink Coder).
View the Code Generation Report

To view the code generation report after transfer, unzip the file and save the two folders at the same folder level in the hierarchy. Navigate to the `model_target_rtw/html/` folder and open the top-level HTML report file named `model_codgen_rpt.html` or `subsystem_codgen_rpt.html` in a Web browser.
Web View of Model in Code Generation Report

In this section...

| “About Model Web View” on page 38-15 |
| “Generate HTML Code Generation Report with Model Web View” on page 38-15 |
| “Model Web View Limitations” on page 38-18 |

About Model Web View

To review and analyze the generated code, it is helpful to navigate between the code and model. You can include a Web view of the model within the HTML code generation report. You can then share your model and generated code outside of the MATLAB environment. When you generate the report, the Web view includes the block diagram attributes displayed in the Simulink Editor, such as, block sorted execution order, signal properties, and port data types.

A Simulink Report Generator license is required to include a Web view (Simulink Report Generator) of the model in the code generation report.

Browser Requirements for Web View

Web view requires a Web browser that supports Scalable Vector Graphics (SVG). Web view uses SVG to render and navigate models.

You can use the following Web browsers:

- Mozilla Firefox Version 1.5 or later, which has native support for SVG. To download the Firefox browser, go to www.mozilla.com/.
- The Microsoft Internet Explorer® Web browser with the Adobe® SVG Viewer plug-in. To download the Adobe SVG Viewer plug-in, go to www.adobe.com/svg/.
- Apple Safari Web browser

Generate HTML Code Generation Report with Model Web View

This example shows how to create an HTML code generation report which includes a Web view of the model diagram.
1. Open the `rtwdemo_mdlreftop` model.
2. Open the Configuration Parameters dialog box or Model Explorer and navigate to the Code Generation pane.
3. Specify `ert.tlc` for the System target file parameter.
5. Select the following parameters:
   - Create code generation report
   - Open report automatically
   - Generate model Web view

   **Note** These settings specify only the top model, not referenced models.
7. Open the Configuration Parameters for the referenced model, `rtwdemo_mdlrefbot` and perform steps 3–6.
8. Save the models, `rtwdemo_mdlreftop` and `rtwdemo_mdlrefbot`.
9. From the top model diagram, press Ctrl+B. After building the model and generating code, the code generation report for the top model opens in a MATLAB Web browser.
10. In the left navigation pane, select a source code file. The corresponding source code is displayed in the right pane and includes hyperlinks.
11 Click a link in the code. The model Web view displays and highlights the corresponding block in the model.

12 To highlight the generated code for a referenced model block in your model, click CounterB. The corresponding code is highlighted in the source code pane.

Note You cannot open the referenced model diagram in the Web view by double-clicking the referenced model block in the top model.

13 To open the code generation report for a referenced model, in the left navigation pane, below Referenced Models, click the link, rtwdemo_mdlrefbot. The source files for the referenced model are displayed along with the Web view of the referenced model.
To go back to the code generation report for the top model, at the top of the left navigation pane, click the Back button until the top model’s report is displayed.

For more information about exploring a model in a Web view, see “Navigate the Web View” (Simulink Report Generator).

For more information about navigating between the generated code and the model diagram, see “Trace Simulink Model Elements in Generated Code” on page 64-8.

Model Web View Limitations

The HTML code generation report includes the following limitations when using the model Web view:

- Code is not generated for virtual blocks. In the model Web view of the code generation report, when tracing between the model and the code, when you click a virtual block, it is highlighted yellow.
- In the model Web view, you cannot open a referenced model diagram by double-clicking the referenced model block in the top model. Instead, open the code generation report for the referenced model by clicking a link under Referenced Models in the left navigation pane.
- Stateflow truth tables, events, and links to library charts are not supported in the model Web view.
- Searching in the code generation report does not find or highlight text in the model Web view.
- If you navigate from the actual model diagram (not the model Web view in the report), to the source code in the HTML code generation report, the model Web view is disabled and not visible. To enable the model Web view, open the report again, see “Open Code Generation Report” (Simulink Coder).
- For a subsystem build, the traceability hyperlinks of the root level inport and outport blocks are disabled.
- “Traceability Limitations” on page 64-6 that apply to tracing between the code and the actual model diagram.
Analyze the Generated Code Interface

Code Interface Report Overview

When you select the Create code generation report option for an ERT-based model, a Code Interface Report section is automatically included in the generated HTML report. The Code Interface Report section provides documentation of the generated code interface, including model entry-point functions and interface data, for consumers of the generated code. The information in the report can help facilitate code review and code integration.

The code interface report includes the following subsections:

- **EntryPoint Functions** — interface information about each model entry-point function, including `model_initialize`, `model_step`, and (if applicable) `model_reset` and `model_terminate`.
- **Inports and Outports** — interface information about each model inport and outport.
- **Interface Parameters** — interface information about tunable parameters that are associated with the model.
- **Data Stores** — interface information about global data stores and data stores with non-auto storage that are associated with the model.

For limitations that apply to code interface reports, see “Code Interface Report Limitations” on page 38-31.

For illustration purposes, this section uses the following models:
• rtwdemo_basicsc (with the ExportedGlobal Storage Class button selected in the model window) for examples of report subsections
• rtwdemo_mrmtbb for examples of timing information
• rtwdemo_fcnprotoctrl for examples of function argument and return value information

Generating a Code Interface Report

To generate a code interface report for your model:

1. Open your model, go to the Code Generation pane of the Configuration Parameters dialog box, and select ert.tlc or an ERT-based System target file, if one is not already selected.

2. Go to the Code Generation > Report pane of the Configuration Parameters dialog box and select the option Create code generation report, if it is not already selected. The rtwdemo_basicsc, rtwdemo_mrmtbb, and rtwdemo_fcnprotoctrl models used in this section select multiple Report pane options by default. But selecting only Create code generation report, generates a Code Interface Report section in the HTML report.

Alternatively, you can programmatically select the option by issuing the following MATLAB command:

```
set_param(bdroot, 'GenerateReport', 'on')
```

If the Code-to-model parameter is selected, the generated report contains hyperlinks to the model. Leave this value selected unless you plan to use the report outside the MATLAB environment.

3. Build the model. If you selected the Report pane option Open report automatically, the code generation report opens automatically after the build process is complete. (Otherwise, you can open it manually from within the model build folder.)

4. To display the code interface report for your model, go to the Contents pane of the HTML report and click the Code Interface Report link. For example, here is the generated code interface report for the model rtwdemo_basicsc (with the ExportedGlobal Storage Class button selected in the model window).
Code Interface Report for rtwdemo_basicsc

Table of Contents

- Entry-Point Functions
- Imports
- Outputs

Entry-Point Functions

Function: rtwdemo_basicsc_initialize

Prototype: void rtwdemo_basicsc_initialize(void)
Description: Initialization entry point of generated code
Timing: Must be called exactly once
Arguments: None
Return value: None
Header file: rtwdemo_basicsc.h

Function: rtwdemo_basicsc_step

Prototype: void rtwdemo_basicsc_step(void)
Description: Output entry point of generated code
Timing: Must be called periodically, every 1 second
Arguments: None
Return value: None
Header file: rtwdemo_basicsc.h

For help navigating the content of the code interface report subsections, see “Navigating Code Interface Report Subsections” on page 38-22. For help interpreting the content of the code interface report subsections, see the sections beginning with “Interpreting the Entry-Point Functions Subsection” on page 38-23.

**Navigating Code Interface Report Subsections**

To help you navigate code interface descriptions, the code interface report provides collapse/expand tokens and hyperlinks, as follows:

- For a large subsection, the report provides [-] and [+] symbols that allow you to collapse or expand that section. In the example in the previous section, the symbols are provided for the Inports and Interface Parameters sections.
- Several forms of hyperlink navigation are provided in the code interface report. For example:
  - The Table of Contents located at the top of the code interface report provides links to each subsection.
  - You can click each function name to go to its definition in model.c.
  - You can click each function's header file name to go to the header file source listing.
  - If you selected the Code-to-model parameter for your model, to go to the corresponding location in the model display, you can click hyperlinks for any of the following:
    - Function argument
    - Function return value
    - Inport
    - Outport
    - Interface parameter (if the parameter source is a block)
    - Data store (if the data store source is a Data Store Memory block)

For backward and forward navigation within the HTML code generation report, use the Back and Forward buttons above the Contents section in the upper-left corner of the report.
Interpreting the Entry-Point Functions Subsection

The **Entry-Point Functions** subsection of the code interface report provides the following interface information about each model entry-point function, including `model_initialize`, `model_step`, and (if applicable) `model_reset` and `model_terminate`.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Function:</strong></td>
<td>Lists the function name. You can click the function name to go to its definition in <code>model.c</code>.</td>
</tr>
<tr>
<td><strong>Prototype</strong></td>
<td>Displays the function prototype, including the function return value, name, and arguments.</td>
</tr>
<tr>
<td><strong>Description</strong></td>
<td>Provides a text description of the function's purpose in the application.</td>
</tr>
<tr>
<td><strong>Timing</strong></td>
<td>Describes the timing characteristics of the function, such as how many times the function is called, or if it is called periodically, and at what time interval. For a multirate timing example, see the following <code>rtwdemo_mrmtbb</code> report excerpt.</td>
</tr>
<tr>
<td><strong>Arguments</strong></td>
<td>If the function has arguments, displays the number, name, data type, and Simulink description for each argument. If you select the <strong>Code-to-model</strong> parameter for your model, you can click the hyperlink in the description to go to the block corresponding to the argument in the model display. For argument examples, see the <code>rtwdemo_fcnprotoctr</code> report excerpt below.</td>
</tr>
<tr>
<td><strong>Return value</strong></td>
<td>If the function has a return value, this field displays the return value data type and Simulink description. If you selected the <strong>Code-to-model</strong> parameter for your model, you can click the hyperlink in the description to go to the block corresponding to the return value in the model display. For a return value example, see the following <code>rtwdemo_fcnprotoctr</code> report excerpt.</td>
</tr>
<tr>
<td><strong>Header file</strong></td>
<td>Lists the name of the header file for the function. You can click the header file name to go to the header file source listing.</td>
</tr>
</tbody>
</table>

For example, here is the **Entry-Point Functions** subsection for the model `rtwdemo_basicssc`. 
To illustrate how timing information might be listed for a multirate model, here are the **Entry-Point Functions** and **Inports** subsections for the model `rtwdemo_mrmtbb`. This multirate, discrete-time, multitasking model contains Inport blocks 1 and 2, which specify 1-second and 2-second sample times, respectively. The sample times are constrained to the specified times by the **Periodic sample time constraint** option on the **Solver** pane of the Configuration Parameters dialog box.
To illustrate how function arguments and return values are displayed in the report, here is the entry-point function description of the model step function for model `rtwdemo_fcnprotoctrl`. 
Interpreting the Inports and Outports Subsections

The Inports and Outports subsections of the code interface report provide the following interface information about each inport and outport in the model.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Block Name</td>
<td>Displays the Simulink block name of the inport or outport. If you selected the Code-to-model parameter for your model, you can click on each inport or outport Block Name value to go to its location in the model display.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>Code Identifier</strong></td>
<td>Lists the identifier associated with the inport or outport data in the generated code, as follows:</td>
</tr>
<tr>
<td></td>
<td>• If the data is defined in the generated code, the field displays the identifier text.</td>
</tr>
<tr>
<td></td>
<td>• If the data is declared but not defined in the generated code — for example, if the data is resolved with an imported storage class — the field displays the identifier text prefixed with the label 'Imported data:'.</td>
</tr>
<tr>
<td></td>
<td>• If the data is neither defined nor declared in the generated code — for example, if <strong>Reusable function</strong> code interface packaging is selected for the model — the field displays the text 'Defined externally'.</td>
</tr>
<tr>
<td><strong>Data Type</strong></td>
<td>Lists the data type of the inport or outport.</td>
</tr>
<tr>
<td><strong>Scaling</strong></td>
<td>For fixed-point entries, lists the data type and fraction length using Simulink fixed-point data type notation.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong> You must have a Fixed-Point Designer license to see fixed-point scaling information in the report. For more information on how scaling is represented in the table, see “Fixed-Point Data Type and Scaling Notation” (Fixed-Point Designer).</td>
</tr>
<tr>
<td><strong>Dimension</strong></td>
<td>Lists the dimensions of the inport or outport (for example, 1 or [4, 5]).</td>
</tr>
</tbody>
</table>

For example, here are the **Imports** and **Outports** subsections for the model rtwdemo_basicsc.
Interpreting the Interface Parameters Subsection

The Interface Parameters subsection of the code interface report provides the following interface information about tunable parameters that are associated with the model.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parameter Source</td>
<td>Lists the source of the parameter value, as follows:</td>
</tr>
<tr>
<td></td>
<td>• If the source of the parameter value is a block, the field displays the block name, such as <code>&lt;Root&gt;/Gain2</code> or <code>&lt;S1&gt;/Lookup1</code>. If you selected the Code-to-model parameter for your model, you can click the Parameter Source value to go to the parameter's location in the model display.</td>
</tr>
<tr>
<td></td>
<td>• If the source of the parameter value is a workspace variable, the field displays the name of the workspace variable.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Code Identifier</td>
<td>Lists the identifier associated with the tunable parameter data in the generated code, as follows:</td>
</tr>
<tr>
<td></td>
<td>• If the data is defined in the generated code, the field displays the identifier text.</td>
</tr>
<tr>
<td></td>
<td>• If the data is declared but not defined in the generated code — for example, if the data is resolved with an imported storage class — the field displays the identifier text prefixed with the label 'Imported data:'.</td>
</tr>
<tr>
<td></td>
<td>• If the data is neither defined nor declared in the generated code — for example, if Reusable function code interface packaging is selected for the model — the field displays the text 'Defined externally'.</td>

</tbody>
</table>
### Field | Description
---|---
**Code Identifier** | Lists the identifier associated with the data store data in the generated code, as follows:
- If the data is defined in the generated code, the field displays the identifier text.
- If the data is declared but not defined in the generated code — for example, if the data is resolved with an imported storage class — the field displays the identifier text prefixed with the label 'Imported data:'.
- If the data is neither defined nor declared in the generated code — for example, if Reusable function code interface packaging is selected for the model — the field displays the text 'Defined externally'.

**Data Type** | Lists the data type of the data store.

**Scaling** | For fixed-point entries, lists the data type and fraction length using Simulink fixed-point data type notation.

**Note** You must have a Fixed-Point Designer license to see fixed-point scaling information in the report. For more information on how scaling is represented in the table, see “Fixed-Point Data Type and Scaling Notation” (Fixed-Point Designer).

**Dimension** | Lists the dimensions of the data store (for example, 1 or [1, 2]).

For example, here is the **Data Stores** subsection for the model `rtwdemo_basicsc` (with the ExportedGlobal Storage Class button selected in the model window).

**Data Stores**

<td><code>mode</code></td>
<td><code>boolean</code></td>
<td><code>1</code></td>
</tr>
</tbody>
</table>

**Code Interface Report Limitations**

The following limitations apply to the code interface section of the HTML code generation reports.
• The code interface report does not support the GRT interface with an ERT target or C++ class code interface packaging. For these configurations, the code interface report is not generated and does not appear in the HTML code generation report Contents pane.

• The code interface report supports data resolved with most custom storage classes (CSCs), except when the CSC properties are set in any of the following ways:
  
  • The CSC property Type is set to FlatStructure. For example, the BitField and Struct CSCs in the Simulink package have Type set to FlatStructure.
  • The CSC property Type is set to Other. For example, the GetSet CSC in the Simulink package has Type set to Other.
  • The CSC property Data access is set to Pointer, indicating that imported symbols are declared as pointer variables rather than simple variables. This property is accessible only when the CSC property Data scope is set to Imported or Instance-specific.

  In these cases, the report displays empty Data Type and Dimension fields.

• For outports, the code interface report cannot describe the associated memory (data type and dimensions) if the memory is optimized. In these cases, the report displays empty Data Type and Dimension fields.

• The code interface report does not support data type replacement using the Code Generation > Data Type Replacement pane of the Configuration Parameters dialog box. The data types listed in the report will link to built-in data types rather than their specified replacement data types.

About Static Code Metrics

The code generator performs static analysis on page 38-34 of the generated C or C++ code and provides these metrics in the Static Code Metrics Report section of the HTML Code Generation Report.

You can use the information in the report to:

• Find the number of files and lines of code in each file.
• Estimate the number of lines of code and stack usage per function.
• Compare the difference in terms of how many files, functions, variables, and lines of code are generated every time you change the model or MATLAB algorithm.
• Determine a target platform and allocation of RAM to the stack, based on the size of global variables plus the estimated stack size.
• Determine possible performance slow points, such as the largest global variables or the most costly call path in terms of stack usage.
• View the cyclomatic complexity of a function, which counts the number of linearly independent paths through a function.
• View the function call tree. Determine the longest call path to estimate the worst case execution timing.
• View how target functions, provided by the selected code replacement library, are used in the generated code.

For examples, see

• “Generate Static Code Metrics Report for Simulink Model” on page 38-37
• “Generate a Static Code Metrics Report for MATLAB Code” on page 38-42
Static Code Metrics Analysis

Static analysis of the generated code is performed only on the source code without executing the program. The results of the static code metrics analysis are included in the Static Code Metrics section of the HTML Code Generation Report. The report is not available if you generate a MEX function from MATLAB code.

Static analysis of the generated source code files:

• Uses the specified C data types. For Simulink models, you specify these data types in the Hardware Implementation > Production hardware pane of the Configuration Parameters dialog box. For code generation from MATLAB code, you specify them in the Hardware tab of the MATLAB Coder project settings dialog box or using a code generation configuration object. Actual object code metrics might differ due to target-specific compiler and platform settings.

• Includes custom code only if you specify it. For Simulink models, you specify custom code on the Code Generation > Custom Code pane in the model configuration. For code generation from MATLAB code, you specify it on the Debugging tab of the MATLAB Coder project settings dialog box or using a code generation configuration object. An error report is generated if the generated code includes platform-specific files not contained in the standard C run-time library.

• For Simulink models, includes the generated code from referenced models.

• Uses 1-byte alignment for all members of a structure for estimating global and local data structure sizes. The size of a structure is calculated by summing the sizes of all of its fields. This estimation represents the smallest possible size for a structure.

• Calculates the self stack size of a function as the size of local data within a function, excluding input arguments. The accumulated stack size of a function is the self stack size plus the maximum of the accumulated stack sizes of its called functions. For example, if the accumulated stacks sizes for the called functions are represented as accum_size1...accum_sizeN, then the accumulated stack size for a function is

\[
\text{accumulated_stack_size} = \text{self_stack_size} + \max(\text{accum_size1}, \ldots, \text{accum_sizeN})
\]

• When estimating the stack size of a function, static analysis stops at the first instance of a recursive call. The Function Information table indicates when recursion occurs in a function call path. Code generation generates only recursive code for Stateflow event broadcasting and for graphical functions if it is written as a recursive function.

• Calculates the cyclomatic complexity of a function as the number of decisions plus one:

\[
\text{CC} = \text{Number of decisions} + 1
\]
The following constructs add a decision:

- If statement
- Else-If statement
- Switch statement (1 decision for each case branch)
- Loop statements: While, For, Do-while

**Note** Boolean operators in the above constructs do not add extra decisions.

- Does not include ert_main.c, because you have the option to provide your own main.c.

**View Static Code Metrics and Definitions Within the Generated Code**

When you view code in the code generation report, to get access to code metrics and definitions, you can use the following tools:

- On the **Code Generation > Report** pane, if you select the **Static code metrics** check box you can hover your cursor over global variables and functions in the code window to see code metrics information.

- In the code window, if you click linked variables or functions, the code inspect window is displayed. The window provides links to definitions for the variables or functions. On the **Code Generation > Report** pane, if you selected the **Static code metrics** check box, you can also see code metrics information for the variable or function.

Generate Static Code Metrics Report for Simulink Model

The **Static Code Metrics Report** is a section included in the HTML Code Generation Report. For more information on the static analysis of the generated code, see “Static Code Metrics Analysis” on page 38-34.

1. Before generating the HTML Code Generation Report, open the Configuration Parameters dialog box for your model. On the **Code Generation > Report** pane, select the “Static code metrics” (Simulink Coder) check box.

   If your model includes referenced models, select the **Static code metrics** check box in each referenced model’s configuration set. Otherwise, you cannot view a separate static code metrics report for a referenced model.

2. Press **Ctrl+B** to build your model and generate the HTML code generation report. For more information, see “Generate a Code Generation Report” on page 38-5.

3. If the HTML Code Generation Report is not already open, open the report. On the left navigation pane, in the **Contents** section, select **Static Code Metrics Report**.

4. To see the generated files and how many lines of code are generated per file, look at the **File Information** section.
1. File Information [hide]

[-] Summary (excludes ert_main.c)

</tbody>
</table>

5 Hover your cursor over column titles and some column values to see a description of the corresponding data.

6 If your model includes referenced models, the File information section includes a Referenced Model column. In this column, click the referenced model name to open its static code metrics report. If the static code metrics report is not available for a referenced model, specify the Static code metrics parameter in the referenced model’s configuration set and rebuild your model.

7 To view the global variables in the generated code, their size, and the number of accesses, see the Global Variables section.

2. Global Variables [hide]

Global variables defined in the generated code.

<table>
<thead>

</tbody>
</table>

The second column, **Called By**, lists functions that call the function listed in the first column, using the following criteria:

- If a function is called by multiple functions, all functions are listed.
- If a function has no called function, this column is empty.
For example, Fueling_Mode is called by Fail and fuel_rate_control_step. The number of call sites is included in parentheses. Fail calls Fueling_Mode twice.
Generate a Static Code Metrics Report for MATLAB Code

Generate a Static Code Metrics Report Using the MATLAB Coder App

This example shows how to generate a static code metrics report for a static C library that is generated from MATLAB code using the MATLAB Coder app.

By default, if you have an Embedded Coder license, when you use MATLAB Coder to generate standalone C/C++ code, the code generation report includes a static code metrics report. The static code metrics report is not available for generated MEX functions.

Create the Example File

In a local, writable folder, create a MATLAB file, moving_average.m, that contains:

```matlab
function [avg,z] = moving_average(x,z)
    %#codegen
    z(2:end) = z(1:end-1); % Update buffer
    z(1) = x; % Add new value
    avg = mean(z); % Compute moving average
end
```

Create a Test File

In the same local, writable folder, create a test file, moving_average_test.m, that contains:

```matlab
function moving_average_test( )
    z = zeros(10,1);
    for i = 1:10
        [avg, z] = moving_average(i,z);
    end
    disp(avg)
end
```

Set Up the MATLAB Coder Project

1   To open the MATLAB Coder app and set up a project, at the command line, enter:

coder -new moving_average.prj
The app adds `moving_average` to the list of entry-point functions.

2 Click **Next** to go to the **Define Input Types** step.

**Define Input Types**

1 To automatically define the input types, select or enter the test file `moving_average_test.m`. Click **Autodefine Input Types**.

The app determines that `x` is `double(1x1)` and `z` is `double(10x1)`.

2 Click **Next** to go to the **Check for Run-Times Issues** step.

The **Check for Run-Times Issues** step generates a MEX file from your entry-point functions, runs the MEX function, and reports issues. This step is optional. However, it is a best practice to perform this step. You can detect and fix run-time errors that are harder to diagnose in the generated C code.

**Check for Run-Time Issues**

1 To open the **Check for Run-Time Issues** dialog box, click the **Check for Issues** arrow.

The app populates the test file field with `moving_average_test.m`, the test file that you used to define input types.

2 Click **Check for Issues**.

The app does not detect issues.

3 Click **Next** to go to the **Generate Code** step.

**Configure the Build Settings**

1 On the **Generate Code** page, to open the **Generate** dialog box, click the **Generate** arrow.

2 Set **Build type** to **Static library**.

The default output file name is `moving_average`.

3 Click **More Settings**.

4 On the **Debugging** tab, verify that the **Static code metrics** check box is selected.

5 Click **Close**.
Generate C Code

1. To generate the library, click **Generate**.

   MATLAB Coder generates a C static library and supporting files in the default folder, `codegen/lib/moving_average`.

2. Click **Next** to go to the **Finish Workflow** step.

View the Static Code Metrics Report

1. To open the code generation report, under **Generated Output**, click **Code Generation Report**.

2. In the code generation report, on the **Summary** tab, next to **Reports**, click **Code Metrics**.

3. To see the generated files and the number of lines of code per file, click **File Information**.

<table>

</tbody>
</table>

The second column, **Called By**, lists functions that call the function listed in the first column. If multiple functions call the function, all functions are listed. If no functions call the function, this column is empty.

### Enable a Static Code Metrics Report at the Command Line

To enable a static code metrics report at the command line:

1. Create a code generation configuration object for standalone code generation. For example, to generate a static library, use:
   ```
   cfg = coder.config('lib', 'ecoder', true);
   ```

2. Generate code, passing the configuration object as a parameter and specifying the `-report` option. For example:
   ```
   codegen -config cfg -report foo
   ```

Alternatively, you can:

1. Create a code generation configuration object for standalone code generation. For example:
   ```
   cfg = coder.config('lib', 'ecoder', true);
   ```

2. Set the configuration object **GenerateReport** and **GenerateCodeMetricsReport** parameters to `true`. 

---

38-46
cfg.GenerateReport = true;
cfg.GenerateCodeMetricsReport = true;

3 Generate code, passing the configuration object as a parameter. For example:

codegen -config cfg foo

More About

- “Code Generation Reports” (MATLAB Coder)
Analyze Code Replacements in Generated Code

When you select the check box **Summarize which blocks triggered code replacements** (Simulink Coder) for an ERT-based model, a Code Replacements Report section is automatically included in the generated HTML report. The Code Replacements Report section documents the code replacement library (CRL) functions that were used for code replacements during code generation, providing a mapping between each replacement instance and the Simulink block that triggered the replacement. To enable display of the Simulink block information, select the **Code Generation > Comments** check box **Include comments**. On the same pane, select either the **Simulink block comments** checkbox or the **Simulink block descriptions** check box if present, or both.

You can use the report to:

- Determine which replacement functions were used in the generated code.
- Trace each replacement instance back to the block that triggered the replacement.

The figure below shows a Code Replacements Report generated for the CRL model `rtwdemo_crladdsub`. Each replacement function used is listed with a link to the block that triggered the replacement.
If you click a block path in the report, the block that triggered the replacement is highlighted in the model diagram. If the replacement was triggered by a Stateflow chart or a MATLAB function, a window opens to display the chart or function.

For more information, see Trace Code Replacements Generated Using Your Code Replacement Library on page 54-85.
Document Generated Code with Simulink Report Generator

The Simulink Report Generator software creates documentation from your model in multiple formats, including HTML, PDF, RTF, Microsoft Word, and XML. This example shows one way to document a code generation project in Microsoft Word. The generated report includes:

- System snapshots (model and subsystem diagrams)
- Block execution order list
- Simulink Coder and model version information for generated code
- List of generated files
- Optimization configuration parameter settings
- System target file selection and build process configuration parameter settings
- Subsystem map
- File name, path, and generated code listings for the source code

To adjust Simulink Report Generator settings to include custom code and then generate a report for a model, complete the following tasks:

1. “Generate Code for the Model” on page 38-51
2. “Open the Report Generator” on page 38-51
3. “Set Report Name, Location, and Format” on page 38-53
4. “Include Models and Subsystems in a Report” on page 38-54
5. “Customize the Report” on page 38-55
A Simulink Report Generator license is required for the following report formats: PDF, RTF, Microsoft Word, and XML. For more information on generating reports in these formats, see the Simulink Report Generator documentation.

**Generate Code for the Model**

Before you use the Report Generator to document your project, generate code for the model.

1. In the MATLAB Current Folder browser, navigate to a folder where you have write access.
2. Create a working folder from the MATLAB command line by typing:
   ```
   mkdir report_ex
   ```
3. Make report_ex your working folder:
   ```
   cd report_ex
   ```
4. Open the slexAircraftExample model by entering the model name on the MATLAB command line.
5. In the model window, choose **File > Save As**, navigate to the working folder, report_ex, and save a copy of the slexAircraftExample model as myModel.
6. Open the Configuration Parameters dialog box by selecting **Model Configuration Parameters** from the **Simulation** menu.
7. Select the **Solver** pane. In the **Solver selection** section, specify the **Type** parameter as **Fixed-step**.
8. Select the **Code Generation** pane. Select **Generate code only**.
9. Click **Apply**.
10. In the model window, press **Ctrl+B**. The build process generates code for the model.

**Open the Report Generator**

After you generate the code, open the Report Generator.

1. In the model diagram window, select **Tools > Report Generator**.
2. In the Report Explorer window, in the options pane (center), click the folder **rtw** (`\toolbox\rtw`). Click the setup file that it contains, **codegen.rpt**.
Double-click `codegen.rpt` or select it and click the **Open report** button. The Report Explorer displays the structure of the setup file in the outline pane (left).
Set Report Name, Location, and Format

Before generating a report, you can specify report output options, such as the folder, file name, and format. For example, to generate a Microsoft Word report named MyCGModelReport.rtf:

1. In the properties pane, under **Report Options**, review the options listed.
2 Leave the Directory field set to Present working directory.

3 For Filename, select Custom: and replace index with the name MyModelCGReport.

4 For File format, specify Rich Text Format and replace Standard Print with Numbered Chapters & Sections.

Include Models and Subsystems in a Report

Specify the models and subsystems that you want to include in the generated report by setting options in the Model Loop component.

1 In the outline pane (left), select Model Loop. Report Generator displays Model Loop component options in the properties pane.

2 If not already selected, select Current block diagram for the Model name option.
3 In the outline pane, click Report - codegen.rpt*.

Customize the Report

After specifying the models and subsystems to include in the report, you can customize the sections included in the report.

1 In the outline pane (left), expand the node Chapter - Generated Code. By default, the report includes two sections, each containing one of two report components.

2 Expand the node Section 1 — Code Generation Summary.

3 Select Code Generation Summary. Options for the component are displayed in the properties pane.

4 Click Help to review the report customizations that you can make with the Code Generation Summary component. For this example, do not customize the component.

5 In the Report Explorer window, expand the node Section 1 — Generated Code Listing.

6 Select Import Generated Code. Options for the component are displayed in the properties pane.

7 Click Help to review the report customizations that you can make with the Import Generated Code component.
Generate the Report

After you adjust the report options, from the Report Explorer window, generate the report by clicking File > Report. A Message List dialog box opens, which displays messages that you can monitor as the report is generated. Model snapshots also appear during report generation. The Message List dialog box might be hidden behind other dialog boxes.

![Message List dialog box](image)

When the report is complete, open the report, MyModelCGReport.rtf in the folder report_ex (in this example).
Get Code Description of Generated Code

You can use the code descriptor API to obtain meta-information about the generated code. For each model build, the code generator, by default, creates a `codedescriptor.dmr` file in the build folder. When simulating the model in Accelerator and Rapid Accelerator modes, the `codedescriptor.dmr` is not generated.

You can use the code descriptor API once the code is generated. Use the code descriptor API to describe these items in the generated code:

- Data Interfaces: inports, outports, parameters, and global data stores.
- Function Interfaces: initialize, output, update, and terminate.
- Run-time information of the data and function interfaces, such as timing requirements of each interface entity.
- Model hierarchy information and code description of referenced models.

Get Data Interface Information

The `coder.descriptor.DataInterface` object describes various properties for a specified data interface in the generated code. In the model `rtwdemo_comments`, there are four inports, one outport, and a tunable global parameter. For more information about the data interfaces in your model, use the `coder.codedescriptor.CodeDescriptor` object and its methods.

1. Build the model.

   ```matlab
   rtwbuild('rtwdemo_comments')
   ```
2 Create a `coder.codedescriptor.CodeDescriptor` object for the required model by calling the `getCodeDescriptor` function.

```matlab
codeDescriptor = coder.getCodeDescriptor('rtwdemo_comments')
```

3 To obtain a list of all the data interface types in the generated code, call the `getDataInterfaceTypes` method.

```matlab
dataInterfaceTypes = codeDescriptor.getDataInterfaceTypes()
```

A list of all the data interface types in `rtwdemo_comments` model is returned.

```json
{
'inports'  
'outports' 
'parameters'
'globalparameters'
}
To obtain a list of all the supported data interfaces, call the `getAllDataInterfaceTypes` method.

4 To obtain more information about a particular data interface type, call the `getDataInterfaces` method.

```matlab
dataInterface = codeDescriptor.getDataInterfaces('Inports')```

This call returns properties of the Inport blocks in the generated code.

5 Because this model has four inports, `dataInterface` is an array of `coder.descriptor.DataInterface` objects. Obtain the details of the first Inport of the model by accessing the first location in the array.

```matlab
dataInterface(1)```

The first `coder.descriptor.DataInterface` object corresponding to the `In1` block in the model is returned with its properties.

```matlab
    Type: [1×1 coder.descriptor.types.Double]
    SID: 'rtwdemo_comments:1'
    GraphicalName: 'In1'
    VariantInfo: [0x0 coder.descriptor.VariantInfo]
    Implementation: [1×1 coder.descriptor.StructExpression]
    Timing: [1×1 coder.descriptor.TimingInterface]
```

### Get Function Interface Information

The function interfaces are the entry-point functions in the generated code. In the model `rtwdemo_roll`, the entry-point functions are `model_initialize`, `model_step`, and `model_terminate`. For more information about the function interfaces in your model, use the `coder.codedescriptor.CodeDescriptor` object.

1 Build the model.

```matlab
rtwbuild('rtwdemo_roll')```
2 Create a `coder.codedescriptor.CodeDescriptor` object for the required model by calling the `getCodeDescriptor` function. Use the code descriptor object to call the methods currently available in the API.

```matlab
codeDescriptor = coder.getCodeDescriptor('rtwdemo_roll')
```

3 To obtain a list of all the function interface types in the generated code, call the `getFunctionInterfaceTypes` method.

```matlab
functionInterfaceTypes = codeDescriptor.getFunctionInterfaceTypes()
```

A list of all the function interface types in `rtwdemo_roll` model is returned.

```matlab
{'Initialize'}
{'Output'}
{'Terminate'}
```

To obtain a list of all the supported function interfaces, call the `getAllFunctionInterfaceTypes` method.

4 To obtain more information about a particular function interface type, call the `getFunctionInterfaces` method.

```matlab
functionInterface = codeDescriptor.getFunctionInterfaces('Initialize')
```

This call returns properties of a specified function interface in the generated code.
functionInterface is a coder.descriptor.FunctionInterface object. The properties of the `rtwdemo_roll_initialize` function are returned.

Prototype: [1×1 coder.descriptor.types.Prototype]
ActualReturn: [0×0 coder.descriptor.DataInterface]
VariantInfo: [0×0 coder.descriptor.VariantInfo]
Timing: [1×1 coder.descriptor.TimingInterface]
ActualArgs: [1x0 coder.descriptor.DataInterface List]

You can further expand on the properties to obtain detailed information. To get the function return value, name, and arguments:

```
functionInterface.Prototype
```

The object of coder.descriptor.types.Prototype is returned with properties.

```
Name: 'rtwdemo_roll_initialize'
Return: [0×0 coder.descriptor.types.Argument]
HeaderFile: 'rtwdemo_roll.h'
SourceFile: 'rtwdemo_roll.c'
Arguments: [1x0 coder.descriptor.types.Argument List]
```

**Get Model Hierarchy Information**

Use the coder.codedescriptor.CodeDescriptor object to get the entire model hierarchy information. The model `rtwdemo_async_mdlreftop` has model `rtwdemo_async_mdlrefbot` as the referenced model.

1 Build the root model.

```
rtwbuild('rtwdemo_async_mdlreftop')
```
2 Create a `coder.codedescriptor.CodeDescriptor` object for the root model by calling `getCodeDescriptor` function.

```matlab
codeDescriptor = coder.getCodeDescriptor('rtwdemo_async_mdlrefbot')
```

3 Get a list of all the referenced models by calling the `getReferencedModelNames` method.

```matlab
refModels = codeDescriptor.getReferencedModelNames()

refModels has the list of referenced model.

{'rtwdemo_async_mdlrefbot'}
To obtain the `coder.codedescriptor.CodeDescriptor` object for the referenced model, call the `getReferencedModelCodeDescriptor(refModelName)` method.

```plaintext
refCodeDescriptor = codeDescriptor.getReferencedModelCodeDescriptor('rtwdemo_asyncmdlrefbot')
```

You can now use the `refCodeDescriptor` object to obtain more information about the referenced model by calling all the available methods in the Code Descriptor API.

Add Custom Comments to Generated Code

You can include auto-generated comments in the generated code as described in “Configure Code Comments” (Simulink Coder). For ERT targets, include additional custom comments by setting parameters on the Code Generation > Comments pane in the Configuration Parameters dialog box. With these parameters, you can enable or suppress generation of descriptive information in comments for blocks and other model elements.

<table>
<thead>
<tr>
<th>Goal</th>
<th>Specify</th>
</tr>
</thead>
<tbody>
<tr>
<td>Include the text specified in the Description field of a block's Block Properties dialog box as comments in the code generated for each block.</td>
<td>Simulink block descriptions</td>
</tr>
<tr>
<td>Add a comment that includes the block name at the start of the code for each block.</td>
<td>Simulink block descriptions</td>
</tr>
<tr>
<td>Include the text specified in the Description field of a Simulink data object (such as a signal, parameter, data type, or bus) in the Simulink Model Explorer as comments in the code generated for each object.</td>
<td>Simulink data object descriptions</td>
</tr>
<tr>
<td>Include comments just above signals and parameter identifiers in the generated code as specified in the MATLAB or TLC function.</td>
<td>Custom comments (MPT objects only)</td>
</tr>
<tr>
<td>Include the text specified in the Description field in the Properties dialog box for a Stateflow object as comments just above the code generated for each object.</td>
<td>Stateflow object descriptions</td>
</tr>
<tr>
<td>Include requirements assigned to Simulink blocks in the generated code comments (for more information, see “Generate Code for Models with Requirements Links” (Simulink Requirements)).</td>
<td>Requirements in block comments</td>
</tr>
<tr>
<td>Include MATLAB function description comments and other user comments in the generated code.</td>
<td>MATLAB user comments</td>
</tr>
</tbody>
</table>

When you select Simulink block descriptions:
• The code generator includes strings for model parameters, block names, signal names, and Stateflow object names in the generated code comments. If those strings are unrepresented in the character set encoding for the model, the code generator replaces the strings with XML escape sequences. For example, the code generator replaces the Japanese full-width Katakana letter 佗 with the escape sequence &#x30A2;. For more information, see “Internationalization and Code Generation” (Simulink Coder).

• The code generation software automatically inserts comments into the generated code for custom blocks. Therefore, you do not need to include block comments in the associated TLC file for a custom block.

Note If you have existing TLC files with manually inserted comments for block descriptions, the code generation process emits these comments instead of the automatically generated comments. Consider removing existing block comments from your TLC files. Manually inserted comments might be poorly formatted in the generated code and code-to-model traceability might not work.

• For virtual blocks or blocks that have been removed due to block reduction, comments are not generated.

For more information, see “Model Configuration Parameters: Code Generation Comments” (Simulink Coder).
Add Custom Comments for Variables in the Generated Code

To control code generation options for signals, states, and parameters in a model, you can create data objects in a workspace or data dictionary. You can generate comments in the code that help you to document the purpose and properties of the data in each object. Associate handwritten comments with each object, or write a function that generates comments based on the properties of the object.

For more information about data objects, see “Data Objects” (Simulink).

In this section...

|“Embed Handwritten Comments for Signals or Parameters” on page 39-5 | “Generate Dynamic Comments Based on Data Properties” on page 39-6 |

Embed Handwritten Comments for Signals or Parameters

To embed handwritten comments in the generated code near the definition of a signal, state, or parameter:

1. Create a data object to represent a signal, state, or parameter. You can use a data object from any package. For example, use a data object of the classes `Simulink.Signal` or `Simulink.Parameter`, which are defined in the package `Simulink`.

   ```
   myParam = Simulink.Parameter(15.23);
   ```

2. Set the storage class of the data object so that optimizations do not eliminate the signal or parameter from the generated code. For example, use the storage class `ExportedGlobal`.

   ```
   myParam.StorageClass = 'ExportedGlobal';
   ```

3. Set the `Description` property of the object. The description that you specify appears in the generated code as lines of comments.

   ```
   myParam.Description = 'This parameter represents wind speed.';
   ```

4. Set `Configuration Parameters > Code Generation > System target file` to an ERT-based target such as `ert.tlc`. 

39-5
To generate comments from data object descriptions, you must use an ERT-based target.

5 Select **Configuration Parameters > Code Generation > Comments > Simulink data object descriptions**.

6 Generate code from the model. In the code, the data object description appears near the definition of the corresponding variable.

```c
/* Exported block parameters */
real_T myParam = 15.23;     /* Variable: myParam
   * Referenced by: '<S1>/Gain'
   * This parameter represents wind speed. */
```

**Generate Dynamic Comments Based on Data Properties**

You can generate dynamic comments that include the properties of the data object such as data type, units, and dimensions. If you change the properties of the data object in Simulink, the code generator maintains the accuracy of the comments. For example, this comment displays some of the property values for a data object named `MAP`:

```c
/*     Unit:       psi                                      */
/*     Owner:                                               */
/*     DefinitionFile: specialDef                           */
real_T MAP = 0.0;
```

1 Create a data object from the package `mpt` and apply a custom storage class to the object. The default storage class for objects that you create from the package `mpt` is the custom storage class `Global (Custom)`.

```c
MAP = mpt.Signal;
```

To generate dynamic comments, you must use a data object from the package `mpt`, and you must apply a custom storage class to the object.

2 Write a MATLAB or TLC function that generates the comment text. For an example MATLAB function, see the function `matlabroot/toolbox/rtw/rtwdemos/rtwdemo_comments_mptfun.m`.

The function must accept three input arguments that correspond to `objectName`, `modelName`, and `request`. If you write a TLC file, you can use the library function `LibGetSLDataObjectInfo` to get the property values of the data object.
3  Save the function as a MATLAB file or a TLC file, and place the file in a folder that is on your MATLAB path.

4  In the model, select Configuration Parameters > Code Generation > Comments > Custom comments (MPT objects only).

5  Set Custom comments function to the name of the MATLAB file or TLC file that you created.

6  Generate code from the model. The comments that your function generates appear near the code that represents each data object.

Limitations

• To generate comments by using the Custom comments (MPT objects only) and Custom comments function options, you must create data objects from the package mpt. The data objects must use a custom storage class.

• Only the custom storage classes from the mpt package that create unstructured variables support a custom comments function.

Add Global Comments

<table>
<thead>
<tr>
<th>In this section…</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Use a Simulink DocBlock to Add a Comment” on page 39-8</td>
</tr>
<tr>
<td>“Use a Simulink Annotation to Add a Comment” on page 39-11</td>
</tr>
<tr>
<td>“Use a Stateflow Note to Add a Comment” on page 39-11</td>
</tr>
<tr>
<td>“Use Sorted Notes to Add Comments” on page 39-12</td>
</tr>
</tbody>
</table>

The following examples show how to add a global comment to a Simulink model so that the comment text appears in the generated file or files where you want. Specify a template symbol name with a Simulink DocBlock, a Simulink annotation, or a Stateflow note. You can also use a sorted-notes capability that works with Simulink annotations or Stateflow notes (but not DocBlocks). For more information about template symbols, see “Template Symbols and Rules” on page 39-97.

**Note** Template symbol names Description and ModifiedHistory also are fields in the Model Properties dialog box. If you use one of these symbol names for global comment text, and its Model Properties field also has text in it, both names appear in the generated files.

### Use a Simulink DocBlock to Add a Comment

1. With the model open, from the View menu, select **Library Browser**.
2. Drag the DocBlock from **Model-Wide Utilities** in the Simulink library into the model.
3. Double-click the DocBlock and type the comment that you want in the editor. Save and close the editor.
4. Right-click the DocBlock and select **Mask > Mask Parameters**.
5. In the **Code generation template symbol** box, type one of the following:
   - Abstract
   - Description
   - History
   - ModifiedHistory
• Notes

Click **OK**. Template symbol names are case-sensitive.

If you are using a DocBlock to add comments to your code, set the **Document type** to **Text**. If you set **Document type** to RTF or HTML, your comments will not appear in the code.

6 In the Block Properties dialog box, on the **Block Annotation** tab, select `%<ECoderFlag>` and click **OK**. The symbol name that you typed in the previous step now appears under the DocBlock in the model.
7  Save the model. After you generate code, the code generator places the comment in each generated file whose template has the symbol name that you typed. The code generator places the comment in the generated file at the location that corresponds to where the symbol name is located in the template file.

8  To add more comments to the generated files, repeat steps 1-7.
Use a Simulink Annotation to Add a Comment

1. Double-click the unoccupied area on the model where you want to place the comment. See “Describe Models Using Annotations” (Simulink).

2. Type `<S:Symbol_name>` followed by the comment. `Symbol_name` is one of the following:
   - Abstract
   - Description
   - History
   - ModifiedHistory
   - Notes

   For example, type `<S:Description>This is the description I want.`

   Template symbol names are case-sensitive. (The "S" before the colon indicates "symbol.") If you want the code generator to sort multiple comments for the `Notes` symbol name, replace the next step with “Use Sorted Notes to Add Comments” on page 39-12.

3. Click outside the rectangle and save the model. After you generate code, the code generator places the comment in each generated file whose template has the symbol name that you typed. The code generator places the comment in the generated file at the location that corresponds to where the symbol name is located in the template file. If you want the code generator to sort multiple comments for the `Notes` symbol name, replace the next step with “Use Sorted Notes to Add Comments” on page 39-12.

4. To add one or more other comments to the generated files, repeat steps 1–3.

Use a Stateflow Note to Add a Comment

1. Right-click the unoccupied area on the Stateflow chart where you want to place the comment.

2. Select the annotation icon from the palette.

3. Type `<S:Symbol_name>` followed by the comment. `Symbol_name` is one of the following:
   - Abstract
• Description
• History
• ModifiedHistory
• Notes

For example, type `<S:Description>This is the description I want.</S:Description>`. Template symbol names are case-sensitive. If you want the code generator to sort multiple comments for the Notes symbol name, replace the next step with “Use Sorted Notes to Add Comments” on page 39-12.

4 Click outside the note and save the model. After you generate code, the code generator places the comment in each generated file whose template has the symbol name that you typed. The code generator places the comment in the generated file at the location that corresponds to where the symbol name is located in the template file.

5 To add one or more other comments to the generated files, repeat steps 1–4.

Use Sorted Notes to Add Comments

The sorted-notes capability allows you to add automatically sorted comments to the generated files. The code generator places these comments in each generated file at the location that corresponds to where the Notes symbol is located in the template file.

The code generator uses the following sorting order:

• Numbers before letters.
• Among numbers, 0 is first.
• Among letters, uppercases are before lowercases.

You can use sorted notes with a Simulink annotation or a Stateflow note, but not with a DocBlock.

• In the Simulink annotation or the Stateflow note, type `<S:NoteY>` followed by the first comment. Y is a number or a letter.
• Repeat for as many additional comments you want. Replace Y with a subsequent number or letter.

The figure illustrates sorted notes on a model, and where the code generator places each note in a generated file.
The relevant fragment from the generated file for this model is:

** NOTES

** Note1: This is the first comment I want associated with the Notes symbol.
Note2: This is the second comment I want under Notes.
Noteb: This is the third comment.

**
Customize Generated Identifier Naming Rules

In this section...

| “Apply Naming Rules to Identifiers Globally” on page 39-14 |
| “Apply Naming Rules to Simulink Data Objects” on page 39-16 |

For GRT and RSim targets, the code generator constructs identifiers for variables and functions in the generated code. For ERT targets, you can customize the naming of identifiers in the generated code by specifying parameters on the Code Generation > Symbols pane in the Configuration Parameters dialog box. You can also specify parameters that control identifiers generated from Simulink data objects. For detailed information about these parameters, see “Model Configuration Parameters: Code Generation Symbols” (Simulink Coder).

<tr>
<td><strong>Macros</strong>: Parameters are expressed as variables (with <code>#define</code> macros). This setting makes code more readable.</td>
</tr>
</tbody>
</table>

---

**Apply Naming Rules to Simulink Data Objects**

When your model uses Simulink data objects from the Simulink package, identifiers in generated code copy the names of the objects by default. For example, a Simulink.Signal object named Speed appears as the identifier Speed in generated code.

You can control these identifiers by specifying naming rules that are specific to Simulink data objects. On the **Code Generation > Symbols** pane of the Configuration Parameters dialog box, adjust the settings in the **Simulink data object naming rules** section.

When you specify naming rules for generated code, follow ANSI C/C++ rules for naming identifiers.

**Specify Naming Rule Using a Function**

This example shows how to customize identifiers in generated code by defining a MATLAB function.

1. Write a MATLAB function that returns an identifier by modifying a data object name, and save the function in your working folder. For example, the following function returns an identifier name by appending the text `_param` to a data object name.

   ```matlab
   function revisedName = append_text(name, object)
   % APPEND_TEXT: Returns an identifier for generated
   % code by appending text to a data object name.
   %
   ```

---

5. ANSI is a registered trademark of the American National Standards Institute, Inc.
% Input arguments:
% name: data object name as spelled in model
% object: target data object
% Output arguments:
% revisedName: altered identifier returned for use in
% generated code.
% text = '_param';

revisedName = [name,text];

2 Open the model rtwdemo_namerules.
3 Double-click the yellow box labeled View Symbols Configuration to open the Code Generation > Symbols pane in the Configuration Parameters dialog box.
4 From the Parameter naming (Simulink Coder) drop-down list, select Custom M-function.

5 In the M-function field, type the name of the file that defines the MATLAB function, append_text.m.
6 Click Apply.
7 Generate code for the model.
8 Inspect the code generation report to confirm the parameter object naming rule. For example, the generated file rtwdemo_namerules.h represents the parameter objects G1, G2, and G3 with the variables G1_param, G2_param, and G3_param.

Specify Naming Rule for Storage Class Define

You can specify a naming rule that applies only to Simulink data objects whose storage class you set to Define. For these data objects, the specified naming rule overrides the other parameter and signal object naming rules. On the Code Generation > Symbols pane in the Configuration Parameters dialog box, adjust the #define naming (Simulink Coder) setting.
Override Data Object Naming Rules

This example shows how to override a data object naming rule for a single data object.

You can override data object naming rules by specifying the Alias property of an individual Simulink data object. Generated code uses the text that you specify as the identifier to represent the data object, regardless of naming rules.

1. Open the model rtwdemo_namerules.
2. In the model, select View > Model Data Editor.
3. In the Model Data Editor, on the Parameters tab, click the Show/refresh additional information button.
4. In the data table, find the row that corresponds to the Simulink.Parameter object G1, which resides in the base workspace.
5. In the row, double-click the parameter icon.
6. In the Model Explorer Dialog pane (the right pane), for G1, specify the Alias property as mySpecialParam. Click Apply.
7  Generate code for the model.
8  In the code generation report, confirm the alias for the parameter object G1. The generated file rtwdemo_namerules.h represents G1 with the variable mySpecialParam.

**Apply Custom Naming Conventions to Identifiers**

This example shows how to apply uniform naming rules for Simulink® data objects, including signals, parameters, and data store memory variables.

```matlab
model='rtwdemo_namerules';
open_system(model)
```
Description
Many organizations employ coding standards that include naming rules for variables. This model shows how to apply uniform naming rules for Simulink data objects, including signals, parameters, and data store memory variables. Predefined conventions exist to apply upper and lower case naming, and arbitrary custom rules can be defined in a user-supplied MATLAB script.

Instructions
1. Double-click the yellow View Symbols Configuration button to inspect the "Simulink data object naming rules."
2. Double-click the yellow Inspect Data Objects button to inspect the data objects for this model.
3. Generate code using the blue button in the upper right of the diagram. An HTML report automatically appears.
4. Inspect the data that is defined toward the top of rtwdemo_namerules.c.

Note
The model is configured to "Force lower case." Therefore, the variables in the code are defined in lower case even though the data is declared upper case in the model.

Identifier Format Control

You can customize generated identifiers by specifying the Identifier format control parameters on the Code Generation > Symbols pane in the Configuration Parameters dialog box. For each parameter, you can enter a macro that specifies whether, and in what order, certain text is included within generated identifiers. For example, you can specify that the root model name be inserted into each identifier using the $R token.

The macro can include:

- Valid tokens, which are listed in Identifier Format Tokens. You can use or omit tokens depending on what you want to include in the identifier name. The Shared utilities identifier format parameter requires you to specify the checksum token, $C. The other parameters require the mangling token, $M. For more information, see “Control Name Mangling in Generated Identifiers” on page 39-30. The mangling token is subject to the use and ordering restrictions noted in Identifier Format Control Parameter Values.

- Token decorators, which are listed in “Control Case with Token Decorators” on page 39-27. You can use token decorators to control the case of generated identifiers for each token.

- Valid C or C++ language identifier characters (a-z, A-Z, _, 0-9).

The build process generates each identifier by expanding tokens and inserting the resultant text into the identifier. The tokens are expanded in the order listed in Identifier Format Tokens. Groups of characters are inserted in the positions that you specify around tokens directly into the identifier. Contiguous token expansions are separated by the underscore (_) character.
### Identifier Format Tokens

<table>
<thead>
<tr>
<th>Token</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$C$</td>
<td>This token is required for <strong>Shared utilities identifier format</strong>. If the identifier exceeds the <strong>Maximum identifier length</strong>, the code generator inserts an 8-character checksum to avoid naming collisions. The position of the $C$ token in the <strong>Identifier format control</strong> parameter specification determines the position of the checksum in the generated identifier. For example, if you use the specification $N$C, the checksum is appended to the end of the identifier. This token is available only for shared utilities.</td>
</tr>
<tr>
<td>$M$</td>
<td>This token is required. If necessary, the code generator inserts namemangling text to avoid naming collisions. Modify checksum character length by using <strong>Shared checksum length</strong> parameter. The position of the $M$ token in the <strong>Identifier format control</strong> parameter specification determines the position of the name-mangling text in the generated identifier. For example, if you use the specification $R$N$M$, the name-mangling text is appended (if required) to the end of the identifier. For more information, see “Control Name Mangling in Generated Identifiers” on page 39-30.</td>
</tr>
<tr>
<td>$U$</td>
<td>Insert text that you specify for the $U$ token. Use the <strong>Custom token text</strong> parameter to specify this text.</td>
</tr>
<tr>
<td>$F$</td>
<td>Insert method name (for example, _Update for update method). This token is available only for subsystem methods.</td>
</tr>
<tr>
<td>$N$</td>
<td>Insert name of object (block, signal or signal object, state, parameter, shared utility function or parameter object) for which identifier is being generated.</td>
</tr>
<tr>
<td>$R$</td>
<td>Insert root model name into identifier, replacing unsupported characters with the underscore (_) character. When you use referenced models, this token is required in addition to $M$ (see “Avoid Identifier Name Collisions with Referenced Models” on page 39-32). <strong>Note:</strong> This token replaces the <strong>Prefix model name to global identifiers</strong> option in previous releases.</td>
</tr>
<tr>
<td>Token</td>
<td>Description</td>
</tr>
<tr>
<td>-------</td>
<td>-------------</td>
</tr>
<tr>
<td>$H$</td>
<td>Insert tag indicating system hierarchy level. For root-level blocks, the tag is the text <code>root_</code>. For blocks at the subsystem level, the tag is of the form <code>sN_</code>. <code>N</code> is a unique system number assigned by the Simulink software. This token is available only for subsystem methods and field names of global types.  &lt;br&gt;&lt;br&gt;Note: This token replaces the <strong>Include System Hierarchy Number in Identifiers</strong> option in previous releases.</td>
</tr>
<tr>
<td>$A$</td>
<td>Insert data type acronym (for example, <code>i32</code> for integers) to signal and work vector identifiers. This token is available for local block output variables, local temporary variables, and field names of global types.  &lt;br&gt;&lt;br&gt;Note: This token replaces the <strong>Include data type acronym in identifier</strong> option in previous releases.</td>
</tr>
<tr>
<td>$I$</td>
<td>[ ] Insert <code>u</code> if the argument is an input.  &lt;br&gt;[ ] Insert <code>y</code> if the argument is an output.  &lt;br&gt;[ ] Insert <code>uy</code> if the argument is an input and output.  &lt;br&gt;&lt;br&gt;For example, <code>rtu_</code> for an input argument, <code>rty_</code> for an output argument, and <code>rtuy_</code> for an input and output argument. This token is available only for subsystem method arguments.</td>
</tr>
<tr>
<td>$G$</td>
<td>Insert the name of a storage class that is associated with the data item. This token is also available in the naming rule that you specify for the <strong>Header File</strong> for a storage class in the Embedded Coder Dictionary.</td>
</tr>
<tr>
<td>$E$</td>
<td>Insert the file type. <code>$E$</code> represents these instances of file types:  &lt;br&gt;[ ] <code>capi</code>  &lt;br&gt;[ ] <code>capi_host</code>  &lt;br&gt;[ ] <code>dt</code>  &lt;br&gt;[ ] <code>testinterface</code>  &lt;br&gt;[ ] <code>private</code>  &lt;br&gt;[ ] <code>types</code>  &lt;br&gt;&lt;br&gt;This token is required for <strong>Header files</strong> and <strong>Source files</strong>.</td>
</tr>
</tbody>
</table>
Identifier Format Control Parameter Values lists the default macro value, the supported tokens, and the applicable restrictions for each **Identifier format control** parameter.
## Identifier Format Control Parameter Values

<td>$R, $F, $H, $G, $E, and $A$ are not allowed.</td>
</tr>
<tr>
<td><strong>Local temporary variables</strong> (Simulink Coder)</td>
<td>$N$M</td>
<td>$M, $N, $A, $U</td>
<td>$F, $H, $G, $E, and $I$ are not allowed.</td>
</tr>
<tr>
<td><strong>Local block output variables</strong> (Simulink Coder)</td>
<td>rtb_$N$M</td>
<td>$M, $N, $A, $U</td>
<td>$R, $F, $H, $G, $E, and $I$ are not allowed.</td>
</tr>
<tr>
<td><strong>Constant macros</strong> (Simulink Coder)</td>
<td>$R$N$M</td>
<td>$M, $R, $N, $U</td>
<td>$F, $H, $A, $G, $E, and $I$ are not allowed.</td>
</tr>
<tr>
<td><strong>Shared utilities identifier format</strong> (Simulink Coder)</td>
<td>$N$C</td>
<td>$N, $C, $R, $U</td>
<td>$C$ is required. $M, $F, $H, $A, $G, $E, and $I$ are not allowed.</td>
</tr>
<tr>
<td><strong>EMX array utility functions identifier format</strong> (Simulink Coder)</td>
<td>emx$M$N</td>
<td>$M, $N,$R</td>
<td>$C, $U, $F, $H, $A, $G, $E, and $I$ are not allowed.</td>
</tr>
<tr>
<td><strong>EMX array types identifier format</strong> (Simulink Coder)</td>
<td>emxArray_ $M$N</td>
<td>$M, $N,$R</td>
<td>$C, $U, $F, $H, $A, $G, $E, and $I$ are not allowed.</td>
</tr>
</tbody>
</table>
Non-ERT-based targets (such as the GRT target) implicitly use a default $R$N$M$ specification. This default specification consists of the root model name, followed by the name of the generating object (signal, parameter, state, and so on), followed by name-mangling text.

For limitations that apply to Identifier format control parameters, see “Exceptions to Identifier Formatting Conventions” on page 39-35 and “Identifier Format Control Parameters Limitations” on page 39-36.

### Control Case with Token Decorators

On the Code Generation > Symbols pane, you can use token decorators to control the case of generated identifiers. Place a decorator immediately after the target token and enclose the decorator in square brackets `[ ]`. For example, you can set Global variables to $R[uL]$N$M$, which capitalizes the first letter of the model name and forces the remaining characters in the model name to lowercase.

The table shows how to manipulate the expansion of the $R$ token for a model whose name is modelName.

<table>
<thead>
<tr>
<th>Desired Expansion</th>
<th>Description</th>
<th>Token and Decorator</th>
</tr>
</thead>
<tbody>
<tr>
<td>ModelName</td>
<td>First letter of model name is uppercase. Remaining characters are not modified.</td>
<td>$R[u]$</td>
</tr>
<tr>
<td>Modelname</td>
<td>First letter of model name is uppercase. Remaining characters are lowercase.</td>
<td>$R[uL]$</td>
</tr>
<tr>
<td>Desired Expansion</td>
<td>Description</td>
<td>Token and Decorator</td>
</tr>
<tr>
<td>------------------</td>
<td>------------------------------------------------------------------</td>
<td>---------------------</td>
</tr>
<tr>
<td>MODELNAME</td>
<td>All characters are uppercase.</td>
<td>$R[U]</td>
</tr>
<tr>
<td>modelname</td>
<td>All characters are lowercase.</td>
<td>$R[L]</td>
</tr>
<tr>
<td>mODELNAME</td>
<td>First letter of model name is lowercase. Remaining characters are uppercase.</td>
<td>$R[LU]</td>
</tr>
<tr>
<td>modelName</td>
<td>First letter of model name is lowercase. Remaining characters are not modified.</td>
<td>$R[l]</td>
</tr>
</tbody>
</table>

When you use a decorator, the code generator removes the underscore character (_) that appears between tokens by default. However, you can append each decorator with an underscore: $R[U_]$N. For example, if you set the Global variables parameter to $R[u_]$N[uL]$M for a model named modelName and a DWork structure represented by DW, the result is ModelName_Dw.

**Control Formatting of Identifiers**

This example shows how you can customize generated identifiers by specifying the Identifier format control parameters on the Code Generation > Symbols pane in the Configuration Parameters dialog box.

```matlab
demo='rtwdemo_symbols';
open_system(demo)
```
Embedded Coder(R) Symbol Naming and Traceability

**Formatting Symbols**

Symbols in Embedded Coder(R) can be formatted via the "Identifier format control" option group. These options can be composed of predefined macros and C-language literal characters.

Common macros include:
- $R$ = Root model name
- $N$ = Name of object (block, signal, state, etc.)
- $M$ = Mangle used to uniqify symbol

For a complete list of macros and the rules by which they are expanded, see the Symbol format help link below.

Different identifier format control strings control different types of identifiers. Double-click the yellow buttons at the bottom to modify the format control strings for global variable names and global type names. Double-click the blue button to generate and inspect code for the change.

- **Double-click to view symbol format**
- **Double-click to view symbol format help**

**Creating Traceability**

One aspect of traceability is making sure that incremental revisions to a model have minimal impact on the symbol names that appear in generated code. There are two ways of achieving this in Simulink:

1) Name objects in Simulink (blocks, signals, states, etc.) as uniquely as possible.
2) Make use of name mangling when conflicts cannot be avoided.

For a complete discussion of how name mangling can be used to create traceable code, see the help link below.

- **Double-click to view mangle settings**
- **Double-click to view traceability help**

```
% Cleanup
rtwdemoclean;
close_system(model,0)
```
Control Name Mangling in Generated Identifiers

The position of the $M$ token in the Identifier format control parameter specification determines the position of the name-mangling text in the generated identifiers. For example, if you use the specification $R$N$M$, the name-mangling text is appended (if required) to the end of the identifier. For more information, see “Identifier Format Control” on page 39-22.

Name-Mangling Text Per Object

<table>
<thead>
<tr>
<th>Object Type</th>
<th>Source of Mangling Text</th>
</tr>
</thead>
<tbody>
<tr>
<td>Block diagram</td>
<td>Name of block diagram</td>
</tr>
<tr>
<td>Simulink block</td>
<td>Simulink identifier (for details, see “Locate Diagram Components Using Simulink Identifiers” (Simulink))</td>
</tr>
<tr>
<td>Simulink parameter</td>
<td>Full name of parameter owner (model or block) and parameter name</td>
</tr>
<tr>
<td>Simulink signal</td>
<td>Signal name, full name of source block, and port number</td>
</tr>
<tr>
<td>Stateflow objects</td>
<td>Complete path to Stateflow block and Stateflow computed name (unique within chart)</td>
</tr>
</tbody>
</table>

The length of the name-mangling text is specified by the Minimum mangle length (Simulink Coder) parameter. The default value is 1, but this automatically increases during code generation as a function of the number of collisions. To minimize disturbance to the generated code during development, specify a larger Minimum mangle length. A Minimum mangle length of 4 is a conservative value. A value of 4 allows for over 1.5 million collisions for a particular identifier before the mangle length is increased.

Minimize Name Mangling

The length of generated identifiers is limited by the Maximum identifier length (Simulink Coder) parameter. When a name collision exists, the $M$ token is expanded to the minimum number of characters required to avoid the collision. Other tokens are expanded in the order listed in Identifier Format Tokens. If the Maximum identifier length is not large enough to accommodate full expansions of the other tokens, partial expansions are used. To avoid partial expansions, it is good practice to:

- Avoid name collisions. One way to avoid name collisions is to not use default block names (for example, Gain1, Gain2...) when there are many blocks of the same type in the model.
• Where possible, increase the **Maximum identifier length** to accommodate the length of the identifiers that you expect to generate.

• Set the **Maximum identifier length** parameter to reserve at least three characters for the name-mangling text. The length of the name-mangling text increases as the number of name collisions increases.

  If changes to the model create more or fewer collisions, existing name-mangling text increases or decreases in length. If the length of the name-mangling text increases, additional characters are appended to the existing text. For example, the mangling text 'xyz' can change to 'xyzQ'. For fewer collisions, the name-mangling text 'xyz' changes to 'xy'.
Avoid Identifier Name Collisions with Referenced Models

Within a model that uses referenced models, collisions between the names of the models are not allowed. When generating code from a model that uses model referencing:

- You must include the $R$ token in the Identifier format control parameter specifications (in addition to the $M$ token).
- The Maximum identifier length must be large enough to accommodate full expansions of the $R$ and $M$ tokens. If Maximum identifier length is too small, a code generation error occurs.

When a name conflict occurs between an identifier within the scope of a higher-level model and an identifier within the scope of a referenced model, the identifier from the referenced model is preserved. Name mangling is performed on the identifier from the higher-level model.

If your model contains two referenced models with the same input or output port names, and one of the referenced models contains an atomic subsystem with “Function packaging” (Simulink) set to Nonreuseable function, a name conflict can occur and the build process produces an error.

Use Model Advisor to Detect Identifier Names Changed During Code Generation

For a referenced model, if the following Configuration Parameters > Code Generation > Symbols parameters have settings that do not contain a $R$ token (which represents the name of the reference model), code generation prepends the $R$ token to the identifier format.

- Global variables
- Global types
- Subsystem methods
- Constant macros

You can use the Model Advisor to identify referenced models in a model referencing hierarchy for which code generation changes these configuration parameter settings.

1. In the Simulink Editor, select Analysis > Model Advisor.
2 Select **By Task**.

3 Run the **Check code generation identifier formats used for model reference check.**
Maintain Traceability for Generated Identifiers

To verify your model, you can trace back and forth between generated identifiers and corresponding entities within the model. To maintain traceability, it is important that incremental revisions to a model have minimal impact on the identifier names that appear in generated code. There are two ways to minimally impact the identifier names:

- Choose unique names for Simulink objects (blocks, signals, states, and so on) as much as possible.
- Use name mangling when conflicts cannot be avoided.

The position of the name-mangling text is specified by the placement of the $M$ token in the **Identifier format control** parameters. Mangle characters consist of alphanumeric characters that are unique to each object. For more information, see “Control Name Mangling in Generated Identifiers” on page 39-30.
Exceptions to Identifier Formatting Conventions

There are some exceptions to the identifier formatting conventions described in “Identifier Format Control” on page 39-22.

• Type name generation: name mangling conventions do not apply to type names (that is, typedef statements) generated for global data types. If the $R token is included in the `Identifier format control` parameter specification, the model name is included in the typedef. When generating type definitions, the `Maximum identifier length` parameter is not respected.

• Non-Auto storage classes: the `Identifier format control` parameters specification does not affect objects (such as signals and parameters) that have a storage class other than Auto (such as ImportedExtern or ExportedGlobal).

• For shared utilities, code generation inserts the checksum specified by $C to prevent name collisions in the following situations:
  • $C is specified without $N.
  • The length of $N plus the length of the text that you specify exceeds the `Maximum identifier length`. Code generation truncates $N and inserts an 8-character checksum where you specified $C in the formatting scheme.
Identifier Format Control Parameters Limitations

The following limitations apply to the Identifier format control parameters:

- The following autogenerated identifiers currently do not fully comply with the setting of the Maximum identifier length parameter on the Code Generation > Symbols pane of the Configuration Parameters dialog box.
  - Model methods
    - The applicable format scheme is $R$F, and the longest $F$ is _derivatives_, which is 12 characters long. The model name can be up to 19 characters without exceeding the default Maximum identifier length of 31.
  - Local functions generated by S-functions or by add-on products such as DSP System Toolbox that rely on S-functions
  - Local variables generated by S-functions or by add-on products such as DSP System Toolbox that rely on S-functions
  - DW identifiers generated by S-functions in referenced models
  - Fixed-point shared utility macros or shared utility functions
  - Simulink rtm macros
    - Most are within the default Maximum identifier length of 31, but some exceed the limit. Examples are RTMSpecAccsGetStopRequestedValStoredAsPtr, RTMSpecAccsGetErrorStatusPointer, and RTMSpecAccsGetErrorStatusPointerPointer.
  - Define protection guard macros
    - Header file guards, such as _RTW_HEADER_$(filename)_h_, which can exceed the default Maximum identifier length of 31 given a filename such as $R_private.h.
    - Include file guards, such as _$R_COMMON_INCLUDES_.
    - typedef guards, such as _CSCI_$R_CHARTSTRUCT_.
  - In some situations, the following identifiers potentially can conflict with others.
    - Model methods
    - Reentrant model function arguments
• Local functions generated by S-functions or by add-on products such as DSP System Toolbox that rely on S-functions
• Local variables generated by S-functions or by add-on products such as DSP System Toolbox that rely on S-functions
• Fixed-point shared utility macros or shared utility functions
• Include header guard macros
• The following external identifiers that are unknown to the Simulink software might conflict with autogenerated identifiers.
  • Identifiers defined in custom code
  • Identifiers defined in custom header files
  • Identifiers introduced through a non-ANSI C standard library
  • Identifiers defined by custom TLC code
• Identifiers generated for simulation targets might exceed the Maximum identifier length. Simulation targets include the model reference simulation target, the accelerated simulation target, the RSim target, and the S-function target.
• Identifiers generated using a model name and bus object data type name, which are both long names, might exceed the Maximum identifier length. For example, a ground value variable name is generated as `<model_name>_rtZ<bus_name>`. If the `model_name` and `bus_name` are close to the maximum identifier length, the name exceeds the maximum identifier length.
Control Code Style

In this section...

<table>
<thead>
<tr>
<th>Goal</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specify whether to preserve order of operands in expressions</td>
<td>See “Optimize Code by Reordering Commutable Operands” on page 39-41.</td>
</tr>

</tr>
</tbody>
</table>

You can change the code style, cast expressions, and indentation of your generated code to conform to certain coding standards. Modify style options by setting parameters on the **Code Generation > Code Style** pane.
Control Parentheses in Generated Code

C code contains some syntactically required parentheses, and can contain additional parentheses that change semantics by overriding default operator precedence. C code can also contain optional parentheses that have no functional significance, but only increase the readability of the code. Optional C parentheses vary between two stylistic extremes:

- Include the minimum parentheses required by C syntax and precedence overrides so that C precedence rules specify all semantics unless overridden by parentheses.
- Include the maximum parentheses that can exist without duplication so that C precedence rules become irrelevant. Parentheses alone completely specify all semantics.

Understanding code with minimum parentheses can require applying nonobvious precedence rules. Maximum parentheses can hinder code reading by belaboring obvious precedence rules. Various parenthesesation standards exist that specify one or the other extreme, or define an intermediate style useful to people who read code.

For more information on this parameter, see “Parentheses level”.

Control Use of Parentheses

This example shows that Embedded Coder® provides three levels of control for parentheses in the generated code.
model='rtwdemo_parentheses';
open_system(model)

Parentheses level "Minimum":  \[Out = \text{In2} - \text{In1} > 1.0 \&\& \text{In2} > 2.0;\]
Parentheses level "Nominal":  \[Out = (\text{In2} - \text{In1} > 1.0) \&\& (\text{In2} > 2.0);\]
Parentheses level "Maximum":  \[Out = ((\text{In2} - \text{In1} > 1.0) \&\& (\text{In2} > 2.0));\]

**Description**
Embedded Coder(R) provides three levels of control for parentheses in the generated code. The control level "Minimum" generates the most compact code, with the smallest number of parentheses allowed under C syntax rules. The control level "Nominal" adds parentheses as needed to optimize readability. The control level "Maximum" generates the largest number of parentheses. The parentheses explicitly define the sequence of operations in an expression without relying on C precedence rules. Specifying control level "Maximum" provides full compliance with the MISRA-C(TM) standard.

**Instructions**
1. View and set the parentheses level by double-clicking the yellow button to the right.
2. Generate code by double-clicking the blue button to the right.
   An HTML report is displayed automatically.
3. Inspect the generated source files, comparing them with the three code examples above.
Optimize Code by Reordering Commutable Operands

This example shows how to reorder commutable operands to make expressions left-recursive. This optimization improves code efficiency.

Example Model

To reorder commutable operands, create the following model and name it `operand_order`. In this model, the output signal is the result of multiplying the signal from Inport block `In1` by the sum of the signals from Inport blocks `In2` and `In3`.

![Model diagram](image)

Generate Code

1. Open the Model Configuration Parameters dialog box. On the Code Style tab, select the Preserve operand order in expression parameter.

2. Generate code for the model.

In the `operand_order.c` file, the `operand_order_step` function contains the following code:

```c
operand_order_Y.Out1 = operand_order_U.In1 * (operand_order_U.In2 + operand_order_U.In3);
```
The code generator preserves the specified expression order in the model. Preserving the specified expression order increases the readability of the code for code traceability purposes.

**Generate Code with Optimization**

1. Open the Model Configuration Parameters dialog box. On the **Code Style** tab, clear the **Preserve operand order in expression** parameter.

2. Generate code for the model.

In the `operand_order.c` file, the `operand_order_step` function contains the following code:

```c
operand_order_Y.Out1 = (operand_order_U.In2 + operand_order_U.In3) * operand_order_U.In1;
```

The code generator optimizes the code by reordering the commutable operands to make the expression left-recursive. Left-recursive expressions improve code efficiency.

For more information on the **Preserve operand order in expression** parameter, see “Preserve operand order in expression”.

**Suppress Generation of Default Cases for Unreachable Stateflow Switch Statements**

This example shows how to specify whether to generate default cases for switch-case statements in the code for Stateflow charts. Generated code that does not contain default cases conserves ROM consumption and enables better code coverage because every branch in the generated code is falsifiable.

Some coding standards, such as MISRA, require the default case for switch-case statements. If you want to increase your chances of producing MISRA C compliant code, generate default cases for unreachable Stateflow switch statements.

**Example**

Figures 1, 2, and 3 show relevant portions of the `sldemo_fuelsys` model, a closed-loop system containing a plant and controller. The Air-fuel rate controller logic is a Stateflow chart that specifies the different operation modes.
Fault-Tolerant Fuel Control System

Figure 1: Top-level model of the plant and controller

Fuel Rate Control Subsystem

Figure 2: Fuel rate controller subsystem
Generate Code with Default Cases for Unreachable Stateflow Switch Statements

1. In the MATLAB Command Window, to open sldemo_fuelsys via rtwdemo_fuelsys enter:

   ```
   rtwdemo_fuelsys
   ```

2. Open the Model Configuration parameters dialog box. On the Code Generation > Code Style tab, clear the Suppress generation of default cases for Stateflow statements if unreachable parameter.

3. In the MATLAB Command Window, to build the model, enter:

   ```
   rtwbuild('sldemo_fuelsys/fuel_rate_control');
   ```
For the different operation modes, the `fuel_rate_control.c` file contains default cases for unreachable switch statements. For example, for the Shutdown operation mode, the generated code contains this default statement:

```c
default:
    /* Unreachable state, for coverage only */
    rtDWork.bitsForTID0.is_Fuel_Disabled = IN_NO_ACTIVE_CHILD;
    break;
```

For the Warmup operation mode, the generated code contains this default statement:

```c
default:
    /* Unreachable state, for coverage only */
    rtDWork.bitsForTID0.is_Low_Emissions = IN_NO_ACTIVE_CHILD;
    break;
```

### Suppress Default Cases for Unreachable Stateflow Switch Statements

1. Open the Configuration Parameters dialog box. On the Code Generation > Code Style tab, select the Suppress generation of default cases for Stateflow statements if unreachable parameter.

2. Build the model.

Read through the `fuel_rate_control.c` file. The default cases for unreachable switch statements are not in the generated code.

For more information on the Suppress generation of default cases for Stateflow statements if unreachable parameter, see “Suppress generation of default cases for Stateflow switch statements if unreachable”.

### Replace Multiplication by Powers of Two with Signed Bitwise Shifts

This example shows how to generate code that replaces multiplication by powers of two with signed bitwise shifts. Code that contains bitwise shifts is more efficient than code that contains multiplication by powers of two.

Some coding standards, such as MISRA, do not allow bitwise operations on signed integers. If you want to increase your chances of producing MISRA C compliant code, do not replace multiplication by powers of two with bitwise shifts.
**Example**

To replace multiplication by powers of two with bitwise shifts, create the following model. In this model, a signal of **Data type** `int16` feeds into a Shift Arithmetic block. In the Shift Arithmetic Block Parameters dialog box, the **Bits to shift > Direction** parameter is set to **Left**. The **Bits to shift > Number** parameter is set to 3. This parameter corresponds to a value of 8, or raising 2 to the power of 3.

![Diagram of the model](image)

**Generate Code with Signed Bitwise Shifts**

1. Open the Model Configuration Parameters dialog box and select the **Code Style** tab. The **Replace multiplications by powers of two with signed bitwise shifts** parameter is on by default.

2. Generate code for the model.

In the `bitwise_multiplication.c` file, the `bitwise_multiplication` step function contains this code:

```c
bitwise_multiplication_Y.Out1 = (int16_T)(bitwise_multiplication_U.In1 << 3);
```

The signed integer `bitwise_multiplication_U.In1` is shifted three bits to the left.

**Generate Code with Multiplication by Powers of Two**

1. Open the Model Configuration Parameters dialog box and select the **Code Style** tab.

2. Clear the **Replace multiplications by powers of two with signed bitwise shifts** parameter.

3. Generate code for the model.

In the `bitwise_multiplication.c` file, the `bitwise_multiplication` step function contains this code:

```c
bitwise_multiplication_Y.Out1 = (int16_T)(bitwise_multiplication_U.In1 * 8);
```

The signed integer `bitwise_multiplication_U.In1` is multiplied by 8.
For more information on the Replace multiplications by powers of two with signed bitwise shifts parameter, see “Replace multiplications by powers of two with signed bitwise shifts”.

**Generate Code with Right Shifts on Signed Integers**

This example shows how to control whether the generated code contains right shifts on signed integers. Generated code that does not contain right shifts on signed integers first casts the signed integers to unsigned integers, and then right shifts the unsigned integers.

Some coding standards, such as MISRA, do not allow right shifts on signed integers because different hardware can store negative integers differently. For negative integers, you can get different answers depending on the hardware. If you want to increase your chances of producing MISRA C compliant code, do not allow right shifts on signed integers.

**Example Model**

To generate code with right shifts on signed integers, create the following model. In this model, a signal of *Data type* int16 feeds into a Shift Arithmetic block. In the Shift Arithmetic Block Parameters dialog box, the Bits to shift > Direction parameter is set to Right. The Bits to shift > Number parameter is set to 3.

![Example Model Diagram](image)

**Generate Code with Right Shifts on Signed Integers**

1. Open the Model Configuration Parameters dialog box and select the Code Style tab. The Allow right shifts on signed integers parameter is on by default.

2. Generate code for the model.

In the rightshift.c file, the rightshift_step function contains this code:

```c
rightshift_Y.Out1 = (int16_T)(rightshift_U.In1 >> 3);
```
The signed integer `rightshift_U.In1` is shifted three bits to the right.

**Generate Code That Does Not Allow Right Shifts on Signed Integers**

1. Open the Model Configuration Parameters dialog box and select the **Code Style** tab. Clear the **Allow right shifts on signed integers** parameter.
2. Generate code for the model.

In the `rightshift.c` file, the `rightshift_step` function contains this code:

```c
rightshift_Y.Out1 = (int16_T)asr_s32(rightshift_U.In1, 3U);
```

When you clear the **Allow right shifts on signed integers** parameter, the generated code contains a function call instead of a right shift on a signed integer. The function `asr_s32` contains this code:

```c
int32_T asr_s32(int32_T u, uint32_T n)
{
    int32_T y;
    if (u >= 0) {
        y = (int32_T)((uint32_T)u >> n);
    } else {
        y = -(int32_T)((uint32_T) -(u + 1) >> n) - 1;
    }

    return y;
}
```

The `asr_s32` function casts a signed integer to an unsigned integer, and then right shifts the unsigned integer.

For more information on the **Allow right shifts on signed integers** parameter, see “Allow right shifts on signed integers”.

**Control Indentation Style in Generated Code**

For code indentation, you can set the following parameters:

- **Indent style** controls the placement of braces in generated code.
- **Indent size** controls the number of characters per indent level in generated code (2–8 characters).

You can set **Indent style** to K&R or Allman style.
**K&R**

K&R stands for Kernighan and Ritchie. Each function has the opening and closing brace on its own line at the same level of indentation as the function header. Code within the function is indented according to the **Indent size**.

For blocks within a function, opening braces are on the same line as the control statement. Closing braces are on a new line at the same level of indentation as the control statement. Code within the block is indented according to the **Indent size**.

For example, here is generated code with the **Indent style** set to K&R with an **Indent size** of 2:

```c
void rt_OneStep(void)
{
    static boolean_T OverrunFlag = 0;
    if (OverrunFlag) {
        rtmSetErrorStatus(rtwdemo_counter_M, "Overrun");
        return;
    }

    OverrunFlag = TRUE;
    rtwdemo_counter_step();
    OverrunFlag = FALSE;
}
```

**Allman**

Each function has the opening and closing brace on its own line at the same level of indentation as the function header. Code within the function is indented according to the **Indent size**.

For blocks within a function, opening and closing braces for control statements are on a new line at the same level of indentation as the control statement. This is the key difference between K&R and Allman styles. Code within the block is indented according to the **Indent size**.

For example, here is generated code with the **Indent style** set to Allman with an **Indent size** of 4:

```c
void rt_OneStep(void)
{
    static boolean_T OverrunFlag = 0;
```
if (OverrunFlag)
{
    rtmSetErrorStatus(rtwdemo_counter_M, "Overrun");
    return;
}

OverrunFlag = TRUE;
rtwdemo_counter_step();
OverrunFlag = FALSE;

**Control Cast Expressions in Generated Code**

You can choose how the code generator specifies data type casts in the generated code. In the Configuration Parameters dialog box, select **Code Generation > Code Style**. From the **Casting modes** drop-down list, three parameter options control how the code generator casts data types.

- **Nominal** instructs the code generator to generate code that has minimal data type casting. When you do not have special data type information requirements, choose Nominal.

- **Standards Compliant** instructs the code generator to cast data types to conform to MISRA standards when it generates code. The MISRA data type casting eliminates common MISRA standard violations, including address arithmetic and assignment. It reduces 10.1, 10.2, 10.3, and 10.4 violations.

  For more information, see “MISRA C Guidelines” on page 12-6.

- **Explicit** instructs the code generator to cast data type values explicitly when it generates code. You can see how a value is stored, which tells you how much memory space the code uses for the variable. The data type informs you how much precision is possible in calculations involving the variable.

  Open the example model `rtwdemo_rtwecintro`. 
Enable Nominal Casting Mode and Generate Code

When you choose Nominal casting mode, the code generator does not create data type casts for variables in the generated code.

1. On the **Code Generation > Code Style** pane, from the **Casting modes** drop-down list, select **Nominal**.
2. On the **Code Generation > Report** pane, select **Create code generation report**.
3. On the **Code Generation** pane, select **Generate code only**.
4. Click **Apply**.
5. In the model window, press **Ctrl+B** to generate code.
6. In the Code Generation report left pane, click `rtwdemo_rtwecintro.c` to see the code.

```c
/* Model step function */
void rtwdemo_rtwecintro_step(void)
{
    boolean_T rtb_equal_to_count;

    /* Sum: 'XRootX/Sum' incorporates:
        * Constant: 'XRootX/INC'
        * UnitDelay: 'XRootX/X'
    */
    rtDWork.X++;

    /* RelationalOperator: 'XRootX/RelOpt' incorporates:
        * Constant: 'XRootX/LIMIT'
    */
    rtb_equal_to_count = (rtDWork.X != 16);

    /* Outputs for Triggered SubSystem: 'XRootX/Amplifier' incorporates:
        * TriggerPort: 'XS1X/Trigger'
*/
```
if (rtb_equal_to_count && (rtPrevZCSigState.Amplifier_Trig_ZCE != POS_ZCSIG))
{
    /* Outport: 'XRootX/Output' incorporates:
       * Gain: 'XS1X/Gain'
       * Inport: 'XRootX/Input'
       */
    rtY.Output = rtU.Input << 1;
}

rtPrevZCSigState.Amplifier_Trig_ZCE = (uint8_T)(rtb_equal_to_count ? (int32_T)POS_ZCSIG : (int32_T)ZERO_ZCSIG);

/* End of Outputs for SubSystem: 'XRootX/Amplifier' */

/* Switch: 'XRootX/Switch' */
if (!rtb_equal_to_count) {
    /* Update for UnitDelay: 'XRootX/X' incorporates:
       * Constant: 'XRootX/RESET'
       */
    rtDWork.X = 0U;
}

/* End of Switch: 'XRootX/Switch' */

Enable Standards Compliant Casting Mode and Generate Code

When you choose Standards Compliant casting mode, the code generator creates
MISRA standards compliant data type casts for variables in the generated code.

1. On the Code Style pane, from the Casting modes drop-down list, select Standards
   Compliant.
2. On the Code Generation pane, click Apply.
3. In the model window, press Ctrl+B to generate code.
4. In the Code Generation report left pane, click rtwdemo_rtwecintro.c to see the
   code.

void rtwdemo_rtwecintro_step(void)
{
    boolean_T rtb_equal_to_count;

    /* Sum: '<Root>/Sum' incorporates:
       * Constant: '<Root>/INC'
       * UnitDelay: '<Root>/X'
       */
    rtDWork.X++;

    /* RelationalOperator: '<Root>/RelOpt' incorporates:
       * Constant: '<Root>/LIMIT'
       */
    rtb_equal_to_count = (boolean_T)(int32_T)((int32_T)rtDWork.X != (int32_T)16);

    /* Outputs for Triggered SubSystem: '<Root>/Amplifier' incorporates:
       * TriggerPort: '<S1>/Trigger' */
if (((int32_T)rtb_equal_to_count) && (rtPrevZCSigState.Amplifier_Trig_ZCE != POS_ZCSIG)) {
    /* Outport: '<Root>/Output' incorporates:
        * Gain: '<S1>/Gain'
        * Inport: '<Root>/Input'
    */
    rtY.Output = (int32_T)(uint32_T)((uint32_T)rtU.Input << (uint32_T)(int8_T)1);
}

rtPrevZCSigState.Amplifier_Trig_ZCE = (uint8_T)(int32_T)(rtb_equal_to_count ?
    (int32_T)(uint8_T)POS_ZCSIG : (int32_T)(uint8_T)ZERO_ZCSIG);

/* End of Outputs for SubSystem: '<Root>/Amplifier' */

/* Switch: '<Root>/Switch' */
if (!rtb_equal_to_count) {
    /* Update for UnitDelay: '<Root>/X' incorporates:
        * Constant: '<Root>/RESET'
    */
    rtDWork.X = 0U;
}

/* End of Switch: '<Root>/Switch' */

Enable Explicit Casting Mode and Generate Code

When you choose Explicit casting mode, the code generator creates explicit data type casts for variables in the generated code.

1. On the Code Style pane, from the Casting modes drop-down list, select Explicit.
2. On the Code Generation pane, click Apply.
3. In the model window, press Ctrl+B to generate code.
4. In the Code Generation report left pane, click rtwdemo_rtwecintro.c to see the code.

/* Model step function */
void rtwdemo_rtwecintro_step(void)
{
    boolean_T rtb_equal_to_count;

    /* Sum: '<Root>/Sum' incorporates:
        * Constant: '<Root>/INC'
        * UnitDelay: '<Root>/X'
    */
    rtDWork.X = (uint8_T)(1U + (uint32_T)(int32_T)rtDWork.X);

    /* RelationalOperator: '<Root>/RelOpt' incorporates:
        * Constant: '<Root>/LIMIT'
    */
    rtb_equal_to_count = (boolean_T)((int32_T)(int32_T)rtDWork.X != 16);

    /* Outputs for Triggered SubSystem: '<Root>/Amplifier' incorporates:
        * TriggerPort: '<S1>/Trigger'
    */
if (((int32_T)rtb_equal_to_count) && ((int32_T)((int32_T)rtPrevZCSigState.Amplifier_Trig_ZCE != (int32_T)POS_ZCSIG))) {
    /* Outport: '<Root>/Output' incorporates:
    *  Gain: '<S1>/Gain'
    *  Inport: '<Root>/Input'
    */
    rtY.Output = rtU.Input << 1;
}
rtPrevZCSigState.Amplifier_Trig_ZCE = (uint8_T)(rtb_equal_to_count ? (int32_T)POS_ZCSIG : (int32_T)ZERO_ZCSIG);

/* End of Outputs for SubSystem: '<Root>/Amplifier' */

/* Switch: '<Root>/Switch' */
if (!(int32_T)rtb_equal_to_count) {
    /* Update for UnitDelay: '<Root>/X' incorporates:
    *  Constant: '<Root>/RESET'
    */
    rtDWork.X = 0U;
}
/* End of Switch: '<Root>/Switch' */

Control Newline Style in Generated Code

In the generated code, the newline character differs according to the operating system that the code is generated on. You can now customize the newline character irrespective of the operating system. Set the style of the newline character by using the Newline style parameter. Default is the default option. You can customize the newline character irrespective of the operating system.

You can set Newline style to any of these options:

Default

This option is the default selected option. When you select this option, it generates the newline character based on the operating system that the code is generated on. For example, if the code is generated on a Windows machine, the newline character inserted by default is "\r\n". If the code is generated on a UNIX machine, the newline character inserted by default is "\n".

LF (Linefeed)

This option enables you to add the Line Feed (LF) character. "\n" is inserted as the newline character.
**CR+LF (Carriage Return + Line Feed)**

This option enables you to add the Carriage Return + Line Feed (CR+LF) character. "\r\n" is inserted as the newline character.

<tbody>
<tr>
<td>“Custom File Processing Components” on page 39-56</td>
</tr>
<tr>
<td>“Custom File Processing Configuration” on page 39-57</td>
</tr>
</tbody>
</table>

Custom file processing (CFP) tools allow you to customize the organization and formatting of generated code. With these tools, you can:

- Generate a source (.c or .cpp) or header (.h) file. If you configure the `Code interface packaging` for a model to be Reusable function or Nonreuseable function (not C++ class), you can use a `custom file processing template` to control how the code generator:
  - Emits code to standard generated files---`model.c` or `model.cpp` and `model.h`
  - Produces files that are independent of model code
  - Organize generated code into sections (such as includes, typedefs, functions, and more). Your CFP template can emit code (for example, functions), directives (such as `#define` or `#include` statements), or comments into each section.
  - Generate custom `file banners` (comment sections) at the start and end of generated code files and custom `function banners` that precede functions in the generated code.
  - Generate code to call model functions, such as `model_initialize`, `model_step`, and so on.
  - Generate code to read and write model inputs and outputs.
  - Generate a main program module.
  - Obtain information about the model and the generated files from the model.

**Custom File Processing Components**

The custom file processing features are based on the following interrelated components:

- `Code generation template` (CGT) files: a CGT file defines the top-level organization and formatting of generated code. See “Code Generation Template (CGT) Files” on page 39-60.
- The `code template API`: a high-level Target Language Compiler (TLC) API that provides functions with which you can organize code into named sections and subsections of
generated source and header files. The code template API also provides utilities that return information about generated files, generate standard model calls, and perform other functions. See “Code Template API Summary” on page 39-85.

- **Custom file processing (CFP) templates**: a CFP template is a TLC file that manages the process of custom code generation. A CFP template assembles code to be generated into buffers. A CFP template also calls the code template API to emit the buffered code into specified sections of generated source and header files. A CFP template interacts with a CGT file, which defines the ordering of major sections of the generated code. See “Custom File Processing (CFP) Templates” on page 39-66.

To use CFP templates, you must understand TLC programming, for more information, see “Target Language Compiler” (Simulink Coder).

### Custom File Processing Configuration

Customize generated code by specifying code and data templates on the **Code Generation > Templates** pane:

<table>
<thead>
<tr>
<th>Goal</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specify a template that defines the top-level organization and formatting of generated source code (.c or .cpp) files</td>
<td>Enter a code generation template (CGT) file for the <strong>Source file (*.c) template</strong> parameter.</td>
</tr>
<tr>
<td>Specify a template that defines the top-level organization and formatting of generated header (.h) files</td>
<td>Enter a CGT file for the <strong>Header file (*.h) template</strong> parameter. This template file can be the same template file that you specify for <strong>Source file (*.c) template</strong>. If you use the same template file, source and header files contain identical banners. The default template is <code>matlabroot/toolbox/rtw/targets/encoder/ert_code_template.cgt</code>.</td>
</tr>
<tr>
<td>Specify a template that organizes generated code into sections (such as includes, typedefs, functions, and more)</td>
<td>Enter a custom file processing (CFP) template file for the “File customization template” parameter. A CFP template can emit code, directives, or comments into each section. For more information, see “Custom File Processing (CFP) Templates” on page 39-66.</td>
</tr>
<tr>
<td>Generate a model-specific example main program module</td>
<td>Select <strong>Generate an example main program</strong>. For more information, see “Generate a Standalone Program” on page 52-2.</td>
</tr>
</tbody>
</table>
**Note** Place the template files that you specify on the MATLAB path.
Specify Templates For Code Generation

To use custom file processing features, create CGT files and CFP templates. These files are based on default templates provided by the code generation software. Once you have created your templates, you must integrate them into the code generation process.

Select and edit CGT files and CFP templates, and specify their use in the code generation process in the Code Generation > Templates pane of a model configuration set. The following figure shows options configured for their defaults.

The options related to custom file processing are:

- The Source file (.c) template field in the Code templates and Data templates sections. This field specifies the name of a CGT file to use when generating source (.c or .cpp) files. You must place this file on the MATLAB path.

- The Header file (.h) template field in the Code templates and Data templates sections. This field specifies the name of a CGT file to use when generating header (.h) files. You must place this file on the MATLAB path.

By default, the template for both source and header files is matlabroot/toolbox/rtw/targets/ecoder/ert_code_template.cgt.

- The File customization template edit field in the Custom templates section. This field specifies the name of a CFP template file to use when generating code files. You must place this file on the MATLAB path. The default CFP template is matlabroot/toolbox/rtw/targets/ecoder/example_file_process.tlc.

In each of these fields, click Browse to navigate to and select an existing CFP template or CGT file. Click Edit to open the specified file into the MATLAB editor where you can customize it.
**Code Generation Template (CGT) Files**

Code Generation Template (CGT) files define the top-level organization and formatting of generated source code and header files. CGT files have the following applications:

- Generation of custom banners (comments sections) in code files. See “Generate Custom File and Function Banners” on page 39-89.
- Generation of custom code using a CFP template requires a CGT file. To use CFP templates, you must understand the CGT file structure. In many cases, however, you can use the default CGT file without modifying it.

**Default CGT file**

The code generation software provides a default CGT file, `matlabroot/toolbox/rtw/targets/ecoder/ert_code_template.cgt`. Base your custom CGT files on the default file.

**CGT File Structure**

A CGT file consists of one required section and four optional sections:

**Code Insertion Section**

(Required) This section contains tokens that define an ordered partitioning of the generated code into a number of sections (such as Includes and Defines sections). Tokens have the form of:

```
%<SectionName>
```

For example,

```
%<Includes>
```

The code generation software defines a minimal set of required tokens. These tokens generate C or C++ source or header code. They are built-in tokens (see “Built-In Tokens and Sections” on page 39-61). You can also define custom tokens on page 39-80 and custom sections on page 39-78.

Each token functions as a placeholder for a corresponding section of generated code. The ordering of the tokens defines the order in which the corresponding sections appear in
the generated code. If you do not include a token, then the corresponding section is not generated. To generate code into a given section, explicitly call the code template API from a CFP template, as described in “Custom File Processing (CFP) Templates” on page 39-66.

The CGT tokens define the high-level organization of generated code. Using the code template API, you can partition each code section into named subsections, as described in “Subsections” on page 39-63.

In the code insertion section, you can also insert C or C++ comments between tokens. Such comments emit directly into the generated code.

**File Banner Section**

(Optional) This section contains comments and tokens you use in generating a custom file banner.

**Function Banner Section**

(Optional) This section contains comments and tokens for use in generating a custom function banner.

**Shared Utility Function Banner Section**

(Optional) This section contains comments and tokens for use in generating a custom shared utility function banner.

**File Trailer Section**

(Optional) This section contains comments for use in generating a custom trailer banner.

For more information on these sections, see “Generate Custom File and Function Banners” on page 39-89.

**Built-In Tokens and Sections**

The following code extract shows the required code insertion section of the default CGT file with the required built-in tokens.

```
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
%% Code insertion section (required)
%% These are required tokens. You can insert comments and other tokens in
%% between them, but do not change their order or remove them.
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
```
Note the following requirements for customizing a CGT file:

- Do not remove required built-in tokens.
- Built-in tokens must appear in the order shown because each successive section has dependencies on previous sections.
- Only one token per line.
- Do not repeat tokens.
- You can add custom tokens and comments to the code insertion section as long as you do not violate the previous requirements.

**Note** If you modify a CGT file and then rebuild your model, the code generation process does not force a top model build. To regenerate the code, see “Force Regeneration of Top Model Code” (Simulink Coder).

The following table summarizes the built-in tokens and corresponding section names, and describes the code sections.
### Built-In CGT Tokens and Corresponding Code Sections

<table>
<thead>
<tr>
<th>Token and Section Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Includes</td>
<td><code>#include</code> directives section</td>
</tr>
<tr>
<td>Defines</td>
<td><code>#define</code> directives section</td>

<tr>
<td>Types</td>
<td><code>typedef</code> section. <em>Typedefs can depend on a previously defined type</em></td>
</tr>
<tr>
<td>Enums</td>
<td>Enumerated types section</td>
</tr>
<tr>
<td>Definitions</td>
<td>Data definitions (for example, <code>double x = 3.0;</code>)</td>
</tr>
<tr>
<td>Declarations</td>
<td>Data declarations (for example, <code>extern double x;</code>)</td>
</tr>
<tr>
<td>Functions</td>
<td>C or C++ functions</td>
</tr>
</tbody>
</table>

### Subsections

You can define one or more named subsections for any section. Some of the built-in sections have predefined subsections summarized in table *Subsections Defined for Built-In Sections*.

**Note** Sections and subsections emit to the source or header file in the order listed in the CGT file.

Using the custom section feature, you can define additional sections. See “Generate a Custom Section” on page 39-78.
### Subsections Defined for Built-In Sections

### Format Generated Code Files Using Templates

This example shows how to use code generation templates to add custom code banners, rearrange data and functions, and insert additional code segments and documentation into generated code files.

```matlab
model='rtwdemo_codetemplate';
open_system(model)
```
<S:Note>This Simulink annotation maps to the code template %<Note> symbol.

**Description**

This model extracts text from the Model Description, a DOC block, and a Simulink annotation. The Simulink annotation maps to the code template %<Note> symbol. Many symbols are available that extract information from a model automatically. Refer to Module Packaging Features in the Embedded Coder documentation to see a complete list.

Many organizations employ coding standards that include consistent file layout and elaboration. Embedded Coder provides extensible code generation templates for formatting generated code. The layout and format of the code template file controls the output of the generated code.

Code generation templates (.cgt files) allow you to add custom code banners, rearrange data and functions, and insert additional code segments and documentation into generated code files. Code generation templates are picked up automatically from the MATLAB path and employed during the code generation process. For this model, the code generation template "rtwdemocodetemplate.cgt" is used.

**Instructions**

1. Double-click the yellow View Templates Configuration button to view the templates configuration.
2. Click the Edit button to the right of the "rtwdemocodetemplate.cgt" template, and inspect the code template.
3. Double-click the blue button in the upper right to generate code. An HTML report appears automatically.
4. Open rtwdemo_codetemplate.c to inspect the generated code for this model.

```
rtwdemoclean;
close_system(model,0)
```
Custom File Processing (CFP) Templates

The files provided to support custom file processing are:

- `matlabroot/rtw/c/tlc/mw/codetemplatelib.tlc`: A TLC function library that implements the code template API. `codetemplatelib.tlc` also provides the comprehensive documentation of the API in the comments headers preceding each function.

- `matlabroot/toolbox/rtw/targets/ecoder/example_file_process.tlc`: An example custom file processing (CFP) template, which you should use as the starting point for creating your own CFP templates. Guidelines and examples for creating a CFP template are provided in “Generate Source and Header Files with a Custom File Processing (CFP) Template” on page 39-73.

- TLC files supporting generation of single-rate and multirate main program modules (see “Customizing Main Program Module Generation” on page 39-77).

Once you have created a CFP template, you must integrate it into the code generation process, using the **File customization template** edit field. See “Specify Templates For Code Generation” on page 39-59.

Custom File Processing (CFP) Template Structure

A custom file processing (CFP) template imposes a simple structure on the code generation process. The template, a code generation template (CGT) file, partitions the code generated for each file into a number of sections. These sections are summarized in Built-In CGT Tokens and Corresponding Code Sections and Subsections Defined for Built-In Sections.

Code for each section is assembled in buffers and then emitted, in the order listed, to the file being generated.

To generate a file section, your CFP template must first assemble the code to be generated into a buffer. Then, to emit the section, your template calls the TLC function `LibSetSourceFileSection(fileH, section, tmpBuf)`

where

- `fileH` is a file reference to a file being generated.
section is the code section or subsection to which code is to be emitted. section must be one of the section or subsection names listed in Subsections Defined for Built-In Sections.

Determine the section argument as follows:

- If Subsections Defined for Built-In Sections does not define subsections for a given section, use the section name as the section argument.
- If Subsections Defined for Built-In Sections defines one or more subsections for a given section, you can use either the section name or a subsection name as the section argument.
- If you have defined a custom token denoting a custom section, do not call LibSetSourceFileSection. Special API calls are provided for custom sections (see “Generate a Custom Section” on page 39-78).

- tmpBuf is the buffer containing the code to be emitted.

There is no requirement to generate all of the available sections. Your template need only generate the sections you require in a particular file.

Note that legality or syntax checking is not performed on the custom code within each section.

See “Generate Source and Header Files with a Custom File Processing (CFP) Template” on page 39-73, for typical usage examples.
Change the Organization of a Generated File

The files created during code generation are organized according to the general code generation template. This template has the filename *ert_code_template.cgt*, and is specified by default in **Code Generation > Templates** pane of the Configuration Parameters dialog box.

The following fragment shows the *rtwdemo_basicsc.c* file header that is generated using this default template:

```c
/*
 * File: rtwdemo_basicsc.c
 *
 * Code generated for Simulink model 'rtwdemo_basicsc'.
 *
 * Model version : 1.299
 * Simulink Coder version : 8.11 (R2017a) 01-Aug-2016
 * C/C++ source code generated on : Fri Aug 19 12:45:59 2016
 *
 * Target selection: ert.tlc
 * Embedded hardware selection: Intel->x86-64 (Windows64)
 * Code generation objectives: Unspecified
 * Validation result: Not run
 */
```

You can change the organization of generated files using code templates and data templates. Code templates organize the files that contain functions, primarily. Data templates organize the files that contain identifiers. In this procedure, you organize the generated files, using the supplied code and data templates:

1. Display the active **Templates** configuration parameters.
2. In the **Code templates** section of the **Templates** pane, type `code_c_template.cgt` into the **Source file (*.c) templates** text box.
3. Type `code_h_template.cgt` into the **Header file (*.h) templates** text box.
4. In the **Data templates** section, type `data_c_template.cgt` into the **Source file (*.c) templates** text box.
5. Type `data_h_template.cgt` into the **Header file (*.h) templates** text box, and click **Apply**.
6. In the model window, press **Ctrl+B**. Now the files are organized using the templates you specified. For example, the *rtwdemo_basicsc.c* file header now is organized like this:
Change the Organization of a Generated File

Customize Generated File Names

The code generator creates `model.*` files during the code generation and build process. When you generate C/C++ code for ERT-based models, you can customize the names of the generated header, source, and data files. Custom file names enable you to:

- Comply with naming standards of the company or industry.
- Integrate with external code.

In the Configuration Parameters dialog box, on the Code Generation > Code Placement pane, use the Auto-generated file naming rules group to customize the names of generated files. When you use Modular or Compact(with separate date file) file packaging, you can specify custom names for generated header, source, and data files. When you use Compact file packaging, you can specify custom names for generated header and source files.

1. Open any ERT-based model, for example, `rtwdemo_dynamicio`. In the Configuration Parameters dialog box, change the System target file to `ert.tlc`.
2. On the Code Generation > Code Placement pane, select File packaging format as Compact(with separate date file).
3. Specify custom file names by using the naming rules for these parameters:
   - **Header files**: `$R$E_header`
   - **Source files**: `$R$E_source`
   - **Data files**: `$R_data`

$E is mandatory for **Header files** and **Source files**. $E represents these instances of file types:

- `capi`
- `capi_host`
- `dt`
- `testinterface`
- `private`
- `types`

4. To build the model, press Ctrl + B. In the code generation report, the generated files are listed on the left pane under Model files and Data files section.
In this example, $E$ resolves to `private` and `types`. The generated header files resolve to the model name with the value for $E$ and custom text `header`. The generated source files resolve to the model name with custom text `source`. The generated data file resolves to the model name with custom text `data`. Here is a summary of naming rules applied and the corresponding generated files:

<table>
<thead>
<tr>
<th>Type of File</th>
<th>Token Specification</th>
<th>Custom Text</th>
<th>Generated File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Header file</td>
<td>$R$E</td>
<td>header</td>
<td>rtwdemo_dynamicio_header.h</td>
</tr>
<tr>

This example shows you the process of generating a simple source (.c or .cpp) and header (.h) file using the example CFP template. Then, it examines the template and the code generated by the template.

The example CFP template, `matlabroot/toolbox/rtw/targets/ecoder/example_file_process.tlc`, demonstrates some of the capabilities of the code template API, including

- Generation of simple source (.c or .cpp) and header (.h) files
- Use of buffers to generate file sections for includes, functions, and so on
- Generation of includes, defines, into the standard generated files (for example, `model.h`)
- Generation of a main program module

Generate Code with a CFP Template

This section sets up a CFP template and configures a model to use the template in code generation. The template generates (in addition to the standard model files) a source file (`timestwo.c` or `.cpp`) and a header file (`timestwo.h`).

Follow the steps below to become acquainted with the use of CFP templates:

1. Copy the example CFP template, `matlabroot/toolbox/rtw/targets/ecoder/example_file_process.tlc`, to a folder outside of the MATLAB folder structure (that is, not under `matlabroot`). If the folder is not on the MATLAB path or the TLC path, then add it to the MATLAB path. It is good practice to locate the CFP template in the same folder as your system target file, which is on the TLC path.
2 Rename the copied example_file_process.tlc to test_example_file_process.tlc.

3 Open test_example_file_process.tlc into the MATLAB editor.

4 Uncomment the following line:

```matlab
%%  %assign ERTCustomFileTest = TLC_TRUE
```

It now reads:

```matlab
%assign ERTCustomFileTest = TLC_TRUE
```

If ERTCustomFileTest is not assigned as shown, the CFP template is ignored in code generation.

5 Save your changes to the file. Keep test_example_file_process.tlc open, so you can refer to it later.

6 Open the rtwdemo_udt model.

7 Open the Simulink Model Explorer. Select the active configuration set of the model, and open the Code Generation pane of the active configuration set.

8 On the Templates tab, in the File customization template field, specify test_example_file_process.tlc. This is the file you previously edited and is now the specified CFP template for your model.

9 On the General tab, select the Generate code only check box.

10 Click Apply.

11 In the model window, press Ctrl+B. During code generation, notice the following message in the Diagnostic Viewer:

```
Warning: Overriding example ert_main.c!
```

This message is displayed because test_example_file_process.tlc generates the main program module, overriding the default action of the ERT target. This is explained in greater detail below.

12 The rtwdemo_udt model is configured to generate an HTML code generation report. After code generation is complete, view the report.

Notice that the Generated Code list contains the following files:

- Under Main file, ert_main.c.
- Under Other files, timestwo.c and timestwo.h.
The files were generated by the CFP template. The next section examines the template to learn how this was done.

Keep the model, the code generation report, and the `test_example_file_process.tlc` file open so you can refer to them in the next section.

**Analysis of the Example CFP Template and Generated Code**

This section examines excerpts from `test_example_file_process.tlc` and some of the code it generates. Refer to the comments in `matlabroot/rtw/c/tlc/mw/codetemplatelib.tlc` while reading the following discussion.

**Generating Code Files**

Source (.c or .cpp) and header (.h) files are created by calling `LibCreateSourceFile`, as in the following excerpts:

```plaintext
%assign cFile = LibCreateSourceFile("Source", "Custom", "timestwo")
...
%assign hFile = LibCreateSourceFile("Header", "Custom", "timestwo")
```

Subsequent code refers to the files by the file reference returned from `LibCreateSourceFile`.

**File Sections and Buffers**

The code template API lets you partition the code generated to each file into sections, tagged as **Definitions**, **Includes**, **Functions**, **Banner**, and so on. You can append code to each section as many times as required. This technique gives you a great deal of flexibility in the formatting of your custom code files.

Subsections Defined for Built-In Sections describes the available file sections and their order in the generated file.

For each section of a generated file, use `%openfile` and `%closefile` to store the text for that section in temporary buffers. Then, to write (append) the buffer contents to a file section, call `LibSetSourceFileSection`, passing in the desired section tag and file reference. For example, the following code uses two buffers (`typesBuf` and `tmpBuf`) to generate two sections (tagged "Includes" and "Functions") of the source file `timestwo.c` or `.cpp` (referenced as `cFile`):

```plaintext
%openfile typesBuf
```
```c
#include "rtwtypes.h"

/* Times two function */
real_T timestwofcn(real_T input) {
    return (input * 2.0);
}

These two sections generate the entire timestwo.c or .cpp file:
#include "rtwtypes.h"

/* Times two function */
FLOAT64 timestwofcn(FLOAT64 input)
{
    return (input * 2.0);
}

Adding Code to Standard Generated Files

The timestwo.c or .cpp file generated in the previous example was independent of the standard code files generated from a model (for example, model.c or .cpp, model.h, and so on). You can use similar techniques to generate custom code within the model files. The code template API includes functions to obtain the names of the standard models files and other model-related information. The following excerpt calls LibGetMdlPubHdrBaseName to obtain the name for the model.h file. It then obtains a file reference and generates a definition in the Defines section of model.h:

```
% Add a #define to the model's public header file model.h
%assign pubName = LibGetMdlPubHdrBaseName()
%assign modelH = LibCreateSourceFile("Header", "Simulink", pubName)
%openfile tmpBuf

#define ACCELERATION 9.81
```
Examine the generated rtwdemo_udt.h file to see the generated #define directive.

**Customizing Main Program Module Generation**

Normally, the ERT target determines whether and how to generate an ert_main.c or .cpp module based on the settings of the Generate an example main program and Target operating system options on the Templates pane of the Configuration Parameters dialog box. You can use a CFP template to override the normal behavior and generate a main program module customized for your target environment.

To support generation of main program modules, two TLC files are provided:

- **bareboard_srmain.tlc**: TLC code to generate an example single-rate main program module for a bareboard target environment. Code is generated by a single TLC function, FcnSingleTaskingMain.
- **bareboard_mrmain.tlc**: TLC code to generate a multirate main program module for a bareboard target environment. Code is generated by a single TLC function, FcnMultiTaskingMain.

In the example CFP template file matlabroot/toolbox/rtw/targets/ecoder/example_file_process.tlc, the following code generates either a single- or multitasking ert_main.c or .cpp module. The logic depends on information obtained from the code template API calls LibIsSingleRateModel and LibIsSingleTasking:

```%
% If LibIsSingleRateModel() || LibIsSingleTasking()
% include "bareboard_srmain.tlc"
%<FcnSingleTaskingMain()>
elseif
% include "bareboard_mrmain.tlc"
%<FcnMultiTaskingMain()>
%endif
```

Note that bareboard_srmain.tlc and bareboard_mrmain.tlc use the code template API to generate ert_main.c or .cpp.

When generating your own main program module, you disable the default generation of ert_main.c or .cpp. The TLC variable GenerateSampleERTMain controls generation of ert_main.c or .cpp. You can directly force this variable to TLC_FALSE. The examples bareboard_mrmain.tlc and bareboard_srmain.tlc use this technique, as shown in the following excerpt from bareboard_srmain.tlc.
Alternatively, you can implement a `SelectCallback` function for your target. A `SelectCallback` function is a MATLAB function that is triggered during model loading, and also when the user selects a target with the System Target File browser. Your `SelectCallback` function should deselect and disable the **Generate an example main program** option. This prevents the TLC variable `GenerateSampleERTMain` from being set to TLC_TRUE.

See the “rtwgensettings Structure” (Simulink Coder) section for information on creating a `SelectCallback` function.

The following code illustrates how to deselect and disable the **Generate an example main program** option in the context of a `SelectCallback` function.

```matlab
slConfigUISetVal(hDlg, hSrc, 'GenerateSampleERTMain', 'off');
slConfigUISetEnabled(hDlg, hSrc, 'GenerateSampleERTMain',0);
```

**Note** Creation of a main program for your target environment requires some customization; for example, in a bareboard environment you need to attach `rt_OneStep` to a timer interrupt. It is expected that you will customize either the generated code, the generating TLC code, or both. See “Guidelines for Modifying the Main Program” on page 52-4 and “Guidelines for Modifying rt_OneStep” on page 52-9 for further information.

**Generate a Custom Section**

You can define custom tokens on page 39-80 in a CGT file and direct generated code into an associated built-in section. This feature gives you additional control over the formatting of code within each built-in section. For example, you could add subsections to built-in sections that do not already define subsections. Custom sections must be associated with one of the built-in sections: Includes, Defines, Types, Enums, Definitions, Declarations, or Functions. To create custom sections, you must

- Add a custom token to the code insertion section of your CGT file.
- In your CFP file:
• Assemble code to be generated to the custom section into a buffer.
• Declare an association between the custom section and a built-in section, with the code template API function LibAddSourceFileCustomSection.
• Emit code to the custom section with the code template API function LibSetSourceFileCustomSection.

The following code examples illustrate the addition of a custom token, Myincludes, to a CGT file, and the subsequent association of the custom section Myincludes with the built-in section Includes in a CFP file.

**Note** If you have not already created custom CGT and CFP files for your model, copy the default template files `matlabroot/toolbox/rtw/targets/ecoder/ert_code_template.cgt` and `matlabroot/toolbox/rtw/targets/ecoder/example_file_process.tlc` to a work folder that is outside the MATLAB folder structure but on the MATLAB or TLC path, rename them (for example, add the prefix `test_` to each file), and update the **Templates** pane of the Configuration Parameters dialog box to reference them.

First, add the token Myincludes to the code insertion section of your CGT file. For example:

```
%<Includes>
%<Myincludes>
%<Defines>
%<Types>
%< Enums>
%<Definitions>
%<Declarations>
%<Functions>
```

Next, in the CFP file, add code to generate include directives into a buffer. For example, in your copy of the example CFP file, you could insert the following section between the Includes section and the Create a simple main section:

```
%% Add a custom section to the model's C file model.c

%openfile tmpBuf
#include "moretables1.h"
#include "moretables2.h"
%closefile tmpBuf
```
The `LibAddSourceFileCustomSection` function call declares an association between the built-in section `Includes` and the custom section `Myincludes`. `Myincludes` is a subsection of `Includes`. The `LibSetSourceFileCustomSection` function call directs the code in the `tmpBuf` buffer to the `Myincludes` section of the generated file. `LibSetSourceFileCustomSection` is syntactically identical to `LibSetSourceFileSection`.

In the generated code, the include directives generated to the custom section appear after other code directed to `Includes`.

```c
#include "rtwdemo_udt.h"
#include "rtwdemo_udt_private.h"

/*! #include "mytables.h" */
#include "moretables1.h"
#include "moretables2.h"
```

**Note** The placement of the custom token in this example CGT file is arbitrary. By locating `%<Myincludes>` after `%<Includes>`, the CGT file specifies only that the `Myincludes` code appears after `Includes` code.

### Custom Tokens

Custom tokens are automatically translated to TLC syntax as a part of the build process. To escape a token, that is to prepare it for normal TLC expansion, use the '!' character. For example, the token `%<!TokenName>` is expanded to `%<TokenName>` by the template conversion program. You can specify valid TLC code, including TLC function calls: `%<!MyTLCFcn()>`. 

---

39-80
Comparison of a Template and Its Generated File

This figure shows part of a user-modified custom file processing (CFP) template and the resulting generated code. The figure illustrates how you can use a template to:

- Define what code the code generation software should add to the generated file
- Control the location of code in the file
- Optionally insert comments in the generated file

Notice %<Includes>, for example, on the template. The term Includes is a symbol name. A percent sign and brackets (%< >) must enclose every symbol name. You can add the desired symbol name (within the %< > delimiter) at a particular location in the template. This is how you control where the code generator places an item in the generated file.
Template and Generated File

```c
/*#INCLUDES*/   (1)
%<Includes>
/*#DEFINES*/    (2)
%<Defines>
#pragma string1 (3)
/*DEFINITIONS*/ (4)
%<Definitions>
#pragma string2 (5)
%<Declarations> (6)
%<Functions>   (7)

```
## Mapping Template Specification to Code Generation

<table>
<thead>
<tr>
<th>This part of the template...</th>
<th>Generates in the file...</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>(1) /<em>##INCLUDES</em>/%&lt;Includes&gt;</td>
<td>26–28 An /<em>##INCLUDES</em>/ comment, followed by #include statements</td>
<td>The code generator adds the C/C++ comment as a header, and then interprets the %&lt;Includes&gt; template symbol to list the required #include statements in the file. This code is first in this section of the file because the template entries are first.</td>
</tr>
<tr>
<td>(2) /<em>##DEFINES</em>/%&lt;Defines&gt;</td>
<td>30 A /<em>##DEFINES</em>/ comment, but no #define statements</td>
<td>Next, the code generator places the comment as a header for #define statements, but the file does not need #define. No code is added.</td>
</tr>
<tr>
<td>(3) #pragma string1</td>
<td>31 #pragma statements</td>
<td>While the code generator requires %&lt;&gt; delimiter for template symbols, it can also interpret C/C++ statements in the template without delimiters. In this case, the generator adds the specified statements to the code, following the order in which the statements appear in the template.</td>
</tr>
<tr>
<td>(5) #pragma string2</td>
<td>42</td>
<td></td>
</tr>
<tr>
<td>(4) /<em>DEFINITIONS</em>/%&lt;Definitions&gt;</td>
<td>32–41 /<em>DEFINITIONS</em>/ comment, followed by definitions</td>
<td>The code generator places the comment and definitions in the file between the #pragma statements, according to the order in the template. It also inserts comments (lines 33 and 36) that are preset in the model's Configuration Parameters dialog box.</td>
</tr>
<tr>
<td>This part of the template...</td>
<td>Generates in the file...</td>
<td>Explanation</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-------------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>%&lt;Declarations&gt;</td>
<td>43</td>
<td>No declarations</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The file needs no declarations, so the code generator does not generate declarations for this file. The template does not have a comment to provide a header. Line 43 is left blank.</td>
</tr>
<tr>
<td>%&lt;Functions&gt;</td>
<td>44-74</td>
<td>Functions</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Finally, the code generator adds functions from the model, plus comments that are preset in the Configuration Parameters dialog box. But it adds no comments as a header for the functions, because the template does not have one. This code is last because the template entry is last.</td>
</tr>
</tbody>
</table>

For a list of template symbols and the rules for using them, see “Template Symbol Groups” on page 39-98, “Template Symbols” on page 39-101, and “Rules for Modifying or Creating a Template” on page 39-104. To set comment options, from the Simulation menu, select Model Configuration Parameters. On the Configuration Parameters dialog box, select the Code Generation > Comments pane. For details, see “Configure Code Comments” (Simulink Coder).
Code Template API Summary

Code Template API Functions summarizes the code template API. See the source code in `matlabroot/rtw/c/tlc/mw/codetemplatelib.tlc` for detailed information on the arguments, return values, and operation of these calls.
## Code Template API Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LibClearFileSectionContents</td>
<td>Clears a file section with custom values before writing file to disk.</td>
</tr>
<tr>
<td>LibGetNumSourceFiles</td>
<td>Returns the number of created source files (.c or .cpp and .h).</td>
</tr>
<tr>
<td>LibGetSourceFileTag</td>
<td>Returns <code>&lt;filename&gt;_h</code> and <code>&lt;filename&gt;_c</code> for header and source files, respectively, where <code>filename</code> is the name of the model file.</td>
</tr>
<tr>
<td>LibCreateSourceFile</td>
<td>Creates a new C or C++ file and returns its reference. If the file already exists, simply returns its reference.</td>
</tr>
<tr>
<td>LibGetFileRecordName</td>
<td>Returns a model file name (including the path) without the extension.</td>
</tr>
<tr>
<td>LibGetSourceFileFromIdx</td>
<td>Returns a model file reference based on its index. This is useful for a common operation on all files, such as to set the leading file banner of all files.</td>
</tr>
<tr>
<td>LibSetSourceFileSection</td>
<td>Adds to the contents of a specified section within a specified file (see also “Custom File Processing (CFP) Template Structure” on page 39-66).</td>
</tr>
<tr>
<td>LibIndentSourceFile</td>
<td>Indents a file (from within the TLC environment).</td>
</tr>
<tr>
<td>LibCallModelInitialize</td>
<td>Returns code for calling the model's <code>model_initialize</code> function (valid for ERT only).</td>
</tr>
<tr>
<td>LibCallModelStep</td>
<td>Returns code for calling the model's <code>model_step</code> function (valid for ERT only).</td>
</tr>
<tr>
<td>LibCallModelTerminate</td>
<td>Returns code for calling the model's <code>model_terminate</code> function (valid for ERT only).</td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>-------------</td>
</tr>
<tr>
<td>LibCallSetEventForThisBaseStep</td>
<td>Returns code for calling the model's set events function (valid for ERT only).</td>
</tr>
<tr>
<td>LibWriteModelData</td>
<td>Returns data for the model (valid for ERT only).</td>
</tr>
<tr>
<td>LibSetRTModelErrorStatus</td>
<td>Returns the code to set the model error status.</td>
</tr>
<tr>
<td>LibGetRTModelErrorStatus</td>
<td>Returns the code to get the model error status.</td>
</tr>
<tr>
<td>LibIsSingleRateModel</td>
<td>Returns true if model is single rate and false otherwise.</td>
</tr>
<tr>
<td>LibGetModelName</td>
<td>Returns name of the model (without an extension).</td>
</tr>
<tr>
<td>LibGetMdlSrcBaseName</td>
<td>Returns the name of model's main source file (for example, <code>model.c</code> or <code>.cpp</code>).</td>
</tr>
<tr>
<td>LibGetMdlPubHdrBaseName</td>
<td>Returns the name of model's public header file (for example, <code>model.h</code>).</td>
</tr>
<tr>
<td>LibGetMdlPrvHdrBaseName</td>
<td>Returns the name of the model's private header file (for example, <code>model_private.h</code>).</td>
</tr>
<tr>
<td>LibIsSingleTasking</td>
<td>Returns true if the model is configured for single-tasking execution.</td>
</tr>
<tr>
<td>LibWriteModelInput</td>
<td>Returns the code to write to a particular root input (that is, a model inport block). (valid for ERT only).</td>
</tr>
<tr>
<td>LibWriteModelOutput</td>
<td>Returns the code to write to a particular root output (that is, a model outport block). (valid for ERT only).</td>
</tr>
<tr>
<td>LibWriteModelInputs</td>
<td>Returns the code to write to root inputs (that is, all model inport blocks). (valid for ERT only).</td>
</tr>
<tr>
<td>LibWriteModelOutputs</td>
<td>Returns the code to write to root outputs (that is, all model outport blocks). (valid for ERT only).</td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>LibNumDiscreteSampleTimes</td>
<td>Returns the number of discrete sample times in the model.</td>
</tr>
<tr>
<td>LibSetSourceFileCodeTemplate</td>
<td>Set the code template to be used for generating a specified source file.</td>
</tr>
<tr>
<td>LibSetSourceFileOutputDirectory</td>
<td>Set the folder into which a specified source file is to be generated.</td>
</tr>
<tr>
<td>LibAddSourceFileCustomSection</td>
<td>Add a custom section to a source file. The custom section must be associated with one of the built-in (required) sections: Includes, Defines, Types, Enums, Definitions, Declarations, or Functions.</td>
</tr>
<tr>
<td>LibSetSourceFileCustomSection</td>
<td>Adds to the contents of a specified custom section within a specified file. The custom section must have been previously created with LibAddSourceFileCustomSection.</td>
</tr>
</tbody>
</table>
Generate Custom File and Function Banners

Using code generation template (CGT) files, you can specify custom file banners and function banners for the generated code files. File banners are comment sections in the header and trailer sections of a generated file. Function banners are comment sections for each function in the generated code. Use these banners to add a company copyright statement, specify a special version symbol for your configuration management system, remove time stamps, and for many other purposes. These banners can contain characters, which propagate to the generated code.

To specify banners, create a custom CGT file with customized banner sections. The build process creates an executable TLC file from the CGT file. The code generation process then invokes the TLC file.

You do not need to be familiar with TLC programming to generate custom banners. You can modify example files that are supplied with the ERT target.

Note Prior releases supported direct use of customized TLC files as banner templates. You specified these with the Source file (.c) banner template and Header file (.h) banner template options of the ERT target. You can still use a custom TLC file banner template, however, you can now use CGT files instead.

ERT template options on the Code Generation > Templates pane of a configuration set, in the Code templates section, support banner generation.

The options for function and file banner generation are:

- “Code templates: Source file (*.c) template”: CGT file to use when generating source (.c or .cpp) files. Place this file on the MATLAB path.
- “Code templates: Header file (*.h) template”: CGT file to use when generating header (.h) files. You must place this file on the MATLAB path. This file can be the same template specified in the Code templates: Source file (*.c) template field, in which case identical banners are generated in source and header files.

By default, the template for both source and header files is matlabroot/toolbox/rtw/targets/ecoder/ert_code_template.cgt.

- In each of these fields, click Browse to navigate to and select an existing CGT file for use as a template. Click Edit to open the specified file into the MATLAB editor, where you can customize it.
Create a Custom File and Function Banner Template

To customize a CGT file for custom banner generation, make a local copy of the default code template and edit it, as follows:

1. Activate the configuration set that you want to work with.
2. Open the Code Generation pane of the active configuration set.
3. Click the Templates tab.
4. By default, the code template specified in the Code templates: Source file (*.c) template and Code templates: Header file (*.h) template fields is `matlabroot/toolbox/rtw/targets/ecoder/ert_code_template.cgt`.
5. If you want to use a different template as your starting point, click Browse to locate and select a CGT file.
6. Click Edit button to open the CGT file into the MATLAB editor.
7. Save a local copy of the CGT file. Store the copy in a folder that is outside of the MATLAB folder structure, but on the MATLAB path. If required, add the folder to the MATLAB path.
8. If you intend to use the CGT file with a custom target, locate the CGT file in a folder under your target root folder.
9. Rename your local copy of the CGT file. When you rename the CGT file, update the associated Code templates: Source file (*.c) template or Code templates: Header file (*.h) template field to match the new file name.
11. Save your changes to the CGT file.
12. Click Apply to update the configuration set.
13. Save your model.
14. Generate code. Examine the generated source and header files to confirm that they contain the banners specified by the template or templates.
Customize a Code Generation Template (CGT) File for File and Function Banner Generation

This section describes how to edit a CGT file for custom file and function banner generation. For a description of CGT files, see “Code Generation Template (CGT) Files” on page 39-60.

Components of the File and Function Banner Sections in the CGT file

In a CGT file, you can modify the following sections: file banner, function banner, shared utility function banner, and file trailer. Each section is defined by open and close tags. The tags specific to each section are shown in the following table.

<table>
<thead>
<tr>
<th>CGT File Section</th>
<th>Open Tag</th>
<th>Close Tag</th>
</tr>
</thead>
<tbody>
<tr>
<td>File Banner on page 39-93</td>
<td><code>&lt;FileBanner&gt;</code></td>
<td><code>&lt;/FileBanner&gt;</code></td>
</tr>
<tr>
<td>Function Banner on page 39-95</td>
<td><code>&lt;FunctionBanner&gt;</code></td>
<td><code>&lt;/FunctionBanner&gt;</code></td>
</tr>
<tr>
<td>Shared-utility Banner on page 39-95</td>
<td><code>&lt;SharedUtilityBanner&gt;</code></td>
<td><code>&lt;/SharedUtilityBanner&gt;</code></td>
</tr>
<tr>
<td>File Trailer on page 39-96</td>
<td><code>&lt;FileTrailer&gt;</code></td>
<td><code>&lt;/FileTrailer&gt;</code></td>
</tr>
</tbody>
</table>

You can customize your banners by including tokens and comments between the open and close tag for each section. Tokens are typically TLC variables, for example `<ModelVersion>`, which are replaced with values in the generated code.

You can customize your banners by including tokens and comments between the open and close tag for each section. Tokens are typically TLC variables, for example `<ModelVersion>`, which are replaced with values in the generated code.

Note: Including C comment indicators, `/*` or `*/`, in the contents of your banner might introduce an error in the generated code.

An open tag includes tag attributes. Enclose the value of the attribute in double quotes. The attributes available for an open tag are:

- **width**: specifies the width of the file or function banner comments in the generated code. The default value is 80.
- **style**: specifies the boundary for the file or function banner comments in the generated code.

The open tag syntax is as follows:
Note If the Configuration Parameters > Code Generation > Language parameter is set to C++, to select a comment style that uses C comment notation (/*...*/), you must also set the Configuration Parameters > Comments > Comment style parameter to Multi-line.

The built-in style options for the style attribute are:

- **classic**
  
  /* single line comments */
  /*
   * multiple line comments
   * second line
   */

- **classic_cpp**
  
  // single line comments
  //
  // multiple line comments
  // second line
  //

- **box**
  
  /**********************************************************
  */
  /* banner contents */
  /**********************************************************/

- **box_cpp**

  /////////////////////////////////////////////////////////////////////////////////
  // banner contents
  /////////////////////////////////////////////////////////////////////////////////

- **open_box**

  /**********************************************************
  * banner contents
  **********************************************************/

- **open_box_cpp**
File Banner

This section contains comments and tokens for use in generating a custom file banner. The file banner precedes C or C++ code generated by the model. If you omit the file banner section from the CGT file, then no file banner emits to the generated code.
**Note** If you customize your file banner, the software does not emit the customized banner for the file const_params.c.

The following section is the file banner section provided with the default CGT file, `matlabroot/toolbox/rtw/targets/ecoder/ert_code_template.cgt`.

```c
%%%%%%%%%%%%%%%%%%%%%%
%% Custom file banner section (optional)
%%
<FileBanner style="classic">
File: %<FileName>
Code generated for Simulink model %<ModelName>.

Model version : %<ModelVersion>
Simulink Coder version : %<RTWFileVersion>
TLC version : %<TLCVersion>
C/C++ source code generated on : %<SourceGeneratedOn>
%<CodeGenSettings>
</FileBanner>
```

### Summary of Tokens for File Banner Generation

<table>
<thead>
<tr>
<th>Token</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FileName</td>
<td>Name of the generated file (for example, &quot;rtwdemo_udt.c&quot;).</td>
</tr>
<tr>
<td>FileType</td>
<td>Either &quot;source&quot; or &quot;header&quot;. Designates whether generated file is a .c or .cpp file or an .h file.</td>
</tr>
<tr>
<td>FileTag</td>
<td>Given file names file.c or .cpp and file.h; the file tags are &quot;file_c&quot; and &quot;file_h&quot;, respectively.</td>
</tr>
<tr>
<td>ModelName</td>
<td>Name of generating model.</td>
</tr>
<tr>
<td>ModelVersion</td>
<td>Version number of model.</td>
</tr>
<tr>
<td>RTWFileVersion</td>
<td>Version number of model.rtw file.</td>
</tr>
<tr>
<td>RTWFileGeneratedOn</td>
<td>Timestamp of model.rtw file.</td>
</tr>
<tr>
<td>TLCVersion</td>
<td>Version of Target Language Compiler.</td>
</tr>
<tr>
<td>SourceGeneratedOn</td>
<td>Timestamp of generated file.</td>
</tr>
<tr>
<td>CodeGenSettings</td>
<td>Code generation settings for model: target language, target selection, production hardware selection, test hardware selection, code generation objectives (in priority order), and Code Generation Advisor validation result.</td>
</tr>
</tbody>
</table>
Function Banner

This section contains comments and tokens for use in generating a custom function banner. The function banner precedes C or C++ function generated during the build process. If you omit the function banner section from the CGT file, the default function banner emits to the generated code. The following section is the default function banner section provided with the default CGT file, `matlabroot/toolbox/rtw/targets/encoder/ert_code_template.cgt`.

```
% Custom function banner section (optional)
% Customize function banners by using the following predefined tokens:
% %<ModelName>, %<FunctionName>, %<FunctionDescription>, %<Arguments>,
% %<ReturnType>, %<GeneratedFor>, %<BlockDescription>.
% <FunctionBanner style="classic">
%<FunctionDescription>
%<BlockDescription>
</FunctionBanner>
```

Summary of Tokens for Function Banner Generation

<table>
<thead>
<tr>
<th>FunctionName</th>
<th>Name of function</th>
</tr>
</thead>
<tbody>
<tr>
<td>Arguments</td>
<td>List of function arguments</td>
</tr>
<tr>
<td>ReturnType</td>
<td>Return type of function</td>
</tr>
<tr>
<td>ModelName</td>
<td>Name of generating model</td>
</tr>
<tr>
<td>FunctionDescription</td>
<td>Short abstract about the function</td>
</tr>
<tr>
<td>GeneratedFor</td>
<td>Full block path for the generated function</td>
</tr>
<tr>
<td>BlockDescription</td>
<td>User input from the <strong>Block Description</strong> parameter of the block properties dialog box. <code>BlockDescription</code> contains an optional token attribute, <code>style</code>. The only valid value for <code>style</code> is <code>content_only</code>, which is case-sensitive and enclosed in double quotes. Use the <code>content_only</code> style when you want to include only the block description content that you entered in the block parameter dialog. The syntax for the token attribute <code>style</code> is:</td>
</tr>
<tr>
<td></td>
<td>%&lt;BlockDescription style = &quot;content_only&quot;&gt;</td>
</tr>
</tbody>
</table>

Shared Utility Function Banner

The shared utility function banner section contains comments and tokens for use in generating a custom shared utility function banner. The shared utility function banner
precedes C or C++ shared utility function generated during the build process. If you omit the shared utility function banner section from the CGT file, the default shared utility function banner emits to the generated code. The following section is the default shared utility function banner section provided with the default CGT file, `matlabroot/toolbox/rtw/targets/ecoder/ert_code_template.cgt`.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
%% Custom shared utility function banner section (optional)
%% Customize banners for functions generated in shared location by using the
%% following predefined tokens: %<FunctionName>, %<FunctionDescription>,
%% %<Arguments>, %<ReturnType>.
%%
%% <SharedUtilityBanner style="classic">
%% %<FunctionDescription>
%% </SharedUtilityBanner>

**Summary of Tokens for Shared Utility Function Banner Generation**

<table>
<thead>
<tr>
<th>FunctionName</th>
<th>Name of function</th>
</tr>
</thead>
<tbody>
<tr>
<td>Arguments</td>
<td>List of function arguments</td>
</tr>
<tr>
<td>ReturnType</td>
<td>Return type of function</td>
</tr>
<tr>
<td>FunctionDescription</td>
<td>Short abstract about function</td>
</tr>
</tbody>
</table>

**File Trailer**

The file trailer section contains comments for generating a custom file trailer. The file trailer follows C or C++ code generated from the model. If you omit the file trailer section from the CGT file, no file trailer emits to the generated code. The following section is the default file trailer provided in the default CGT file.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
%% Custom file trailer section (optional)
%%
%% <FileTrailer style="classic">
%% File trailer for generated code.
%%
%% [EOF]
%% </FileTrailer>

Tokens available for the file banner are available for the file trailer. See Summary of Tokens for File Banner Generation.
Template Symbols and Rules

</tr>
<tr>
<td>“Rules for Modifying or Creating a Template” on page 39-104</td>
</tr>
</tbody>
</table>

Introduction

“Template Symbol Groups” on page 39-98 and “Template Symbols” on page 39-101 describe custom file processing (CFP) template symbols and rules for using them. The location of a symbol in one of the supplied template files (code_c_template.cgt, code_h_template.cgt, data_c_template.cgt, or data_h_template.cgt) determines where the items associated with that symbol are located in the corresponding generated file. “Template Symbol Groups” on page 39-98 identifies the symbol groups, starting with the parent (“Base”) group, followed by the children of each parent. “Template Symbols” on page 39-101 lists the symbols alphabetically.

Note If you are using custom CGT sections, for files generated to the _sharedutils folder, you can only use symbol names in the Base symbol group.
## Template Symbol Groups

* Symbol names must be enclosed between %< >. For example, %<Functions>.

** This symbol can be used to add a comment to the generated files. See “Add Global Comments” on page 39-8. The code generator places the comment in each generated file whose template has this symbol name. The code generator places the comment at the location that corresponds to where the symbol name is located in the template file.

*** The description can be deduced from the symbol name. For example, GlobalCalibrationScalar is a symbol that identifies a scalar. It contains data of global scope that you can calibrate.

**Rules for Modifying or Creating a Template**

The following are the rules for creating an MPF template. “Comparison of a Template and Its Generated File” on page 39-81 illustrates several of these rules.

1. Place a symbol on a template within the %< > delimiter. For example, the symbol named Includes should look like this on a template: %<Includes>. *Note that symbol names are case-sensitive.*

2. Place a symbol on a template where desired. Its location on the template determines where the item associated with this symbol is located in the generated file. If no item is associated with it, the symbol is ignored.

3. Place a C/C++ statement outside of the %< > delimiter, and on a different line than a %< > delimiter, for that statement to appear in the generated file. For example, #pragma message ("my text") in the template results in #pragma message ("my text") at the corresponding location in the generated file. *Note that the statement must be compatible with your C/C++ compiler.*

4. Use the .cgt extension for every template filename. (*cgt* stands for code generation template.)
5 Note that \%\% $Revision: 1.1.4.10.4.1$ appears at the top of the MathWorks supplied templates. This is for internal MathWorks use only. It does not need to be placed on a user-defined template and does not show in a generated file.

6 Place a comment on the template between /* */ as in standard ANSI C\textsuperscript{6}. This results in /*comment*/ on the generated file.

7 Each MPF template must have all of the Base group symbols, in predefined order. They are listed in “Template Symbol Groups” on page 39-98. Each symbol in the Base group is a parent. For example, Declarations is a parent symbol.

8 Each symbol in a non-Base group is a child. For example, LocalMacros is a child.

9 Except for Documentation children, children must be placed after their parent, before the next parent, and before the Functions symbol.

10 Documentation children can be located before or after their parent in any order anywhere in the template.

11 If a non-Documentation child is missing from the template, the code generator places the information associated with this child at its parent location in the generated file.

12 If a Documentation child is missing from the template, the code generator omits the information associated with that child from the generated file.

Annotate Code for Justifying Polyspace Checks

With the Polyspace Code Prover product you can apply Polyspace verification to Embedded Coder generated code. The software detects run-time errors in the generated code and helps you to locate and fix model faults.

Polyspace might highlight overflows for certain operations that are legitimate because of the way the code generator implements these operations. Consider the following model and the corresponding generated code.

```c
32 /* Sum: '<Root>/Sum' incorporates:
33   *  Inport: '<Root>/In1'
34   *  Inport: '<Root>/In2'
35  */
36  qY_0 = sat_add_U.In1 + sat_add_U.In2;
37  if ((sat_add_U.In1 < 0) && ((sat_add_U.In2 < 0) && (qY_0 >= 0))) {
38    qY_0 = MIN_int32_T;
39  } else {
40   if ((sat_add_U.In1 > 0) && ((sat_add_U.In2 > 0) && (qY_0 <= 0))) {
41      qY_0 = MAX_int32_T;
42    }
43  }
```

The code generator recognizes that the largest built-in data type is 32-bit. It is not possible to saturate the results of the additions and subtractions using `MIN_INT32` and `MAX_INT32` and a bigger single-word integer data type. Instead the software detects the results overflow and the direction of the overflow, and saturates the result.

If you do not provide justification for the addition operator on line 36, Polyspace verification generates an orange check that indicates a potential overflow. The verification does not take into account the saturation function of lines 37 to 43. In addition, the trace-back functionality of Polyspace Code Prover does not identify the reason for the orange check.

To justify overflows from operators that are legitimate, on the **Configuration Parameters > Code Generation > Comments** pane:
- Under **Overall control**, select the **Include comments** check box.
- Under **Auto generate comments**, select the **Operator annotations** check box.

The code generator annotates generated code with comments for Polyspace. For example:

```c
32 /* Sum: '<Root>/Sum' incorporates:
33   * Inport: '<Root>/In1'
34   * Inport: '<Root>/In2'
35 */
36 qY_0 = sat_add_U.In1 +/*MW:OV0k*/ sat_add_U.In2;
```

When you run a verification using Polyspace Code Prover, the Polyspace software uses the annotations to justify the operator-related orange checks and assigns the **Not a defect** classification to the checks.

Enhance Readability of Code for Flow Charts

In this section...

“Appearance of Generated Code for Flow Charts” on page 39-108
“Convert If-Elseif-Else Code to Switch-Case Statements” on page 39-111
“Example of Converting Code to Switch-Case Statements” on page 39-113

Appearance of Generated Code for Flow Charts

If you have an Embedded Coder license and you generate code for models that include Stateflow objects, the code from a flow chart resembles the samples that follow.

The following characteristics apply:

• By default, the generated code uses if-elseif-else statements to represent switch patterns. To convert the code to use switch-case statements, see “Convert If-Elseif-Else Code to Switch-Case Statements” on page 39-111.
• By default, variables that appear in the flow chart do not retain their names in the generated code. Modified identifiers make sure that no naming conflicts occur.
• Traceability comments for the transitions appear between each set of /* and */ markers. To learn more about traceability, see “Trace Stateflow Elements in Generated Code” on page 64-13.
if (modelname_U.In1 == 1.0) {
    /* Transition: '<S1>:11' */
    /* Transition: '<S1>:12' */
    modelname_Y.Out1 = 10.0;
    /* Transition: '<S1>:15' */
    /* Transition: '<S1>:16' */
} else {
    /* Transition: '<S1>:10' */
    if (modelname_U.In1 == 2.0) {
        /* Transition: '<S1>:13' */
        /* Transition: '<S1>:14' */
        modelname_Y.Out1 = 20.0;
        /* Transition: '<S1>:16' */
    } else {
        /* Transition: '<S1>:17' */
        modelname_Y.Out1 = 30.0;
    }
}

Sample Code for a Decision Logic Pattern
for (sf_i = 0; sf_i < 10; sf_i++) {
    /* Transition: '<S1>:40' */
    /* Transition: '<S1>:41' */
    modelname_B.y = modelname_B.y + modelname_U.In1;
    /* Transition: '<S1>:39' */
}

Sample Code for an Iterative Loop Pattern
if (modelname_U.In1 == 1.0) {
    /* Transition: '<S1>:149' */
    /* Transition: '<S1>:150' */
    modelname_Y.Out1 = 1.0;
    /* Transition: '<S1>:151' */
    /* Transition: '<S1>:152' */
    /* Transition: '<S1>:158' */
    /* Transition: '<S1>:159' */
} else {
    /* Transition: '<S1>:156' */
    if (modelname_U.In1 == 2.0) {
        /* Transition: '<S1>:153' */
        /* Transition: '<S1>:154' */
        modelname_Y.Out1 = 2.0;
        /* Transition: '<S1>:155' */
        /* Transition: '<S1>:158' */
        /* Transition: '<S1>:159' */
    } else {
        /* Transition: '<S1>:161' */
        modelname_Y.Out1 = 3.0;
    }
}

Sample Code for a Switch Pattern

Convert If-Elseif-Else Code to Switch-Case Statements

When you generate code for embedded real-time targets, you can choose to convert if-elseif-else code to switch-case statements. This conversion can enhance readability of the code. For example, when a flow chart contains a long list of conditions, the switch-case structure:

- Reduces the use of parentheses and braces
- Minimizes repetition in the generated code

How to Convert If-Elseif-Else Code to Switch-Case Statements

The following procedure describes how to convert generated code for the flow chart from if-elseif-else to switch-case statements.
Step | Task | Reference
--- | --- | ---
1 | Verify that your flow chart follows the rules for conversion. | “Verify the Contents of the Flow Chart” on page 39-116
2 | Enable the conversion. | “Enable the Conversion” on page 39-116
3 | Generate code for your model. | “Generate Code for Your Model” on page 39-117
4 | Troubleshoot the generated code.  
   • If you see switch-case statements for your flow chart, you can stop.  
   • If you see if-elseif-else statements for your flow chart, update the chart and repeat the previous step. | “Troubleshoot the Generated Code” on page 39-117

**Rules of Conversion**

For the conversion to occur, the following rules must hold. LHS and RHS refer to the left-hand side and right-hand side of a condition, respectively.

<table>
<thead>
<tr>
<th>Construct</th>
<th>Rules to Follow</th>
</tr>
</thead>
</table>
| Flow chart | Must have two or more unique conditions, in addition to a default.  
For more information, see “How the Conversion Handles Duplicate Conditions” on page 39-113. |
| Each condition | Must test equality only.  
Must use the same variable or expression for the LHS. |
| Note | You can reverse the LHS and RHS. |
| Each LHS | Must be a single variable or expression.  
Cannot be a constant.  
Must have an integer or enumerated data type. |
<table>
<thead>
<tr>
<th>Construct</th>
<th>Rules to Follow</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Cannot have any side effects on simulation.</td>
</tr>
<tr>
<td></td>
<td>For example, the LHS can read from but not write to global variables.</td>
</tr>
<tr>
<td>Each RHS</td>
<td>Must be a constant or a parameter.</td>
</tr>
<tr>
<td></td>
<td>Must have an integer or enumerated data type.</td>
</tr>
</tbody>
</table>

**How the Conversion Handles Duplicate Conditions**

If a flow chart has duplicate conditions, the conversion preserves only the first condition. The code discards the other instances of duplicate conditions.

After removal of duplicates, two or more unique conditions must exist. If not, the conversion does not occur and the code contains all duplicate conditions.

**Example of Generated Code**

```java
if (x == 1) {
    block1
} else if (x == 2) {
    block2
} else if (x == 1) {  // duplicate
    block3
} else if (x == 3) {
    block4
} else if (x == 1) {  // duplicate
    block5
} else {
    block6
}
```

```java
switch (x) {
    case 1:
        block1; break;
    case 2:
        block2; break;
    case 3:
        block4; break;
    default:
        block6; break;
}
```

**Code After Conversion**

```java
if (x == 1) {
    block1
} else if (x == 1) {  // duplicate
    block2
} else {
    block3
}
```

No change, because only one unique condition exists

**Example of Converting Code to Switch-Case Statements**

Suppose that you have the following model with a single chart.
The chart contains a flow chart and four MATLAB functions:

The MATLAB functions in the chart contain the code in the following table. In each case, the **Function Inline Option** is Auto. For more information about function inlining, see “Specify Graphical Function Properties” (Stateflow).
<table>
<thead>
<tr>
<th>MATLAB Function</th>
<th>Code</th>
</tr>
</thead>
</table>
| stop            | function stop  
%#codegen  
coder.extrinsic('disp');  
disp('Not moving.')  
traffic_speed = 0; |
| slowdown        | function slowdown  
%#codegen  
coder.extrinsic('disp')  
disp('Slowing down.')  
traffic_speed = 1; |
| accelerate      | function accelerate  
%#codegen  
coder.extrinsic('disp');  
disp('Moving along.')  
traffic_speed = 2; |
| light           | function color = light(x)  
%#codegen  
if (x < 20)  
  color = TrafficLights.GREEN;  
elseif (x >= 20 && x < 25)  
  color = TrafficLights.YELLOW;  
else  
  color = TrafficLights.RED;  
end |

The output color of the function light uses the enumerated type TrafficLights. The enumerated type definition in TrafficLights.m is:

classdef TrafficLights < Simulink.IntEnumType  
enumeration  
  RED(0)  
  YELLOW(5)  
  GREEN(10)  
end  
end

For more information, see “Define Enumerated Data Types” (Stateflow).
Verify the Contents of the Flow Chart

Check that the flow chart in your chart follows the rules in “Rules of Conversion” on page 39-112.

<table>
<thead>
<tr>
<th>Construct</th>
<th>How the Construct Follows the Rules</th>
</tr>
</thead>
<tbody>
<tr>
<td>Flow chart</td>
<td>Two unique conditions exist, in addition to the default:</td>
</tr>
<tr>
<td></td>
<td>• [light(intersection) == RED]</td>
</tr>
<tr>
<td></td>
<td>• [light(intersection) == YELLOW]</td>
</tr>
<tr>
<td>Each condition</td>
<td>Each condition:</td>
</tr>
<tr>
<td></td>
<td>• Tests equality</td>
</tr>
<tr>
<td></td>
<td>• Uses the same function call light(intersection) for the LHS</td>
</tr>
<tr>
<td>Each LHS</td>
<td>Each LHS:</td>
</tr>
<tr>
<td></td>
<td>• Contains a single expression</td>
</tr>
<tr>
<td></td>
<td>• Is the output of a function call and therefore not a constant</td>
</tr>
<tr>
<td></td>
<td>• Is of enumerated type TrafficLights, which you define in TrafficLights.m on the MATLAB path (see “Define Enumerated Data Types” (Stateflow))</td>
</tr>
<tr>
<td></td>
<td>• Uses a function call that does not have side effects</td>
</tr>
<tr>
<td>Each RHS</td>
<td>Each RHS:</td>
</tr>
<tr>
<td></td>
<td>• Is an enumerated value and therefore a constant</td>
</tr>
<tr>
<td></td>
<td>• Is of enumerated type TrafficLights</td>
</tr>
</tbody>
</table>

Enable the Conversion

1. Open the Model Configuration Parameters dialog box.
2. In the Code Generation pane, select ert.tlc for the System target file.

   This step specifies an ERT-based target for your model.
3. In the Code Generation > Code Style pane, select the Convert if-elseif-else patterns to switch-case statements check box.
Tip This conversion works on a per-model basis. If you select this check box, the conversion applies to:

- Flow charts in all charts of a model
- MATLAB functions in all charts of a model
- All MATLAB Function blocks in that model

Generate Code for Your Model

In the model, select Code > C/C++ Code > Build Model to generate source code from the model.

Troubleshoot the Generated Code

The generated code for the flow chart appears something like this:

```c
if (sf_color == RED) {
    /* Transition: '<S1>:11' */
    /* Transition: '<S1>:12' */
    /* MATLAB Function 'stop': '<S1>:23' */
    /* '<S1>:23:6' */
    rtb_traffic_speed = 0;

    /* Transition: '<S1>:15' */
    /* Transition: '<S1>:16' */
} else {
    /* Transition: '<S1>:10' */
    /* MATLAB Function 'light': '<S1>:19' */
    if (ifelse_using_enums_U.In1 < 20.0) {
        /* '<S1>:19:3' */
        /* '<S1>:19:4' */
        sf_color = GREEN;
    } else if ((ifelse_using_enums_U.In1 >= 20.0) &&
               (ifelse_using_enums_U.In1 < 25.0)) {
        /* '<S1>:19:5' */
        /* '<S1>:19:6' */
        sf_color = YELLOW;
    } else {
        /* '<S1>:19:8' */
        sf_color = RED;
    }
}

if (sf_color == YELLOW) {
```
Because the MATLAB function light appears inlined, inequality comparisons appear in these lines of code:

```matlab
if (ifelse_using_enums_U.In1 < 20.0) {
    ....
} else if ((ifelse_using_enums_U.In1 >= 20.0) &&
            (ifelse_using_enums_U.In1 < 25.0)) {
    ....
```

Because inequalities appear in the body of the if-elseif-else code for the flow chart, the conversion to switch-case statements does not occur. To prevent this behavior, do one of the following:

- Specify that the function light does not appear inlined. See “Change the Inlining Property for the Function” on page 39-118.
- Modify the flow chart. See “Modify the Flow Chart to Ensure Switch-Case Statements” on page 39-120.

**Change the Inlining Property for the Function**

If you do not want to modify your flow chart, change the inlining property for the function light:

1. Right-click the function box for light and select **Properties**.
   
   The properties dialog box appears.
2. For **Function Inline Option**, select Function.
3 Click **OK** to close the dialog box.

**Note** You do not have to change the inlining property for the other three MATLAB functions in the chart. Because the flow chart does not call those functions during evaluation of conditions, the inlining property for those functions can remain **Auto**.

When you regenerate code for your model, the code for the flow chart now appears something like this:

```plaintext
switch (ifelse_using Enums_light(ifelse_using Enums_U.In1)) {
  case RED:
    /* Transition: '<S1>:11' */
    /* Transition: '<S1>:12' */
    /* MATLAB Function 'stop': '<S1>:23' */
    /* '<S1>:23:6' */
    ifelse_using Enums_Y.Out1 = 0.0;
    /* Transition: '<S1>:15' */
    /* Transition: '<S1>:16' */
    break;

  case YELLOW:
    /* Transition: '<S1>:10' */
    /* Transition: '<S1>:13' */
    /* Transition: '<S1>:14' */
    /* MATLAB Function 'slowdown': '<S1>:24' */
    /* '<S1>:24:6' */
    ifelse_using Enums_Y.Out1 = 1.0;
    /* Transition: '<S1>:16' */
    break;

  default:
    /* Transition: '<S1>:17' */
    /* MATLAB Function 'accelerate': '<S1>:25' */
    /* '<S1>:25:6' */
    ifelse_using Enums_Y.Out1 = 2.0;
    break;
}
```
Because the MATLAB function `light` no longer appears inlined, the conversion to `switch-case` statements occurs. The `switch-case` statements provide the following benefits to enhance readability:

- The code reduces the use of parentheses and braces.
- The LHS expression `ifelse_using_enums_light(ifelse_using_enums_U.In1)` appears only once, minimizing repetition in the code.

**Modify the Flow Chart to Ensure Switch-Case Statements**

If you do not want to change the inlining property for the function `light`, modify your flow chart:

1. Add chart local data `color_out` with the enumerated type `TrafficLights`.
2. Replace each instance of `light(intersection)` with `color_out`.
3. Add the action `{color_out = light(intersection)}` to the default transition of the flow chart.

The chart should now look something like this:
When you regenerate code for your model, the code for the flow chart uses `switch-case` statements.
Generate Inlined Subsystem Code

You can configure a nonvirtual subsystem to inline the subsystem code with the model code. In the Subsystem Parameters dialog box, the **Function packaging** parameter specifies the format of the subsystem’s generated code. This parameter has four settings: *Auto*, *Inline*, *Nonreusable function*, and *Reusable function*. The code generator can generate inlined code for the *Auto* or *Inline* settings.

The *Inline* setting explicitly directs the code generator to inline the subsystem code unconditionally.

The default *Auto* setting directs the code generator to generate the most efficient code for the subsystem based on the type and number of instances of the subsystem that exist in the model. When there is only one instance of a subsystem, the *Auto* setting inlines the subsystem code. When there are multiple instances of a subsystem, that is not too complex, the *Auto* setting inlines the code for each subsystem. Otherwise, the *Auto* setting generates a single copy of the function (as a reusable function). For a function-call subsystem with multiple callers, the *Auto* setting generates subsystem code that is consistent with the *Nonreusable function* setting.

Configure Subsystem to Inline Code

To configure your subsystem for inlining:

1. Right-click the Subsystem block. From the context menu, select **Block Parameters (Subsystem)**.
2. In the Subsystem Parameters dialog box, if the subsystem is virtual, select **Treat as atomic unit**. This option makes the subsystem nonvirtual. On the **Code Generation** tab, the **Function packaging** option is now available.
3. Click the **Code Generation** tab and select *Auto* or *Inline* from the **Function packaging** parameter.
4. Click **Apply** and close the dialog box.

The border of the subsystem thickens, indicating that it is nonvirtual.

When you generate code from your model, the code generator inlines subsystem code within `model.c` or `model.cpp` (or in its parent system's source file). You can identify this code by system/block identification tags, such as:

```c
/* Atomic SubSystem Block: <Root>/AtomicSubsys1 */
```
Exceptions to Inlining

There are certain cases in which the code generator does not inline a nonvirtual subsystem, even though you select the **Inline** setting.

- If a noninlined S-function calls a function-call subsystem, the code generator ignores the **Inline** setting. Because noninlined S-functions use function pointers to make function calls, the code generator must generate a function with all arguments present.
- In a feedback loop involving function-call subsystems, the code generator generates a function instead of inlined code for one of the subsystems. Based on the internal, sorted order of the subsystems, the code generator selects which subsystem to generate a function.
- If an S-function, an Async Interrupt, or a Task Sync block with the option `SS_OPTION_FORCE_NONINLINED_FCNCALL` set to **TRUE** calls a subsystem, the code generator generates a function instead of inlined code for the subsystem. The VxWorks block library (`vxlib1`), contains the user-defined Async Interrupt and Task Sync blocks.\(^7\)

Code Replacement in Simulink Coder

- “Choose a Code Replacement Library” on page 40-8
- “Replace Code Generated from Simulink Models” on page 40-10
What Is Code Replacement?

Code replacement is a technique to change the code that the code generator produces for functions and operators to meet application code requirements. For example, you can replace generated code to meet requirements such as:

- Optimization for a specific run-time environment, including, but not limited to, specific target hardware.
- Integration with existing application code.
- Compliance with a standard, such as AUTOSAR.
- Modification of code behavior, such as enabling or disabling nonfinite or inline support.
- Application- or project-specific code requirements, such as:
  - Elimination of math.h.
  - Elimination of system header files.
  - Elimination of calls to memcpy or memset.
  - Use of BLAS.
  - Use of a specific BLAS.

To apply this technique, configure the code generator to apply a code replacement library (CRL) during code generation. By default, the code generator does not apply a code replacement library. You can choose from libraries that MathWorks provides and that you create and register by using the Embedded Coder product. The list of available libraries depends on:

- Installed support packages.
- System target file, language, standard math library, and device vendor configuration.
- Whether you have created and registered libraries, using the Embedded Coder product.

Libraries that include GNU99 extensions are intended for use with the GCC compiler. If you use one of those libraries with another compiler, generated code might not compile.

Code Replacement Libraries

A code replacement library consists of one or more code replacement tables that specify application-specific implementations of functions and operators. For example, a library for
a specific embedded processor specifies function and operator replacements that optimize
generated code for that processor.

A code replacement table contains one or more code replacement entries, with each entry
representing a potential replacement for a function or operator. Each entry maps a
conceptual representation of a function or operator to an implementation representation
and priority.

<table>
<thead>
<tr>
<th>Table Entry Component</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Conceptual representation</td>
<td>Identifies the table entry and contains match criteria for the code generator. Consists of:</td>
</tr>
<tr>
<td></td>
<td>• Function name or a key. The function name identifies most functions. For operators and some functions, a series of characters, called a key identifies a function or operator. For example, function name 'cos' and operator key 'RTW_OP_ADD'.</td>
</tr>
<tr>
<td></td>
<td>• Conceptual arguments that observe code generator naming ('y1', 'u1', 'u2', ...), with corresponding I/O types (output or input) and data types.</td>
</tr>
<tr>
<td></td>
<td>• Other attributes, such as an algorithm, fixed-point saturation, and rounding modes, which identify matching criteria for the function or operator.</td>
</tr>
<tr>
<td>Table Entry Component</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| Implementation representation | Specifies replacement code. Consists of:  
  • Function name. For example, 'cos_dbl' or 'u8_add_u8_u8'.  
  • Implementation arguments, with corresponding I/O types (output or input) and data types.  
  • Parameters that provide additional implementation details, such as header and source file names and paths of build resources. |
| Priority | Defines the entry priority relative to other entries in the table. The value can range from 0 to 100, with 0 being the highest priority. If multiple entries have the same priority, the code generator uses the first match with that priority. |

When the code generator looks for a match in a code replacement library, it creates and populates a call site object with the function or operator conceptual representation. If a match exists, the code generator uses the matched code replacement entry populated with the implementation representation and uses it to generate code.

The code generator searches the tables in a code replacement library for a match in the order that the tables appear in the library. If the code generator finds multiple matches within a table, the priority determines the match. The code generator uses a higher-priority entry over a similar entry with a lower priority.

### Code Replacement Terminology

<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cache hit</td>
<td>A code replacement entry for a function or operator, defined in the specified code replacement library, for which the code generator finds a match.</td>
</tr>
<tr>
<td>Cache miss</td>
<td>A conceptual representation of a function or operator for which the code generator does not find a match.</td>
</tr>
<tr>
<td>Term</td>
<td>Definition</td>
</tr>
<tr>
<td>-------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Call site object</td>
<td>Conceptual representation of a function or operator that the code generator uses when it encounters a call site for a function or operator. The code generator uses the object to query the code replacement library for a conceptual representation match. If a match exists, the code generator returns a code replacement object, fully populated with the conceptual representation, implementation representation, and priority, and uses that object to generate replacement code.</td>
</tr>
<tr>
<td>Code replacement library</td>
<td>One or more code replacement tables that specify application-specific implementations of functions and operators. When configured to use a code replacement library, the code generator uses criteria defined in the library to search for matches. If a match is found, the code generator replaces code that it generates by default with application-specific code defined in the library.</td>
</tr>
<tr>
<td>Code replacement table</td>
<td>One or more code replacement table entries. Provides a way to group related or shared entries for use in different libraries.</td>
</tr>
<tr>
<td>Code replacement entry</td>
<td>Represents a potential replacement for a function or operator. Maps a conceptual representation of a function or operator to an implementation representation and priority.</td>
</tr>
<tr>
<td>Conceptual argument</td>
<td>Represents an input or output argument for a function or operator being replaced. Conceptual arguments observe naming conventions (<code>'y1'</code>, <code>'u1'</code>, <code>'u2'</code>, ...) and data types familiar to the code generator.</td>
</tr>
<tr>
<td>Term</td>
<td>Definition</td>
</tr>
<tr>
<td>------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Conceptual representation</td>
<td>Represents match criteria that the code generator uses to qualify functions and operators for replacement. Consists of:</td>
</tr>
<tr>
<td></td>
<td>• Function or operator name or key</td>
</tr>
<tr>
<td></td>
<td>• Conceptual arguments with type, dimension, and complexity specification for inputs and output</td>
</tr>
<tr>
<td></td>
<td>• Attributes, such as an algorithm and fixed-point saturation and rounding modes</td>
</tr>
<tr>
<td>Implementation argument</td>
<td>Represents an input or output argument for a C or C++ replacement function. Implementation arguments observe C/C++ name and data type specifications.</td>
</tr>
<tr>
<td>Implementation representation</td>
<td>Specifies C or C++ replacement function prototype. Consists of:</td>
</tr>
<tr>
<td></td>
<td>• Function name (for example, 'cos_dbl' or 'u8_add_u8_u8')</td>
</tr>
<tr>
<td></td>
<td>• Implementation arguments specifying type, type qualifiers, and complexity for the function inputs and output</td>
</tr>
<tr>
<td></td>
<td>• Parameters that provide build information, such as header and source file names and paths of build resources and compile and link flags</td>
</tr>
<tr>
<td>Key</td>
<td>Identifies a function or operator that is being replaced. A function name or key appears in the conceptual representation of a code replacement entry. The key RTW_OP_ADD identifies the addition operator.</td>
</tr>
</tbody>
</table>
### Term | Definition
---|---
Priority | Defines the match priority for a code replacement entry relative to other entries, which have the same name and conceptual argument list, within a code replacement library. The priority can range from 0 to 100, with 0 being the highest priority. The default is 100. If a library provides two implementations for a function or operator, the implementation with the higher priority shadows the one with the lower priority.

### Code Replacement Limitations

Code replacement verification — It is possible that code replacement behaves differently than you expect. For example, data types that you observe in code generator input might not match what the code generator uses as intermediate data types during an operation. Verify code replacements by examining generated code.

| “Explore Available Code Replacement Libraries” on page 40-8 |
| “Explore Code Replacement Library Contents” on page 40-8 |

About Choosing a Code Replacement Library

By default, the code generator does not use a code replacement library.

If you are considering using a code replacement library:

1. Explore available libraries. Identify one that best meets your application needs.
   - Consider the lists of application code replacement requirements and libraries that MathWorks provides in “What Is Code Replacement?” on page 41-2.

If you do not find a suitable library and you have an Embedded Coder license, you can create a custom code replacement library.

Explore Available Code Replacement Libraries

Select the “Code replacement library” (Simulink Coder) to use for code generation from the Configuration Parameters > Code Generation > Interface pane (Simulink Coder). To view a description of a library, select and hover your cursor over the library name. A tooltip describes the library and lists the tables that it contains. The tooltip lists the tables in the order that the code generator searches for a function or operator match.

Explore Code Replacement Library Contents

Use the Code Replacement Viewer to explore the content of a code replacement library.

1. At the command prompt, type `crviewer`.
The viewer opens. To view the content of a specific library, specify the name of the library as an argument in single quotes. For example:

```
>> crviewer('GNU C99 extensions')
```

In the left pane, select the name of a library. The viewer displays information about the library in the right pane.

3 In the left pane, expand the library, explore the list of tables it contains, and select a table from the list. In the middle pane, the viewer displays the function and operator entries that are in that table, along with abbreviated information for each entry.

4 In the middle pane, select a function or operator. The viewer displays information from the table entry in the right pane.

If you select an operator entry that specifies net slope fixed-point parameters (instantiated from entry class `RTW.TflCOperationEntryGenerator` or `RTW.TflCOperationEntryGenerator_NetSlope`), the viewer displays an additional tab that shows fixed-point settings.

See **Code Replacement Viewer** for details on what the viewer displays.

- “Replace Code Generated from Simulink Models” (Simulink Coder)
Replace Code Generated from Simulink Models

This example shows how to replace generated code, using a code replacement library. Code replacement is a technique you can use to change the code that the code generator produces for functions and operators to meet application code requirements.

Prepare for Code Replacement

1. Make sure that MATLAB, Simulink, Simulink Coder, and a C compiler are installed on your system. Some code replacement libraries available in your development environment can also require Embedded Coder.

   To install MathWorks products, see the MATLAB installation documentation. If you have installed MATLAB and want to see which other MathWorks products are installed, in the Command Window, enter `ver`.

2. Identify an existing or create a Simulink model for which you want the code generator to replace code.

Choose a Code Replacement Library

If you are not sure which library to use, explore the available libraries.

Configure Code Generator To Use Code Replacement Library

1. Configure the code generator to apply a code replacement library during code generation for the model. Do one of the following:
   
   • In the Configuration Parameters dialog box, on the Code Generation > Interface pane, select a library for the “Code replacement library” (Simulink Coder) parameter.
   • Set the CodeReplacementLibrary parameter at the command line or programmatically.

2. Configure the code generator to produce code only (not build an executable) so you can verify your code replacements before building an executable. Do one of the following:
   
   • In the Configuration Parameters dialog box, on the Code Generation pane, select “Generate code only” (Simulink Coder).
   • Set the GenCodeOnly parameter at the command line or programmatically.
Include Code Replacement Information In Code Generation Report

If you have an Embedded Coder license, you can configure the code generator to include a code replacement section in the code generation report. The additional information can help you verify code replacements.

1. Configure the code generator to generate a report. In the Configuration Parameters dialog box, on the Code Generation > Report pane, select “Create code generation report” (Simulink Coder). Consider having the report open automatically. Select “Open report automatically” (Simulink Coder).

2. Include the code replacement section in the report. Select “Summarize which blocks triggered code replacements” (Simulink Coder).

Generate Replacement Code

Generate C/C++ code from the model and, if you configured the code generator accordingly, a code generation report. For example, in the model window, press Ctrl+B.

The code generator produces the code and displays the report.

Verify Code Replacements

Verify code replacements by examining the generated code. It is possible that code replacement behaves differently than you expect. For example, data types that you observe in the code generator input might not match what the code generator uses as intermediate data types during an operation.

Code Replacement for Simulink Models in Embedded Coder

- “Choose a Code Replacement Library” on page 41-8
- “Replace Code Generated from Simulink Models” on page 41-10
What Is Code Replacement?

Code replacement is a technique to change the code that the code generator produces for functions and operators to meet application code requirements. For example, you can replace generated code to meet requirements such as:

- Optimization for a specific run-time environment, including, but not limited to, specific target hardware.
- Integration with existing application code.
- Compliance with a standard, such as AUTOSAR.
- Modification of code behavior, such as enabling or disabling nonfinite or inline support.
- Application- or project-specific code requirements, such as:
  - Elimination of math.h.
  - Elimination of system header files.
  - Elimination of calls to memcpy or memset.
  - Use of BLAS.
  - Use of a specific BLAS.

To apply this technique, configure the code generator to apply a code replacement library (CRL) during code generation. By default, the code generator does not apply a code replacement library. You can choose from libraries that MathWorks provides and that you create and register by using the Embedded Coder product. The list of available libraries depends on:

- Installed support packages.
- System target file, language, standard math library, and device vendor configuration.
- Whether you have created and registered libraries, using the Embedded Coder product.

Libraries that include GNU99 extensions are intended for use with the GCC compiler. If you use one of those libraries with another compiler, generated code might not compile.

Code Replacement Libraries

A code replacement library consists of one or more code replacement tables that specify application-specific implementations of functions and operators. For example, a library for
a specific embedded processor specifies function and operator replacements that optimize generated code for that processor.

A code replacement table contains one or more code replacement entries, with each entry representing a potential replacement for a function or operator. Each entry maps a conceptual representation of a function or operator to an implementation representation and priority.

<table>
<thead>
<tr>
<th>Table Entry Component</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Conceptual representation</td>
<td>Identifies the table entry and contains match criteria for the code generator. Consists of:</td>
</tr>
<tr>
<td></td>
<td>• Function name or a key. The function name identifies most functions. For operators and some functions, a series of characters, called a key identifies a function or operator. For example, function name 'cos' and operator key 'RTW_OP_ADD'.</td>
</tr>
<tr>
<td></td>
<td>• Conceptual arguments that observe code generator naming ('y1', 'u1', 'u2', ...), with corresponding I/O types (output or input) and data types.</td>
</tr>
<tr>
<td></td>
<td>• Other attributes, such as an algorithm, fixed-point saturation, and rounding modes, which identify matching criteria for the function or operator.</td>
</tr>
</tbody>
</table>
### Table Entry Component

<table>
<thead>
<tr>
<th>Component</th>
<th>Description</th>
</tr>
</thead>
</table>
| Implementation representation | Specifies replacement code. Consists of:  
  • Function name. For example, `cos_dbl` or `u8_add_u8_u8`.  
  • Implementation arguments, with corresponding I/O types (output or input) and data types.  
  • Parameters that provide additional implementation details, such as header and source file names and paths of build resources. |
| Priority | Defines the entry priority relative to other entries in the table. The value can range from 0 to 100, with 0 being the highest priority. If multiple entries have the same priority, the code generator uses the first match with that priority. |

When the code generator looks for a match in a code replacement library, it creates and populates a call site object with the function or operator conceptual representation. If a match exists, the code generator uses the matched code replacement entry populated with the implementation representation and uses it to generate code.

The code generator searches the tables in a code replacement library for a match in the order that the tables appear in the library. If the code generator finds multiple matches within a table, the priority determines the match. The code generator uses a higher-priority entry over a similar entry with a lower priority.

### Code Replacement Terminology

<table>

About Choosing a Code Replacement Library

By default, the code generator does not use a code replacement library.

If you are considering using a code replacement library:

1. Explore available libraries. Identify one that best meets your application needs.
   - Consider the lists of application code replacement requirements and libraries that MathWorks provides in “What Is Code Replacement?” on page 41-2.

If you do not find a suitable library and you have an Embedded Coder license, you can create a custom code replacement library.

Explore Available Code Replacement Libraries

Select the “Code replacement library” (Simulink Coder) to use for code generation from the Configuration Parameters > Code Generation > Interface pane (Simulink Coder). To view a description of a library, select and hover your cursor over the library name. A tooltip describes the library and lists the tables that it contains. The tooltip lists the tables in the order that the code generator searches for a function or operator match.

Explore Code Replacement Library Contents

Use the Code Replacement Viewer to explore the content of a code replacement library.

1. At the command prompt, type crviewer.
>> crviewer

The viewer opens. To view the content of a specific library, specify the name of the library as an argument in single quotes. For example:

>> crviewer('GNU C99 extensions')

2  In the left pane, select the name of a library. The viewer displays information about the library in the right pane.

3  In the left pane, expand the library, explore the list of tables it contains, and select a table from the list. In the middle pane, the viewer displays the function and operator entries that are in that table, along with abbreviated information for each entry.

4  In the middle pane, select a function or operator. The viewer displays information from the table entry in the right pane.

If you select an operator entry that specifies net slope fixed-point parameters (instantiated from entry class RTW.TflCOperationEntryGenerator or RTW.TflCOperationEntryGenerator_NetSlope), the viewer displays an additional tab that shows fixed-point settings.

See Code Replacement Viewer for details on what the viewer displays.

Related Examples

-  “Replace Code Generated from Simulink Models” on page 41-10
Replace Code Generated from Simulink Models

This example shows how to replace generated code, using a code replacement library. Code replacement is a technique you can use to change the code that the code generator produces for functions and operators to meet application code requirements.

Prepare for Code Replacement

1. Make sure that MATLAB, Simulink, Simulink Coder, and a C compiler are installed on your system. Some code replacement libraries available in your development environment can also require Embedded Coder.

   To install MathWorks products, see the MATLAB installation documentation. If you have installed MATLAB and want to see which other MathWorks products are installed, in the Command Window, enter ver.

2. Identify an existing or create a Simulink model for which you want the code generator to replace code.

Choose a Code Replacement Library

If you are not sure which library to use, explore the available libraries.

Configure Code Generator To Use Code Replacement Library

1. Configure the code generator to apply a code replacement library during code generation for the model. Do one of the following:
   - In the Configuration Parameters dialog box, on the Code Generation > Interface pane, select a library for the “Code replacement library” (Simulink Coder) parameter.
   - Set the CodeReplacementLibrary parameter at the command line or programmatically.

2. Configure the code generator to produce code only (not build an executable) so you can verify your code replacements before building an executable. Do one of the following:
   - In the Configuration Parameters dialog box, on the Code Generation pane, select “Generate code only” (Simulink Coder).
   - Set the GenCodeOnly parameter at the command line or programmatically.
Include Code Replacement Information In Code Generation Report

If you have an Embedded Coder license, you can configure the code generator to include a code replacement section in the code generation report. The additional information can help you verify code replacements.

1. Configure the code generator to generate a report. In the Configuration Parameters dialog box, on the **Code Generation > Report** pane, select “Create code generation report” (Simulink Coder). Consider having the report open automatically. Select “Open report automatically” (Simulink Coder).

2. Include the code replacement section in the report. Select “Summarize which blocks triggered code replacements” (Simulink Coder).

Generate Replacement Code

Generate C/C++ code from the model and, if you configured the code generator accordingly, a code generation report. For example, in the model window, press **Ctrl+B**.

The code generator produces the code and displays the report.

Verify Code Replacements

Verify code replacements by examining the generated code. It is possible that code replacement behaves differently than you expect. For example, data types that you observe in the code generator input might not match what the code generator uses as intermediate data types during an operation.

External Code Integration in Simulink Coder

The code generator includes multiple approaches for integrating legacy or custom code with generated code. Legacy code is existing handwritten code or code for environments that you integrate with code produced by the code generator. Custom code is legacy code or other user-specified lines of code that you include in the code generator build process. Collectively, legacy and custom code are called external code.

You integrate external code by importing existing external code into code produced by the code generator; exporting generated code into an existing external code base, or you can do both. For example, you can import code by calling an external function, by using the Legacy Code Tool, or place external code at specific locations in generated code by including Custom Code blocks in a model. When you import external code, the resulting generated code interfaces with generated scheduling code.

You can export generated code as a plug-in function for use in an external development environment. When you export generated code, you intend to interface that code manually with a scheduling mechanism in your application run-time environment.

For guidance on choosing an approach based on your application, see “Choose an External Code Integration Workflow” (Simulink Coder).

- “What Is External Code Integration?” on page 42-3

What Is External Code Integration?

Software projects typically involve combining code from multiple sources. A typical system structure for a code generation application consists of a framework that combines code from multiple sources, including external code and code generated from Simulink models.

This figure shows an application that requires integration of existing driver code for hardware devices. The core software algorithms and logic can be a combination of code modules for external reusable algorithms integrated into the Simulink environment and code generated as part of an overall model design.

Several workflows and tools are available for you to integrate external and generated code. Each workflow identifies tooling for generating code that aligns interfaces, code appearance, and other factors, such as optimization between external and generated code.

<td>“Choose a Workflow” on page 42-10</td>
</tr>
</tbody>
</table>

Completing these tasks helps you choose external code integration workflows and tooling that align with your project.

Choose a Software Execution Framework

The code generator supports two types of software execution frameworks—single top model and multiple top-level, as described in “Design Models for Generated Embedded
Code Deployment” on page 1-2. The first question to answer concerns which of the two frameworks applies to your project.

- Single top model

Generate one set of application code files from external code and code that the Simulink C/C++ code generator produces. The generated code includes a scheduler. In this case, you import code into the Simulink code generation environment.

- Single top model or multiple top-level models

Integrate C or C++ code that the code generator produces from model components with external application code and an external scheduler. You export generated code from the Simulink code generation environment.
Importing calls to external device driver code into a model and generating code for that model for export involves importing and exporting code.

Based on goals and requirements, external code integration is characterized in several ways, requiring different workflows and integration tooling:

- Import existing external code into generated code.
  - Call reusable external algorithm code for simulation and code generation.
  - Place external C/C++ code in generated code.
  - Call external device drivers.
  - Apply function and operator code replacements.
  - Interface with external timer interrupt or scheduler.
  - Generate replacement code for specific run-time environment.
• Export generated code for inclusion in external code base.
  • Generate component source code for export.
  • Generate shared library for export.

Next, see “Evaluate Characteristics of External Code” on page 42-7.

**Evaluate Characteristics of External Code**

Before choosing an external integration workflow, evaluate these characteristics of the external code. To interface with external code, generated C or C++ code handles one or more of the external code characteristics. An understanding of these characteristics and your requirements for modeling, simulation, and code generation helps you choose the optimal workflow for your integration scenario. (See “Identify Integration Requirements” on page 42-8.)

<table>
<thead>
<tr>
<th>Characteristic</th>
<th>What to Consider</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hardware dependency</td>
<td>Is the external code hardware-dependent? Utility functions, lookup tables, and filters are examples of hardware-independent code.</td>
</tr>
<tr>
<td></td>
<td>Device drivers interact directly with hardware. They depend on characteristics of the hardware. For example, a device driver for an analog-to-digital converter initializes, reads data from, and writes data to hardware registers. Hardware differences and dependencies concern data type size, endianess, shift operations, compiler directives, and optimized function and operator support. Other code interfaces with device drivers by using an API and data mapped to specific memory addresses. Typically, simulation on a development computer is not possible. Reading from and writing to a register during simulation on a development computer produces unexpected and unwanted results.</td>
</tr>
<tr>
<td>Reusable</td>
<td>Is the external code a reusable software module? Examples include utility functions, lookup tables, filters, specialized integrators, and proportional-integral-derivative (PID) control modules.</td>
</tr>
<tr>
<td>Characteristic</td>
<td>What to Consider</td>
</tr>
<tr>
<td>-------------------------------------------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Dependency on data persistence between function calls</td>
<td>Does the external code require persistent data? For example, a call to a first order filter function uses the output of the previous call to the function to calculate a new output value. You have the option of defining the data as global or using shared memory outside the context of the function.</td>
</tr>
<tr>
<td>Data typing and interface</td>
<td>How complex is the data that the external code uses? What does the data interface look like? It consists of arguments, a return value, global variables, and access functions. What data types does the code use? Are the types limited to basic ANSI C integers, floating-point types, arrays of integers or floating-point types, and pointers to these types? Does the interface include structures or pointers to structures?</td>
</tr>
<tr>
<td>Fixed-point code</td>
<td>Is the external code designed to run on integer-only processors? If yes, the code exchanges and uses data represented as integers only. Data can be associated with fixed-point scaling or offsets.</td>
</tr>
<tr>
<td>External resource dependencies</td>
<td>Does the external code use data, functions, or macros defined outside the scope of the code? For example, the function can use a standard ANSI function, a shared library, or predefined constants. In these cases, you must inform the compiler and linker of the paths and file names of the external resources.</td>
</tr>
<tr>
<td>External solver required</td>
<td>Are you using the external function for advanced development or rapid prototyping to describe a system with a continuous transfer function or a set of differential equations? If yes, the external code relies on an external solver.</td>
</tr>
</tbody>
</table>

Next, see “Identify Integration Requirements” on page 42-8.

**Identify Integration Requirements**

Before choosing an external integration workflow, review these integration requirements. An understanding of these requirements and the characteristics of your external code helps you choose the optimal workflow for your integration scenario. (See “Evaluate Characteristics of External Code” on page 42-7.)
<table>
<thead>
<tr>

Use software-in-the-loop (SIL) or processor-in-the-loop (PIL) testing to verify whether algorithm behavior is the same in both environments.</td>
</tr>
</tbody>
</table>
| Data interface and typing   | • Does your model or generated code need to exchange data with the external function? If so, map inputs, outputs, and parameters to the external function interface. Typical function interfaces involve function arguments and return values, global variables, and access functions, such as `getRPM`.  
  • Do you want to represent arrays, structures, or enumerated types? In the Simulink environment, you can represent these types as vectors, buses, and `IntEnum`, respectively.  
  • Is fixed-point support required? If you use the Simulink fixed-point interface, you can scale and specify offsets.  
  • Does the external code use company-specific data types? If yes and you have Embedded Coder software, create alias types to represent those external types. The code generator uses the alias types in the code that it produces. For example, once defined, you can specify an alias type in a function prototype, for a temporary variable, or for block output.  
  • Does the code exchange data with shared memory? If yes, define and use memory sections. |
| Direct function call        | Do you want to call C external code directly from a model? You can choose from mechanisms, such as the Legacy Code Tool, Stateflow external code interface and chart action language, and the MATLAB Function block. |
### Requirement | What to Consider
---|---
Insertion of external code into generated code | Do you want to control the placement of external code within generated code? Do you want to insert code into generated entry-point functions? You can place code within generated code by using model configuration parameters or custom code blocks.

Code generation optimization support | Do you want to optimize the code that the code generator produces? If so, you can configure the model for the code generator to optimize the code it produces based on application objectives, such as execution, ROM, and RAM efficiency. You also have the option of using code replacement libraries.

Files required | Do you want to minimize the number of files that you maintain? Some external code integration tools require that you maintain separate files for defining simulation and code generation.

Next, see “Choose a Workflow” on page 42-10.

**Choose a Workflow**

To choose a workflow for each integration point, use the following flow diagram. The gray boxes identify common workflows and provide links to more information. Click the gray box that best addresses the requirements of an integration point.

Call Reusable External Algorithm Code for Simulation and Code Generation

Code reuse offers business and technological advantages. From a business perspective, code reuse saves time and resources. From a technological perspective, code reuse promotes consistency and reduces memory requirements. Other considerations include:

- Modularizing an application
- Reusing an optimized algorithm
- Interfacing with a predefined dataset
- Developing application variants

Examples of reusable hardware-independent algorithmic code to consider importing into the Simulink environment for simulation and code generation include:

- Utility functions
- Lookup tables
- Digital filters
- Specialized integrators
- Proportional-integral-derivative (PID) control modules

Workflow

To call reusable external algorithm code for simulation and code generation, iterate through the tasks listed in this table.

### Choose an Integration Approach

Several approaches are available for integrating reusable algorithmic code into the Simulink environment for code generation. Some approaches integrate external code directly. Other approaches convert the external code to Simulink or Stateflow modeling elements for simulation, and later for code generation from the modeled design. The integration approach that you choose depends on:

- Programming language of the external code — MATLAB, C, C++, or Fortran
- Your programming language experience and preference
- Performance requirements
- Whether the algorithm must model continuous time dynamics or you are integrating the algorithm into an application that uses discrete and continuous time
• Whether you want to take advantage of Model-Based Design
• Level of control required over the code that the code generator produces

To choose an approach for a reusable algorithm, see the subsection that matches the programming language of your external algorithm code.

• “Integration Approaches for External MATLAB Code” on page 42-15
• “Integration Approaches for External C or C++ Code” on page 42-18
• “Integration Approaches for External Fortran Code” on page 42-24

**Integration Approaches for External MATLAB Code**

Multiple approaches are available for integrating external MATLAB code into the Simulink environment. The following diagram and table help you choose the best integration approach for your application based on integration requirements.
<table>
<thead>
<tr>
<th>Condition or Requirement</th>
<th>Action</th>
<th>More Information</th>
</tr>
</thead>
</table>
| 1 The algorithm must model continuous state dynamics. | Write a MATLAB S-function and, for generating code, a corresponding TLC file for the algorithm. Add the S-function to your model. | • “MATLAB S-Functions” (Simulink)

**Integration Approaches for External C or C++ Code**

Under most circumstances, you can integrate external code written in C or C++ into the Simulink environment by generating S-functions and TLC files with the Legacy Code Tool. This tool uses specifications that you supply as MATLAB code to transform existing MATLAB functions into C MEX S-functions that you can include in Simulink models and call from generated code. For details, see “Legacy Code Integration” (Simulink) and “Import Calls to External Code into Generated Code with Legacy Code Tool” on page 11-7.

In comparison to alternative approaches, Legacy Code Tool is the easiest to use and generates code optimized enough for embedded systems. Consider alternative approaches if one or more of the following conditions exist:

<table>
<thead>
<tr>
<th>Condition or Requirement</th>
<th>Action</th>
<th>More Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>6 You have C or C++ programming experience and the external MATLAB code is compact and primarily uses C or C++ constructs.</td>

### Modify Programming Language of External Code to Match Generated Code

To integrate external C code with generated C++ code or conversely, modify the language of the external code to match the programming language choice for the generated code. Options for making the programming language match include:

- Writing or rewriting the external code in the language choice for the generated code.
- If you are generating C++ code and the external code is C code, for each C function, create a header file that prototypes the function. Use this format:

```c
#ifdef __cplusplus
extern "C" {
#endif
typ my_c_function_wrapper();
#ifdef __cplusplus
}
#endif
```

The prototype serves as a function wrapper. If your compiler supports C++ code, the value `__cplusplus` is defined. The linkage specification `extern "C"` specifies C linkage without name mangling.

- If you are generating C code and the external code is C++ code, include an `extern "C"` linkage specification in each `.cpp` file. For example, the following example shows C++ code in the file `my_func.cpp`:
extern "C" {
  int my_cpp_function()
  {
  ...
  }
}

Integration Approaches for External Fortran Code

To integrate external Fortran code, write an S-function and corresponding TLC file.

Insert External Code into Stateflow Charts

• “Integrate External Code for Library Charts” on page 42-24
• “Integrate External Code for All Charts” on page 42-25

Integrate External Code for Library Charts

To integrate external code that applies only to Stateflow library charts for code generation, for each library model that contributes a chart to your main model, complete these steps. Then, generate code.

1 In the Stateflow Editor, select Code > C/C++ Code > Code Generation Options.
2 In the Model Configuration Parameters dialog box, select Code Generation > Use local custom code settings (do not inherit from main model).
The library model retains its own custom code settings during code generation.

3 Specify your custom code in the subpanes.

Follow the guidelines in “Specify Relative Paths for Custom Code” (Stateflow).

If you specified custom code settings for simulation, you can apply these settings to code generation. To avoid entering the same information twice, select **Use the same custom code settings as Simulation Target**.

4 Click **OK**.

After completing these steps for each library model, generate code.

**Integrate External Code for All Charts**

To integrate external code that applies to all charts for code generation:

1 Specify custom code options for code generation of your main model.
   a In the Model Configuration Parameters dialog box, select **Code Generation > Custom Code**.
   b In the custom code text fields, specify your custom code.

      Follow the guidelines in “Specify Relative Paths for Custom Code” (Stateflow).

      If you specified custom code settings for simulation, you can apply these settings to code generation. To avoid entering the same information twice, select **Use the same custom code settings as Simulation Target**.

2 Configure code generation for each library model that contributes a chart to your main model.
   a In the Stateflow Editor, select **Code > C/C++ Code > Code Generation Options**.
   b In the **Code Generation** pane, clear the **Use local custom code settings (do not inherit from main model)** check box.

      The library charts inherit the custom code settings of your main model.
   c Click **OK**.

3 Generate code.

Place External C/C++ Code in Generated Code

In this section...

“Workflow” on page 42-27
“Choose an Integration Approach” on page 42-28
“Integrate External Code by Using Custom Code Blocks” on page 42-30
“Integrate External Code by Using Model Configuration Parameters” on page 42-33

You can customize code that the code generator produces for a model by specifying external code with custom code blocks or model configuration parameters.

- Place code at the start and end of the generated code for the root model.
- Place declaration, body, and exit code in generated function code for blocks in the root model or nonvirtual subsystems.

The functions that you can augment with external code depends on the functions that the code generator produces for blocks that are in the model. For example, if a model or atomic subsystem includes blocks that have states, you can specify code for a disable function. Likewise, if you need the code for a block to save data, free memory, or reset target hardware, specify code for a terminate function. For more information, see “Block Target File Methods” (Simulink Coder).

Workflow

To place external C or C++ code at specific locations in code that the code generator produces for root models and subsystems, iterate through the tasks listed in this table.

<table>
<thead>
<tr>
<th>Task</th>
<th>Action</th>

</tr>
</tbody>
</table>
Choose an Integration Approach

Within the Simulink modeling environment, two approaches are available for placing external C or C++ code into sections of code that the code generator produces:

- Add blocks from the Custom Code library to a root model or atomic subsystem.
- Set model configuration parameters on the Code Generation > Custom Code pane.

The following table compares the two approaches. Choose the approach that aligns best with your integration requirements. For more information about how to apply each "Choose an Integration Approach" on page 42-28.

<table>
<thead>

Integrate External Code by Using Custom Code Blocks

- “Custom Code Block Library” on page 42-30
- “Add Custom Code Blocks to the Modeling Canvas” on page 42-31
- “Add External Code to Generated Start Function” on page 42-31

Custom Code Block Library

The Custom Code block library contains blocks that you can use to place external C or C++ code into specific locations and functions within code that the code generator produces. The library consists of 10 blocks that add your code to the model header (model.h) and source (model.c or model.cpp) files that the code generator produces.

The Model Header and Model Source blocks add external code at the top and bottom of header and source files that the code generator produces for a root model. These blocks display two text fields into which you can type or paste code. One field specifies code that you want to place at the top of the generated header or source file. The second field specifies code that you want to place at the bottom of the file.

The remaining blocks add external code to functions that the code generator produces for the root model or atomic subsystem that contains the block. The blocks display text fields into which you can type or paste code that customizes functions that the code generator produces. The text fields correspond to the declaration, execution, and exit sections of code for a given function.

<table>
<thead>
<tr>
<th>To Customize Code That</th>
<th>Use This Block</th>
</tr>
</thead>
<tbody>
<tr>
<td>Computes continuous states</td>

<td>System Update</td>
</tr>
</tbody>
</table>

The block and its location within a model determines where the code generator places the external code. For example, if the System Outputs block is at the root model level, the
code generator places the code in the model Outputs function. If the block resides in a triggered or enabled subsystem, the code generator places the code in the subsystem Outputs function.

If the code generator does not need to generate a function that corresponds to a Custom Code block that you include in a model, the code generator does one of the following:

- Omits the external code that you specify in the Custom Code block.
- Returns an error, indicating that the model does not include a relevant block. In this case, remove the Custom Code block from the model.

For more information, see “Block Target File Methods” (Simulink Coder).

**Add Custom Code Blocks to the Modeling Canvas**

To add the Custom Code library blocks to a model:

1. In the Simulink Library Browser, open the Custom Code block library. You can gain access to the library by:
   - Navigating to Simulink Coder > Custom Code in the browser.
   - Entering the MATLAB command custcode.

2. Drag the blocks that you want into your model or subsystem. Drag Model Header and Model Source blocks into root models only. Drag function-based Custom Code blocks into root models or atomic subsystems.

You can use models that contain Custom Code blocks as referenced models. The code generator ignores the blocks when producing code for a simulation target. When producing code for a code generation target, the code generator includes and compiles the custom code.

**Add External Code to Generated Start Function**

This example shows how to use the System Start block to place external C code in the code that the code generator produces for a model that includes a discrete filter.

1. Create the following model.
2 Configure the model for code generation.
3 Double-click the System Start block.
4 In the block parameters dialog box, in the **System Start Function Declaration Code** field, enter this code:

   ```
   unsigned int *ptr = 0xFFEE;
   ```

5 In the **System Start Function Execution Code** field, enter this code:

   ```
   /* Initialize hardware */
   *ptr = 0;
   ```

6 Click **OK**.
7 Generate code and a code generation report.
8 View the generated `model.c` file. Search for the string `start function`. You should find the following code, which includes the external code that you entered in steps 4 and 5.

   ```
   {
   {
   /* user code (Start function Header) */
   /* System '<Root>' */
   unsigned int *ptr = 0xFFEE;
   /* user code (Start function Body) */
   /* System '<Root>' */
   /* Initialize hardware */
   *ptr = 0;
   }
   }
   ```

For another example, see “Integrate External C Code Into Generated Code By Using Custom Code Blocks and Model Configuration Parameters” on page 42-35.
### Integrate External Code by Using Model Configuration Parameters

Model configuration parameters provide a way to place external C or C++ code into specific locations and functions within code that the code generator produces.

<table>
<thead>
<tr>
<th>To</th>
<th>Select</th>
</tr>
</thead>
<tbody>
<tr>
<td>Insert external code near the top of the generated <em>model.c</em> or <em>model.cpp</em> file</td>
<td><strong>Source file</strong>, and enter the external code to insert.</td>
</tr>
<tr>
<td><strong>Note</strong> If you generate subsystem code into separate files, that code does not have access to external code that you specify with the <strong>Source file</strong> parameter. For example, if you specify an include file as a <strong>Source file</strong> setting, the code generator inserts the <code>#include</code> near the top of the <em>model.c</em> or <em>model.cpp</em> file. The subsystem code that the code generator places in a separate file does not have access to declarations inside your included file. In this case, consider specifying your external code with the <strong>Header file</strong> parameter.</td>
<td></td>
</tr>
<tr>
<td>Insert external code near the top of the generated <em>model.h</em> file</td>
<td><strong>Header file</strong>, and enter the external code to insert.</td>
</tr>
<tr>
<td>Insert external code inside the model initialize function in the <em>model.c</em> or <em>model.cpp</em> file</td>
<td><strong>Initialize function</strong>, and enter the external code to insert.</td>
</tr>
<tr>
<td>Insert external code inside the model terminate function in the <em>model.c</em> or <em>model.cpp</em> file</td>
<td><strong>Terminate function</strong>, and enter the external code to insert. Also select the <strong>Terminate function required</strong> parameter on the <strong>Interface</strong> pane.</td>
</tr>
<tr>
<td>Add preprocessor macro definitions</td>
<td><strong>Defines</strong>, and enter a space-separated list of preprocessor macro definitions to add to the generated code. The list can include simple definitions (for example, <code>-DEF1</code>) and definitions with a value (for example, <code>-DDEF2=1</code>). Definitions can omit the <code>-D</code> (for example, <code>-DFOO=1</code> and <code>FOO=1</code> are equivalent). If a definition includes <code>-D</code>, the toolchain can override the flag if the toolchain uses a different flag for defines.</td>
</tr>
</tbody>
</table>

42-33
<table>
<thead>
<tr>
<th>To</th>
<th>Select</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use the same custom code parameter settings as the settings specified for simulation of MATLAB Function blocks, Stateflow charts, and Truth Table blocks</td>
<td><strong>Use the same custom code settings as Simulation Target</strong></td>
</tr>
<tr>
<td></td>
<td>This parameter refers to the <strong>Simulation Target</strong> pane in the Configuration Parameters dialog box.</td>
</tr>
<tr>
<td>Enable a library model to use custom code settings unique from the parent model to which the library is linked</td>
<td><strong>Use local custom code settings (do not inherit from main model)</strong></td>
</tr>
<tr>
<td></td>
<td>This parameter is available only for library models that contain MATLAB Function blocks, Stateflow charts, or Truth Table blocks.</td>
</tr>
</tbody>
</table>

To include a header file in an external header file, add `#ifndef` code. Using this code avoids multiple inclusions. For example, in `rtwtypes.h`, the following `#include` guards are added:

```
#ifndef RTW_HEADER_rtwtypes_h_
#define RTW_HEADER_rtwtypes_h_
...
#endif /* RTW_HEADER_rtwtypes_h_ */
```

For more information on how to add files names and locations of header, source, and shared library files to the build process, see “Build Integrated Code Within the Simulink Environment” on page 42-42.

**Note** The code generator includes external code that you include in a configuration set when generating code for software-in-the-loop (SIL) and processor-in-the-loop (PIL) simulations. However, the code generator ignores external code that you include in a configuration set when producing code with the S-function, rapid simulation, or simulation system target file.

For more information about **Custom Code** parameters, see “Model Configuration Parameters: Code Generation Custom Code” (Simulink Coder). For an example, see “Integrate External C Code Into Generated Code By Using Custom Code Blocks and Model Configuration Parameters” on page 42-35.
Integrate External C Code Into Generated Code By Using Custom Code Blocks and Model Configuration Parameters

This example shows how to place external code in generated code by using custom code blocks and model configuration parameters.

1. Open the model `rtwdemo_slcustcode`.

```matlab
open_system('rtwdemo_slcustcode')
```
2. Open the Model Configuration Parameters dialog box and navigate to the **Custom Code** pane.

3. Examine the settings for parameters **Source file** and **Initialize function**.
• **Source file** specifies a comment and sets the variable `GLOBAL_INT2` to -1.
• **Initialize function** initializes the variable `GLOBAL_INT2` to 1.

4. Close the dialog box.

5. Double-click the Model Source block. The **Top of Model Source** field specifies that the code generator declare the variable `GLOBAL_INT1` and set it to 0 at the top of the generated file `rtwdemo_slcustcode.c`.

6. Open the triggered subsystem **Amplifier**. The subsystem includes the System Outputs block. The code generator places code that you specify in that block in the generated code for the nearest parent atomic subsystem. In this case, the code generator places the external code in the generated code for the **Amplifier** subsystem. The external code:

   • Declares the pointer variable `*intPtr` and initializes it with the value of variable `GLOBAL_INT1`.
   • Sets the pointer variable to -1 during execution.
   • Resets the pointer variable to 0 before exiting.

7. Generate code and a code generation report.

8. Examine the code in the generated source file `rtwdemo_slcustcode.c`. At the top of the file, after the `#include` statements, you find the following declaration code. The example specifies the first declaration with the **Source file** configuration parameter and the second declaration with the Model Source block.

   ```c
   int_T GLOBAL_INT2 = -1;
   int_T GLOBAL_INT1 = 0;
   ```

   The Output function for the **Amplifier** subsystem includes the following code, which shows the external code integrated with generated code that applies the gain. The example specifies the three lines of code for the pointer variable with the System Outputs block in the **Amplifier** subsystem.

   ```c
   int_T *intPtr = &GLOBAL_INT1;
   *intPtr = -1;
   rtwdemo_slcustcode_Y.Output = rtwdemo_slcustcode_U.Input << 1;
   ```
*intptr = 0;

The following assignment appears in the model initialize entry-point function. The example specifies this assignment with the **Initialize function** configuration parameter.

GLOBAL_INT2 = 1;

Call External Device Drivers

Device drivers for protocols and target hardware are essential to many real-time development projects. For example, you can have a working device driver that you want to integrate with algorithmic code that has to read data from and write data to the I/O device that the driver supports. The code generator can produce a single set of application source files from an algorithm model and integrated driver code written in C or C++.

To call external device driver code from the Simulink environment, iterate through the tasks in this table.

Apply Function and Operator Code Replacements

If your generated code must use functions and operators that are consistent with external code, configure the code generator to use a code replacement library (CRL). By default, the code generator does not apply a code replacement library. You can choose from several libraries that MathWorks provides, including GNU C99 extensions, AUTOSAR 4.0, and several Intel® platform-specific IPP and IPP/SSE libraries. Depending on the products that you have, other libraries might be available. If you have Embedded Coder software, you can view and choose from additional libraries and you can create custom code replacement libraries.

<tr>
<td>Enable a library model to use custom code settings unique from the parent model to which the library is linked</td>
<td><strong>Configuration Parameters</strong> &gt; <strong>Code Generation</strong> &gt; <strong>Custom Code</strong> &gt; <strong>Use local custom code settings (do not inherit from main model)</strong></td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong> This parameter is available only for library models that contain MATLAB Function blocks, Stateflow charts, or Truth Table blocks.</td>
</tr>
</tbody>
</table>
Preserve External Code Files in Build Folder

By default, the build process deletes foreign source files. You can preserve foreign source files by following these guidelines.

If you put a .c/.cpp or .h source file in a build folder, and you want to prevent the code generator from deleting it during the TLC code generation process, insert the text `target specific file` in the first line of the .c/.cpp or .h file. For example:

/* COMPANY-NAME target specific file
 * This file is created for use with the
 * COMPANY-NAME target.
 * It is used for ...
 */
...

Make sure that you spell the text “target specific file” as shown in the preceding example, and that the text is in the first line of the source file. Other text can appear before or after this text.

Flagging user files in this manner prevents postprocessing these files to indent them with generated source files. Auto-indenting occurred in previous releases to build folder files with names having the pattern `model_*.c/.cpp` (where * was text). The indenting is harmless, but can cause differences detected by source control software that can potentially trigger unnecessary updates.

Build Support for S-Functions

User-written S-Function blocks provide a powerful way to incorporate external code into the Simulink development environment. In most cases, you use S-functions to integrate existing external code with generated code. Several approaches to writing S-functions are available:

- “Write Noninlined S-Function and TLC Files” on page 11-67
- “Write Wrapper S-Function and TLC Files” on page 11-69
- “Write Fully Inlined S-Functions” on page 11-78
- “Write Fully Inlined S-Functions with mdlRTW Routine” on page 11-79
- “S-Functions That Support Code Reuse” on page 11-105
- “S-Functions for Multirate Multitasking Environments” on page 11-106
S-functions also provide the most flexible and capable way of including build information for legacy and custom code files in the build process.

There are different ways of adding S-functions to the build process.

**Implicit Build Support**

When building models with S-functions, the build process adds rules, include paths, and source file names to the generated makefile. The source files (.h, .c, and .cpp) for the S-function must be in the same folder as the S-function MEX-file. Whether using the toolchain approach or template makefile approach for builds, the build process propagates this information through the toolchain or template makefile.

- If the file `sfcnname.h` exists in the same folder as the S-function MEX-file (for example, `sfcnname.mexext`), the folder is added to the include path.
- If the file `sfcnname.c` or `sfcnname.cpp` exists in the same folder as the S-function MEX-file, the build process adds a makefile rule for compiling files from that folder.
- When an S-function is not inlined with a TLC file, the build process must compile the S-function source file. To determine the name of the source file to add to the list of files to compile, the build process searches for `sfcnname.cpp` on the MATLAB path. If the source file is found, the build process adds the source file name to the makefile. If `sfcnname.cpp` is not found on the path, the build process adds the file name `sfcnname.c` to the makefile, whether or not it is on the MATLAB path.

**Note** For the Simulink engine to find the MEX-file for simulation and code generation, it must exist on the MATLAB path or exist in our current MATLAB working folder.

**Specify Additional Source Files for an S-Function**

If your S-function has additional source file dependencies, you must add the names of the additional modules to the build process. Specify the file names:

- In the **S-function modules** field in the S-Function block parameter dialog box
- With the `SFunctionModules` parameter in a call to the `set_param` function

For example, suppose you build your S-function with multiple modules.

```
mex sfun_main.c sfun_module1.c sfun_module2.c
```

You can then add the modules to the build process by doing one of the following:
In the S-function block dialog box, specify `sfun_main`, `sfun_module1`, and `sfun_module2` in the **S-function modules** field.

At the MATLAB command prompt, enter:

```matlab
set_param(sfun_block,'SFunctionModules','sfun_module1 sfun_module2')
```

Alternatively, you can define a variable to represent the parameter value.

```matlab
modules = ['sfun_module1 sfun_module2'
          set_param(sfun_block,'SFunctionModules', modules)
```

The **S-function modules** field and `SFunctionModules` parameter do not support complete source file path specifications. To use the parameter, the code generator must find the additional source files when executing the makefile. For the code generator to locate the additional files, place them in the same folder as the S-function MEX-file. You can then leverage the implicit build support described in “Implicit Build Support” on page 42-46.

When you are ready to generate code, force the code generator to rebuild the top model, as described in “Control Regeneration of Top Model Code” (Simulink Coder).

For more complicated S-function file dependencies, such as specifying source files in other locations or specifying libraries or object files, use the `rtwmakecfg.m` API, as described in “Use `rtwmakecfg.m` API to Customize Generated Makefiles” on page 73-26.

**Use TLC Library Functions**

If you inline your S-function by writing a TLC file, you can add source file names to the build process by using the TLC library function `LibAddToModelSources`. For details, see “`LibAddSourceFileCustomSection(file, builtInSection, newSection)`” (Simulink Coder).

**Note** This function does not support complete source file path specifications. The function assumes that the code generator can find the additional source files when executing the makefile.

Another useful TLC library function is `LibAddToCommonIncludes`. Use this function in a `#include` statement to include S-function header files in the generated `model.h` header file. For details, see “`LibAddToCommonIncludes/incFileName)`” (Simulink Coder).

For more complicated S-function file dependencies, such as specifying source files in other locations or specifying libraries or object files, use the `rtwmakecfg.m` API, as described in “Use `rtwmakecfg.m` API to Customize Generated Makefiles” on page 73-26.
**Precompile S-Function Libraries**

You can precompile new or updated S-function libraries (MEX-files) for a model by using the MATLAB language function `rtw_precompile_libs`. Using a specified model and a library build specification, this function builds and places the libraries in a precompiled library folder.

By precompiling S-function libraries, you can optimize system builds. Once your precompiled libraries exist, the build process can omit library compilation from subsequent builds. For models that use numerous libraries, the time savings for build processing can be significant.

To use `rtw_precompile_libs`:

1. Set the library file suffix, including the file type extension, based on your system platform.

   Consider determining the type of platform, and then use the `TargetLibSuffix` parameter to set the library suffix accordingly. For example, when applying a suffix for a GRT target, you can set the suffix to `_std.a` for a UNIX platform and `_vcx64.lib` for a Windows platform.

   ```matlab
   if isunix
       suffix = '_std.a';
   else
       suffix = '_vcx64.lib';
   end
   set_param(my_model,'TargetLibSuffix', suffix);
   ```

   There are a number of factors that influence the precompiled library suffix and extension. The following table provides examples for typical selections of system target file, the compiler toolchain, and other options that affect your choice of suffix and extension. For more information, examine the template make files in the `matlab/rtw/c/grt` folder or `matlab/rtw/c/ert` folder.
<table>

</tr>
<tr>
<td>grt_unix.tmf</td>
<td>unix</td>
<td>n/a</td>
<td>n/a</td>
<td>n/a</td>
<td>_std</td>
<td>.a</td>
</tr>
</tbody>
</table>

2. Set the precompiled library folder.

Use one of the following methods to set the precompiled library folder:

- Set the TargetPreCompLibLocation parameter, as described in “Specify the Location of Precompiled Libraries” on page 73-8.
- Set the makeInfo.precompile field in an rtwmakecfg.m function file. (For more information, see “Use rtwmakecfg.m API to Customize Generated Makefiles” on page 73-26.)

If you set TargetPreCompLibLocation and makeInfo.precompile, the setting for TargetPreCompLibLocation takes precedence.

The following command sets the precompiled library folder for model my_model to folder lib under the current working folder.

```
set_param(my_model,'TargetPreCompLibLocation', fullfile(pwd,'lib'));
```

**Note** If you set both the target folder for the precompiled library files and a target library file suffix, the build process detects whether any precompiled library files are missing while processing builds.

3. Define a build specification.
Set up a structure that defines a build specification. The following table describes fields that you can define in the structure. These fields are optional, except for `rtwmakecfgDirs`.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>rtwmakecfgDirs</code></td>
<td>A cell array of character vectors that name the folders containing <code>rtwmakecfg</code> files for libraries to be precompiled. The function uses the <code>Name</code> and <code>Location</code> elements of <code>makeInfo.library</code>, as returned by <code>rtwmakecfg</code>, to specify the name and location of the precompiled libraries. If you set the <code>TargetPreCompLibLocation</code> parameter to specify the library folder, that setting overrides the <code>makeInfo.library.Location</code> setting.</td>
</tr>
<tr>
<td><strong>Note:</strong> The specified model must contain blocks that use precompiled libraries specified by the <code>rtwmakecfg</code> files because the TMF-to-makefile conversion generates the library rules only if the build process uses the libraries.</td>
<td></td>
</tr>
<tr>
<td><code>libSuffix</code></td>
<td>A character vector that specifies the suffix, including the file type extension, to be appended to the name of each library (for example, <code>.a</code> or <code>_vc.lib</code>). The character vector must include a period (.). You must set the suffix with either this field or the <code>TargetLibSuffix</code> parameter. If you specify a suffix with both mechanisms, the <code>TargetLibSuffix</code> setting overrides the setting of this field.</td>
</tr>
<tr>
<td><code>intOnlyBuild</code></td>
<td>A Boolean flag. When set to true, the flag indicates the libraries are to be optimized such that they are compiled from integer code only. This field applies to ERT targets only.</td>
</tr>
<tr>
<td><code>makeOpts</code></td>
<td>A character vector that specifies an option to be included in the <code>rtwMake</code> command line.</td>
</tr>
</tbody>
</table>
| `addLibs`              | A cell array of structures that specify libraries to be built that are not specified by an `rtwmakecfg` function. Each structure must be defined with two fields that are character arrays:  
  - `libName` — the name of the library without a suffix  
  - `libLoc` — the location for the precompiled library  

The target makefile (TMF) can specify other libraries and how those libraries are built. Use this field to precompile those libraries.
The following commands set up build specification `build_spec`, which indicates that the files to be compiled are in folder `src` under the current working folder.

```matlab
build_spec = []; build_spec.rtwmakecfgDirs = {fullfile(pwd,'src')};
```

4 Issue a call to `rtw_precompile_libs`.

The call must specify the model for which you want to build the precompiled libraries and the build specification. For example:

```matlab
rtw_precompile_libs(my_model,build_spec);
```

Generate Component Source Code for Export to External Code Base

In this section...

“Modeling Options” on page 42-52
“Requirements” on page 42-53
“Limitations for Export-Function Subsystems” on page 42-54
“Workflow” on page 42-55
“Choose an Integration Approach” on page 42-56
“Generate C Function Code for Export-Function Model” on page 42-58
“Generate C++ Function and Class Code for Export-Function Model” on page 42-64
“Generate Code for Export-Function Subsystems” on page 42-69

If you have Embedded Coder software, you can generate function source code from modeling components to use in an external code base. The generated code does not include supporting scheduling code (for example, a step function). Controlling logic outside of the Simulink environment invokes the generated function code.

Modeling Options

You can generate function code to export for these modeling components:

- Export-function models (model containing functional blocks that consist exclusively of function-call subsystems, function-call model blocks, or other export-function models, as described in “Export-Function Models” (Simulink))
- Export-function subsystems (virtual subsystem that contains function-call subsystems)

To export code that the code generator produces for these modeling components, the modeling components must meet specific requirements on page 42-53.

For models designed in earlier releases, the code generator can export functions from triggered subsystems. The requirements stated for export-function subsystems also apply to exporting functions from triggered subsystems, with the following exceptions:

- Encapsulate triggered subsystems from which you intend to export functions in a top-level virtual subsystem.
• Triggered subsystems do not have to meet requirements and limitations identified for virtual subsystems that contain function-call subsystem.
• “Export Functions That Use Absolute or Elapsed Time” on page 42-54 does not apply to exporting functions from triggered subsystems.

Requirements

• Model solver must be a fixed-step discrete solver.
• You must configure each root-level Inport block that triggers a function-call subsystem to output a function-call trigger. These Inport blocks cannot connect to an Asynchronous Task Specification block.
• Model or subsystem, must contain only the following blocks at the root level:
  • Function-call blocks (such as Function-Call Subsystem, Simulink Function, S-Functions, and Function-Call Model blocks at the root level if the solver parameter Tasking and sample time options > Periodic sample time constraint is set to Ensure sample time independent)
  • Inport and Outport blocks (ports)
  • Constant blocks (including blocks that resolve to constants, such as Add)
  • Blocks with a sample time of Inf
  • Merge and data store memory blocks
  • Virtual connection blocks (such as, Function-Call Split, Mux, Demux, Bus Creator, Bus Selector, Signal Specification, and virtual subsystems that contain these blocks)
  • Signal-viewer blocks, such as Scope blocks (export-function subsystems only)
• When a constant block appears at the top level of the model or subsystem, you must set the model configuration parameter Optimization > Default parameter behavior for the model or containing model to Inlined.
• Blocks inside the model or subsystem must support code generation.
• Blocks that use absolute or elapsed time must be inside a periodic function-call subsystem with a discrete sample time specified on the corresponding function-call root-level Inport block. See “Export Functions That Use Absolute or Elapsed Time” on page 42-54.
• Data signals that cross the boundary of an exported system cannot be a virtual bus and cannot be implemented as a Goto-From connection. Data signals that cross the export boundary must be scalar, muxed, or a nonvirtual bus.
In addition, for export-function models, data logging and signal-viewer blocks, such as the Scope block, are not allowed at the root level or within the function-call blocks.

For export-function subsystems, the following additional requirements apply:

- A trigger signal that crosses the boundary of an export-function subsystem must be scalar. Input and output data signals that do not act as triggers do not have to be scalar.
- When a constant signal drives an output port of an export-function subsystem, the signal must specify a storage class.

**Export Functions That Use Absolute or Elapsed Time**

If you want to export function code for a modeling component with blocks that use absolute or elapsed time, those blocks must be inside a function-call subsystem that:

- You configure for periodic execution
- You configure the root-level Inport block with a discrete sample time

To configure a function-call subsystem for periodic execution:

1. In the function-call subsystem, right-click the Trigger block and choose **Block Parameters** from the context menu.
2. In the **Sample time type** field, specify periodic.
3. Set the **Sample time** to the same granularity specified (directly or by inheritance) in the function-call initiator.
4. Click **OK** or **Apply**.

For more information, see “Absolute and Elapsed Time Computation” (Simulink Coder).

**Limitations for Export-Function Subsystems**

- Subsystem block parameters do not control the names of the files containing the generated code. The file names begin with the name of the exported subsystem.
- Subsystem block parameters do not control the names of top-level functions in the generated code. Each function name reflects the name of the signal that triggers the function or (for an unnamed signal) reflects the block from which the signal originates.
- The code generator cannot export reusable code for export-function subsystems. The **Code interface packaging** value **Reusable function** does not apply for export-function subsystems.
• You can export function-call systems for the C++ class code interface packaging only when its function specification is set to **Default step method**. See “Customize Generated C++ Class Interfaces” on page 29-36. The exported function is compatible with single-threaded execution. To avoid potential data race conditions for shared signals, invoke all members for the class from the same execution thread.

• The code generator supports a SIL or PIL block in accelerator mode only if its function-call initiator is noninlined in accelerator mode. Examples of noninlined initiators include Stateflow charts.

• A Level-2 S-function initiator block, such as a Stateflow chart or the built-in Function-Call Generator block, must drive a SIL block.

• You can export an asynchronous (sample-time) function-call system, but the software does not support the SIL or PIL block for an asynchronous system.

• The software does not support MAT-file logging for export-function subsystems. Specifications that enable MAT-file logging are ignored.

• The use of the TLC function `LibIsFirstInit` has been removed for export-function subsystems.

**Workflow**

To generate code for an exported function, iterate through the tasks listed in this table.

**Choose an Integration Approach**

Multiple approaches are available for generating function code for export to an external development environment. The following table compares approaches. Choose the approach that aligns best with your integration requirements. For more information on
how to create export-function models, see “Export-Function Models” (Simulink). For more information on generating code for function call subsystems, see “Generate Component Source Code for Export to External Code Base” on page 42-52.

**Generate C Function Code for Export-Function Model**

This example shows how to generate function code for individual Simulink function blocks and function-call subsystems in a model without generating scheduling code.

To generate function code for export:

1. Create a model that contains the functions for export.
2. Create a test harness model that schedules execution of the functions during simulation.
3. Simulate the model that contains the functions by using the test harness model.
4    Generate code for the model that contains the functions.

Create Model That Contains Functions for Export

The model with functions for export must satisfy architectural constraints at the model root level. At the root level, valid blocks are:

- Inport
- Outport
- Function-Call Subsystem
- Simulink Function
- Goto
- From
- Merge

The code generator produces function code for Function-Call Subsystem and Simulink Function blocks and Initialize and Reset Function blocks. For a Function-call Subsystem block, you connect the block input ports to root Inport blocks that assert function-call signals. The subsystem is executed based on the function-call signal that it receives. A Simulink Function block is executed in response to the execution of a corresponding Function Caller block or Stateflow chart. An Initialize Function block is executed on a model initialize event and a Reset Function block is executed on a user-defined reset event.

For exporting functions, model rtwdemo_functions contains two function-call subsystems (f1_alg and f2_alg) and a Simulink Function block (f3) for exporting functions. The model also contains an Initialize Function block (Initialize Function) and a Reset Function block (Reset Function). To calculate initial conditions for blocks with state in other parts of the model, the State Writer blocks are used inside the Initialize and Reset Function blocks.

open_system('rtwdemo_functions')
Create Model That Contains Function Caller Block

Use a Function Caller block to invoke a Simulink Function block. The Function Caller block can be in the same model or in a different model as the Simulink Function block.

Multiple Function Caller blocks can invoke a Simulink Function block. You can place the Function Caller block inside a function-call subsystem. During code generation, the code generator exports a function from the function-call subsystem.

The model rtwdemo_caller exports a function-call subsystem that contains a Function Caller block.

```
open_system('rtwdemo_caller')
```
Create Test Harness Model for Simulation

When you export functions, the generated code does not include a scheduler. Create a test harness model to handle scheduling during simulation. Do not use the test harness model to generate code that you deploy.

Model `rtwdemo_export_functions` is a test harness. The model:

- Schedules the Simulink Function block with the Function Caller block in `rtwdemo_caller`.
- Provides function-call signals to other models in this example to schedule the model contents, including the model initialize and reset events.

`open_system('rtwdemo_export_functions')`
Simulate the Test Harness Model

Verify that the model containing the functions that you want to export is executed as you expect by simulating the test harness model. For example, simulate `rtwdemo_export_functions`.

```
sim('rtwdemo_export_functions')
```

Generate Function Code and Report

Generate code and a code generation report for the functions that you want to export. For example, generate code for `rtwdemo_functions`.

```
rtwbuild('rtwdemo_functions')
```

### Starting build procedure for model: rtwdemo_functions
### Successful completion of code generation for model: rtwdemo_functions

Review Generated Code

From the code generation report, review the generated code.
• ert_main.c is an example main program (execution framework) for the model. This code shows how to call the exported functions. The code also shows how to initialize and execute the generated code.

• rtwdemo_functions.c calls the initialization function, including Initialize Function, and exported functions for model components f1_alg, f2_alg, and f3.

• rtwdemo_functions.h declares model data structures and a public interface to the exported entry-point functions and data structures.

• f3.h is a shared file that declares the call interface for the Simulink function f3.

• rtwtypes.h defines data types, structures, and macros that the generated code requires.

Write Interface Code

Open and review the Code Interface Report. To write the interface code for your execution framework, use the information in that report.

1 Include the generated header files by adding directives #include rtwdemo_functions.h, #include f3.h, and #include rtwtypes.h.
2 Write input data to the generated code for model Inport blocks.
3 Call the generated entry-point functions.
4 Read data from the generated code for model Outport blocks.

Input ports:

• rtU.U1 of type real_T with dimension 1
• rtU.U2 of type real_T with dimension 1

Entry-point functions:

• Initialize entry-point function, void rtwdemo_functions_initialize(void). At startup, call this function once.
• Reset entry-point function, void rtwdemo_functions_reset(void). Call this function as needed.
• Exported function, void f1(void). Call this function as needed.
• Exported function, void f2(void). Call this function as needed.
• Simulink function, void f3(real_T rtu_u, real_T *rty_y). Call this function as needed.
Output ports:

- `rtY.Accumulator1` of type `int8_T` with dimension [2]
- `rtY.Accumulator2` of type `int8_T` with dimension [2]
- `rtY.TicToc10` of type `int8_T` with dimension 1

```

Generate C++ Function and Class Code for Export-Function Model

This example shows how to generate function code for an export-function model that includes a function-call subsystem. The code generator produces function and class code that does not include scheduling code.

To generate function code for export:

1. Create a model that contains the functions for export.
2. Create a test harness model that schedules execution of the functions during simulation.
3. Simulate the model that contains the functions by using the test harness model.
4. Generate code for the model that contains the functions.
Create Model That Contains Functions and C++ Class Interface for Export

The model with functions for export with a C++ model class interface must satisfy architectural constraints at the model root level. For C++ class generation, blocks that are valid at the root level are:

- Inport
- Outport
- Function-Call Subsystem
- Goto
- From
- Merge

**Note:** Export Function-Call Subsystem with C++ class interface does not support Simulink Function blocks.

The code generator produces function code for the Function-Call Subsystem block. For a Function-call Subsystem block, you connect the block input ports to root Inport blocks that assert function-call signals. The subsystem is executed based on the function-call signal that it receives.

Model `rtwdemo_cppclass_functions` contains function-call subsystems `f1`, `f2`, and `f3` for exporting functions.

`open_system('rtwdemo_cppclass_functions')`
Create Test Harness Model for Simulation

When you export functions, the generated code does not include a scheduler. Create a test harness model to handle scheduling during simulation. Do not use the test harness model to generate code that you deploy.

Model `rtwdemo_cppclass_export_functions` is a test harness. The model provides function-call signals to other models in this example to schedule the model contents.

```matlab
open_system('rtwdemo_cppclass_export_functions')
```
Simulate the Test Harness Model

Verify that the model containing the functions that you want to export is executed as you expect by simulating the test harness model. For example, simulate `rtwdemo_cppclass_export_functions`.

```matlab
sim('rtwdemo_cppclass_export_functions')
```

Generate Function Code and Report

Generate code and a code generation report for the functions that you want to export. For example, generate code for `rtwdemo_cppclass_functions`.

```matlab
rtwbuild('rtwdemo_cppclass_functions')
```

### Starting build procedure for model: rtwdemo_cppclass_functions
### Successful completion of build procedure for model: rtwdemo_cppclass_functions

Review Generated Code

From the code generation report, review the generated code.
• **ert_main.cpp** is an example main program (execution framework) for the model. This code shows how to call the exported functions. The code also shows how to initialize and execute the generated code.

• **rtwdemo_cppclass_functions.cpp** calls the initialization function, including *Initialize Function*, and exported functions for model subsystem components f1, f2, and f3.

• **rtwdemo_cppclass_functions.h** declares model data structures and a public interface to the exported entry-point functions and data structures.

• **rtwtypes.h** defines data types, structures, and macros that the generated code requires.

### Write Interface Code

Open and review the Code Interface Report. To write the interface code for your execution framework, use the information in that report.

1. Include the generated header files by adding directives `#include rtwdemo_cppclass_functions.h` and `#include rtwtypes.h`.
2. Write input data to the generated code for model Inport blocks.
3. Call the generated entry-point functions.
4. Read data from the generated code for model Outport blocks.

**Input ports:**

- rtU.U1 of type `real_T` with dimension 1
- rtU.U2 of type `real_T` with dimension 1
- rtU.U3 of type `real_T` with dimension 1

**Entry-point functions:**

- Initialize entry-point function, `void initialize(void)`. At startup, call this function once.
- Exported function, `void t_1tic_A(void)`. Call this function as needed.
- Exported function, `void t_1tic_B(void)`. Call this function as needed.
- Exported function, `void t_1tic_C(void)`. Call this function as needed.

**Output ports:**
rtY.TicToc1 of type int8_T with dimension [2]
rtY.TicToc2 of type int8_T with dimension [2]
rtY.TicToc10 of type int8_T with dimension 1

Generate Code for Export-Function Subsystems

- “Specify a Custom Initialize Function Name” on page 42-70
- “Specify a Custom Description” on page 42-70
- “Optimize Code Generated for Export-Function Subsystems” on page 42-71

To generate code for an export-function subsystem:

1. Verify that the subsystem for which you are generating code satisfies exporting requirements on page 42-53.
2. In the Configuration Parameters dialog box:
   a. On the **Code Generation** pane, specify an ERT-based system target file, such as ert.tlc.
   b. If you want a SIL block with the generated code, for verification purposes, from the **Configuration Parameters > Code Generation > Verification > Advanced parameters > Create block** drop-down list, select SIL.
   c. Click **OK** or **Apply**.
3. Right-click the subsystem block and choose **C/C++ Code > Export Functions** from the context menu.
The operation creates a new model, *subsystem.slx*, that contains the content of the original subsystem and creates a ScratchModel that contains a Model block. This block references the newly created *subsystem.slx* model.

The **Build code for subsystem: Subsystem** dialog box opens. This dialog box is not specific to export-function subsystems. Generating code does not require entering information in the dialog box.

4  Click **Build** to build the newly created *subsystem.slx* model.

The code generator produces code and places it in the working folder.

If you set **Create block** to SIL in step 2b, Simulink opens a new window that contains an S-function block that represents the generated code. This block has the same size, shape, and connectors as the original subsystem.

Code generation and optional block creation are now complete. You can test and use the code and optional block as you do for generated ERT code and S-function block. For optional workflow tasks, see “Specify a Custom Initialize Function Name” on page 42-70 and “Specify a Custom Description” on page 42-70.

**Specify a Custom Initialize Function Name**

You can specify a custom name for the initialize function of your exported function as an argument to the `rtwbuild` command. The command takes the following form:

```matlab
blockHandle = rtwbuild('subsystem', 'Mode', 'ExportFunctionCalls',...
          'ExportFunctionInitializeFunctionName', 'fcnname')
```

`fcnname` specifies the function name. For example, if you specify the name 'myinitfcn', the build process emits code similar to:

```c
/* Model initialize function */
void myinitfcn(void){
  ...
}
```

**Specify a Custom Description**

You can enter a custom description for an exported function by using the Block Properties dialog box of an Inport block.

1  Right-click the Inport block that drives the control port of the subsystem for which you are exporting code.
2 Select **Properties**.

3 In the **General** tab, in the **Description** field, enter your descriptive text.

During function export, the text you enter is emitted to the generated code in the header for the Inport block. For example, if you open the example program `rtwdemo_exporting_functions` and enter a description in the Block Properties dialog box for port `t_1tic_A`, the code generator produces code that is similar to:

```c
/*
 * Output and update for exported function: t_1tic_A
 *
 * My custom description of the exported function
 */
void t_1tic_A(void)
{
 ...
}
```

### Optimize Code Generated for Export-Function Subsystems

To optimize the code generated for an export-function subsystem, specify a separate storage class for each input signal and output signal that crosses the boundary of the subsystem.

For each function-call subsystem that you are exporting:

1 Right-click the subsystem.
2 From the context menu, choose **Block Parameters (Subsystem)**.
3 Select the **Code Generation** tab.
4 Set **Function packaging** to Auto.
5 Click **OK** or **Apply**.

| “Limitations” on page 42-78 |
| “Interface to a Development Computer Simulator By Using a Shared Library” on page 42-79 |

About Generated Shared Libraries

If you have Embedded Coder software, you can generate a shared library—Windows dynamic link library (.dll), UNIX shared object (.so), or Macintosh OS X dynamic library (.dylib)—from a model component. You or others can integrate the shared library into an application that runs on a Windows, UNIX, or Macintosh OS X development computer. Uses of shared libraries include:

- Adding a software component to an application for system simulation
- Reusing software modules among applications on a development computer
- Hiding intellectual property associated with software that you share with vendors

When producing a shared library, the code generator exports:

- Variables and signals of type ExportedGlobal as data
- Real-time model structure (model_M) as data
- Functions essential to executing the model code

Workflow

To generate a shared library from a model component and use the library, complete the tasks listed in this table.
<table>

<td></td>
</tr>
</tbody>
</table>

**Generate Shared Libraries**

1. When configuring the model for code generation, select the system target file `ert_shrlib.tlc`. 

42-74
2 Build the model. The code generator produces source code for the model and a shared library version of the code. The code generator places the source code in the code generation folder and the shared library (.dll, .so, or .dylib file) in your current working folder. The code generator also produces and retains a .lib file to support implicit linking.

Create Application Code That Uses Generated Shared Libraries

This example application code is generated for the example “Interface to a Development Computer Simulator By Using a Shared Library” on page 42-79.

1 Create an application header file that contains type declarations for model external input and output. For example:

```c
#ifndef _APP_MAIN_HEADER_
define _APP_MAIN_HEADER_

typedef struct {
    int32_T Input;
} ExternalInputs_rtwdemo_shrlib;

typedef struct {
    int32_T Output;
} ExternalOutputs_rtwdemo_shrlib;

define _APP_MAIN_HEADER_*/
```

2 In the application C source code, dynamically load the shared library. Use preprocessing conditional statements to invoke platform-specific commands. For example:

```c
#if (defined(_WIN32)||defined(_WIN64)) /* WINDOWS */
#include <windows.h>
define GETSYMBOLADDR GetProcAddress
define LOADLIB LoadLibrary
define CLOSELIB FreeLibrary
#else /* UNIX */
#include <dlfcn.h>
define GETSYMBOLADDR dlsym
define LOADLIB dlopen
define CLOSELIB dlclose
```
int main()
{
    void* handleLib;
    ...
#if defined(_WIN64)
    handleLib = LOADLIB("./rtwdemo_shrlib_win64.dll");
#else #if defined(_WIN32)
    handleLib = LOADLIB("./rtwdemo_shrlib_win32.dll");
#else /* UNIX */
    handleLib = LOADLIB("./rtwdemo_shrlib.so", RTLD_LAZY);
#endif
    ...
    return(CLOSELIB(handleLib));
}

From the application C source code, access exported data and functions generated from the model. The code uses hooks to add user-defined initialization, step, and termination code.

    int32_T i;
...
    void (*mdl_initialize)(boolean_T);
    void (*mdl_step)(void);
    void (*mdl_terminate)(void);

    ExternalInputs_rtwdemo_shrlib (*mdl_Uptr);
    ExternalOutputs_rtwdemo_shrlib (*mdl_Yptr);

    uint8_T (*sum_outptr);
...
#if (defined(LCCDLL)||defined(BORLANDCDLL))
/* Exported symbols contain leading underscores when DLL is linked with LCC or BORLANDC */
mdl_initialize =
    (void(*)(boolean_T))GETSYMBOLADDR(handleLib ,
    "_rtwdemo_shrlib_initialize");
mdl_step =
    (void(*)(void))GETSYMBOLADDR(handleLib ,
    "_rtwdemo_shrlib_step");
mdl_terminate =
    (void(*)(void))GETSYMBOLADDR(handleLib ,
    "_rtwdemo_shrlib_terminate");
#endif
"_rtwdemo_shrlib_terminate";
mdl_Uptr =
  (ExternalInputs_rtwdemo_shrlib*)GETSYMBOLADDR(handleLib, 
  "_rtwdemo_shrlib_U");
mdl_Yptr =
  (ExternalOutputs_rtwdemo_shrlib*)GETSYMBOLADDR(handleLib, 
  "_rtwdemo_shrlib_Y");
sum_outptr =
  (uint8_T*)GETSYMBOLADDR(handleLib, "_sum_out");
#else
mdl_initialize =
  (void(*)(boolean_T))GETSYMBOLADDR(handleLib, 
  "rtwdemo_shrlib_initialize");
mdl_step =
  (void(*)(void))GETSYMBOLADDR(handleLib, 
  "rtwdemo_shrlib_step");
mdl_terminate =
  (void(*)(void))GETSYMBOLADDR(handleLib, 
  "rtwdemo_shrlib_terminate");
mdl_Uptr =
  (ExternalInputs_rtwdemo_shrlib*)GETSYMBOLADDR(handleLib, 
  "rtwdemo_shrlib_U");
mdl_Yptr =
  (ExternalOutputs_rtwdemo_shrlib*)GETSYMBOLADDR(handleLib, 
  "rtwdemo_shrlib_Y");
sum_outptr =
  (uint8_T*)GETSYMBOLADDR(handleLib, "sum_out");
#endif
if ((mdl_initialize && 
  mdl_step && 
  mdl_terminate && 
  mdl_Uptr && 
  mdl_Yptr && 
  sum_outptr)) {
  /* user application 
     initialization function */
  mdl_initialize(1); 
  /* insert other user defined 
     application initialization code here */

  /* user application 
     step function */
  for(i=0;i<=12;i++){
mdl_Uptr->Input = i;
mdl_step();
printf("Counter out(sum_out):
%d\tAmplifier in(Input):
%d\tout(Output):
%d\n", *sum_outptr, i,
mdl_Yptr->Output);
/* insert other user defined
application step function
code here */
}

/* user application
terminate function */
mdl_terminate();
/* insert other user defined
application termination
code here */
}
else {
    printf("Cannot locate the specified
reference(s) in the shared library.\n");
    return(-1);
}

Limitations

- Code generation for the ert_shrlib.tlc system target file exports the following as data:
  - Variables and signals of type ExportedGlobal
  - Real-time model structure (model_M)
- Code generation for the ert_shrlib.tlc system target file supports the C language only (not C++). When you select ert_shrlib.tlc, language selection is unavailable on the Code Generation pane in the Configuration Parameters dialog box.
- To reconstruct a model simulation by using a generated shared library, the application author must maintain the timing between system and shared library function calls in the original application. The timing must be consistent so that you can compare the simulation and integration results. Additional simulation considerations apply if generating a shared library from a model that enables model configuration parameters Support: continuous time and Single output/update function. For more information, see Single output/update function (Simulink Coder) dependencies.
Interface to a Development Computer Simulator By Using a Shared Library

This example generates a shared library for interfacing to a simulator that runs on your development computer. Generate the shared library by using the system target file ert_shrlib.tlc.

To build a shared library from the model and use the library in an application:

1. Develop your model. For this example, open the model rtwdemo_shrlib.

    open_system('rtwdemo_shrlib');
The model is a single-rate, discrete-time model. An 8-bit counter feeds the triggered subsystem named Amplifier. Parameters INC, LIMIT, and RESET are set to constant 42.
values 1, 4, and 0, respectively. When signal `equal_to_count` is true, the subsystem amplifies its input signal by a gain factor $K=3$ and the output signal is updated.

2. Configure the model for code generation, specifying `ert_shrlib.tlc` as the system target file. Click the yellow button on the model to view the configuration settings on the **Code Generation** pane in the Configuration Parameters dialog box.

3. Build the shared library file. The file that the code generator produces depends on your development platform. For example, on a Windows system, the code generator produces the library file `rtwdemo_shrlib_win64.dll`.

4. Create application code that uses the shared library. This example uses application code that is available in the these files:

```plaintext
matlabroot\toolbox\rtw\rtwdemos\shrlib_demo\rtwdemo_shrlib_app.h
matlabroot\toolbox\rtw\rtwdemos\shrlib_demo\rtwdemo_shrlib_app.c
```

To view the source code in these files, in the model, click the white buttons for the `.h` and `.c` files.

5. Compile and link the file application and shared library files to produce an executable program. The following script compiles, builds, and runs the program.

```plaintext
matlabroot\toolbox\rtw\rtwdemos\shrlib_demo\rtwdemo_shrlib_app.m
```

To view the script code, in the model, click the white button for the `.m` file.

To build the model and run the application that uses the generated shared library, in the model, double-click the blue button.

For more information about using a shared library, see “Package Generated Code as Shared Libraries” on page 50-2.

Build Integrated Code Outside the Simulink Environment

Identify required files and interfaces for calling generated code in an external build process.

Learn how to:

• Collect files required for building integrated code outside of Simulink®.
• Interface with external variables and functions.

For information about the example model and related examples, see “Generate C Code from a Control Algorithm for an Embedded System”.

Collect and Build Required Data and Files

The code that Embedded Coder® generates requires support files that MathWorks® provides. To relocate the generated code to another development environment, such as a dedicated build system, you must relocate these support files. You can package these files in a zip file by using the packNGo utility. This utility finds and packages the files that you need to build an executable image. The utility uses tools for customizing the build process after code generation, which include a buildinfo_data structure, and a packNGo function. These files include external files that you identify in the Code Generation > Custom Code pane in the Model Configuration Parameters dialog box. The utility saves the buildinfo MAT-file in the model_ert_rtw folder.

Open the example model, rtwdemo_PCG_Eval_P5.

This model is configured to run packNGo after code generation.

Generate code from the entire model.

To generate the zip file manually:

1 Load the file buildInfo.mat (located in the rtwdemo_PCG_Eval_P5_ert_rtw subfolder).
2 At the command prompt, enter the command packNGo(buildInfo).

The number of files in the zip file depends on the version of Embedded Coder® and on the configuration of the model that you use. The compiler does not require all of the files in the zip file. The compiled executable size (RAM/ROM) depends on the linking process. The linker likely includes only the object files that are necessary.
**Integrating the Generated Code into an Existing System**

This example shows how to integrate the generated code into an existing code base. The example uses the Eclipse™ IDE and the Cygwin™/gcc compiler. The required integration tasks are common to all integration environments.

**Overview of Integration Environment**

A full embedded controls system consists of multiple hardware and software components. Control algorithms are just one type of component. Other components can be:

- An operating system (OS)
- A scheduling layer
- Physical hardware I/O
- Low-level hardware device drivers

Typically, you do not use the generated code in these components. Instead, the generated code includes interfaces that connect with these components. MathWorks® provides hardware interface block libraries for many common embedded controllers. For examples, see the Embedded Targets block library.

This example provides files to show how you can build a full system. The main file is `example_main.c`, which contains a simple main function that performs only basic actions to exercise the code.

View `example_main.c`.
The file:

- Defines function interfaces (function prototypes).
- Includes files that declare external data.
- Defines extern data.
- Initializes data.
- Calls simulated hardware.
- Calls algorithmic functions.

The order of function execution matches the order of subsystem execution in the test harness model and in `rtwdemo_PCG_Eval_P5.h`. If you change the order of execution in `example_main.c`, results that the executable image produces differ from simulation results.
**Match System Interfaces**

Integration requires matching the *Data* and *Function* interfaces of the generated code and the existing system code. In this example, the `example_main.c` file imports and exports the data through `#include` statements and `extern` declarations. The file also calls the functions from the generated code.

**Connect Input Data**

The system has three input signals: `pos_rqst`, `fbk_1`, and `fbk_2`. The generated code accesses the two feedback signals through direct reference to imported global variables (storage class `ImportedExtern`). The code accesses the position signal through an imported pointer (storage class `ImportedExternPointer`).

The handwritten file `defineImportedData.c` defines the variables and the pointer. The generated code does not define the variables and the pointer because the handwritten code defines them. Instead, the generated code declares the imported data (`extern`) in the file `rtwdemo_PCG_Eval_P5_Private.h`. In a real system, the data typically comes from other software components or from hardware devices.

View `defineImportedData.c`.

```c
/* Define imported data */
#include "rtwtypes.h"
#include "defineImportedData.h"

real_T fbk_1;
real_T fbk_2;
real_T dummy_pos_value = 10.0;
real_T *pos_rqst;
void defineImportedData(void)
{
    pos_rqst = &dummy_pos_value;
}
```

View `rtwdemo_PCG_Eval_P5_Private.h`. 
Connect Output Data

In this example, you do not access the output data of the system. The example “Test Generated Code” shows how you can save the output data to a standard log file. You can access the output data by referring to the file rtwdemo_PCG_Eval_P5.h.

View rtwdemo_PCG_Eval_P5.h.

Access Additional Data

The generated code contains several structures that store commonly used data including:

- Block state values (integrator, transfer functions)
- Local parameters
- Time

The table lists the common data structures. Depending on the configuration of the model, some or all of these structures appear in the generated code. The data is declared in the file rtwdemo_PCG_Eval_P5.h, but in this example, you do not access this data.

<table>
<thead>

</tbody>
</table>

Match Function Call Interfaces

By default, functions that the code generator generates have a void `Func(void)` interface. If you configure the model or atomic subsystem to generate reentrant code, the
code generator creates a more complex function prototype. In this example, the `example_main` function calls the generated functions with the correct input arguments.

```c
PI_Cntrl_Reusable(*pos_rqst), fbk_1, &rtwdemo_PCIE_EVAL_P5_B.PI_ctrl_1,
    &rtwdemo_PCIE_EVAL_P5_DWork.PI_ctrl_1);
PI_Cntrl_Reusable(*pos_rqst), fbk_2, &rtwdemo_PCIE_EVAL_P5_B.PI_ctrl_2,
    &rtwdemo_PCIE_EVAL_P5_DWork.PI_ctrl_2);
pos_cmd_one = rtwdemo_PCIE_EVAL_P5_B.PI_ctrl_1.Saturation1;
pos_cmd_two = rtwdemo_PCIE_EVAL_P5_B.PI_ctrl_2.Saturation1;

rtwdemo_Pos_Command_Arbitration(pos_cmd_one, &Throt_Param, pos_cmd_two,
    &rtwdemo_PCIE_EVAL_P5_B.sf_Pos_Command_Arbitration);
```

Calls to the function `PI_Cntrl_Reusable` use a mixture of separate, unstructured global variables and Simulink® Coder™ data structures. The handwritten code defines these variables. The structure types are defined in `rtwdemo_PCIE_EVAL_P5.h`.

**Build Project in Eclipse™ Environment**

This example uses the Eclipse™ IDE and the Cygwin™ GCC debugger to build the embedded system. The example provides installation files for both programs. Software components and versions numbers are:

- Eclipse™ SDK 3.2
- Eclipse™ CDT 3.3
- Cygwin™/GCC 3.4.4-1
- Cygwin™/GDB 20060706-2

To install and use Eclipse™ and GCC, see “Install and Use Cygwin and Eclipse”.

You can install the files for this example by clicking this hyperlink:

Set up the build folder.

Alternatively, to install the files manually:

1  Create a build folder (`Eclipse_Build_P5`).
2  Unzip the file `rtwdemo_PCIE_EVAL_P5.zip` into the build folder.
3  Delete the files `rtwdemo_PCIE_EVAL_P5.c`, `ert_main.c` and `rt_logging.c`, which are replaced by `example_main.c`. 
You can use the Eclipse™ debugger to step through and evaluate the execution behavior of the generated C code. See the example “Install and Use Cygwin and Eclipse”.

To exercise the model with input data, see “Test Generated Code”.

Exchange Data Between External C/C++ Code and Simulink Model or Generated Code

Whether you import your external code into a Simulink model (for example, by using the Legacy Code Tool) or export the generated code to an external environment, the model or the generated code typically exchange data (signals, states, and parameters) with your code.

Functions in C or C++ code, including your external functions, can exchange data with a caller or a called function through:

- Arguments (formal parameters) of functions. When a function exchanges data through arguments, an application can call the function multiple times. Each instance of the called function can manipulate its own independent set of data so that the instances do not interfere with each other.
- Direct access to global variables. Global variables can:
  - Enable different algorithms (functions) and instances of the same algorithm to share data such as calibration parameters and error status.
  - Enable the different rates (functions) of a multitasking system to exchange data.
  - Enable different algorithms to exchange data asynchronously.

In Simulink, you can organize and configure data so that a model uses these exchange mechanisms to provide, extract, and share data with your code.

Before you attempt to match data interfaces, to choose an overall integration approach, see “Choose an External Code Integration Workflow” on page 42-4.

Import External Code into Model

To exchange data between your model and your external function, choose an exchange mechanism based on the technique that you chose to integrate the function.

- To exchange data through the arguments of your external function, construct and configure your model to create and package the data according to the data types of the arguments. Then, you connect and configure the block that calls or represents your function to accept, produce, or refer to the data from the model.

For example, if you use the Legacy Code Tool to generate an S-Function block that calls your function, the ports and parameters of the block correspond to the
arguments of the function. You connect the output signals of upstream blocks to the
input ports and set parameter values in the block mask. Then, you can create signal
lines from the output ports of the block and connect those signals to downstream
blocks.

- To exchange data through global variables that your external code already defines, a
  best practice is to use a Stateflow chart to call your function and to access the
  variables. You write algorithmic C code in the chart so that during simulation or
  execution of the generated code, the model reads and writes to the variables.

To use such a global variable as an item of parameter data (not signal or state data)
elsewhere in a model, you can create a numeric MATLAB variable or
Simulink.Parameter object that represents the variable. If you change the value of
the C-code variable in between simulation runs, you must manually synchronize the
value of the Simulink variable or object. If your algorithmic code (function) changes
the value of the C-code variable during simulation, the corresponding Simulink
variable or object does not change.

If you choose to create a Simulink representation of the C-code variable, you can
configure the Simulink representation so that the generated code reads and writes to
the variable but does not duplicate the variable definition. Apply a storage class to the
Simulink representation.

Exchange Data Between External Calling Code and Generated Code

To export the generated code into your external code, you configure the generated code to match the data interface of your external code. For example, if your external code defines a global variable for storing output data and you need the generated code to read that data as input, you can configure a corresponding Inport block so that the generated code interacts with the existing variable.

- You can generate reentrant code from a model. The generated entry-point functions typically accept data through arguments. Your calling code passes data through these arguments. You can call the functions multiple times in a single application—the application can maintain multiple instances of the model. See “Data Exchange for Reentrant Generated Code” (Simulink Coder).

- When you generate nonreentrant code, by default, the entry-point functions exchange data between the generated code and your code through global variables. You can generate variable definitions for your code to use or you can share and reuse existing variables that your code already defines. See “Data Exchange for Nonreentrant Generated Code” (Simulink Coder).

Alternatively, you can configure the entry-point functions to exchange system inputs and outputs (root-level Inport and Outport blocks) through arguments instead of global variables. Apply function prototype control to the model, which requires Embedded Coder. For more information about function prototype control, see “Customize Generated C Function Interfaces” on page 29-2.

For general information about exchanging data between generated and external code, including how to match specific C code patterns, see “Exchange Data Between External C/C++ Code and Simulink Model or Generated Code” (Simulink Coder).

Data Exchange for Reentrant Generated Code

When you generate reentrant code, the model entry-point functions exchange data through arguments. You can control some of the characteristics of the arguments. For more information, see “Control Data and Function Interface in Generated Code” (Simulink Coder).

For information about creating a separate set of data for each call site in your external code, see “Modify Static Main to Allocate and Access Model Instance Data” on page 52-14.
Data Exchange for Nonreentrant Generated Code

To make the generated code read or write to an item of signal, state, or parameter data as a global variable, apply a storage class or custom storage class to the data in the model. The storage class also determines whether the generated code exports the variable definition to your external code or imports the definition from your code. For general information about controlling the data interface of a model that you configure to generate nonreentrant code, see “Control Data Interface for Nonreentrant Code” (Simulink Coder). For examples, see “Design Data Interface by Configuring Inport and Outport Blocks” (Simulink Coder) and “Integrate External Application Code with Code Generated from PID Controller” on page 26-62.

When you generate code that defines (allocates memory for) global data, the generated code exports that data. When your external code defines data, the generated code imports that data. Typically, storage classes that import data have the word Import in the storage class name, for example, ImportedExternPointer.

Control File Placement of Exported Global Data (Embedded Coder)

When you export data from the generated code by using storage classes or custom storage classes, the code generator creates an extern declaration. By default, this declaration typically appears in the generated header file model.h. You can include (#include) this header file in your external code.

By default, the definition (memory allocation) of exported data typically appears in model.c.

You can control the file placement of the declarations and definitions to:

• Create separate object files that store only global parameter data.
• Modularize the generated code by organizing declarations into separate files.

For more information about controlling file placement of declarations and definitions, see “Control Placement of Global Data Definitions and Declarations in Generated Files” on page 23-2. For an example, see “Definition, Initialization, and Declaration of Parameter Data” on page 14-7.

Prevent Duplicate Initialization Code for Global Variables

When your external code defines global variables, you can generate code that interacts with those variables. For example, use the custom storage class ImportFromFile (see
Choose a Storage Class for Controlling Data Representation in the Generated Code
(Simulink Coder).

For imported variables that represent signal or state data, the code generator can produce initialization code as described in “Initialization of Signal, State, and Parameter Data in the Generated Code” (Simulink Coder). If your code already initializes a variable, consider preventing the generation of duplicate initialization code. Create your own custom storage class and, for that storage class, set Data initialization to None. For information about creating and applying your own custom storage class, see “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 20-2.

Protect Global Data with Keywords const and volatile

When your external code and the generated code exchange data through global variables, you can generate code that uses const and volatile to protect data integrity and improve the safety of your application. For example:

- Apply const to a calibration parameter.
- Apply volatile to a global variable that stores the output of a hardware device operating asynchronously.
- Apply const and volatile to signals, states, and parameters that represent data defined by your external code. Then, the generated code declares and interacts with the external data by using the correct storage type qualifiers.

You must have Embedded Coder. For more information, see “Protect Global Data with const and volatile Keywords” on page 30-17.

Select C or C++ Programming Language

The default programming language selection for code generation is C language. In the code generation workflow, after the steps in “Select a Solver That Supports Code Generation” (Simulink Coder) and “Select a System Target File from STF Browser” (Simulink Coder), an optional step is to change the programming language selection for code generation.

To change the programming language setting:

1. From Configuration Parameters > Code Generation > Language, select C or C++ for the code generation language. Alternatively, set the TargetLang parameter at the command line.

   The code generator produces .c or .cpp files, depending on your selection, and places the generated files in your build folder.

   For more information, see “Language” (Simulink Coder).

2. Check whether you must choose and configure a compiler. If you select C++, you must choose and configure a compiler. For details, see “Select and Configure C or C++ Compiler or IDE” (Simulink Coder).

   For more information, see “Standard math library” (Simulink Coder).

More About

- “Select and Configure C or C++ Compiler or IDE” (Simulink Coder)
- “Troubleshoot Compiler Issues” (Simulink Coder)
Select and Configure C or C++ Compiler or IDE

The build process requires a supported compiler. Compiler, in this context, refers to a development environment (IDE) containing a linker and make utility, and a high-level language compiler. For details on supported compiler versions, see:

https://www.mathworks.com/support/compilers/current_release

When creating an executable program, the build process must be able to access a supported compiler. The build process can find a compiler to use based on your default MEX compiler.

The build process also requires the selection of a toolchain or template makefile. The toolchain or template makefile determines which compiler runs, during the make phase of the build. For more information, see “Choose Build Approach and Configure Build Process” (Simulink Coder)

To determine which templates makefiles are available for your compiler and system target file, see “Compare System Target File Support” (Simulink Coder).

For both generated files and user-supplied files, the file extension, .c or .cpp, determines whether the build process uses a C or a C++ compiler. If the file extension is .c, the build process uses C compiler to compile the file, and the symbols use the C linkage convention. If the file extension is .cpp, the build process uses a C++ compiler to compile the file, and the symbols use the C++ linkage specification.

Language Standards Compliance

The code generator produces code that is compliant with the following standards:
Language | Supported Standard
--- | ---
C | ISO/IEC 9899:1990, also known as C89/C90
C++ | ISO/IEC 14882:2003

Code that the code generator produces from these sources is ANSI C/C++ compliant:

- Simulink built-in block algorithmic code
- Generated system-level code (task ID [TID] checks, management, functions, and so on)
- Code from other blocksets, including the Fixed-Point Designer product and the Communications System Toolbox product
- Code from other code generators, such as MATLAB functions

Also, the code generator can incorporate code from:

- Embedded system target files (for example, startup code, device driver blocks)
- Custom S-functions or TLC files

**Note** Coding standards for these two sources are beyond the control of the code generator. These standards can be a source for compliance problems, such as code that uses C99 features not supported in the ANSI C, C89/C90 subset.

**Programming Language Considerations**

The code generator produces C and C++ code. Consider the following as you choose a programming language:

- Does your project require you to configure the code generator to use a specific compiler? C/C++ code generation on Windows requires this selection.
- Does your project require you to change the default language configuration setting for the model? See “Select C or C++ Programming Language” on page 43-2.
- Does your project require you to integrate legacy or custom code with generated code? For a summary of integration options, see “What Is External Code Integration?” on page 42-3.
- Does your project require you to integrate C and C++ code? If so, see “What Is External Code Integration?” on page 42-3.
Note You can mix C and C++ code when integrating generated code with custom code. However, you must be aware of the differences between C and default C++ linkage conventions, and add the extern "C" linkage specifier where required. For the details of the differing linkage conventions and how to apply extern "C", refer to a C++ programming language reference book.

- Does your project require code generation support from other products? See “C++ Language Support Limitations” on page 43-5.

For C++ code generation examples with Stateflow, see the sfcndemo_cppcount model or sf_cpp model.

### C++ Language Support Limitations

To use C++ language support, you could need to configure the code generator to use a specific compiler. For example, if a supported compiler is not installed on your Microsoft Windows computer, the default compiler is the lcc C compiler shipped with the MATLAB product. This compiler does not support C++. If you do not configure the code generator to use a C++ compiler before you specify C++ for code generation, the software produces an error message.

Code generator limitations on C++ support include:

- The code generator does not support C++ code generation for the following:
  - Simscape Driveline
  - Simscape Multibody First Generation (Simscape Multibody Second Generation is supported)
  - Simscape Power Systems
  - Simulink Real-Time

- For ERT and ERT-based system target files with Configuration Parameters > Data Placement > Interface > Code interface packaging set to Nonreusable function, the following fields currently do not accept the .cpp extension. If you specify a file name with a .c extension or without an extension and specify C++ for the code generation language, the code generator produces a .cpp file.

  - Configuration Parameters > Code Placement > Data definition filename field (available when Configuration Parameters > Code Placement > Data definition is set to Data defined in a single separate source file)

  - Definition file field for a data object in Model Explorer. Data objects are objects of the class Simulink.Signal, Simulink.Parameter, and subclasses.
Code Generator Assumes Wrap on Signed Integer Overflows

The code generator reduces memory usage and enhances generated code execution by assuming signed integer C operations wrap on overflow. A signed integer overflow occurs when the result of an arithmetic operation is outside the range of values that the output data type can represent. The C programming language does not define the results of such operations. Some C compilers aggressively optimize signed operations for in-range values at the expense of overflow conditions. Other compilers preserve the full wrap-on-overflow behavior. For example, the gcc and MinGW compilers provide an option to wrap on overflow reliably for signed integer overflows. The generated program image for a model can produce results that differ from model simulation results because the handling of overflows varies, depending on your compiler.

When you generate code, if you use a supported compiler with the default options configured by the code generator, the compiler preserves the full wrap-on-overflow behavior. If you change the compiler options or compile the code in another development environment, it is possible that the compiler does not preserve the full wrap-on-overflow behavior. In this case, the executable program can produce unpredictable results.

If this issue is a concern for your application, consider one or more of the following actions:

- Verify that the compiled code produces expected results.
- If your compiler can force wrapping behavior, turn it on. For example, for the gcc compiler or a compiler based on gcc, such as MinGW, configure the build process to use the compiler option -fwrapv.
- Choose a compiler that wraps on integer overflow.
- If you have Embedded Coder installed, develop and apply a custom code replacement library to replace code generated for signed integers. For more information, see “Code Replacement Customization”.

Choose and Configure Compiler

The compiler for your model build appears in the build process parameters in Configuration Parameters > Code Generation. To view the installed compilers and select the default compiler, in the Command Window type:

```plaintext
mex -setup
```
On a Windows computer, you can install supported compilers and select a default compiler.

On a UNIX platform, the default compiler is GNU gcc/g++ for GNU or Xcode for Mac.

Unless the build approach configuration selects a specific compiler, the code generator uses the default compiler for the build process.

Primarily, the specified system target file determines the compiler that the code generator requires:

- If you select a toolchain-based system target file such as grt.tlc (Generic Real-Time Target), ert.tlc (Embedded Coder), or autosar.tlc (Embedded Coder for AUTOSAR), the Build process subpane displays toolchain parameters for configuring the build process. Use the Toolchain parameter to select a compiler and associated tools for your model build. To validate the selected toolchain, click the Validate button for the Configuration Parameters > Code Generation > Build process > Toolchain settings box.

- If you select a template makefile (TMF) based system target file, such as rsim.tlc, the Build process subpane displays template makefile parameters for configuring the build process. The Template makefile parameter displays the default TMF file for the selected system target file. If the system target file supports compiler-specific template makefiles (for example, Rapid Simulation or S-Function system target files), you can set Template makefile to a compiler-specific TMF, such as rsim_lcc.tmf or rsim_unix.tmf. (See “Compare System Target File Support” (Simulink Coder) for valid TMF names.)

Include S-Function Source Code

When the code generator builds models with S-functions, source code for the S-functions can be either in the current folder or in the same folder as their MEX-file. The code generator adds an include path to the generated makefiles whenever it finds a file named sfncname.h in the same folder as the S-function MEX-file. This folder must be on the MATLAB path.

Similarly, the code generator adds a rule for the folder when it finds a file sfncname.c (or .cpp) in the same folder as the S-function MEX-file is in.

Compiler Version Mismatch Errors

Description

The build process produces a compiler version mismatch error.

Action

1. Check the list of supported and compatible compilers available at www.mathworks.com/support/compilers/current_release/.
2. Upgrade or change your compiler. For more information, see “Choose and Configure Compiler” on page 43-6.
3. Rebuild the model.

Results for Model Simulation and Program Execution Differ

Description

The program generated for the model produces different results from model simulation results. The generated source code includes an arithmetic operation that produces a signed integer overflow. It is possible that your compiler does not implement wrapping behavior for signed integer overflow conditions. Or, if you are using a compiler that supports wrapping, it is possible that you did not configure it to use the -fwrapv option.

For more information, see “Code Generator Relies on Undefined Behavior of C Language for Integer Overflows.”
**Action**

- If your compiler can force wrapping behavior, turn it on. For example, for the gcc compiler or a compiler based on gcc, such as MinGW, specify the compiler option `-fwrapv`.
- Choose a compiler that checks for integer overflows.
- If you have Embedded Coder, develop and apply a code replacement library to replace code generated for signed integers.

**Generates Expected Code and Produces Unexpected Results**

**Description**

The build process generates expected source code, but the executable program produces unexpected results. The generated source code appears as expected. However, the executable program produces unexpected results.

**Action**

Do one of the following:

- Lower the compiler optimization level.

  1. Select **Custom** for the Model Configuration parameter **Code Generation > Compiler optimization level**.
  2. In the **Custom compiler optimization flags** field, specify a lower optimization level.
  3. Rebuild the model.

- Disable compiler optimizations.

  1. Select **Optimizations off (faster builds)** for the Model Configuration parameter **Code Generation > Compiler optimization level**.
  2. Rebuild the model.

For more information, see “Control Compiler Optimizations” (Simulink Coder) and your compiler documentation.
## Compile-Time Issues

<table>
<thead>
<tr>
<th>Issue</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Error is present in the compiler configuration.</td>
<td>Make sure that MATLAB supports the compiler and version that you want to use. For a list of currently supported and compatible compilers, see <a href="http://www.mathworks.com/support/compilers/current_release/">www.mathworks.com/support/compilers/current_release/</a>. If necessary, upgrade or change your compiler (see “Choose and Configure Compiler” on page 43-6 or “Choose and Configure Compiler” on page 43-6).</td>
</tr>
<tr>
<td>Environment variables are incorrectly set up for your make utility, compiler, or linker. For example, installation of Cygwin tools on a Windows platform affects environment variables used by other compilers.</td>
<td>Review the environment variable settings for your system by using the <code>set</code> command on a Windows platform or <code>setenv</code> on a UNIX platform. Make sure that the settings match what is required for the tools you are using.</td>
</tr>
<tr>
<td>Error is present in custom code specified as an S-function block or in <strong>Configuration Parameters &gt; Code Generation &gt; Custom Code</strong>. For example, the code refers to a header file that the compiler cannot find.</td>
<td>To isolate the source of the problem, remove the custom code from the model, debug, and rebuild the model.</td>
</tr>
<tr>
<td>The model includes a block, such as a device driver block, which is not intended for use with the currently selected system target file.</td>
<td>Remove the system target file-specific block or configure the model for use with another system target file.</td>
</tr>
</tbody>
</table>
A linker error about an undefined reference to the data appears when the model build generates an executable from the model reference hierarchy and all these conditions are true:

- You represent signal, state, or parameter data by creating a data object such as Simulink.Signal. You use the object in a model reference hierarchy.
- You use a custom storage class with the data object. Custom storage classes require Embedded Coder.
- You set the owner of the object to a model that does not directly access the data.
- You use the toolchain lcc-win64.

To resolve the issue, choose one of these methods:

- In the data object, clear the Owner property. Alternatively, set the owner to a model that directly accesses the data.
- Use a different toolchain, such as gcc, instead of lcc.

### LCC Compiler Does Not Support Ampersands in Source Folder Paths

**Description**

If you use the LCC compiler and your model folder path contains an ampersand (&), the build process produces an error.

**Action**

Remove the ampersand from the model folder path. Then, rebuild the model.
LCC Compiler Might Not Support Line Lengths of Rapid Accelerator Code

Description

If you are compiling Rapid Accelerator code, the LCC compiler might produce an error related to line limits. Rapid Accelerator code can have longer line lengths due to obfuscation.

Action

Compile your Rapid Accelerator code using a compiler that supports longer code lines.

Choose Build Approach and Configure Build Process

The code generator supports these approaches for building (compiling and linking) code that you generate from Simulink models:

- **Toolchain** — A build process that generates optimized makefiles and supports custom toolchains. This approach:
  - Provides control of your build process with toolchain information objects. You can define these objects using MATLAB scripts.
  - Supports model referencing, SIL, PIL, and Rapid Accelerator builds.
  - Supports Simulink Coder, Embedded Coder, and MATLAB Coder.

- **Template makefile** — A build process that uses a template makefile with a toolchain that you specify. This approach:
  - Supports model referencing, SIL, and PIL.
  - Supports Simulink Coder and Embedded Coder.

The “System target file” (Simulink Coder) parameter, located in the **Configuration Parameters > Code Generation** pane, lets you select the build process for a model. When you set the **System target file** to:

- ert.tlc, ert_shrlib.tlc, grt.tlc, or any toolchain-compliant system target file, the build process uses the toolchain approach on page 43-14 by default.
- Any non-toolchain-compliant system target file, the build process uses the template makefile approach on page 43-20.

You can switch from the toolchain approach to the template makefile approach with this command:

```
set_param(model, 'MakeCommand', 'make_rtw TMF=1')
```

**Toolchain Approach**

**Toolchain settings** appear under **Build process** when you set **System target file** to:

- grt.tlc — Generic Real-Time Target
- ert.tlc — Embedded Coder (requires the Embedded Coder product)
• **ert_shrlib.tlc** — Embedded Coder (host-based shared library target) (requires Embedded Coder)

• Any toolchain-compliant system target file (If ERT-based, requires Embedded Coder)

For more information about toolchain-compliant system target files, see “Support Toolchain Approach with Custom Target” (Simulink Coder).

The **Toolchain settings** include:

• The “Toolchain” (Simulink Coder) parameter specifies the collection of third-party software tools that builds the generated code. A toolchain can include a compiler,
linker, archiver, and other prebuild or postbuild tools that download and run the executable on the target hardware.

The default value of **Toolchain** is *Automatically locate an installed toolchain*. The **Toolchain** parameter displays name of the located toolchain just below *Automatically locate an installed toolchain*.

Click the **Validate** button for the **Configuration Parameters > Code Generation > Build process > Toolchain settings** parameter to check that the toolchain is present and validate that the code generator has the information required to use the toolchain. The resulting Validation Report gives a pass/fail for the selected toolchain, and identifies issues to resolve.

- The “Build configuration” (Simulink Coder) parameter lets you choose or customize the optimization settings. By default, **Build Configuration** is set to *Faster Builds*. You can also select *Faster Runs*, *Debug*, and *Specify*. When you select *Specify* and click **Apply**, you can customize the toolchain options for each toolchain. These custom toolchain settings only apply to the current model.

**Note** The following system target files, which use the template makefile approach, have the same names but different descriptions from system target files that use the toolchain approach:

- ert.tlc — Create Visual C/C++ Solution File for Embedded Coder
- grt.tlc — Create Visual C/C++ Solution File for Simulink Coder

To avoid confusion, click **Browse** to select the system target file and look at the description of each file.

### Upgrade Model to Use Toolchain Approach

When you open a model created before R2013b that uses the following system target files, the software tries to upgrade the model. The upgrade changes the configuration from using template makefile settings to using the toolchain settings:

- ert.tlc — Embedded Coder
- ert_shrlib.tlc — Embedded Coder (host-based shared library target)
- grt.tlc — Generic Real-Time Target
Note To upgrade models using a custom system target file to use the toolchain approach, see “Support Toolchain Approach with Custom Target” on page 74-82.

Some model configuration parameter values prevent the software from upgrading a model to use toolchain settings. The following instructions show you ways to complete the upgrade process.

Consider upgrading your models and use the toolchain build approach. Doing so is not required. You can continue generating code from a model that has not been upgraded.

Note The software does not upgrade models that use the following system target files:
- ert.tlc — Create Visual C/C++ Solution File for Embedded Coder
- grt.tlc — Create Visual C/C++ Solution File for Simulink Coder

To see if a model was upgraded:

1 Open the model configuration parameters by pressing Ctrl+E.
2 Select Configuration Parameters > Code Generation.
3 If the Build process subpane contains the Toolchain and Build configuration parameters, the model has already been upgraded.
If the Build process area displays Makefile configuration parameters, such as Generate makefile, Make command, and Template makefile, the software has not upgraded the model.

Start by creating a working copy of the model using File > Save As. This action preserves the original model and configuration parameters for reference.

Try to upgrade the model using Upgrade Advisor:

1. In your model, select Analysis > Model Advisor > Upgrade Advisor.
2. In Upgrade Advisor, select Check and update model to use toolchain approach to build generated code and click Run This Check.
3 Perform the suggested actions and/or click **Update Model**.

When you cannot upgrade the model using Upgrade Advisor, one or more of the following parameters is not set to its default value, shown here:

- **Compiler optimization level** — Optimizations off (faster builds)
- **Generate makefile** — Enabled
- **Template makefile** — System target file-specific template makefile
- **Make command** — make_rtw without arguments

Sometimes, a model cannot be upgraded. Try the following procedure:

- If **Generate makefile** is disabled, this case cannot be upgradable. However, you can try enabling it and try upgrading the model using Upgrade Advisor.
- If **Compiler optimization level** is set to Optimizations on (faster runs):
  1. Set **Compiler optimization level** is to Optimizations off (faster builds).
  2. Upgrade the model using Upgrade Advisor.
  3. Set **Build configuration** to Faster Runs.
- If **Compiler optimization level** is set to Custom:
  1. Copy the **Custom compiler optimization flags** to a text file.
  2. Set **Compiler optimization level** to Optimizations off (faster builds).
  3. Upgrade the model using Upgrade Advisor.
  4. Set **Build configuration** to Specify.
  5. To perform the same optimizations, edit the compiler options.
- If **Template makefile** uses a customized template makefile, this case cannot be upgradable. However, you can try the following:
  1. Update **Template makefile** to use the default makefile for the system target file.

**Note** To get the default makefile name, change the **System target file**, click **Apply**, change it back, and click **Apply** again.

2 Upgrade the model using Upgrade Advisor.
3 If the template makefile contains build tool options, such as compiler optimization flags, set **Build configuration** to Specify and update the options.
4 If the template makefile uses custom build tools, create and register a custom toolchain, as described in “Custom Toolchain Registration” (MATLAB Coder). Then, set the **Toolchain** parameter to use the custom toolchain.

**Note** After registering the custom toolchain, update **Toolchain** to use the custom toolchain.

5 If the template makefile contains custom rules and logic, these customizations cannot be applied to the upgraded model.

**Template Makefile Approach**

When the **System target file** is set to a **tlc** file that uses the template makefile approach, the software displays **Compiler optimization level**, **Generate makefile**, **Make command**, and **Template makefile** parameters.
Specify Whether to Generate a Makefile

The **Generate makefile** option specifies whether the build process is to generate a makefile for a model. By default, the build process generates a makefile. Suppress generation of a makefile, for example in support of custom build processing that is not based on makefiles, by clearing **Generate makefile**. When you clear this parameter:

- The **Make command** and **Template makefile** options are unavailable.
- Set up post code generation build processing using a user-defined command, as explained in “Customize Post-Code-Generation Build Processing” (Simulink Coder).
Specify a Make Command

Each template makefile-based system target file has an associated `make` command. The code generator uses this internal MATLAB command to control the build process. The command appears in the Make command field and runs when you start a build.

Most system target files use the default command, `make_rtw`. Third-party system target files could supply another `make` command. See the documentation from the vendor.

In addition to the name of the `make` command, you can supply makefile options in the Make command field. These options could include compiler-specific options, include paths, and other parameters. When the build process invokes the `make` utility, these options are passed on the `make` command line, which adds them to the overall flags passed to the compiler:

“Template Makefiles and Make Options” on page 43-26 lists the Make command options you can use with each supported compiler.

Specify the Template Makefile

The Template makefile field has these functions:

- If you selected a system target file with the System Target File Browser, this field displays the name of a MATLAB language file that selects a template makefile for your development environment. For example, in “Model Configuration Parameters: Code Generation” (Simulink Coder), the Template makefile field displays `grt_default_tmf`, indicating that the build process invokes `grt_default_tmf.m`.

“Template Makefiles and Make Options” on page 43-26 gives a detailed description of the logic by which the build process selects a template makefile.

- Alternatively, you can explicitly enter the name of a specific template makefile (including the extension) or a MATLAB language file that returns a template makefile in this field. Use this approach if you are using a system target file that does not appear in the System Target File Browser. For example, use this approach if you have written your own template makefile for a custom system target file.

If you specify your own template makefile, be sure to include the file name extension. If you omit the extension, the build process attempts to find and execute a file with the extension `.m` (that is, a MATLAB language file). The template make file (or a MATLAB language file that returns a template make file) must be on the MATLAB path. To determine whether the file is on the MATLAB path, enter the following command in the MATLAB Command Window:
Associate the Template Makefile with a Toolchain

Specify a toolchain for the template makefile build process. This example provides a definition for a minimal toolchain and shows how you can associate the toolchain with a template makefile that is a copy of ert_unix.tmf or ert_vcx64.tmf.

Use this code for the toolchain definition file.

```matlab
function tc = minimalToolchainForTMF
    % Create a toolchain object
    tc = coder.make.ToolchainInfo('Name', 'Minimal Toolchain for TMF Build');

    % Specify that the linker requires a response file instead of
    % including all object file modules on the linker command line
    tc.addAttribute('RequiresCommandFile', true);

    if ispc
        objExt = '.obj';
    else
        objExt = '.o';
    end

    % Specify source file and object file extension used by the C compiler
    tool = tc.getBuildTool('C Compiler');
    tool.setFileExtension(  'Source', '.c');
    tool.setFileExtension(  'Header', '.h');
    tool.setFileExtension(  'Object',   objExt);

    % Specify source file and object file extension used by the C++ compiler
    tool = tc.getBuildTool('C++ Compiler');
    tool.setFileExtension(  'Source', '.cpp');
    tool.setFileExtension(  'Header', '.hpp');
    tool.setFileExtension(  'Object',   objExt);

    % Specify source file and object file extension used by the C compiler
    tool = tc.getBuildTool('C Compiler');
    tool.setFileExtension(  'Source', '.c');
    tool.setFileExtension(  'Header', '.h');
    tool.setFileExtension(  'Object',   objExt);

    % Specify source file and object file extension used by the C++ compiler
    tool = tc.getBuildTool('C++ Compiler');
    tool.setFileExtension(  'Source', '.cpp');
    tool.setFileExtension(  'Header', '.hpp');
    tool.setFileExtension(  'Object',   objExt);

    % Specify source file and object file extension used by the C compiler
    tool = tc.getBuildTool('C Compiler');
    tool.setFileExtension(  'Source', '.c');
    tool.setFileExtension(  'Header', '.h');
    tool.setFileExtension(  'Object',   objExt);

    % Specify source file and object file extension used by the C++ compiler
    tool = tc.getBuildTool('C++ Compiler');
    tool.setFileExtension(  'Source', '.cpp');
    tool.setFileExtension(  'Header', '.hpp');
    tool.setFileExtension(  'Object',   objExt);

    use a copy of ert_unix.tmf or ert_vcx64.tmf as the template makefile.
    copyfile(fullfile(matlabroot,'rtw','c','ert','ert_vcx64.tmf'), 'ert_copy.tmf')
    In the template makefile, i.e. ert_copy.tmf, edit the TOOLCHAIN_NAME macro.
    TOOLCHAIN_NAME = "Minimal Toolchain for TMF Build"

    Associate the toolchain with the template make file.
Run the toolchain definition file, which generates a ToolchainInfo object, `tc`.

```matlab
tc = minimalToolchainForTMF;
```

Save the ToolchainInfo object to a MAT file.

```matlab
save('tcMinimal','tc')
```

Register the toolchain in RTW.TargetRegistry.

- Place this code in an `rtwTargetInfo.m` file.

```matlab
function rtwTargetInfo(tr)
    tr.registerTargetInfo(@loc_createToolchain);
end

function config = loc_createToolchain
    config(1) = coder.make.ToolchainInfoRegistry;
    config(1).Name = 'Minimal Toolchain for TMF Build';
    config(1).FileName = fullfile(fileparts(mfilename('fullpath')),...
    'tcMinimal.mat');
    config(1).TargetHWDeviceType = {'*'};
    config(1).Platform = {computer('arch')};
end
```

- Save the file in the current working folder or in a folder that is on the MATLAB search path.

- Reset the TargetRegistry.

```matlab
RTW.TargetRegistry.getInstance('reset');
```

Associate the template makefile with your model and build the model.

```matlab
set_param(model, 'TemplateMakefile', 'ert_copy.tmf');
rtwbuild(model);
```

**Specify TLC for Code Generation**

Target Language Compiler (TLC) is an integral part of the code generator. It enables you to customize generated code. Through customization, you can produce platform-specific code, or you can incorporate your own algorithmic changes for performance, code size, or compatibility with existing methods that you prefer to maintain. For additional information, see “Target Language Compiler Overview” (Simulink Coder).
TLC options that you specify for code generation appear in the summary section of the generated HTML code generation report.

**Note** Specifying TLC command-line options does not add flags to the make command line.

You can specify Target Language Compiler (TLC) command-line options and arguments for code generation using the model parameter `TLCOptions` in a `set_param` function call. For example,

```matlab
>> set_param(gcs,'TLCOptions','-p0 -aWarnNonSaturatedBlocks=0')
```

Some common uses of TLC options include the following:

- `-aVarName=1` to declare a TLC variable and/or assign a value to it
- `-IC:\Work` to specify an include path
- `-v` to obtain verbose output from TLC processing (for example, when debugging)

- “Executable Program Generation” on page 43-69
Template Makefiles and Make Options

The code generator includes a set of built-in template makefiles that build programs for specific system target files.

In this section...

“Types of Template Makefiles” on page 43-26
“Specify Template Makefile Options” on page 43-27
“Template Makefiles for UNIX Platforms” on page 43-27
“Template Makefiles for the Microsoft Visual C++ Compiler” on page 43-28
“Template Makefiles for the LCC Compiler” on page 43-30

Types of Template Makefiles

There are two types of template makefiles:

- **Compiler-specific** template makefiles are for a particular compiler or development system.

  By convention, compiler-specific template makefiles names correspond to the system target file and compiler (or development system). For example, `grt_vcx64.tmf` is the template makefile for building a generic real-time program under the Visual C++ compiler; `ert_lcc.tmf` is the template makefile for building an Embedded Coder program under the lcc compiler.

- **Default** template makefiles make your model designs more portable, by choosing the compiler-specific makefile and compiler for your installation. “Select and Configure C or C++ Compiler or IDE” on page 43-3 describes the operation of default template makefiles in detail.

  Default template makefiles have names that follow the pattern `target_default_tmf`. They are MATLAB language files that, when run, select the TMF for the specified system target file configuration. For example, `grt_default_tmf` is the default template makefile for building a generic real-time program; `ert_default_tmf` is the default template makefile for building an Embedded Coder program.
For details on the structure of template makefiles, see “Customize Template Makefiles” on page 74-62. This section describes compiler-specific template makefiles and common options you can use with each.

**Specify Template Makefile Options**

You can specify template makefile options by using the **Make command** box in **Configuration Parameters > Code Generation**. Append the options after `make_rtw` (or other `make` command), as in the following example:

```
make_rtw OPTS="-DMYDEFINE=1"
```

The syntax for `make` command options differs slightly for different compilers.

**Note** To control compiler optimizations for a makefile build at the Simulink GUI level, use the **Configuration Parameters > Code Generation > Build process > Compiler optimization level** parameter. The **Compiler optimization level** parameter provides

- System target file-independent values *Optimizations on* (faster runs) and *Optimizations off* (faster builds), which easily allow you to toggle compiler optimizations on and off during code development
- The value *Custom* for entering custom compiler optimization flags at Simulink GUI level (rather than at other levels of the build process)

If you specify compiler options for your makefile build using **OPT_OPTS**, **MEX_OPTS** (except **MEX_OPTS="-v"**), or **MEX_OPT_FILE**, the value of **Compiler optimization level** is ignored and a warning is issued about the ignored parameter.

**Template Makefiles for UNIX Platforms**

The template makefiles for UNIX platforms are for the Free Software Foundation's GNU Make. These makefiles conform to the guidelines specified in the IEEE® Std 1003.2-1992 (POSIX) standard.

- ert_unix.tmf
- grt_unix.tmf

---

8. IEEE is a registered trademark of The Institute of Electrical and Electronics Engineers, Inc.
You can supply options to makefiles using the **Make command** box in the **Configuration Parameters > Code Generation** pane. Options specified in **Make command** are passed to the command-line invocation of the `make` utility, which adds them to the overall flags passed to the compiler. The following options can be used to modify the behavior of the build:

- **OPTS** — User-specific options, for example,
  
  \[\text{OPTS} = "-DMYDEFINE=1"\]

- **OPT_OPTS** — Optimization options. Default is `-O`. To enable debugging, specify the option as `OPT_OPTS=-g`. Because of optimization problems in IBM_RS, the default is no optimization.

- **CPP_OPTS** — C++ compiler options.

- **USER_SRCS** — Additional user sources, such as files used by S-functions.

- **USER_INCLUDES** — Additional include paths, for example,
  
  \[\text{USER_INCLUDES} = "-Iwhere-ever -Iwhere-ever2"\]

- **DEBUG_BUILD** — Add debug information to generated code, for example,
  
  \[\text{DEBUG_BUILD} = 1\]

These options are also documented in the comments at the head of the respective template makefiles.

**Template Makefiles for the Microsoft Visual C++ Compiler**

- “Visual C++ Executable Build” on page 43-28
- “Visual C++ Code Generation Only” on page 43-29

**Visual C++ Executable Build**

To build an executable using the Visual C++ compiler within the build process, use one of the `target_vcx64.tmf` template makefiles:

- `ert_vcx64.tmf`
- `grt_vcx64.tmf`
• rsim_vcx64.tmf
• rtwsfcn_vcx64.tmf

You can supply options to makefiles using the **Make command** field in the **Configuration Parameters > Code Generation** pane. Options specified in **Make command** are passed to the command-line invocation of the `make` utility, which adds them to the overall flags passed to the compiler. The following options can be used to modify the behavior of the build:

- **OPT_OPTS** — Optimization option. Default is `-O2`. To enable debugging, specify the option as `OPT_OPTS=-Zi`.
- **OPTS** — User-specific options.
- **CPP_OPTS** — C++ compiler options.
- **USER_SRCS** — Additional user sources, such as files used by S-functions.
- **USER_INCLUDES** — Additional include paths, for example,
  
  ```
  USER_INCLUDES="-Iwhere-ever -Iwhere-ever2"
  ```
- **DEBUG_BUILD** — Add debug information to generated code, for example,
  
  ```
  DEBUG_BUILD=1
  ```

These options are also documented in the comments at the head of the respective template makefiles.

**Visual C++ Code Generation Only**

To create a Visual C++ project makefile (*model.mak*) without building an executable, use one of the `target_msvc.tmf` template makefiles:

• `ert_msvc.tmf`
• `grt_msvc.tmf`

These template makefiles are for `nmake`, which is bundled with the Visual C++ compiler.

You can supply options to makefiles using the **Make command** field in the **Configuration Parameters > Code Generation** pane. Options specified in **Make command** are passed to the command-line invocation of the `make` utility, which adds them to the overall flags passed to the compiler. The following options can be used to modify the behavior of the build:
• **OPTS** — User-specific options, for example,

  ```
  OPTS="/D MYDEFINE=1"
  ```

• **USER_SRCS** — Additional user sources, such as files used by S-functions.

• **USER_INCLUDES** — Additional include paths, for example,

  ```
  USER_INCLUDES="-Iwhere-ever -Iwhere-ever2"
  ```

• **DEBUG_BUILD** — Add debug information to generated code, for example,

  ```
  DEBUG_BUILD=1
  ```

These options are also documented in the comments at the head of the respective template makefiles.

### Template Makefiles for the LCC Compiler

The code generator provides template makefiles to create an executable for the Windows platform using Lcc compiler Version 2.4 and GNU Make (`gmake`).

- `ert_lcc.tmf`
- `grt_lcc.tmf`
- `rsim_lcc.tmf`
- `rtwsfcn_lcc.tmf`

You can supply options to makefiles using the **Make command** field in the **Configuration Parameters > Code Generation** pane. Options specified in **Make command** are passed to the command-line invocation of the `make` utility, which adds them to the overall flags passed to the compiler. The following options can be used to modify the behavior of the build:

• **OPTS** — User-specific options, for example,

  ```
  OPTS="/D MYDEFINE=1"
  ```

• **OPT_OPTS** — Optimization options. Default is no options. To enable debugging, specify `-g4`:

  ```
  OPT_OPTS="-g4"
  ```

• **CPP_OPTS** — C++ compiler options.

• **USER_SRCS** — Additional user sources, such as files used by S-functions.
• **USER_INCLUDES** — Additional include paths. For example:

```
USER_INCLUDES="-Iwhere-ever -Iwhere-ever2"
```

For lcc, use / as file separator before the file name instead of \, for example, `d:\work\proj1/myfile.c`.

• **DEBUG_BUILD** — Add debug information to generated code, for example,

```
DEBUG_BUILD=1
```

These options are also documented in the comments at the head of the respective template makefiles.

Build Process Workflow for Real-Time Systems

The building process includes generating code in C or C++ from a model and building an executable program from the generated code. This example can use a generic real-time (GRT) or an embedded real-time (ERT) system target file (STF) for code generation. The resulting standalone program runs on your development computer, independent of external timing and events.

Working Folder

This example uses a local copy of the slexAircraftExample model, stored in its own folder, aircraftexample. Set up your working folder as follows:

1. In the MATLAB Current Folder browser, navigate to a folder to which you have write access.
2. To create the working folder, enter the following MATLAB command:
   ```
   mkdir aircraftexample
   ```
3. Make aircraftexample your working folder:
   ```
   cd aircraftexample
   ```
4. Open the slexAircraftExample model:
   ```
   slexAircraftExample
   ```
   The model appears in the Simulink Editor model window.
5. In the model window, choose File > Save As. Navigate to your working folder, aircraftexample. Save a copy of the slexAircraftExample model as myAircraftExample.

Build Folder and Code Generation Folders

While producing code, the code generator creates a build folder within your working folder. The build folder name is model_target_rtw, derived from the name of the source model and the chosen system target file. The build folder stores generated source code and other files created during the build process. Examine the build folder contents at the end of this example.

When a model contains Model blocks (references to other models), the model build creates special subfolders in your “Code generation folder” (Simulink) to organize code
for the referenced models. These code generation folders exist alongside product build folders and are named `slprj`. “Generate Code for Referenced Models” on page 4-4 describes navigating code generation folder structures in Model Explorer.

Under the `slprj` folder, a subfolder named `_sharedutils` contains generated code that can be shared between models.

**Set Model Parameters for Code Generation**

To generate code from your model, you must change some of the model configuration parameters. In particular, the generic real-time (GRT) system target file and most other system target files require that the model specifies a fixed-step solver.

**Note** The code generator produces code for models, using variable-step solvers, for rapid simulation (`rsim`) and S-function system target files only.

To set model configuration parameters by using the Configuration Parameters dialog box:

1. Open the `myAircraftExample` model if it is not already open.
2. From the model window, open the Configuration Parameters dialog box by selecting **Simulation > Model Configuration Parameters**.
3. Select **Configuration Parameters > Solver**. Enter the following parameter values (some could already be set):
   - **Start time**: 0.0
   - **Stop time**: 60
   - **Type**: Fixed-step
   - **Solver**: ode5 (Dormand-Prince)
   - **Fixed step size (fundamental sample time)**: 0.1
   - **Treat each discrete rate as a separate task**: Off
4. Click **Apply**.
5. Save the model. Simulation parameters persist with the model for use in future sessions.
Configure Build Process

To configure the build process for your model, choose a system target file, a toolchain or template makefile, and a make command.

In these examples and in most applications, you do not need to specify these parameters individually. The examples use the ready-to-run generic real-time target (GRT) configuration. The GRT system target file builds a standalone executable program that runs on your desktop computer.

To select the GRT system target file using the Configuration Parameters dialog box:

1. With the myAircraftExample model open, select Simulation > Model Configuration Parameters to open the Configuration Parameters dialog box.
2. Select Configuration Parameters > Code Generation.
3. For System target file, enter grt.tlc, and click Apply.

The Configuration Parameters > Code Generation pane displays selections for the System target file (grt.tlc), Toolchain (Automatically locate an installed toolchain), and Build Configuration (Faster Builds).
Note If you click Browse, a System Target File Browser opens and displays the system target files on the MATLAB path. Some system target files require additional products. For example, ert.tlc requires Embedded Coder.

4 Save the model.

Set Code Generation Parameters

With the myAircraftExample model open, select Simulation > Model Configuration Parameters:
1. Select **Code Generation > Report > Create code generation report**. This action enables the software to create and display a code generation report for the `myAircraftExample` model.

2. Use the default **Code Generation > Comments** settings.

3. The **Code Generation > Symbols** options control the look and feel of generated code. Use the default settings.

4. These **Code Generation > Advanced parameters** parameters control build verbosity and debugging:
   - **Verbose build** (RTWVerbose parameter)
   - **Retain .rtw file** (RetainRTWFile parameter)
   - **Profile TLC** (ProfileTLC parameter)
   - **Start TLC debugger when generating code** (TLCDebug parameter)
   - **Start TLC coverage when generating code** (TLCCoverage parameter)
   - **Enable TLC assertion** (TLCAssert parameter)

   Use the default settings.

5. Select **Code Generation > Interface**.
   - For the **Shared code placement** parameter, select **Shared location**. The build process places generated code for utilities in a subfolder within your “Code generation folder” (Simulink).
   - Clear the **Advanced parameters > Classic call interface** check box.

6. Click **Apply** and save the model.

**Build and Run a Program**

The build process generates C code from the model. It then compiles and links the generated program to create an executable image. To build and run the program:

1. With the `myAircraftExample` model open, initiate code generation and the build process for the model by using any of the following options:
   - Click the **Build Model** button.
   - Press **Ctrl+B**.
   - Select **Code > C/C++ Code > Build Model**.
• Invoke the `rtwbuild` command from the MATLAB command line.
• Invoke the `slbuild` command from the MATLAB command line.

Some messages concerning code generation and compilation appear in the Command Window. The initial message is:

```text
### Starting build procedure for model: myAircraftExample
```

The contents of many of the succeeding messages depends on your compiler and operating system. The final messages include:

```text
### Created executable myAircraftExample.exe
### Successful completion of build procedure for model: myAircraftExample
### Creating HTML report file myAircraftExample_codegen_rpt.html
```

The code generation folder now contains an executable, `myAircraftExample.exe` (Microsoft Windows platforms) or `myAircraftExample` (UNIX platforms). In addition, the build process has created an `slprj` folder and a `myAircraftExample_grt_rtw` folder in your “Code generation folder” (Simulink).

**Note** After generating the code for the `myAircraftExample` model, the build process displays a code generation report. See “Report Generation” (Simulink Coder) for more information about how to create and use a code generation report.

2 To see the contents of the working folder after the build, enter the `dir` or `ls` command:

```text
>> dir
.
  myAircraftExample.slx  slprj
..  myAircraftExample.slx.autosave
myAircraftExample.exe  myAircraftExample_grt_rtw
```

3 To run the executable from the Command Window, type `!myAircraftExample`.

The `!` character passes the command that follows it to the operating system, which runs the standalone `myAircraftExample` program.

```text
>> !myAircraftExample
** starting the model **
** created myAircraftExample.mat **
```

4 To see the files created in the build folder, use the `dir` or `ls` command again. The exact list of files produced varies among MATLAB platforms and versions. Here is a sample list from a Windows platform:

```text
>> dir myAircraftExample_grt_rtw
```
Contents of the Build Folder

The build process creates a build folder and names it `model_target_rtw`, where `model` is the name of the source model and `target` is the system target file selected for the model. In this example, the build folder is named `myAircraftExample_grt_rtw`.

The build folder includes the following generated files.

<table>
<thead>
<tr>
<th>File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>myAircraftExample.c</code></td>
<td>Standalone C code that implements the model</td>
</tr>
<tr>
<td><code>myAircraftExample.h</code></td>
<td>An include header file containing definitions of parameters and state variables</td>
</tr>
<tr>
<td><code>myAircraftExample_private.h</code></td>
<td>Header file containing common include definitions</td>
</tr>
<tr>
<td><code>myAircraftExample_types.h</code></td>
<td>Forward declarations of data types used in the code</td>
</tr>
<tr>
<td><code>rtmodel.h</code></td>
<td>Master header file for including generated code in the static main program (its name does not change, and it simply includes <code>myAircraftExample.h</code>)</td>
</tr>
</tbody>
</table>

The code generation report that you created for the `myAircraftExample` model displays a link for each of these files. You can click the link to explore the file contents.

The build folder contains other files used in the build process. They include:

- `myAircraftExample.mk` — Makefile for building executable using the specified Toolchain.
- Object (.obj) files
- `myAircraftExample.bat` — Batch control file
• **rtw_proj.tmw** — Marker file
• **buildInfo.mat** — Build information for relocating generated code to another development environment
• **defines.txt** — Preprocessor definitions required for compiling the generated code
• **myAircraftExample_ref.rsp** — Data to include as command-line arguments to `mex` (Windows systems only)

The build folder also contains a subfolder, `html`, which contains the files that make up the code generation report. For more information, see “Reports for Code Generation” (Simulink Coder).

### Customized Makefile Generation

After producing code, the code generator produces a customized makefile, `model.mk`. The generated makefile instructs the `make` system utility to compile and link source code generated from the model, any required harness program, libraries, or user-provided modules. The code generator produces the file `model.mk` regardless of the approach that you use for build process control:

- **If you use the toolchain approach**, the code generator creates `model.mk` based on the model **Toolchain settings**. You can modify generation of the makefile through the `rtwmakecfg.m` API.
- **If you use the template makefile approach**, the code generator creates `model.mk` from a system template file, `system.tmf` (where `system` stands for the selected system target file name). The system template makefile is designed for your system target file. You can modify the template makefile to specify compilers, compiler options, and additional information for the creation of the executable.

For more information, see “Choose Build Approach and Configure Build Process” on page 43-14.

Rebuild a Model

If you update generated source code or makefiles manually to add customizations, you can rebuild the files with the `rtwrebuild` command. This command recompiles the modified files by invoking the generated makefile. Alternatively, you can use this command from the Model Explorer:

1. Open the top model. To open the Model Explorer window, select View > Model Explorer.
2. In the Model Hierarchy pane, expand the node for the model.
3. Click the Code for model node.
4. In the Code pane, next to Code Recompile Command, click rebuild generated code.

More About

- rtwrebuild
- “Build Process Workflow for Real-Time Systems” (Simulink Coder)
**Control Regeneration of Top Model Code**

When you rebuild a model, by default, the build process performs checks to determine whether changes to the model or relevant settings require regeneration of the top model code. The model build regenerates top model code if any of the following conditions is true:

- The structural checksum of the model has changed.
- The top-model-only checksum has changed. The top-model-only checksum provides information about top model parameters, such as application lifespan, maximum stack size, make command, verbose and `.rtw` file debug settings, and TLCOptions.
- Any of the following TLC debugging model options, on the Configuration Parameters > Code Generation > Advanced parameters tab, is on:
  - **Start TLC debugger when generating code** (TLCDdebug)
  - **Start TLC coverage when generating code** (TLCCoverage)
  - **Enable TLC assertion** (TLCAssert)
  - **Profile TLC** (ProfileTLC)

Whether the top model code is regenerated, the build process calls the build process hooks and reruns the makefile. The hooks include the `STF_make_rtw_hook` functions and the post code generation command. This process recompiles and links the external dependencies.

System target file authors can perform actions related to code regeneration in the `STF_make_rtw_hook` functions that the build process calls. These actions include forcing or reacting to code regeneration. For more information, see “Control Code Regeneration Using STF_make_rtw_hook.m” on page 73-34.

**Regeneration of Top Model Code**

If the checks determine that top model code generation is required, the build process fully regenerates and compiles the model code. An example check is whether previously generated code is not current due to a model update.

The build process omits regeneration of the top model code when the checks indicate both:
• The top model generated code is current for the model.
• No model settings require full regeneration,

This omission can significantly reduce model build times.

With an Embedded Coder license, if you modify a code generation template (CGT) file then rebuild your model, the code generation process does not force a top model build. In this case, see “Force Regeneration of Top Model Code” on page 43-44.

**Force Regeneration of Top Model Code**

If you want to control or override the default top model build behavior, use one of the following command-line options:

• To ignore the checksum and force regeneration of the top model code:
  - `rtwbuild(model,'ForceTopModelBuild',true)`
  - `slbuild(model,'StandaloneRTWTTarget','ForceTopModelBuild',true)`

• To clean the model build area enough to trigger regeneration of the top model code at the next build (slbuild only):
  - `slbuild(model,'CleanTopModel')`

You can force regeneration of the top model code by deleting the slprj folder or the generated model code folder from the “Code generation folder” (Simulink).

Reduce Build Time for Referenced Models

In a parallel computing environment, you can increase the speed of code generation and compilation for models containing large model reference hierarchies. Achieve the speed by building referenced models in parallel whenever conditions allow. For example, if you have Parallel Computing Toolbox software, code generation and compilation for each referenced model can be distributed across the cores of a multicore host computer. If you also have MATLAB Distributed Computing Server™ software, you can distribute code generation and compilation for each referenced model across remote workers in your MATLAB Distributed Computing Server configuration.

In this section...

“Parallel Building for Large Model Reference Hierarchies” on page 43-45
“Parallel Building Configuration Requirements” on page 43-46
“Build Models in a Parallel Computing Environment” on page 43-46

“View Build Process Status” on page 43-50
“Apply Build Process Status to Improve Parallel Builds” on page 43-51

Parallel Building for Large Model Reference Hierarchies

The performance gain realized by using parallel builds for referenced models depends on several factors. These factors include how many models can be built in parallel for a given model referencing hierarchy, the size of the referenced models, and parallel computing resources. The resources include the number of local and/or remote workers available and the hardware attributes of the local and remote machines. Examples of hardware attributes are the amount of RAM and number of cores.

For configuration requirements that could apply to your parallel computing environment, see “Parallel Building Configuration Requirements” on page 43-46.

For a description of the general workflow for building referenced models in parallel whenever conditions allow, see “Build Models in a Parallel Computing Environment” on page 43-46.

For information on how to configure a custom embedded system target file to support parallel builds, see “Support Model Referencing” (Simulink Coder).
**Note** In a MATLAB Distributed Computing Server parallel computing configuration, parallel building is designed to work interactively with the software. You can initiate builds from the Simulink user interface or from the MATLAB Command Window using commands such as `slbuild`. You cannot initiate builds using `batch` or other batch mode workflows.

**Parallel Building Configuration Requirements**

The following requirements apply to configuring your parallel computing environment for building model reference hierarchies in parallel whenever conditions allow:

- For local pools, the host machine must have enough RAM to support the number of local workers (MATLAB sessions) that you plan to use. For example, using `parpool(4)` to create a parallel pool with four workers results in five MATLAB sessions on your machine. Each pool uses the amount of memory required for MATLAB and the code generator at startup. For memory requirements, see System Requirements for MATLAB & Simulink.
- Remote MATLAB Distributed Computing Server workers participating in a parallel build and the client machine must use a common platform and compiler.
- A consistent MATLAB environment must be set up in each MATLAB worker session as in the MATLAB client session — for example, shared base workspace variables, MATLAB path settings, and so forth. One approach is to use the `PreLoadFcn` callback of the top model. If you configure your model to load the top model with each MATLAB worker session, its preload function can be used for any MATLAB worker session setup.

**Build Models in a Parallel Computing Environment**

To take advantage of parallel building for a model reference hierarchy:

1. Set up a pool of local and/or remote MATLAB workers in your parallel computing environment.
   - Make sure that Parallel Computing Toolbox software is licensed and installed.
   - To use remote workers, make sure that MATLAB Distributed Computing Server software is licensed and installed.
   - Issue MATLAB commands to set up the parallel pool, for example, `parpool(4)`.
2. From the top model of the model reference hierarchy, open the Configuration Parameters dialog box. Go to the **Model Referencing** pane and select the **Enable**
**parallel model reference builds** (Simulink) option. This selection enables the parameter **MATLAB worker initialization for builds** (Simulink).

For **MATLAB worker initialization for builds**, select one of the following values:

- **None** if it is preferable that the software does not perform special worker initialization. Specify this value if the child models in the model reference hierarchy do not rely on anything in the base workspace beyond what they explicitly set up. An example is a model load function.

- **Copy base workspace** if it is preferable that the software attempts to copy the base workspace to each worker. Specify this value if you use a setup script to prepare the base workspace for multiple models to use.
• **Load top model** if it is preferable that the software loads the top model on each worker. Specify this value if the top model in the model reference hierarchy handles the base workspace setup. An example is a model load function.

**Note** Only set **Enable parallel model reference builds** for the top model of the model reference hierarchy to which it applies.

3 Optionally, turn on verbose messages for simulation builds, code generation builds, or both. If you select verbose builds, the build messages report the progress of each parallel build with the name of the model.

• To turn on verbose messages in model builds for simulation, go to **Configuration Parameters > Optimization > Advanced parameters** and select **Verbose accelerator builds**.

• To turn on verbose messages in model builds for code generation, go to **Configuration Parameters > Code Generation > Advanced parameters** and select **Verbose build**.

Verbose options control the build messages in the MATLAB Command Window and in parallel build log files.

4 Optionally, inspect the model reference hierarchy to determine, based on model dependencies, which models are built in parallel. For example, you can use the Model Dependency Viewer from the Simulink **Analysis > Model Dependencies** menu.

5 Build your model. Messages in the MATLAB Command Window record when each parallel or serial build starts and finishes. The order in which referenced models build is nondeterministic. They could build in a different order each time the model is built.

If you need more information about a parallel build, for example, if a build fails, see “Locate Parallel Build Logs” on page 43-48.

**Locate Parallel Build Logs**

If verbose builds are turned on when you build a model for which referenced models are built in parallel, messages in the MATLAB Command Window record when each parallel or serial build starts and finishes. For example,

```markdown
### Initializing parallel workers for parallel model reference build.
### Parallel worker initialization complete.
### Starting parallel model reference SIM build for 'bot_model001'
### Starting parallel model reference SIM build for 'bot_model002'
```
To obtain more detailed information about a parallel build, you can examine the parallel build log. For each referenced model built in parallel, the build process generates a file named `model_buildlog.txt`, where `model` is the name of the referenced model. This file contains the full build log for that model.

If a parallel build completes, you can find the build log file in the build subfolder corresponding to the referenced model. For example, for a build of referenced model `bot_model004`, look for the build log file `bot_model004_buildlog.txt` in a referenced model subfolder such as `build_folder/slprj/grt/bot_model004`, `build_folder/slprj/ert/bot_model004`, or `build_folder/slprj/sim/bot_model004`. The build log (diagnostic viewer) provides a relative path to the location of each build log file.

If a parallel build fails, you can find the build log file in a referenced model subfolder under the build subfolder `/par_mdl_ref/model`. For example, for a failed parallel build of model `bot_model001`, look for the build log file `bot_model001_buildlog.txt` in a
subfolder such as `build_folder/par_mdl_ref/bot_model001/slprj/grt/bot_model001`, `build_folder/par_mdl_ref/bot_model001/slprj/ert/bot_model001`, or `build_folder/par_mdl_ref/bot_model001/slprj/sim/bot_model001`.

**View Build Process Status**

The **Build Process Status** window lets you view in-progress build status or cancel in-progress parallel builds of models. After completing a model build, you can view the completion status by using the **Build Process Status** window. For more information, see “Apply Build Process Status to Improve Parallel Builds” on page 43-51.

**Note** The **Build Process Status** window support parallel builds of referenced model hierarchies. Do not use the **Build Process Status** window for sequential (non-parallel) builds.

To open the **Build Process Status** window, use any of these options:

- To open the **Build Process Status** window for a *model*, in the command window, type:

  ```
  coder.buildstatus.open('model')
  ```

- To open the **Build Process Status** window for a *model* with the `rtwbuild` function, in the command window, type:

  ```
  rtwbuild('model', ...) 
  'OpenBuildStatusAutomatically',true)
  ```

- To open the **Build Process Status** window for a *model* with the `slbuild` function, in the command window, type:

  ```
  slbuild('model','StandaloneRTWTarget', ...) 
  'OpenBuildStatusAutomatically',true)
  ```

To cancel an in-progress model build, the **Build Process Status** window provides a **Cancel** button. This button cancels the build after completion of the current model or referenced model build. Using cancel to stop a build ends a build process without creating out-dated build artifacts that require post-build clean up.
Apply Build Process Status to Improve Parallel Builds

The **Build Process Status** window lets you view in-progress build status or cancel in-progress parallel builds of models. For more information, see “View Build Process Status” on page 43-50.

This example shows how apply build process status from parallel builds. The status information can help you identify ways to improve parallel builds by modifying the referenced model hierarchy.

1. Open a parallel pool for the build process.
   
   ```
   parpool('local', 2)
   ```

2. Open the top-level model in a reference model hierarchy. The `a_1` model refers to a number of referenced models.
   
   ```
   open_system('a_1')
   ```
3 View the model dependencies with Analysis > Model Dependencies > Model Dependency Viewer > Models Only. This view displays the dependencies for the referenced model hierarchy.

During the build process, the Build Process Status window displays the progress of the code generator as it works its way up the referenced model hierarchy. The code generator builds the referenced models in the order that they block building of models further up the dependency tree.

4 Start a parallel build of the referenced model hierarchy and open the Build Process Status window.

    rtwbuild('a_1','OpenBuildStatusAutomatically',true)

5 As the build progresses, the Build Process Status window displays the status for each referenced model.
The table describes the types of build status.

<table>
<thead>
<tr>
<th>Build Process Status</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Blocked</td>
<td>The code generator cannot schedule the model build because the build is blocked by dependencies. For example, another model build must complete before the blocked build can be scheduled.</td>
</tr>
<tr>
<td>Scheduled</td>
<td>For parallel build processes, the code generator schedules the model build when it is not blocked by dependencies. The model build waits at the scheduled status until a parallel core is available to process the model build.</td>
</tr>
<tr>
<td>Building</td>
<td>The code generator is executing the build process for the model.</td>
</tr>
<tr>
<td>Completed or Error</td>
<td>When the build process exits successfully, the status is Completed. When the build process is not success, the status is Error.</td>
</tr>
<tr>
<td>Up To Date</td>
<td>When the build process detects that no code generation is needed (for example, generated code is current with the model), the status is Up to Date.</td>
</tr>
</tbody>
</table>
**Build Process Status** | **Description**
--- | ---
**Canceling or Canceled** | When you use the **Cancel Build** button, the build process changes the status of all incomplete builds (for example, all except Completed or Error status) to Canceling. After processing the Canceling operation, the build process changes the status of these builds to Canceled.

The elapse time shows you where the build process spends time. Use the dependency tree of the model hierarchy and the elapse time of reference model builds to identify locations where the build process spends the most time and restricts the build progress. Some options for reducing the parallel build time include:

- Restructure the referenced model hierarchy to reduce build time for individual models.
- Provide sufficient parallel workers in the pool to match the number of referenced model dependencies being built.

Relocate Code to Another Development Environment

If you require relocating the static and generated code files for a model to another development environment, use the pack-and-go utility. This condition occurs when your system or integrated development environment (IDE) does not include MATLAB and Simulink products.

In this section...

| “Code Relocation” on page 43-56 |
| “Package Code Using the User Interface” on page 43-56 |
| “Package Code Using the Command-Line Interface” on page 43-58 |
| “Build Integrated Code Outside the Simulink Environment” on page 43-61 |
| “packNGo Function Limitations” on page 43-67 |

Code Relocation

The pack-n-go utility uses the tools for customizing the build process after code generation and a packNGo function to find and package files for building an executable image. The files are packaged in a compressed file that you can relocate and unpack using a standard zip utility.

To package model code files, you can do either of the following:

- Use the model option **Package code and artifacts** (Simulink Coder) in the **Configuration Parameters > Code Generation** pane. See “Package Code Using the User Interface” on page 43-56.
- Use MATLAB commands to configure a **PostCodeGenCommand** parameter with a call to the packNGo function. See “Package Code Using the Command-Line Interface” on page 43-58. The command-line interface provides more control over the details of code packaging.

Package Code Using the User Interface

To package and relocate code for your model using the user interface:

1. Open **Configuration Parameters > Code Generation**.
2 Select the option **Package code and artifacts** (Simulink Coder). This option configures the build process to run the `packNGo` function after code generation to package generated code and artifacts for relocation.

3 In the **Zip file name** (Simulink Coder) field, enter the name of the zip file in which to package generated code and artifacts for relocation. You can specify the file name with or without the `.zip` extension. If you specify no extension or an extension other than `.zip`, the `zip` utility adds the `.zip` extension. If you do not specify a value, the build process uses the name `model.zip`, where `model` is the name of the top model for which code is being generated.
4 Apply changes and generate code for your model. To verify that it is ready for relocation, inspect the resulting zip file. Depending on the zip tool that you use, you could be able to open and inspect the file without unpacking it.

5 Relocate the zip file to the destination development environment and unpack the file.

**Package Code Using the Command-Line Interface**

To package and relocate code for your model using the command-line interface:

1 Select a structure for the zip file. on page 43-58
2 Select a name for the zip file. on page 43-59
3 Package the model code files in the zip file. on page 43-59
4 Inspect the generated zip file. on page 43-60
5 Relocate and unpack the zip file. on page 43-60

**Select a Structure for the Zip File**

Before you generate and package the files for a model build, decide whether you want the files to be packaged in a flat or hierarchical folder structure. By default, the packNGo function packages the files in a single, flat folder structure.

<table>
<thead>
<tr>
<th>If...</th>
<th>Then Use a...</th>
</tr>
</thead>
<tbody>
<tr>
<td>You are relocating files to an IDE that does not use the generated makefile, or the code is not dependent on the relative location of required static files</td>
<td>Single, flat folder structure</td>
</tr>
<tr>
<td>The destination development environment must maintain the folder structure of the source environment because it uses the generated makefile, or the code depends on the relative location of files</td>
<td>Hierarchical structure</td>
</tr>
</tbody>
</table>

If you use a hierarchical structure, the packNGo function creates two levels of zip files, a primary zip file, which in turn contains the following secondary zip files:

- `mlrFiles.zip` — files in your `matlabroot` folder tree
- sDirFiles.zip — files in and under your build folder where you initiated code generation for the model
- otherFiles.zip — required files not in the `matlabroot` or start folder trees

Paths for the secondary zip files are relative to the root folder of the primary zip file, maintaining the source development folder structure.

**Select a Name for the Zip File**

By default, the `packNGo` function names the primary zip file `model`. You have the option of specifying a different name. If you specify a file name and omit the file type extension, the function appends `.m` to the name that you specify.

**Package Model Code in a Zip File**

Package model code files by using the `PostCodeGenCommand` configuration parameter, `packNGo` function, and build information object for the model. You can set up the packaging operation to use:

- A system generated build information object.

  In this case, before generating the model code, use `set_param` to set the configuration parameter `PostCodeGenCommand` to an explicit call to the `packNGo` function. For example:

  ```
  set_param(bdroot, 'PostCodeGenCommand', 'packNGo(buildInfo);');
  ```

  After generating and writing the model code to disk and before generating a makefile, this command instructs the build process to evaluate the call to `packNGo`. This command uses the system generated build information object for the currently selected model.

- A build information object that you construct programmatically.

  In this case, you could use other build information functions to include paths and files selectively in the build information object that you then specify with the `packNGo` function. For example:

  ```
  ...
  ...
  myModelBuildInfo = RTW.BuildInfo;
  addSourceFiles('myModelBuildInfo, {'test1.c' 'test2.c' 'driver.c'});
  ```
The following examples show how you can change the default behavior of `packNGo`.

<table>
<thead>
<tr>
<th>To...</th>
<th>Specify...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change the structure of the file packaging to hierarchical</td>
<td><code>packNGo(buildInfo, {'packType' 'hierarchical'})</code></td>
</tr>
<tr>
<td>Rename the primary zip file</td>
<td><code>packNGo(buildInfo, {'fileName' 'zippedsrcs'})</code></td>
</tr>
<tr>
<td>Change the structure of the file packaging to hierarchical and rename the primary zip file</td>
<td><code>packNGo(buildInfo, {'packType' 'hierarchical'... 'fileName' 'zippedsrcs'})</code></td>
</tr>
<tr>
<td>Include header files found on the include path in the zip file</td>
<td><code>packNGo(buildInfo, {'minimalHeaders' false})</code></td>
</tr>
<tr>
<td>Generate warnings for parse errors and missing files</td>
<td><code>packNGo(buildInfo, {'ignoreParseError' true... 'ignoreFileMissing' true})</code></td>
</tr>
</tbody>
</table>

**Note** The `packNGo` function can potentially modify the build information passed in the first `packNGo` argument. As part of packaging model code, `packNGo` could find additional files from source and include paths recorded in build information for the model and add them to the build information.

**Inspect a Generated Zip File**

To verify that it is ready for relocation, inspect the generated zip file. Depending on the zip tool that you use, you could be able to open and inspect the file without unpacking it. If unpacking the file and you packaged the model code files as a hierarchical structure, unpacking requires you to unpack the primary and secondary zip files. When you unpack the secondary zip files, relative paths of the files are preserved.

**Relocate and Unpack a Zip File**

Relocate the generated zip file to the destination development environment and unpack the file.
**Code Packaging Example**

This example shows how to package code files generated for the example model `rtwdemo_rtwintro` using the command-line interface:

1. Set your working folder to a writable folder.
2. Open the model `rtwdemo_rtwintro` and save a copy to your working folder.
3. Enter the following MATLAB command:

   ```matlab
   set_param('rtwdemo_rtwintro', 'PostCodeGenCommand',
             'packNGo(buildInfo, {''packType'' 'ührerarchical''})');
   ```

   You must double the single-quotes due to the nesting of character arrays
   `'packType'` and `'hierarchical'` within the character array that specifies the call
   to `packNGo`.
4. Generate code for the model.
5. Inspect the generated zip file, `rtwdemo_rtwintro.zip`. The zip file contains the two secondary zip files, `mlrFiles.zip` and `sDirFiles.zip`.
6. Inspect the zip files `mlrFiles.zip` and `sDirFiles.zip`.
7. Relocate the zip file to a destination environment and unpack it.

**Build Integrated Code Outside the Simulink Environment**

Identify required files and interfaces for calling generated code in an external build process.

Learn how to:

- Collect files required for building integrated code outside of Simulink®.
- Interface with external variables and functions.

For information about the example model and related examples, see “Generate C Code from a Control Algorithm for an Embedded System”.

**Collect and Build Required Data and Files**

The code that Embedded Coder® generates requires support files that MathWorks® provides. To relocate the generated code to another development environment, such as a dedicated build system, you must relocate these support files. You can package these files in a zip file by using the `packNGo` utility. This utility finds and packages the files that you
need to build an executable image. The utility uses tools for customizing the build process after code generation, which include a buildinfo_data structure, and a packNGo function. These files include external files that you identify in the Code Generation > Custom Code pane in the Model Configuration Parameters dialog box. The utility saves the buildinfo MAT-file in the model_ert_rtw folder.

Open the example model, rtwdemo_PCG_Eval_P5.

This model is configured to run packNGo after code generation.

Generate code from the entire model.

To generate the zip file manually:

1. Load the file buildInfo.mat (located in the rtwdemo_PCG_Eval_P5_ert_rtw subfolder).
2. At the command prompt, enter the command packNGo(buildInfo).

The number of files in the zip file depends on the version of Embedded Coder® and on the configuration of the model that you use. The compiler does not require all of the files in the zip file. The compiled executable size (RAM/ROM) depends on the linking process. The linker likely includes only the object files that are necessary.

**Integrating the Generated Code into an Existing System**

This example shows how to integrate the generated code into an existing code base. The example uses the Eclipse™ IDE and the Cygwin™/gcc compiler. The required integration tasks are common to all integration environments.

**Overview of Integration Environment**

A full embedded controls system consists of multiple hardware and software components. Control algorithms are just one type of component. Other components can be:

- An operating system (OS)
- A scheduling layer
- Physical hardware I/O
- Low-level hardware device drivers

Typically, you do not use the generated code in these components. Instead, the generated code includes interfaces that connect with these components. MathWorks® provides
hardware interface block libraries for many common embedded controllers. For examples, see the Embedded Targets block library.

This example provides files to show how you can build a full system. The main file is `example_main.c`, which contains a simple main function that performs only basic actions to exercise the code.

View `example_main.c`.

```c
int_T main(void)
{
    /* Initialize model */
    rt_Pos_Command_Arbitration_Init(); /* Set up the data structures for chart*/
    rtwdemo_PC__Define_Throt_Param(); /* SubSystem: '<Root>/Define_Throt_Param' */
    defineImportData(); /* Defines the memory and values of inputs */

    do /* This is the "Schedule" loop. Functions would be called based on a scheduling algorithm */
    {
        /* HARDWARE I/O */

        /* Call control algorithms */
        PI_Cntrl_Reusable(("pos_rqst"),fbk_1,&rtwdemo_PCG_Eval_P5_B.PI_ctrl_1,
                         &rtwdemo_PCG_Eval_P5_B_DWork.PI_ctrl_1);
        PI_Cntrl_Reusable(("pos_rqst"),fbk_2,&rtwdemo_PCG_Eval_P5_B.PI_ctrl_2,
                         &rtwdemo_PCG_Eval_P5_B_DWork.PI_ctrl_2);
        pos_cmd_one = rtwdemo_PCG_Eval_P5_B.PI_ctrl_1.Saturation1;
        pos_cmd_two = rtwdemo_PCG_Eval_P5_B.PI_ctrl_2.Saturation1;
        rtwdemo_Pos_Command_Arbitration(pos_cmd_one, &Throt_Param, pos_cmd_two,
                                        &rtwdemo_PCG_Eval_P5_B.sf_Pos_Command_Arbitration);
    }
}
```

The file:
- Defines function interfaces (function prototypes).
- Includes files that declare external data.
- Defines `extern` data.
- Initializes data.
- Calls simulated hardware.
• Calls algorithmic functions.

The order of function execution matches the order of subsystem execution in the test harness model and in `rtwdemo_PCG_Eval_P5.h`. If you change the order of execution in `example_main.c`, results that the executable image produces differ from simulation results.

**Match System Interfaces**

Integration requires matching the *Data* and *Function* interfaces of the generated code and the existing system code. In this example, the `example_main.c` file imports and exports the data through `#include` statements and `extern` declarations. The file also calls the functions from the generated code.

**Connect Input Data**

The system has three input signals: `pos_rqst`, `fbk_1`, and `fbk_2`. The generated code accesses the two feedback signals through direct reference to imported global variables (storage class `ImportedExtern`). The code accesses the position signal through an imported pointer (storage class `ImportedExternPointer`).

The handwritten file `defineImportedData.c` defines the variables and the pointer. The generated code does not define the variables and the pointer because the handwritten code defines them. Instead, the generated code declares the imported data (`extern`) in the file `rtwdemo_PCG_Eval_P5_Private.h`. In a real system, the data typically comes from other software components or from hardware devices.

View `defineImportedData.c`. 
Connect Output Data

In this example, you do not access the output data of the system. The example “Test Generated Code” shows how you can save the output data to a standard log file. You can access the output data by referring to the file rtwdemo_PCG_Eval_P5.h.

Access Additional Data

The generated code contains several structures that store commonly used data including:

- Block state values (integrator, transfer functions)
- Local parameters
- Time
The table lists the common data structures. Depending on the configuration of the model, some or all of these structures appear in the generated code. The data is declared in the file `rtwdemo_PCG_Eval_P5.h`, but in this example, you do not access this data.

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Data Name</th>
<th>Data Purpose</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</tbody>
</table>

**Match Function Call Interfaces**

By default, functions that the code generator generates have a `void Func(void)` interface. If you configure the model or atomic subsystem to generate reentrant code, the code generator creates a more complex function prototype. In this example, the `example_main` function calls the generated functions with the correct input arguments.

```c
PI_Cntrl_Reusable((*pos_rqst),fbk_1,&rtwdemo_PCG_Eval_P5_B.PI_ctrl_1,
   &rtwdemo_PCG_Eval_P5_DWork.PI_ctrl_1);
PI_Cntrl_Reusable((*pos_rqst),fbk_2,&rtwdemo_PCG_Eval_P5_B.PI_ctrl_2,
   &rtwdemo_PCG_Eval_P5_DWork.PI_ctrl_2);
pos_cmd_one = rtwdemo_PCG_Eval_P5_B.PI_ctrl_1.Saturation1;
pos_cmd_two = rtwdemo_PCG_Eval_P5_B.PI_ctrl_2.Saturation1;
rtwdemo_Pos_Command_Arbitration(pos_cmd_one, &Throt_Param, pos_cmd_two,
   &rtwdemo_PCG_Eval_P5_B.sf_Pos_Command_Arbitration);
```

Calls to the function `PI_Cntrl_Reusable` use a mixture of separate, unstructured global variables and Simulink® Coder™ data structures. The handwritten code defines these variables. The structure types are defined in `rtwdemo_PCG_Eval_P5.h`.

**Build Project in Eclipse™ Environment**

This example uses the Eclipse™ IDE and the Cygwin™ GCC debugger to build the embedded system. The example provides installation files for both programs. Software components and versions numbers are:
- Eclipse™ SDK 3.2
- Eclipse™ CDT 3.3
- Cygwin™/GCC 3.4.4-1
- Cygwin™/GDB 20060706-2

To install and use Eclipse™ and GCC, see “Install and Use Cygwin and Eclipse”.

You can install the files for this example by clicking this hyperlink:

Set up the build folder.

Alternatively, to install the files manually:

1. Create a build folder (Eclipse_Build_P5).
2. Unzip the file rtwdemo_PCG_Eval_P5.zip into the build folder.
3. Delete the files rtwdemo_PCG_Eval_P5.c, ert_main.c and rt_logging.c, which are replaced by example_main.c.

You can use the Eclipse™ debugger to step through and evaluate the execution behavior of the generated C code. See the example “Install and Use Cygwin and Eclipse”.

To exercise the model with input data, see “Test Generated Code”.

**packNGo Function Limitations**

The following limitations apply to the packNGo function:

- The function operates on source files, such as *.c, *.cpp, and *.h files, only. The function does not support compile flags, defines, or makefiles.
- Unnecessary files could be included. The function could find additional files from source and include paths recorded in build information for the model and include them, even if they are not used.

More About

- packNGo
- “Choose Build Approach and Configure Build Process” on page 43-14
- “Build Process Workflow for Real-Time Systems” (Simulink Coder)
- “Executable Program Generation” on page 43-69
Executable Program Generation

The following figure shows how the process for program building.

During the final stage of processing, the build process invokes the generated makefile, `model.mk`, which in turn compiles and links the generated code. On PC platforms, a batch file is created to invoke the generated makefile. The batch file sets up the environment for invoking the make utility and related compiler tools. To avoid recompiling C files, the make utility performs date checking on the dependencies between the object and C files; only out-of-date source files are compiled. Optionally, the makefile can download the resulting executable image to your target hardware.
This stage is optional, as illustrated by the control logic in the preceding figure. You could choose to omit this stage (for example, if you are targeting an embedded microcontroller board).

To omit this stage of processing, select the **Configuration Parameters > Code Generation** pane and select the **Generate code only** check box. You can then cross-compile your code and download it to your target hardware.

If you select the **Configuration Parameters > Code Generation > Report** pane and select **Create code generation report**, the code generator produces a navigable summary of source files when the model is built. The report files occupy a folder called `html` within the build folder. The following display shows an example of an HTML code generation report for a generic real-time (GRT) system target file.

Profile Code Performance

By profiling the performance of generated code, you can help verify that the code meets performance requirements.

Profiling can be especially important early in the development cycle for identifying potential architectural issues that can be more expensive to address later in the process. Profiling can also identify bottlenecks and procedural issues that indicate a need for optimization, for example, with an inner loop or inline code.

**Note** If you have an Embedded Coder license, see “Code Execution Profiling” for an alternative and simpler approach based on software-in-the-loop (SIL) or processor-in-the-loop (PIL) simulations.

<table>
<thead>

</tbody>
</table>

Use the Profile Hook Function Interface

You can profile code generated with code generation technology by using a Target Language Compiler (TLC) hook function interface.

To use the profile hook function interface:

1. For your system target file, create a TLC file that defines the following hook functions. Write the functions so that they specify profiling code. The code generator adds the hook function code to code generated for atomic systems in the model.
<table>
<thead>
<tr>
<th>Function</th>
<th>Input Arguments</th>
<th>Output Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ProfilerTypedefs</td>
<td>void</td>
<td>typedefs</td>
<td>Generate code statements for profiler type definitions.</td>
</tr>
<tr>
<td>ProfilerGlobal-Data</td>
<td>system</td>
<td>Global data for the specified system</td>
<td>Generate code statements that declare global data.</td>
</tr>
<tr>
<td>ProfilerExtern-DataDecls</td>
<td>system</td>
<td>extern declarations for the specified system</td>
<td>Generate code statements that create global extern declarations.</td>
</tr>
<tr>
<td>ProfilerSystem-Decls</td>
<td>system, functionType</td>
<td>Declarations for the specified system for the specified functionType</td>
<td>Generate code for required variable declarations within the scope of an atomic subsystem Output, Update, OutputUpdate, or Derivatives function.</td>
</tr>
<tr>
<td>ProfilerSystem-Start</td>
<td>system, functionType</td>
<td>Profiler start commands for the specified system and functionType</td>
<td>Generate code that starts the profiler within the scope of an atomic subsystem Output, Update, OutputUpdate, or Derivatives function.</td>
</tr>
<tr>
<td>ProfilerSystem-Finish</td>
<td>system, functionType</td>
<td>Profiler end commands for the specified system and functionType</td>
<td>Generate code that stops the profiler within the scope of the Output, Update, OutputUpdate, or Derivatives functions of an atomic subsystem.</td>
</tr>
<tr>
<td>Function</td>
<td>Input Arguments</td>
<td>Output Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>-----------------</td>
<td>--------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>ProfilerSystem-Terminate</td>
<td>system</td>
<td>Profiler termination code for the specified system</td>
<td>Generate code that terminates profiling (and possibly reports results) for an atomic subsystem.</td>
</tr>
</tbody>
</table>

For an example TLC file, see `matlabroot/toolbox/rtw/rtwdemos/rtwdemo_profile_hook.tlc`.

2 In your `target.tlc` file, define the following global variables.

<table>
<thead>
<tr>
<th>Define...</th>
<th>To Be...</th>
</tr>
</thead>
<tbody>
<tr>
<td>ProfileGenCode</td>
<td>TLC_TRUE or 1 to turn on profiling (TLC_FALSE or 0 to turn off profiling)</td>
</tr>
<tr>
<td>ProfilerTLC</td>
<td>The name of the TLC file that you created in step 1</td>
</tr>
</tbody>
</table>

A quick way to define global variables is to define the parameters with the `-a` option. You can apply this option by using the `set_param` command to set the model configuration parameter `TLCOptions`. For example,

```matlab
>> set_param(gcs,'TLCOptions', ...
    '-aProfileGenCode=1 -aProfilerTLC="rtwdemo_profile_hook.tlc"')
```

3 Consider setting configuration parameters for generating a code generation report. You can then examine the profiling code in the context of the code generated for the model.

4 Build the model. The build process embeds the profiling code in the hook function locations in the generated code for the model.

5 Run the generated executable file. In the MATLAB Command Window, enter `!model-name`. You see the profiling report you programmed in the profiling TLC file that you created. For example, a profile report could list the number of calls made to each system in a model and the number of CPU cycles spent in each system.

For details on programming a `.tlc` file and defining TLC configuration variables, see “Target Language Compiler” (Simulink Coder).
Profile Hook Function Interface Limitation

The TLC hook function interface for profiling code performance does not support the S-function system target file (rtwsfcn.tlc).

Host-Target Communication with External Mode Simulation

You can use external mode simulations for rapid prototyping. An external mode simulation establishes a communication channel between Simulink on your development computer (host) and the target hardware that runs the executable file created by the code generation and build process.

Through the communication channel, you can:

- Modify or tune block parameters in real time. When you change parameters in the model, Simulink downloads the new values to the executing target application.
- Monitor and save signal data from the executing target application.

The low-level transport layer of the channel handles the physical transmission of messages. Simulink and the generated model code are independent of this layer. The transport layer and its interface code are isolated in separate modules that format, transmit, and receive messages and data packets.
Simulink supports two communication mechanisms for external mode simulation. This table can help you to decide which mechanism to use.
<table>

External Mode Simulation with XCP Communication

Set up and run external mode simulations (Simulink Coder) that use an XCP communication channel.

Run XCP External Mode Simulation From Simulink Editor

Configure and run an external mode simulation (Simulink Coder) that uses the XCP communication protocol. During the simulation:

• Monitor a signal with a Scope block, a Dashboard block, and the Simulation Data Inspector.
• Tune a parameter with a Dashboard block.

Configure Signal Monitoring and Parameter Tuning for XCP External Mode

1 Create a folder for this example.
   ```
   mkdir ext_mode_xcp_example
   cd ext_mode_xcp_example
   ```

2 Open Simulink and create a simple model, xcpExample, which contains these blocks:
   • Sine Wave
   • Scope
   • Half Gauge
   • Knob

3 Double-click the Sine Wave block. Set **Sample time** to 0.1, and then click **OK**.

4 Connect the Sine Wave block to the Scope block, and name the connection, for example, **Test Signal**.

5 Configure the signal for logging:
   a Right-click **Test Signal**.
   b From the context menu, select **Log Selected Signals**. If you do not enable signal logging, you cannot view the signal with the Scope block or stream signal data to the Simulation Data Inspector.

6 Configure the Half Gauge block to monitor the value of **Test Signal**.
Double-click the Half Gauge block.
In the Simulink Editor, select Test Signal.
In the Block Parameters dialog box:
  • Connect the block to Test Signal.
  • In the Maximum field, enter a value, for example, 1.
Click OK.
7 Configure the Knob block to tune the Amplitude parameter of the Sine Wave block:
Double-click the Knob block.
In the Simulink Editor, select the Sine Wave block.
In the Block Parameters dialog box:
  • Connect the block to the Amplitude parameter of the Sine Wave block.
  • In the Minimum and Maximum fields, enter values, for example, 0.1 and 1 respectively.
Click OK.
8 Save the model.
Build Target Application for XCP External Mode

1. Select Simulation > Model Configuration Parameters.

2. On the Solver pane:
   - In the Type field, specify Fixed-step.
   - Under Solver details, in the Fixed-step size field, specify a value, for example, 0.1.

3. On the Code Generation pane, set System target file to grt.tlc or ert.tlc (requires Embedded Coder license).

4. On the Code Generation > Optimization pane, set Default parameter behavior to Tunable.

5. On the Code Generation > Interface pane, select the External mode check box.

6. Set Transport layer to XCP on TCP/IP, which specifies ext_xcp for MEX-file name.

7. In the Mex-file arguments field, enter 'localhost' 1 5555. These arguments specify that the:
   - Target hardware is your development computer.
   - Verbosity level is 1
   - Port number of the TCP/IP server is 5555.

8. Leave the Static memory allocation check unselected. The platform abstraction layer of the XCP slave software provides a configurable memory allocator.

9. If System target file is ert.tlc, on the Code Generation > Templates pane:
   - Select the Generate an example main program check box. The code generator uses matlabroot\toolbox\coder\xcp\src\target\ext_mode\include \ext_mode.h to produce an example main file, ert_main.c.
   - Set Target operating system to BareBoardExample.

10. Click OK. Then save the model.

In Windows, in addition to the executable file, xcpExample.exe, the build process creates xcpExample.pdb, which is a debugging symbols file for signals and parameters.
In Linux, the build process places DWARF format debugging information in the created ELF executable file, xcpExample.

**Run Target Application**

1. Open a command window for your operating system and navigate to the ext_mode_xcp_example folder.
2. In the command window, enter:

   ```
   xcpExample -w -tf inf -port 5555
   ```

   The target application runs as a separate process on your development computer:

   - `-w` (optional) specifies that the target application enters a wait state until it receives a message from Simulink. The target application runs but does not yet execute model code.
   
     If you do not specify `-w`, the target application executes model code immediately. The model code runs with parameter values from the time when you built the model.
   
   - `-tf inf` (optional) specifies that, when model code is executed, the model runs indefinitely. Use this option to override the model parameter, `StopTime`.

3. Connect Simulink to the target application:

   a. Select **Simulation > Mode > External**.

   b. On the Simulink Editor toolbar, click the Connect to Target button. Simulink downloads current parameter values from the model to the target application.

4. To run the generated model code, click the Run button.

**Monitor Signal and Tune Parameter**

You can monitor **Test Signal** through the:

- Scope block – Double-click the block.
- Simulation Data Inspector – Click the Simulation Data Inspector button. When the Simulation Data Inspector opens, select the **Test Signal** check box, which displays streamed data.
- Half-Gauge block.
To change the amplitude of the sine wave, rotate the pointer on the Knob block to the required value.

You can also use these methods to tune tunable (Simulink) block parameters during a simulation:

- If a block parameter is a variable in the MATLAB workspace, from the Command Window, assign a new value to the variable. Then, in the Simulink Editor, select **Simulation > Update Diagram**. Simulink downloads the new value to the target application.
- Open the Block Parameter dialog box. In the parameter field, specify the required value. When you click **Apply** or **OK**, Simulink downloads the new parameter value to the target application.

For more information about parameter tuning with generated code, see:

- “External Mode Simulation with TCP/IP or Serial Communication” on page 44-36
- “Create Tunable Calibration Parameter in the Generated Code” on page 22-121

**Stop Target Application**

To stop the execution of generated model code (before **StopTime** is reached) and disconnect the target application, on the Simulink Editor toolbar, click the Stop button.

If you want to disconnect the target application from Simulink without stopping code execution, click the Disconnect from Target button 👉.

**Target Application Arguments**

You can run your target application with optional arguments.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-w</td>
<td>Specify that the target application enters and stays in a wait state until it receives a message from Simulink. If you do not specify -w, the target application executes model code immediately. The model code runs with parameter values from the time when you built the model.</td>
</tr>
<tr>
<td>Argument</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>-tf time</td>
<td>Override the model parameter, StopTime. -tf inf specifies that the model runs indefinitely when model code is executed.</td>
</tr>
</tbody>
</table>

For host-based external mode simulations, you can specify additional rtiostream on page 67-48 arguments.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
</table>
| -verbose level | Specify verbosity level:  
  • 0 -- No information  
  • 1 -- Detailed information                                                      |
| -port number  | For XCP on TCP/IP transport layer, specify port number of TCP/IP server. An integer value between 256 and 65535. Default is 17725.  
  
  For XCP on Serial transport layer, specify serial port ID. For example:  
  • On Windows, 'COM1' or 1 for COM1, 'COM2' or 2 for COM2, etc.  
  • On Linux, '/dev/ttyS0', etc. |
| -baud value   | For XCP on Serial transport layer, specify baud value. 1200, 2400, 4800, 9600, 14400, 19200, 38400, 57600 (default), or 115200. |

**Graphical Controls for XCP External Mode Simulations**

You can control an XCP external mode simulation through:

- The Simulink Editor toolbar.
- A Simulink Editor menu.
- The External Mode Control Panel. To open this dialog box, in Simulink Editor, select Code > External Mode Control Panel.
This table gives the controls that you can use for an XCP external mode simulation.

<table>
<thead>
<tr>
<th>External Mode Action</th>
<th>Toolbar</th>
<th>Menu</th>
<th>External Mode Control Panel</th>
</tr>
</thead>
<tbody>
<tr>
<td>Set simulation mode of model to external mode.</td>
<td>From the simulation mode drop-down list, select External.</td>
<td><strong>Simulation &gt; Mode &gt; External</strong></td>
<td>Connect</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>If the model simulation mode is not already set, clicking the button sets the simulation mode to external.</td>
</tr>
<tr>
<td>Connect Simulink to a waiting or running target application.</td>
<td>Connect to Target button</td>
<td><strong>Simulation &gt; Connect to Target</strong></td>
<td>Connect</td>
</tr>
<tr>
<td></td>
<td>Connect to Target button</td>
<td></td>
<td>When the Simulink is connected to the target application, the button changes to <strong>Disconnect</strong>.</td>
</tr>
<tr>
<td><strong>External Mode Action</strong></td>
<td><strong>Toolbar</strong></td>
<td><strong>Menu</strong></td>
<td><strong>External Mode Control Panel</strong></td>
</tr>
<tr>
<td>--------------------------</td>
<td>-------------</td>
<td>----------</td>
<td>---------------------------------</td>
</tr>
</tbody>
</table>
| Start real-time execution of generated code in the target environment. | Run button | Simulation > Run (keyboard shortcut Ctrl+T) | Start Real-Time Code  
When the generated code starts executing, the button changes to Stop Real-Time Code. |
<p>| Disconnect Simulink from the target environment, but do not stop real-time execution of code. | Disconnect from Target button | Simulation &gt; Disconnect from Target | Disconnect |
| Stop target application execution and disconnect Simulink from the target environment. | Stop button | Simulation &gt; Stop (keyboard shortcut Ctrl+Shift+T) | Stop Real-Time Code |</p>
<table>
<thead>
<tr>
<th>External Mode Action</th>
<th>Toolbar</th>
<th>Menu</th>
<th>External Mode Control Panel</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tune batch of block parameters.</td>
<td>N/A</td>
<td>N/A</td>
<td><strong>Batch download</strong></td>
</tr>
</tbody>
</table>

To tune a batch of block parameters:

1. In the External Mode Control Panel, select **Batch download**.
2. In Simulink Editor, modify the required block parameters.
3. When you modify parameters, the External Mode Control Panel displays this message next to **Download**:

   **Parameter changes pending...**

   Simulink stores the modified parameters locally.
4. Click **Download**. Simulink downloads the batch of modified parameters to the target application.

---

**Run XCP External Mode Simulation From Command Line**

You can use commands or scripts to run XCP external mode simulations. Use `get_param` and `set_param` commands to retrieve and set the values of model parameters.

These commands assume that a Simulink model is open and a target application is running:
1 Set simulation mode of the model to external mode.
   ```matlab
   set_param(gcs, 'SimulationMode', 'external');
   ```
2 Connect Simulink to the target application.
   ```matlab
   set_param(gcs, 'SimulationCommand', 'connect');
   ```
3 Run generated model code.
   ```matlab
   set_param(gcs, 'SimulationCommand', 'start');
   ```
4 To tune a parameter, change its workspace variable value through a line command. For example, if a block parameter value is specified as a `Simulink.Parameter` object, assign the new value to the `Value` property.
   ```matlab
   myParamObj.Value = 5.23;
   ```
5 To download the new value to the target application, update the model.
   ```matlab
   set_param(gcs, 'SimulationCommand', 'update');
   ```
6 Stop the target application and disconnect Simulink from the target environment.
   ```matlab
   set_param(gcs, 'SimulationCommand', 'stop');
   ```
   To disconnect Simulink from the target application without stopping execution of generated code, use this command:
   ```matlab
   set_param(gcs, 'SimulationCommand', 'disconnect');
   ```

**XCP External Mode Limitations**

This table describes limitations that apply to external mode simulations that use XCP communication.
<table>
<thead>
<tr>
<th>Feature</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parameter updates that change model structure</td>
<td>You cannot change, for example:</td>
</tr>
<tr>
<td></td>
<td>• The number of states, inputs, or outputs of a block</td>
</tr>
<tr>
<td></td>
<td>• The sample time or the number of sample times</td>
</tr>
<tr>
<td></td>

Customize XCP Slave Software

The XCP communication protocol for Simulink external mode simulations is a master-slave communication protocol. By default, the software supports XCP external mode simulations:

- On your development computer for code that is generated using ERT (ert.tlc) and GRT (g rt.tlc) system target files.
- For some support packages on page 44-2.

If your system target file for custom target hardware is derived from the ERT or GRT system target files, you can use supplied APIs to provide XCP target connectivity. XCP external mode limitations on page 44-17 apply.

The external mode target connectivity software comprises:

- External mode abstraction layer
- XCP slave protocol layer
- XCP slave transport layer
- XCP platform abstraction layer
External Mode Abstraction Layer

To communicate with Simulink during an external mode simulation, your target application must invoke functions from the external mode abstraction layer.

The parent folder for source files is:

```
matlabroot\toolbox\coder\xcp\src\target\ext_mode
```

The layer APIs are declared in `include\ext_mode.h` and implemented in `src\xcp_ext_mode.c`.

---

Customize XCP Slave Software
To communicate with Simulink, the target application uses services exposed by the external mode abstraction layer. This flow chart shows the target application steps that are required to establish communication with Simulink.

This tables gives the functions that your target application must invoke at each stage.
<table>
<thead>
<tr>
<th>Stage</th>

<td>------------------</td>
<td>-------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>extmodeReset</td>
<td>Reset external mode target connectivity to initial state.</td>
</tr>
</tbody>
</table>

The following pseudo-code example shows how you can implement the various stages in your target application. During the RUN stage, the external mode run-time environment requires at least two threads:

- A periodic thread that is responsible for the execution of the generated model code.
- A background thread that is responsible for running the external mode communication stack and transmitting and receiving packets.

The pseudo-code simulates multithreading by running periodicThread and extmodeBackgroundRun sequentially within the same while() loop.

```c
/*------------- Pseudo-Code Example -------------*/
/* Define periodic thread */
void periodicThread(void)
{
    /* Run model step function */
    modelName_step();
    /* Notify external mode abstraction layer about periodic event */
    extmodeEvent(PERIODIC_EVENT_ID, currentSimulationTime);
}

/* Main function for target application */
main(int argc, char *argv[])
{
    /*------------- INITIALIZE -------------*/
    /* Parse external mode command line arguments */
    extmodeParseArgs(argc, argv);
    /* Initialize model */
    modelName_initialize();
    /* Initialize external mode target connectivity */
    extmodeInit(extModeInfo, finalSimulationTime);

    /*------------- HOST START REQUEST -------------*/
    /* Wait until a start request is received from development computer */
    extmodeWaitForHostRequest(EXTMODE_WAIT_FOREVER);

    /*------------- RUN -------------*/
    periodicThread();
    extmodeBackgroundRun();

    /*------------- RESET -------------*/
    /* Terminate model */
```
To see code that invokes the functions, do the example in “External Mode Simulation with XCP Communication” on page 44-8 with **System target file** set to ertz.tlc. Then, from the code generation folder, open ertz_main.c.

**XCP Slave Protocol Layer**

The XCP slave protocol layer interprets XCP commands and data according to the Association for Standardisation of Automation and Measuring Systems (ASAM) standard, ASAM MCD-1 XCP.

The source folder is:

```
matlabroot\toolbox\coder\xcp\src\target\slave\protocol\src
```

In an external mode simulation, the build process automatically adds the required files to the build information object (Simulink Coder).

**XCP Slave Transport Layer**

The XCP slave transport layer transmits and receives messages from the communication medium according to ASAM specifications.

The source folder is:

```
matlabroot\toolbox\coder\xcp\src\target\slave\transport\src
```

In an external mode simulation, the build process automatically adds the required files to the build information object (Simulink Coder).

**XCP Platform Abstraction Layer**

The XCP platform abstraction layer provides:

- An XCP driver on page 44-28 for sending and receiving raw data through the physical communication interface.
The implementation of a static memory allocator on page 44-28.

Other target hardware-specific functionality (Simulink Coder).

For a customization example, see “Create Custom Abstraction Layer” on page 44-33.

**XCP Driver**

The XCP driver sends and receives XCP messages through the communication channel. In an external mode simulation, the build process automatically adds the driver files to the build information object.

The XCP driver is based on the rtiostream on page 67-48 API. For example, host-based external mode simulations use these rtiostream files:

- `matlabroot\rtw\c\src\rtiostream\rtiostreamtcpip.c`
- `matlabroot\rtw\c\src\rtiostream\rtiostream_serial.c`

For a custom platform abstraction layer, you must add your rtiostream files to the build information object (Simulink Coder). For an example, see “Create Custom Abstraction Layer” on page 44-33.

**Memory Allocator**

The XCP slave software requires the dynamic allocation of variable-size, contiguous memory blocks to:

- Store XCP messages that are received and transmitted.
- Hold internal data structures.

In an external mode simulation, the build process automatically adds memory allocator files to the build information object.

The `xcpMemBlockSize` and `xcpMemBlockCounts` preprocessor macros define memory allocation.

The default memory allocator can allocate and deallocate up to 16 different sets of memory blocks. For each set, you can override the default allocations during compilation. You can specify:

- The block size through the `XCP_MEM_BLOCK_N_SIZE` preprocessor macro.
- The number of blocks in each set through the `XCP_MEM_BLOCK_N_NUMBER` preprocessor macro.
For example, these preprocessor macros create 4 blocks of 64 bytes and 8 blocks of 256 bytes.

```
#define XCP_MEM_BLOCK_1_SIZE 64
#define XCP_MEM_BLOCK_1_NUMBER 4
#define XCP_MEM_BLOCK_2_SIZE 256
#define XCP_MEM_BLOCK_2_NUMBER 8
```

Configure the block sizes of the different sets in ascending order:

```
XCP_MEM_BLOCK_N_SIZE < XCP_MEM_BLOCK_N+1_SIZE
```

The smallest block size, `XCP_MEM_BLOCK_1_SIZE`, must be large enough to hold a pointer.

Configure alignment for the memory allocator through the `XCP_MEM_ALIGNMENT` preprocessor macro. For example:

```
#define XCP_MEM_ALIGNMENT 8
```

**Other Platform Abstraction Layer Functionality**

This file defines the platform abstraction layer interface:

`matlabroot/toolbox/coder/xcp/src/target/slave/platform/include/xcp_platform.h`

To implement custom platform abstraction layer functionality, add the `XCP_CUSTOM_PLATFORM` preprocessor macro to the build information object. You must provide the implementation of the custom functionality in a file named `xcp_platform_custom.h`. If you do not define `XCP_CUSTOM_PLATFORM`, the build process uses default files that support Linux and Windows systems.

This table describes the functionality that you must provide for the XCP slave software that you deploy on your target hardware.
<table>
<thead>
<tr>
<th><strong>Functionality</strong></th>
<th><strong>Details</strong></th>
</tr>
</thead>
</table>
| Mutual exclusion       | To access system data structures with *mutual exclusion* support, the XCP driver depends on basic APIs for definition, initialization, lock, and unlock. To support mutual exclusion for your target hardware, provide a custom implementation. The default implementation for Linux and Windows supports mutual exclusion.  

```c
#if defined(_WIN32) || defined(__WIN32__) || defined(WIN32)
    ...
#define XCP_MUTEX_DEFINE(lock) HANDLE lock
#define XCP_MUTEX_INIT(lock) lock = CreateMutex(0, FALSE, 0)
#define XCP_MUTEX_LOCK(lock) WaitForSingleObject((lock), INFINITE)
#define XCP_MUTEX_UNLOCK(lock) ReleaseMutex(lock)
#else
    ...
#include <pthread.h>
#define XCP_MUTEX_DEFINE(lock) pthread_mutex_t lock
#define XCP_MUTEX_INIT(lock) pthread_mutex_init(&(lock), NULL)
#define XCP_MUTEX_LOCK(lock) pthread_mutex_lock(&(lock))
#define XCP_MUTEX_UNLOCK(lock) pthread_mutex_unlock(&(lock))
#endif
```
### Functionality | Details
--- | ---
**Sleep** | Provide a sleep API that makes the calling thread sleep until a specified time has elapsed. The default implementation for Linux and Windows systems is:

```c
#if defined(_WIN32) || defined(_WIN32__) || defined(WIN32)
  ...
#define XCP_SLEEP(seconds,microseconds)  Sleep((seconds) * 1000 + (((microseconds) + 1000 - 1) / 1000))
#else
  ...
#if _POSIX_C_SOURCE >= 199309L
#define XCP_SLEEP(seconds,microseconds)  do {struct timespec t;
    t.tv_sec = seconds; t.tv_nsec = microseconds * 1000; nanosleep(&t, NULL);} while(0)
#else /* nanosleep is not available. Use select instead. */
#define XCP_SLEEP(seconds,microseconds)  do {struct timeval t; t.tv_sec = seconds;
    t.tv_usec = microseconds; select(0, NULL, NULL, NULL, &t);} while(0)
#endif /* _POSIX_C_SOURCE >= 199309L */
#endif
```

**Logging** | To generate diagnostic messages, the XCP slave software requires a custom print API that supports logging services provided by the target hardware. If you do not define the XCP_PRINTF preprocessor macro, the default implementation is empty.
## Functionality | Details
---|---
Address conversion | The XCP standard expresses the address of a variable in memory as a 32-bit address with an 8-bit extension.  

The XCP Master extracts the addresses of signals and parameters of the model by parsing the debug information that is created by the build process. The debug information is in DWARF or PDB format.  

The XCP Master requests access to parameters and signals by sending an XCP command that contains the arguments `addressExtension` and `address`.  

When `addressExtension` and `address` information is received by the target hardware, the XCP Slave must convert the address to the location of the variable in the target hardware memory. The variable location is assigned by the loader and is target-specific.  

Use the `XCP_ADDRESS_GET()` macro to specify the conversion logic. The default implementation for Linux and Windows systems is:

```c
#if defined(_MINGW32) || defined(_MINGW64)
#define XCP_ADDRESS_GET(addressExtension, address) (uint8_T*) ((uintptr_t) address)
#else
#define XCP_ADDRESS_GET(addressExtension, address) (uint8_T*) ((address) + (uint8_T*)&__ImageBase)
#endif
```

Currently, only 32-bit hardware architectures are supported, so `addressExtension` is 0.
### Functionality

<table>
<thead>
<tr>
<th>Functionality</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Set and copy memory</td>
<td>You can specify an optimized version of copy memory and set memory operations.</td>
</tr>
<tr>
<td></td>
<td>If you do not define the XCP_MEMCPY and XCP_MEMSET preprocessor macros, the default implementation specifies the standard C functions, memcpy and memset.</td>
</tr>
</tbody>
</table>
|                      | ifndef XCP_MEMCPY
|                      | #define XCP_MEMCPY memcpy
|                      | endif
|                      | ifndef XCP_MEMSET
|                      | #define XCP_MEMSET memset
|                      | endif                                                                                                                                 |
| Parsing command line | If your target hardware does not support the parsing of command line arguments, define the preprocessor macro EXTMODE_DISABLE_ARGS_PROCESSING. |
| arguments            | To replace the -w option, you can use this command to specify that the target application enters and stays in a wait state until it receives a Connect message from Simulink: |
|                      | set_param(modelName, 'OnTargetWaitForStart', 'on');                                                                                            |
|                      | The build process provides the required option (-DON_TARGET_WAIT_FOR_START=1) to the compiler.                                               |

### Create Custom Abstraction Layer

For the build process, you can define a post-code generation command that creates a custom platform abstraction layer.

1. Specify the header file xcp_platform_custom.h. This Linux example defines the required functions.

```c
#ifndef XCP_PLATFORM_CUSTOM_H
#define XCP_PLATFORM_CUSTOM_H

/* XCP_ADDRESS_GET */
#include <stdint.h>
#define XCP_ADDRESS_GET(addressExtension, address)  (uint8_T*) ((uintptr_t) address)

/* XCP_MUTEX */
```

44-33
#include <cassert>
#define XCP_MUTEX_DEFINE(lock)    pthread_mutex_t lock
#define XCP_MUTEX_INIT(lock)      pthread_mutex_init(&(lock), NULL)
#define XCP_MUTEX_LOCK(lock)      pthread_mutex_lock(&(lock))
#define XCP_MUTEX_UNLOCK(lock)    pthread_mutex_unlock(&(lock))

/* XCP_SLEEP */
#include <sys/time.h>    /* gettimeofday */
#if _POSIX_C_SOURCE >= 199309L
#include <time.h>       /* for nanosleep */
#else
#include <stddef.h>
#include <sys/select.h> /* for select */
#endif
/* _POSIX_C_SOURCE >= 199309L */
#if _POSIX_C_SOURCE >= 199309L
#define XCP_SLEEP(seconds,microseconds)  do {struct timespec t;
   t.tv_sec = seconds; t.tv_nsec = microseconds * 1000; nanosleep(&t, NULL);} while(0)
#else
/* nanosleep is not available. Use select instead. */
#define XCP_SLEEP(seconds,microseconds)  do {struct timeval t; t.tv_sec = seconds;
   t.tv_usec = microseconds; select(0, NULL, NULL, NULL, &t);} while(0)
#endif /* _POSIX_C_SOURCE >= 199309L */

2  Define the post-code generation command.

    function myXCPTargetPostCodeGenCommand(buildInfo)
        buildInfo.addDefines('-DXCP_CUSTOM_PLATFORM', 'OPTS');

        % Configure the default memory allocator
        buildInfo.addDefines('-DXCP_MEM_BLOCK_1_SIZE=64', 'OPTS');
        buildInfo.addDefines('-DXCP_MEM_BLOCK_1_NUMBER=46', 'OPTS');
        buildInfo.addDefines('-DXCP_MEM_BLOCK_2_SIZE=256', 'OPTS');
        buildInfo.addDefines('-DXCP_MEM_BLOCK_2_NUMBER=10', 'OPTS');

        % Add my rtiostream
        buildInfo.addSourceFiles(customRtIOStreamFileName, customRtIOStreamSrcPath);

        % If the target hardware does not support parsing of command line arguments
        buildInfo.addDefines('-DEXTMODE_DISABLE_ARGS_PROCESSING', 'OPTS');
    end

More About
• “Host-Target Communication with External Mode Simulation” on page 44-2
• “External Mode Simulation with XCP Communication” on page 44-8

External Websites
• https://www.asam.net/standards/detail/mcd-1-xcp/wiki/
External Mode Simulation with TCP/IP or Serial Communication

Set up and run an external mode simulation that uses a TCP/IP or serial (RS-232) communication channel.

1. Create and configure a simple model.
2. Build the target executable file.
3. Run the target program.
4. Tune parameters.

The example, which uses the GRT target, does not require external hardware. The generated executable file runs:

- On the development computer that hosts Simulink and Simulink Coder.
- As a separate process from MATLAB and Simulink.

Create and Configure Model

In this part of the example, you create a simple model, `ex_extModeExample`. You also create a folder called `ext_mode_example` to store the model and the generated executable.

To create the folder and the model:

1. From the MATLAB command line, type:

   ```
   mkdir ext_mode_example
   ```

2. Make `ext_mode_example` your working folder:

   ```
   cd ext_mode_example
   ```

3. Create a model in Simulink with a Sine Wave block for the input signal, two Gain blocks in parallel, and two Scope blocks. Be sure to label the Gain and Scope blocks as shown.
4 Define and assign two MATLAB workspace variables, A and B:

\[
A = 2; \\
B = 3;
\]

5 Open Gain block A and set its **Gain** parameter to the variable A.

6 Open Gain block B and set its **Gain** parameter to the variable B.

When the target program is built and connected to Simulink in external mode, you can download new gain values to the executing target program. To do this, you can
assign new values to workspace variables A and B, or edit the values in the block parameters dialog box. For more information, see “Tune Parameters” on page 44-44.

7 Verify operation of the model. Open the Scope blocks and run the model. When \( A = 2 \) and \( B = 3 \), the output appears as shown.

8 Save the model as `ex_extModeExample`.

**Build TargetExecutable**

Set up the model and code generation parameters required for an external mode compatible target program. Then, generate code and build the target executable.

1 Open the Configuration Parameters dialog box by selecting Simulation > Model Configuration Parameters.

2 Select the Solver pane.

3 In the Solver selection subpane:
   
   a In the Type field, select Fixed-step.
   
   b In the Solver field, select discrete (no continuous states).
c Open **Additional options**. In the **Fixed-step size** field, specify 0.1. (Otherwise, when you generate code, the Simulink Coder build process posts a warning and supplies a value.)

Leave **Start time** set to the default value of 0.0.

Click **Apply**.

4 Select the **Data Import/Export** pane, and clear the **Time** and **Output** check boxes. In this example, data is not logged to the workspace or to a MAT-file. Click **Apply**.

5 Select the **Optimization** pane. Make sure that **Default parameter behavior** is set to **Tunable**. Inlined parameters are not part of this example. If you have made changes, click **Apply**.

6 Select the **Code Generation** pane. By default, the generic real-time (GRT) target is selected.

7 Select the **Code Generation > Interface** pane. In the **Data exchange interface** section, select **External mode**. This selection enables generation of external mode support code and displays additional external mode configuration parameters.

8 In the **External mode configuration** section, make sure that the default value tcpip is selected for the **Transport layer** parameter.

External mode supports communication via TCP/IP, serial, and custom transport protocols. The **MEX-file name** field specifies the name of a MEX-file that implements host and target communication on the host side. The default for TCP/IP is ext_comm, a MEX-file provided with the Simulink Coder software. You can override this default by supplying other files. If you need to support other transport layers, see “Create a Transport Layer for TCP/IP or Serial External Mode Communication” (Simulink Coder).

The **MEX-file arguments** field lets you specify arguments, such as a TCP/IP server port number, to be passed to the external interface program. These arguments are
specific to the external interface that you are using. For information on setting these arguments, see “MEX-File Optional Arguments for TCP/IP Transport” (Simulink Coder) and “MEX-File Optional Arguments for Serial Transport” (Simulink Coder).

This example uses the default arguments. Leave the MEX-file arguments field blank.

The Static memory allocation check box controls how memory is allocated for external mode communication buffers in the target. For this example, do not select the check box. For more information, see “Control Memory Allocation for Communication Buffers in Target” on page 44-46.

9 Click Apply to save the external mode settings.

10 Save the model.

11 Select the Code Generation pane. Make sure that Generate code only is cleared, and then, in the model window, press Ctrl+B to generate code and create the target program. The software creates the ex_extModeExample target executable in your working folder.

Run Target Program

You now run the ex_extModeExample target executable and use Simulink as an interactive front end to the running target program. The executable file is in your working folder. Run the target program and establish communication between Simulink and the target.

Note An external mode program like ex_extModeExample is a host-based executable. Its execution is not tied to a real-time operating system (RTOS) or a periodic timer interrupt, and it does not run in real time. The program just runs as fast as possible, and the time units it counts off are simulated time units that do not correspond to time in the world outside the program.

The External Signal & Triggering dialog box (accessed from the External Mode Control Panel) displays a list of blocks in your model that support external mode signal monitoring and logging. In the dialog box, you can configure the signals that are viewed, how they are acquired, and how they are displayed.

In this example, you observe and use the default settings of the External Signal & Triggering dialog box.
From the Code menu of the model diagram, select **External Mode Control Panel**. This control panel is where you configure signal monitoring and data archiving. You can also connect to the target program, and start and stop execution of the model code.

1. After the target program starts, you use the top row of buttons.
2. The **Signal & Triggering** button opens the External Signal & Triggering dialog box. Use this dialog box to select the signals that are collected from the target system and viewed in external mode. You can also select a signal that triggers uploading of data when certain signal conditions are met, and define the triggering conditions.
3. The **Data Archiving** button opens the Enable Data Archiving dialog box. Use data archiving to save data sets generated by the target program for future analysis. This example does not use data archiving. See “Configure Host Archiving of Target Program Signal Data” on page 44-60.
2 Click the **Signal & Triggering** button to open the External Signal & Triggering dialog box. The default configuration selects all signals for monitoring and sets signal monitoring to begin once the host and target programs are connected.

![External Signal & Triggering dialog box](image)

3 Make sure that the External Signal & Triggering dialog box options are set to these defaults:

- **Select all** check box is selected. Signals in the **Signal selection** list are marked with an X in the **Selected** column.
- Under **Trigger options**:
  - **Source**: manual
  - **Mode**: normal
- **Duration**: 1000
- **Delay**: 0
- **Arm when connecting to target**: selected

To close the External Signal & Triggering dialog box, click **OK**. Then, close the External Mode Control Panel.

For descriptions of the External Signal & Triggering dialog box parameters, see “Configure Host Monitoring of Target Program Signal Data” on page 44-52.

4. To run the target program, open an operating system command window (on UNIX systems, a terminal emulator window). At the command prompt, use `cd` to navigate to the `ext_mode_example` folder to which you generated the target program executable.

Enter this command:

```
ex_extModeExample -tf inf -w
```

**Note**  Alternatively, you can run the target program from the MATLAB Command Window, using the following syntax.

```
!ex_extModeExample -tf inf -w &
```

The target program begins execution, and enters a wait state.

The `-tf` switch overrides the stop time set for the model in Simulink. The `inf` value directs the model to run indefinitely. The model code runs until the target program receives a stop message from Simulink.

The `-w` switch instructs the target program to enter a wait state until it receives a **Start Real-Time Code** message from the host. If you want to view data from time step 0 of the target program execution, or if you want to modify parameters before the target program begins execution of model code, this switch is required.

5. Open the Scope blocks in the model. Signals are not visible on the scopes. When you connect Simulink to the target program and begin model execution, the signals generated by the target program become visible on the scope displays.
Before communication between the model and the target program can begin, the model must be in external mode. To enable external mode, from the Simulation > Mode menu, select External.

Reopen the External Mode Control Panel (found in the Code menu) and click Connect. This action initiates a handshake between Simulink and the target program. When Simulink and the target are connected, the Start Real-Time Code button becomes enabled, and the label of the Connect button changes to Disconnect.

Click Start Real-Time Code. The outputs of Gain blocks A and B are displayed on the two scopes in your model.

You have established communication between Simulink and the running target program. You can now tune block parameters in Simulink and observe the effects the parameter changes have on the target program.

**Tune Parameters**

You can change the gain factor of either Gain block by assigning a new value to the variable A or B in the MATLAB workspace. When you change block parameter values in the workspace during a simulation, you must explicitly update the block diagram with these changes. When you update the block diagram, the new values are downloaded to the target program.

Under certain conditions, you can also tune the expressions that you use to specify block parameter values. To change an expression during simulation, open the block dialog box.

1. At the command prompt, assign new values to both variables, for example:
   
   ```
   A = 0.5;
   B = 3.5;
   ```

2. Open the ex_extModeExample model window. From the Simulation menu, select Update Diagram. As soon as Simulink has updated the block parameters, the new gain values are downloaded to the target program, and the scopes are changed because of the gain change.

3. In the Sine Wave block dialog box, set Amplitude to 0.5. Click Apply or OK.

When you click Apply or OK, the simulation downloads the new block parameter value to the target program. The Scope block displays the change to reflect the new amplitude value.
To simultaneously disconnect host/target communication and end execution of the target program, from the **Simulation** menu, select **Stop**. Alternatively, in the External Mode Control Panel, click **Stop Real-Time Code**.

You cannot change the sample time of the Sine Wave block during simulation. Block sample times are part of the structural definition of the model and are part of the generated code. Therefore, if you want to change a block sample time, you must stop the external mode simulation, reset the sample time of the block, and rebuild the executable.

Block parameter tunability during external mode simulation depends on the way that the generated code represents block parameters.

For example, in the Gain A block dialog box, you cannot change the expression \( A \) in the **Gain** parameter during simulation. Instead, you must change the value of the variable \( A \) in the base workspace. You cannot change the expression because the generated code does not allocate storage in memory for the **Gain** parameter. Instead, the code creates a field \( A \) in a structure:

```c
/* Parameters (auto storage) */
struct P_ex_extModeExample_T_ {
    real_T A;                            /* Variable: A */
    real_T B;                            /* Variable: B */
    real_T SineWave_Amp;                 /* Expression: 1 */
    real_T SineWave_Bias;                /* Expression: 0 */
    real_T SineWave_Freq;                /* Expression: 1 */
    real_T SineWave_Phase;               /* Expression: 0 */
};
```

The generated code algorithm uses that field in the code that represents the block Gain A. In this case, the global structure variable `ex_extModeExample_P` uses the type `P_ex_extModeExample_T_`:

```c
ex_extModeExample_B.GainA = ex_extModeExample_P.A * rtb_SineWave;
```

When you change the value of \( A \) in the base workspace, the simulation downloads the new value to the field \( A \) in the target program.
You can change the expressions in the Sine Wave block parameters during simulation because the generated code creates a field in the global structure `ex_extModeExample_P` to represent each parameter in the block. When you change an expression in the block dialog box, the simulation first evaluates the new expression. The simulation then downloads the resulting numeric value to the corresponding structure field in the target program.

See “Create Tunable Calibration Parameter in the Generated Code” on page 22-121.

**Control Memory Allocation for Communication Buffers in Target**

If you select the Code Generation > Interface > Static memory allocation check box (for GRT and ERT targets), the code generator produces code for external mode that uses only static memory allocation ("malloc-free" code). Selecting Static memory allocation enables the Static memory buffer size parameter. Use this parameter to specify the size of the external mode static memory buffer. The default value is 1,000,000 bytes. If you enter too small a value for your program, external mode issues an out-of-memory error when it tries to allocate more memory than you allowed. In such cases, increase the value in the Static memory buffer size field and regenerate the code.

To determine how much memory to allocate, enable verbose mode on the target (by including `OPTS=-DVERBOSE` on the make command line). As it executes, external mode displays the amount of memory it tries to allocate and the amount of memory available to it each time it attempts an allocation. If an allocation fails, you can use this console log to adjust the size in the Static memory buffer size field.

**Pure Integer Code with External Mode**

For an ERT target, if you clear the Code Generation > Interface > Support: floating-point numbers check box, you can generate pure integer code that is free of doubles and floats. For more information, see “Model Configuration Parameters: Code Generation Interface” (Simulink Coder).

If you intend to generate pure integer code with External mode selected, note these requirements:

- Trigger signals must be of data type `int32`. Use a Data Type Conversion block if needed.
• When pure integer code is generated, the simulation stop time specified in the **Solver** options is ignored. To specify a stop time, run your target program from the MATLAB command line and use the `-tf` option. See “Run the External Program” (Simulink Coder). If you do not specify this option, the program executes indefinitely (as if the stop time were `inf`).

When executing pure integer target programs, the stop time specified by the `-tf` command line option is interpreted as the number of base rate ticks to execute, rather than as an elapsed time in seconds. The number of ticks is computed as

\[
\text{stop time in seconds} / \text{base rate step size in seconds}
\]

**Control External Mode Simulation Through Editor Toolbar**

This table gives Simulink Editor features that you can use to control an external mode simulation.

<table>
<thead>
<tr>
<th>External Mode Action</th>
<th>Toolbar Control</th>
<th>Menu Control</th>
<th>External Mode Control Panel Button</th>
</tr>
</thead>
<tbody>
<tr>
<td>Set the simulation mode of your model to external mode</td>
<td>From the simulation mode drop-down list, select <strong>External</strong></td>
<td><strong>Simulation &gt; Mode &gt; External</strong></td>
<td><strong>Connect</strong> (if the model simulation mode is not already set, sets the simulation mode to external mode)</td>
</tr>
<tr>
<td>Connect your model to a waiting or running target program</td>
<td><strong>Connect to Target</strong> button</td>
<td><strong>Simulation &gt; Connect to Target</strong></td>
<td><strong>Connect</strong></td>
</tr>
<tr>
<td>Start running real-time code in the target environment</td>
<td><strong>Run</strong> button</td>
<td><strong>Simulation &gt; Run</strong> (keyboard shortcut <strong>Ctrl +T</strong>)</td>
<td><strong>Start Real-Time Code</strong></td>
</tr>
<tr>
<td>Disconnect your model from the target environment (does not halt running real-time code)</td>
<td><strong>Disconnect from Target</strong> button</td>
<td><strong>Simulation &gt; Disconnect from Target</strong></td>
<td><strong>Disconnect</strong></td>

</tbody>
</table>
External Mode Action | Toolbar Control | Menu Control | External Mode Control Panel Button
---|---|---|---
Stop target program execution and disconnect your model from the target environment | **Stop** button | **Simulation > Stop** (keyboard shortcut Ctrl + Shift + T) | **Stop Real-Time Code**

**Control External Mode Simulation Through External Mode Control Panel**

The External Mode Control Panel provides centralized control of external mode operations, including:

- “Connect, Start, and Stop” on page 44-49
- “Upload Target Program Signal Data to Host” on page 44-50
- “Download Parameters to Target Program” on page 44-51
- “Configure Host Monitoring of Target Program Signal Data” on page 44-52
- “Configure Host Archiving of Target Program Signal Data” on page 44-60

To open the External Mode Control Panel dialog box, in the model window, select **Code > External Mode Control Panel**.
Connect, Start, and Stop

The External Mode Control Panel performs the same connect/disconnect and start/stop functions found in the Simulation menu and the Simulink toolbar (see “Control External Mode Simulation Through Editor Toolbar” on page 44-47).

Clicking the Connect button connects your model to a waiting or running target program. While you are connected, the button changes to a Disconnect button. Disconnect disconnects your model from the target environment, but does not halt real-time code running in the target environment.

Connect sets the model simulation mode to external mode.

Clicking the Start Real-Time Code button commands the target to start running real-time code. While real-time code is running in the target environment, the button changes
to a **Stop Real-Time Code** button. **Stop Real-Time Code** stops target program execution and disconnects your model from the target environment.

**Upload Target Program Signal Data to Host**

The External Mode Control Panel allows you to trigger and cancel data uploads to the host. The destination for the uploaded data can be a scope block, Display block, To Workspace block, or another block or subsystem listed in “Blocks and Subsystems Compatible with External Mode” on page 44-63.

The **Arm Trigger** and **Cancel Trigger** buttons provide manual control of data uploading to compatible blocks or subsystems, except floating scopes. (For floating scopes, use the **Floating scope** section of the External Mode Control Panel.)

- To trigger data uploading to compatible blocks or subsystems, click the **Arm Trigger** button. The button changes to **Cancel Trigger**.
- To cancel data uploading, click the **Cancel Trigger** button. The button reverts to **Arm Trigger**.

You can trigger data uploads manually or automatically. To configure signals and triggers for data uploads, see “Configure Host Monitoring of Target Program Signal Data” on page 44-52.

A subset of external mode compatible blocks, including Scope, Time Scope, and To Workspace, allow you to log uploaded data to disk. To configure data archiving, see “Configure Host Archiving of Target Program Signal Data” on page 44-60.

The **Floating scope** section of the External Mode Control Panel controls when and for how long data is uploaded to Floating Scope blocks. When used in external mode, floating scopes:

- Do not appear in the External Signal & Triggering dialog box.
- Do not log data to external mode archiving.
- Support manual triggering only.

The **Floating scope** section contains the following parameters:

- **Enable data uploading** option, which functions as an **Arm Trigger** button for floating scopes. When the target is disconnected, the option controls whether to arm the trigger when connecting the floating scopes. When the target is connected, the option acts as a toggle button to arm or cancel the trigger.
• To trigger data uploading to floating scopes, select **Enable data uploading**.
• To cancel data uploading to floating scopes, clear **Enable data uploading**.

**Duration** edit field, which specifies the number of base-rate steps for which external mode logs floating scopes data after a trigger event. By default, it is set to **auto**, which causes the duration value set in the External Signal & Triggering dialog box to be used. The default duration value is 1000 base rate steps.

**Download Parameters to Target Program**

The **Batch download** option on the External Mode Control Panel enables or disables batch parameter changes.

By default, batch download is disabled. If batch download is disabled, when you click **OK** or **Apply**, changes made directly to block parameters by editing block parameter dialog boxes are sent to the target. When you perform an **Update Diagram**, changes to MATLAB workspace variables are sent.

If you select **Batch download**, the **Download** button is enabled. Until you click **Download**, changes made to block parameters are stored locally. When you click **Download**, the changes are sent in a single transmission.

When parameter changes are awaiting batch download, the External Mode Control Panel displays the message **Parameter changes pending...** to the right of the **Download** button. This message remains visible until the Simulink engine receives notification that the new parameters have been installed in the parameter vector of the target system.

The next figure shows the External Mode Control Panel with the **Batch download** option activated and parameter changes pending.
Configure Host Monitoring of Target Program Signal Data

- “Role of Trigger in Signal Data Uploading” on page 44-53
- “Configure Signal Data Uploading” on page 44-53
- “Default Trigger Options” on page 44-54
- “Select Signals to Upload” on page 44-55
- “Configure Trigger Options” on page 44-55
- “Select Trigger Signal” on page 44-57
- “Set Trigger Conditions” on page 44-58
- “Modify Signal and Triggering Options While Connected” on page 44-59
Role of Trigger in Signal Data Uploading

In external mode, uploading target program signal data to the host depends on a trigger. The trigger is a set of conditions that must be met for data uploading to begin. The trigger can be armed or not armed.

- When the trigger is armed, the software checks for the trigger conditions that allow data uploading to begin.
- If the trigger is not armed, the software does not check for the trigger conditions and data uploading cannot begin.
- The trigger can be armed automatically, when the host connects to the target, or manually, by clicking the Arm Trigger button on the External Mode Control Panel.

When the trigger is armed and the trigger conditions are met, the trigger fires and data uploading begins.

When data has been collected for a defined duration, the trigger event completes and data uploading stops. The trigger can then rearm, or remain unarmed until you click the Arm Trigger button.

To select the target program signals to upload and configure how uploads are triggered, see “Configure Signal Data Uploading” on page 44-53.

Configure Signal Data Uploading

Clicking the Signal & Triggering button of the External Mode Control Panel opens the External Signal & Triggering dialog box.
The External Signal & Triggering dialog box displays a list of blocks and subsystems in your model that support external mode signal uploading. For information on which types of blocks are external mode compatible, see “Blocks and Subsystems Compatible with External Mode” on page 44-63.

In the External Signal & Triggering dialog box, you can select the signals that are collected from the target system and viewed in external mode. You can also select a trigger signal, which triggers uploading of data based on meeting certain signal conditions, and define the triggering conditions.

**Default Trigger Options**

The preceding figure shows the default settings of the External Signal & Triggering dialog box. The default operation of the External Signal & Triggering dialog box simplifies
monitoring the target program. If you use the default settings, you do not need to preconfigure signals and triggers. You start the target program and connect the Simulink engine to it. External mode compatible blocks are selected and the trigger is armed. Signal uploading begins immediately upon connection to the target program.

The default configuration of trigger options is:

- Select all: on
- Source: manual
- Mode: normal
- Duration: 1000
- Delay: 0
- Arm when connecting to target: on

**Select Signals to Upload**

External mode compatible blocks in your model appear in the **Signal selection** list of the External Signal & Triggering dialog box. You use this list to select signals that you want to view. In the **Selected** column, an X appears for each selected block.

The **Select all** check box selects all signals. By default, **Select all** is selected.

If **Select all** is cleared, you can select or clear individual signals using the **on** and **off** options. To select a signal, click its list entry and select the **on** option. To clear a signal, click its list entry and select the **off** option.

The **Clear all** button clears all signals.

**Configure Trigger Options**

As described in “Role of Trigger in Signal Data Uploading” on page 44-53, signal data uploading depends on a trigger. The trigger defines conditions that must be met for uploading to begin. Also, the trigger must be armed for data uploading to begin. When the trigger is armed and trigger conditions are met, the trigger fires and uploading begins. When data has been collected for a defined duration, the trigger event completes and data uploading stops.

To control when and how signal data is collected (uploaded) from the target system, configure the following **Trigger options** in the External Signal & Triggering dialog box.
• **Source**: manual or signal. Controls whether a button or a signal triggers data uploading.

Selecting manual directs external mode to use the Arm Trigger button on the External Mode Control Panel as the trigger to start uploading data. When you click Arm Trigger, data uploading begins.

Selecting signal directs external mode to use a trigger signal as the trigger to start uploading data. When the trigger signal satisfies trigger conditions (that is, the signal crosses the trigger level in the specified direction), a trigger event occurs. (Specify trigger conditions in the Trigger signal section.) If the trigger is armed, external mode monitors for the occurrence of a trigger event. When a trigger event occurs, data uploading begins.

• **Mode**: normal or one-shot. Controls whether the trigger rearms after a trigger event completes.

In normal mode, external mode automatically rearms the trigger after each trigger event. The next data upload begins when the trigger fires.

In one-shot mode, external mode collects only one buffer of data each time you arm the trigger.

For more information on the Mode setting, see “Configure Host Archiving of Target Program Signal Data” on page 44-60.

• **Duration**: Specifies the number of base rate steps for which external mode uploads data after a trigger event (default is 1000). For example, if Duration is set to 1000, and the base (fastest) rate of the model is one second:

  • For a signal sampled at the base rate, one second (1.0 Hz), external mode collects 1000 contiguous samples during a trigger event.
  • For a signal sampled at two seconds (0.5 Hz), external mode collects 500 samples during a trigger event.

• **Delay**: Specifies a delay to be applied to data collection. The delay represents the amount of time that elapses between a trigger event and the start of data collection. The delay is expressed in base rate steps. It can be positive or negative (default is 0). A negative delay corresponds to pretriggering. When the delay is negative, data from the time preceding the trigger event is collected and uploaded.

• **Arm when connecting to target**: Selected or cleared. Whether a button or a signal triggers data uploading (as defined by Source), the trigger must be armed to allow data uploading to begin.
If you select this option, connecting to the target arms the trigger.

- If the trigger **Source** is **manual**, data uploading begins immediately.
- If the trigger **Source** is **signal**, monitoring of the trigger signal begins immediately. Data uploading begins when the trigger signal satisfies trigger conditions (as defined in the **Trigger signal** section).

If you clear **Arm when connecting to target**, manually arm the trigger by clicking the **Arm Trigger** button on the External Mode Control Panel.

When simulating in external mode, each rate in the model creates a buffer on the target. Each entry in the buffer is big enough to hold all of the data required of every signal in that rate for one time step (time plus data plus external mode indices identifying the signal). The number of entries in the circular buffer is determined by the external mode trigger **Duration** parameter (ExtModeTrigDuration). The memory allocated on the target for buffering signals is proportional to the **Duration** and the number of signals uploading. The **Duration** also provides an indication of the number of base rate steps with log data after a trigger event in external mode.

The **Duration** value specifies the number of contiguous points of data to be collected in each buffer of data. You should enter a **Duration** value equal to the number of continuous sample points that you need to collect rather than relying on a series of buffers to be continuous. If you enter a value less than the total number of sample points, you may lose sample points during the time spent transferring values from the data buffer to the MATLAB workspace. The Simulink software maintains point continuity only within one buffer. Between buffers, because of transfer time, some samples may be omitted.

The **Duration** value can affect the **Limit data points to last** value of Scope and To Workspace blocks. The number of sample points that the blocks save to the MATLAB workspace is the smaller of the two values. To set the number of sample points that the blocks save, clear **Limit data points to last**. Then, use **Duration** to specify the number of sample points saved.

**Select Trigger Signal**

You can designate one signal as a trigger signal. To select a trigger signal, from the **Source** menu in the **Trigger options** section, select **signal**. This action enables the parameters in the **Trigger signal** section. Then, select a signal in the **Signal selection** list, and click the **Trigger Signal** button.
When you select a signal to be a trigger, a T appears in the **Trigger** column of the **Signal selection** list. In the next figure, the Scope A signal is the trigger. Scope B is also selected for viewing, as indicated by the X in the **Selected** column.

![Image](image.png)

After selecting the trigger signal, you can use the **Trigger signal** section to define the trigger conditions and set the trigger signal **Port** and **Element** parameters.

**Set Trigger Conditions**

Use the **Trigger signal** section of the **External Signal & Triggering** dialog box to set trigger conditions and attributes. **Trigger signal** parameters are enabled only when the trigger parameter **Source** is set to **signal** in the **Trigger options** section.

By default, any element of the first input port of a specified trigger block can cause the trigger to fire (that is, Port 1, any element). You can modify this behavior by adjusting the
Port and Element values in the Trigger signal section. The Port field accepts a number or the keyword last. The Element field accepts a number or the keywords any or last.

In the Trigger signal section, you also define the conditions under which a trigger event occurs.

- **Direction**: rising, falling, or either. The direction in which the signal must be traveling when it crosses the threshold value. The default is rising.
- **Level**: A value indicating the threshold the signal must cross in a designated direction to fire the trigger. By default, the level is 0.
- **Hold-off**: Applies only to normal mode. Expressed in base rate steps, Hold-off is the time between the termination of one trigger event and the rearming of the trigger.

Modify Signal and Triggering Options While Connected

After you configure signal data uploading, and connect Simulink to a running target executable, you can modify signal and triggering options without disconnecting from the target.

If the trigger is armed (for example, if the trigger option Arm when connecting to the target is selected, which is the default), the External Signal & Triggering dialog box cannot be modified. To modify signal and triggering options:

1. Open the External Mode Control Panel.
2. Click Cancel Trigger. Triggering and display of uploaded data stops.
3. Open the External Signal & Triggering dialog box and modify signal and trigger options as required. For example, in the Signal selection section, you can enable or disable a scope, and in the Trigger options section, change the trigger Mode, for example, from normal to one-shot.
4. Click Arm Trigger. Triggering and display of uploaded data resumes, with your modifications.
Configure Host Archiving of Target Program Signal Data

In external mode, you can use the Simulink Scope and To Workspace blocks to archive data to disk.

To understand how the archiving features work, consider the handling of data when archiving is not enabled. There are two cases, one-shot mode and normal mode.

- In one-shot mode, after a trigger event occurs, each selected block writes its data to the workspace, as it would at the end of a simulation. If another one-shot is triggered, the existing workspace data is overwritten.
- In normal mode, external mode automatically rearms the trigger after each trigger event. Consequently, you can think of normal mode as a series of one-shots. Each one-shot in this series, except for the last, is referred to as an intermediate result. Because the trigger can fire at any time, writing intermediate results to the workspace can
result in unpredictable overwriting of the workspace variables. For this reason, the default behavior is to write only the results from the final one-shot to the workspace. The intermediate results are discarded. If you know that enough time exists between triggers for inspection of the intermediate results, you can override the default behavior by selecting the Write intermediate results to workspace option. This option does not protect the workspace data from being overwritten by subsequent triggers.

If you use a Simulink Scope block to archive data to disk, open the Scope parameters dialog box and select the option Log data to workspace. The option is required for these reasons:

• The data is first transferred from the scope data buffer to the MATLAB workspace, before being written to a MAT-file.
• The Variable name entered in the Scope parameters dialog box is the same as the one in the MATLAB workspace and the MAT-file. Enabling the data to be saved enables a variable named with the Variable name parameter to be saved to a MAT-file.

**Note** If you do not select the Scope block option Log data to workspace, the MAT-files for data logging are created, but they are empty.

The Enable Data Archiving dialog box supports:

• Folder notes
• File notes
• Automated data archiving

On the External Mode Control Panel, click the Data Archiving button to open the Enable Data Archiving dialog box. If your model is connected to the target environment, disconnect it while you configure data archiving. To enable the other controls in the dialog box, select Enable archiving.
These operations are supported by the Enable Data Archiving dialog box.

**Folder Notes**

To add annotations for a collection of related data files in a folder, in the Enable Data Archiving dialog box, click **Edit Directory Note**. The MATLAB editor opens. Place comments that you want saved to a file in the specified folder in this window. By default, the comments are saved to the folder last written to by data archiving.

**File Notes**

To add annotations for an individual data file, in the Enable Data Archiving dialog box, click **Edit File Note**. A file finder window opens, which by default is set to the last file to which you have written. Selecting a MAT-file opens an edit window. In this window, add or edit comments that you want saved with your individual MAT-file.
Automated Data Archiving

To configure automatic writing of logging results to disk, optionally including intermediate results, use the Enable archiving option and the controls it enables. The dialog box provides the following related controls:

- **Directory**: Specifies the folder in which data is saved. If you select Increment directory when trigger armed, external mode appends a suffix.
- **File**: Specifies the name of the file in which data is saved. If you select Increment file after one-shot, external mode appends a suffix.
- **Increment directory when trigger armed**: Each time that you click the Arm Trigger button, external mode uses a different folder for writing log files. The folders are named incrementally, for example, dirname1, dirname2, and so on.
- **Increment file after one-shot**: New data buffers are saved in incremental files: filename1, filename2, and so on. File incrementing happens automatically in normal mode.
- **Append file suffix to variable names**: Whenever external mode increments file names, each file contains variables with identical names. Selecting Append file suffix to variable names results in each file containing unique variable names. For example, external mode saves a variable named xdata in incremental files (file_1, file_2, and so on) as xdata_1, xdata_2, and so on. This approach supports loading the MAT-files into the workspace and comparing variables at the MATLAB command prompt. Without the unique names, each instance of xdata would overwrite the previous one in the MATLAB workspace.
- **Write intermediate results to workspace**: If you want the Simulink Coder software to write intermediate results to the workspace, select this option.

Blocks and Subsystems Compatible with External Mode

- “Compatible Blocks” on page 44-63
- “Signal Viewing Subsystems” on page 44-64
- “Supported Blocks for Data Archiving” on page 44-66

Compatible Blocks

In external mode, you can use the following types of blocks to receive and view signals uploaded from the target program:
• Floating Scope and Scope blocks
• Spectrum Analyzer and Time Scope blocks from the DSP System Toolbox product
• Display blocks
• To Workspace blocks
• User-written S-Function blocks

An external mode method is built into the S-function API. This method allows user-written blocks to support external mode. See `matlabroot/simulink/include/simstruc.h`.

• XY Graph blocks

You can designate certain subsystems as Signal Viewing Subsystems and use them to receive and view signals uploaded from the target program. See “Signal Viewing Subsystems” on page 44-64 for more information.

You select external mode compatible blocks and subsystems, and arm the trigger, by using the External Signal & Triggering dialog box. By default, such blocks in a model are selected, and a manual trigger is set to be armed when connected to the target program.

**Signal Viewing Subsystems**

A Signal Viewing Subsystem is an atomic subsystem that encapsulates processing and viewing of signals received from the target system. A Signal Viewing Subsystem runs only on the host, and does not generate code in the target system. Signal Viewing Subsystems run in normal, accelerator, rapid accelerator, and external simulation modes.

**Note** Signal Viewing Subsystems are inactive if placed inside a SIL or PIL component, such as a top model in SIL or PIL mode, a Model block in SIL or PIL mode, or a SIL or PIL block. However, a SIL or PIL component can feed a Signal Viewing Subsystem running in a supported mode.

Signal Viewing Subsystems are useful in situations where you want to process or condition signals before viewing or logging them, but you do not want to perform these tasks on the target system. By using a Signal Viewing Subsystem, you can generate smaller and more efficient code on the target system.

Like other external mode compatible blocks, Signal Viewing Subsystems are displayed in the External Signal & Triggering dialog box.
To declare a subsystem to be a Signal Viewing Subsystem:

1. In the Block Parameters dialog box, select the Treat as atomic unit option.

   For more information on atomic subsystems, see “Control Generation of Subsystem Functions” (Simulink Coder).

2. To turn the SimViewingDevice property on, use the set_param command:

   ```matlab
   set_param('blockname', 'SimViewingDevice','on')
   ```

   'blockname' is the name of the subsystem.

3. Make sure the subsystem meets the following requirements:

   - It must be a pure Sink block. That is, it must not contain Outport blocks or Data Store blocks. It can contain Goto blocks only if the corresponding From blocks are contained within the subsystem boundaries.
   - It must not have continuous states.

The following model, sink_examp, contains an atomic subsystem, theSink.

![Sine Wave to theSink](image)

The subsystem theSink applies a gain and an offset to its input signal and displays it on a Scope block.

![Gain and Offset](image)

If theSink is declared as a Signal Viewing Subsystem, the generated target program includes only the code for the Sine Wave block. If theSink is selected and armed in the
External Signal & Triggering dialog box, the target program uploads the sine wave signal to theSink during simulation. You can then modify the parameters of the blocks within theSink and observe the uploaded signal.

If theSink were not declared as a Signal Viewing Subsystem, its Gain, Constant, and Sum blocks would run as subsystem code on the target system. The Sine Wave signal would be uploaded to the Simulink engine after being processed by these blocks, and viewed on sink_examp/theSink/Scope2. Processing demands on the target system would be increased by the additional signal processing, and by the downloading of changes in block parameters from the host.

**Supported Blocks for Data Archiving**

In external mode, you can use the following types of blocks to archive data to disk:

- Scope blocks
- To Workspace blocks

You configure data archiving by using the Enable Data Archiving dialog box, as described in “Configure Host Archiving of Target Program Signal Data” on page 44-60.

**External Mode Mechanism for Downloading Tunable Parameters**

- “Download Mechanism” on page 44-66
- “Inlined and Tunable Parameters” on page 44-68

Depending on the setting of the **Default parameter behavior** option when the target program is generated, there are differences in the way parameter updates are handled. “Download Mechanism” on page 44-66 describes the operation of external mode communication with **Default parameter behavior** set to Tunable. “Inlined and Tunable Parameters” on page 44-68 describes the operation of external mode with **Default parameter behavior** set to Inlined.

**Download Mechanism**

In external mode, the Simulink engine does not simulate the system represented by the block diagram. By default, when external mode is enabled, the Simulink engine downloads parameters to the target system. After the initial download, the engine remains in a waiting mode until you change parameters in the block diagram or until the engine receives data from the target.
When you change a parameter in the block diagram, the Simulink engine calls the external interface MEX-file, passing new parameter values (along with other information) as arguments. The external interface MEX-file contains code that implements one side of the interprocess communication (IPC) channel. This channel connects the Simulink process (where the MEX-file executes) to the process that is executing the external program. The MEX-file transfers the new parameter values by using this channel to the external program.

The other side of the communication channel is implemented within the external program. This side writes the new parameter values into the target's parameter structure \((model\_P)\).

The Simulink side initiates the parameter download operation by sending a message containing parameter information to the external program. In the terminology of client/server computing, the Simulink side is the client and the external program is the server. The two processes can be remote, or they can be local. Where the client and server are remote, a protocol such as TCP/IP is used to transfer data. Where the client and server are local, a serial connection or shared memory can be used to transfer data.

The next figure shows this relationship. The Simulink engine calls the external interface MEX-file whenever you change parameters in the block diagram. The MEX-file then downloads the parameters to the external program by using the communication channel.
External Mode Architecture

Inlined and Tunable Parameters

By default, parameters (except those listed in “TCP/IP and Serial External Mode Limitations” on page 44-85) in an external mode program are tunable; that is, you can change them by using the download mechanism described in this section.

If you set Default parameter behavior to Inlined (on the Optimization pane of the Configuration Parameters dialog box), the Simulink Coder code generator embeds the numerical values of model parameters (constants), instead of symbolic parameter names,
in the generated code. Inlining parameters generates smaller and more efficient code. However, inlined parameters, because they effectively become constants, are not tunable.

The Simulink Coder software lets you improve overall efficiency by inlining most parameters, while at the same time retaining the flexibility of run-time tuning for selected parameters that are important to your application. When you inline parameters, you can use Simulink.Parameter objects to remove individual parameters from inlining and declare them to be tunable. In addition, you can use these objects to control how parameters are represented in the generated code.

For more information on tunable parameters, see “Create Tunable Calibration Parameter in the Generated Code” on page 22-121.

**Automatic Parameter Uploading on Host/Target Connection**

Each time the Simulink engine connects to a target program that was generated with Default parameter behavior set to Inlined, the target program uploads the current value of its tunable parameters to the host. These values are assigned to the corresponding MATLAB workspace variables. This procedure synchronizes the host and target with respect to parameter values.

Workspace variables required by the model must be initialized at the time of host/target connection. Otherwise the uploading cannot proceed and an error results. Once the connection is made, these variables are updated to reflect the current parameter values on the target system.

Automatic parameter uploading takes place only if the target program was generated with Default parameter behavior set to Inlined. “Download Mechanism” on page 44-66 describes the operation of external mode communication with Default parameter behavior set to Tunable.

**Choose Communication Protocol for Client and Server**

- “Introduction” on page 44-70
- “Using the TCP/IP Implementation” on page 44-70

- “Implement an External Mode Protocol Layer” on page 44-77
Introduction

The Simulink Coder product provides code to implement both the client and server side of external mode communication using either TCP/IP or serial protocols. You can use the socket-based external mode implementation provided by the Simulink Coder product with the generated code, provided that your target system supports TCP/IP. If not, use or customize the serial transport layer option provided.

A low-level transport layer handles physical transmission of messages. Both the Simulink engine and the model code are independent of this layer. Both the transport layer and code directly interfacing to the transport layer are isolated in separate modules that format, transmit, and receive messages and data packets.

Using the TCP/IP Implementation

You can use TCP/IP-based client/server implementation of external mode with real-time programs on The Open Group UNIX or PC systems. For help in customizing external mode transport layers, see “Create a Transport Layer for TCP/IP or Serial External Mode Communication” (Simulink Coder).

To use Simulink external mode over TCP/IP:

• Make sure that the external interface MEX-file for your target's TCP/IP transport is specified.

Targets provided by MathWorks specify the name of the external interface MEX-file in \matlabroot\toolbox\simulink\simulink\extmode_transports.m. The name of the interface appears as uneditable text in the External mode configuration section of the Interface pane of the Configuration Parameters dialog box. The TCP/IP default is ext_comm.

To specify a TCP/IP transport for a custom target, you must add an entry of the following form to an sl_customization.m file on the MATLAB path:

```matlab
function sl_customization(cm)
    cm.ExtModeTransports.add('stf.tlc', 'transport', 'mexfile', 'Level1');
%end function
```

• `stf.tlc` is the name of the system target file for which you are registering the transport (for example, 'mytarget.tlc')
• `transport` is the transport name to display in the Transport layer menu on the Interface pane of the Configuration Parameters dialog box (for example, 'tcpip')
• *mexfile* is the name of the transport's associated external interface MEX-file (for example, 'ext_comm')

You can specify multiple targets and/or transports with additional `cm.ExtModeTransports.add` lines, for example:

```matlab
function sl_customization(cm)
    cm.ExtModeTransports.add('mytarget.tlc', 'tcpip', 'ext_comm', 'Level1');
    cm.ExtModeTransports.add('mytarget.tlc', 'serial', ...
                                'ext_serial_win32_comm', 'Level1');
%end function
```

• Be sure that the template makefile is configured to link the source files for the TCP/IP server code and that it defines the compiler flags when building the generated code.

• Build the external program.

• Run the external program.

• Set the Simulink model to external mode and connect to the target.

The next figure shows the structure of the TCP/IP-based implementation.
TCP/IP-Based Client/Server Implementation for External Mode

MEX-File Optional Arguments for TCP/IP Transport

In the External Target Interface dialog box, you can specify optional arguments that are passed to the external mode interface MEX-file for communicating with executing targets.

- Target network name: the network name of the computer running the external program. By default, this is the computer on which the Simulink product is running, for example, 'myComputer'. You can also use the IP address, for example, '148.27.151.12'.
- Verbosity level: controls the level of detail of the information displayed during the data transfer. The value is either 0 or 1 and has the following meaning:
0 — No information
1 — Detailed information

- TCP/IP server port number: The default value is 17725. You can change the port number to a value between 256 and 65535 to avoid a port conflict.

The arguments are positional and must be specified in the following order:
<TargetNetworkName> <VerbosityLevel> <ServerPortNumber>

For example, if you want to specify the verbosity level (the second argument), then you must also specify the target network name (the first argument). Arguments can be delimited by white space or commas. For example:

'148.27.151.12' 1 30000

You can specify command-line options to the external program when you launch it. See “Run the External Program” on page 44-75.

**Using the Serial Implementation**

Controlling host/target communication on a serial channel is similar to controlling host/target communication on a TCP/IP channel.

To use Simulink external mode over a serial channel, you must:

- Make sure that the external interface MEX-file for your target's serial transport is specified.

Targets provided by MathWorks specify the name of the external interface MEX-file in `matlabroot/toolbox/simulink/simulink/extmode_transports.m`. The name of the interface appears as uneditable text in the External mode configuration section of the Interface pane of the Configuration Parameters dialog box. The serial default is `serial`.

To specify a serial transport for a custom target, you must add an entry of the following form to an `sl_customization.m` file on the MATLAB path:

```matlab
function sl_customization(cm)
    cm.ExtModeTransports.add('stf.tlc', 'transport', 'mexfile', 'Level1');
%end function
```

- `stf.tlc` is the name of the system target file for which you are registering the transport (for example, 'mytarget.tlc')
• **transport** is the transport name to display in the **Transport layer** menu on the **Interface** pane of the Configuration Parameters dialog box (for example, 'serial')

• **mexfile** is the name of the transport's associated external interface MEX-file (for example, 'ext_serial_win32_comm')

You can specify multiple targets and/or transports with additional `cm.ExtModeTransports.add` lines, for example:

```matlab
function sl_customization(cm)
    cm.ExtModeTransports.add('mytarget.tlc', 'tcpip', 'ext_comm', 'Level1');
    cm.ExtModeTransports.add('mytarget.tlc', 'serial', ...
        'ext_serial_win32_comm', 'Level1');
%end function
```

• Be sure that the template makefile is configured to link the source files for the serial server code and that it defines the compiler flags when building the generated code.

• Build the external program.

• Run the external program.

• Set the Simulink model to external mode and connect to the target.

**MEX-File Optional Arguments for Serial Transport**

In the **MEX-file arguments** field of the **Interface** pane of the Configuration Parameters dialog box, you can specify arguments that are passed to the external mode interface MEX-file for communicating with the executing targets. For serial transport, the optional arguments to `ext_serial_win32_comm` are as follows:

• Verbosity level: This argument controls the level of detail of the information displayed during data transfer. The value of this argument is:
  - 0 (no information), or
  - 1 (detailed information)

• Serial port ID: The port ID of the host, specified as an integer or character vector. For example, specify the port ID of a USB to serial converter as '/dev/ttyusb0'. Simulink Coder prefixes integer port IDs with \\COM on Windows and by /dev/ttyS on Unix.

When you start the target program using a serial connection, you must specify the port ID to use to connect it to the host. Do this by including the **-port** command-line option. For example:

```
mytarget.exe -port 2 -w
```
• Baud rate: Specify an integer value. The default value is 57600.

The MEX-file options arguments are positional and must be specified in the following order:

<VerbosityLevel> <SerialPortID> <BaudRate>

For example, if you want to specify the serial port ID (the second argument), then you must also specify the verbosity level (the first argument). Arguments can be delimited by white space or commas. For example:

1 '/dev/ttyusb0' 57600

When you launch the external program, you can specify command-line options.

**Run the External Program**

Before you can use the Simulink product in external mode, the external program must be running.

If the target program is executing on the same machine as the host and communication is through a loopback serial cable, the target's port ID must differ from that of the host (as specified in the MEX-file arguments edit field).

To run the external program, you type a command of the form:

```
model -opt1 ... -optN
```

*model* is the name of the external program and *-opt1* ... *-optN* are options. (See “Command-Line Options for the External Program” on page 44-76.) In the examples in this section, the name of the external program is *ext_example*.

**Running the External Program in the Windows Environment**

In the Windows environment, you can run the external programs in either of the following ways:

• Open a Command Prompt window. At the command prompt, type the name of the target executable, followed by possible options, such as:

  ```
  ext_example -tf inf -w
  ```

• Alternatively, you can launch the target executable from the MATLAB Command Window. The command must be preceded by an exclamation point (!) and followed by an ampersand (&), as in the following example:
!ext_example -tf inf -w &

The ampersand (&) causes the operating system to spawn another process to run the target executable. If you do not include the ampersand, the program still runs, but you cannot enter commands at the MATLAB command prompt or manually terminate the executable.

**Running the External Program in the UNIX Environment**

In the UNIX environment, you can run the external programs in either of the following ways:

- Open an Xterm window. At the command prompt, type the name of the target executable, followed by possible options, such as:

  ./ext_example -tf inf -w

- Alternatively, you can launch the target executable from the MATLAB Command Window. You must run it in the background so that you can still access the Simulink environment. The command must be preceded by an exclamation point (!), dot slash (/ indicating the current directory), and followed by an ampersand (&), as in the following example:

  !./ext_example -tf inf -w &

  The ampersand (&) causes the operating system to spawn another process to run the target executable.

**Command-Line Options for the External Program**

External mode target executables generated by the Simulink Coder code generator support the following command-line options:

- **-tf n**

  The -tf option overrides the stop time set in the Simulink model. The argument n specifies the number of seconds the program will run. The value inf directs the model to run indefinitely. In this case, the model code runs until the target program receives a stop message from the Simulink engine.

  The following example sets the stop time to 10 seconds.

  ext_example -tf 10
When integer-only ERT targets are built and executed in external mode, the stop time parameter (-tf) is interpreted by the target as the number of base rate ticks rather than the number of seconds to execute.

- **-w**

Instructs the target program to enter a wait state until it receives a message from the host. At this point, the target is running, but not executing the model code. The start message is sent when you select **Start Real-Time Code** from the Simulation menu or click the **Start Real-Time Code** button in the External Mode Control Panel.

Use the **-w** option if you want to view data from time step 0 of the target program execution, or if you want to modify parameters before the target program begins execution of model code.

- **-port n**

Specifies the TCP/IP port number or the serial port ID, n, for the target program. The port number of the target program must match that of the host for TCP/IP transport. The port number depends on the type of transport.

  - For TCP/IP transport: Port number is an integer between 256 and 65535, with the default value being 17725.
  - For serial transport: Port ID is an integer or a character vector. For example, specify the port ID of a USB to serial converter as `/dev/ttyusb0`

- **-baud r**

Specified as an integer, this option is only available for serial transport.

**Implement an External Mode Protocol Layer**

If you want to implement your own transport layer for external mode communication, you must modify certain code modules provided by the Simulink Coder product and create a new external interface MEX-file. See “Create a Transport Layer for TCP/IP or Serial External Mode Communication” (Simulink Coder).

**Use External Mode Programmatically**

You can run external mode simulations from the MATLAB command line or programmatically in scripts. Use the `get_param` and `set_param` commands to retrieve and set the values of model simulation command-line parameters, such as
SimulationMode and SimulationCommand, and external mode command-line parameters, such as ExtModeCommand and ExtModeTrigType.

The following model simulation commands assume that a Simulink model is open and that you have loaded a target program to which the model will connect using external mode.

1. Change the Simulink model to external mode:
   ```
   set_param(gcs,'SimulationMode','external')
   ```

2. Connect the open model to the loaded target program:
   ```
   set_param(gcs,'SimulationCommand','connect')
   ```

3. Start running the target program:
   ```
   set_param(gcs,'SimulationCommand','start')
   ```

4. Stop running the target program:
   ```
   set_param(gcs,'SimulationCommand','stop')
   ```

5. Disconnect the target program from the model:
   ```
   set_param(gcs,'SimulationCommand','disconnect')
   ```

To tune a workspace parameter, change its value at the command prompt. If the workspace parameter is a `Simulink.Parameter` object, assign the new value to the Value property.

```matlab
myVariable = 5.23;
myParamObj.Value = 5.23;
```

To download the workspace parameter in external mode, you update the model diagram. The following model simulation command initiates a model update:

```
set_param(gcs,'SimulationCommand','update')
```

To trigger or cancel data uploading to scopes, use the `ExtModeCommand` values `armFloating` and `cancelFloating`, or `armWired` and `cancelWired`. For example, to trigger and then cancel data uploading to wired (nonfloating) scopes:

```matlab
set_param(gcs,'ExtModeCommand','armWired')
set_param(gcs,'ExtModeCommand','cancelWired')
```

The next table lists external mode command-line parameters that you can use in `get_param` and `set_param` commands. The table provides brief descriptions, valid
values (bold type highlights defaults), and a mapping to External Mode dialog box equivalents. For external mode parameters that are equivalent to **Interface** pane options in the Configuration Parameters dialog box, see “Model Configuration Parameters: Code Generation Interface” (Simulink Coder).
## External Mode Command-Line Parameters

Animate Stateflow Charts in External Mode

If you have Stateflow, you can animate a chart in external mode. In external mode, you can animate states in a chart, and view test point signals in a floating scope or signal viewer.

- “Animate States During Simulation in External Mode” on page 44-84
- “View Test Point Data in Floating Scopes and Signal Viewers” on page 44-85

Animate States During Simulation in External Mode

To animate states in a chart in external mode:

1. Load the chart you want to animate to the target machine.
2. Open the Model Configuration Parameters dialog box.
3. In the left Select pane, select Code Generation > Interface.
4. In the Data exchange interface section, select External mode and click OK.
5. In the Simulink Editor, select Code > External Mode Control Panel.
6. In the External Mode Control Panel dialog box, click Signal & Triggering.
7. In the External Signal & Triggering dialog box, set these parameters.

<table>
<thead>
<tr>
<th>In:</th>
<th>Select:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Signal selection pane</td>
<td>Chart you want to animate</td>
</tr>
<tr>
<td>Trigger pane</td>
<td>Arm when connecting to target check box</td>
</tr>
<tr>
<td>Trigger pane</td>
<td>normal from drop-down menu in Mode field</td>
</tr>
</tbody>
</table>

8. Build the model to generate an executable file.
9. Start the target in the background. At the MATLAB prompt, type:

   `!model_name.exe -w &`

   For example, if the name of your model is `my_control_sys`, enter this command:

   `!my_control_sys.exe -w &`

   -w allows the target code to wait for the Simulink model connection.

10. In the Model Editor, select Simulation > Mode > External, and then select Simulation > Connect to Target.
11 Start simulation. The chart highlights states as they execute.

**View Test Point Data in Floating Scopes and Signal Viewers**

When you simulate a chart in external mode, you can designate chart data of local scope to be test points and view the test point data in floating scopes and signal viewers.

To view test point data during simulation in external mode:

1 Open the Model Explorer and for each data you want to view, follow these steps:
   a In the middle **Contents** pane, select the state or local data of interest.
   b In the right **Dialog** pane, select the **Logging** tab and select **Test point** check box.
2 From a floating scope or signal viewer, click the signal selection button:

   ![Signal Selection Button](image)

   The Signal Selector dialog box opens.
3 In the Signal Selector **Model hierarchy** pane, select the chart.
4 In the Signal Selector **List contents** menu, select **Testpointed/Logged signals only** and then select the signals you want to view.
5 Simulate the model in external mode as described in “Animate States During Simulation in External Mode” on page 44-84.

   The scope or viewer displays the values of the test point signals as the simulation runs.

For more information, see “Behavior of Scopes and Viewers with Rapid Accelerator Mode” (Simulink).

**TCP/IP and Serial External Mode Limitations**

- “Changing Parameters” on page 44-86
- “Mixing 32-Bit and 64-Bit Architectures” on page 44-87
- “Uploading Data” on page 44-87
- “Uploading Variable-Size Signals” on page 44-87
Changing Parameters

In general, you cannot change a parameter if doing so results in a change in the structure of the model. For example, you cannot change

- The number of states, inputs, or outputs of a block
- The sample time or the number of sample times
- The integration algorithm for continuous systems
- The name of the model or of a block
- The parameters to the Fcn block

If you make these changes to the block diagram, then you must rebuild the program with newly generated code.

You can change parameters in transfer function and state space representation blocks in specific ways:

- The parameters (numerator and denominator polynomials) for the Transfer Fcn (continuous and discrete) and Discrete Filter blocks can be changed (as long as the number of states does not change).
- Zero entries in the State-Space and Zero Pole (both continuous and discrete) blocks in the user-specified or computed parameters (that is, the A, B, C, and D matrices obtained by a zero-pole to state-space transformation) cannot be changed once external simulation is started.
- In the State-Space block, if you specify the matrices in the controllable canonical realization, then all changes to the A, B, C, D matrices that preserve this realization and the dimensions of the matrices are allowed.
If the Simulink block diagram does not match the external program, Simulink produces an error stating that the checksums do not match. The checksums take into account the top models, but not referenced models. Use the updated block diagram to rebuild the target program.

**Mixing 32-Bit and 64-Bit Architectures**

When you use external mode, the machine running the Simulink product and the machine running the target executable must have matching bit architectures, either 32-bit or 64-bit. The Simulink Coder software varies a model's checksum based on whether it is configured for a 32-bit or 64-bit platform.

If you attempt to connect from a 32-bit machine to a 64-bit machine or vice versa, the external mode connection fails.

**Uploading Data**

External mode does not support uploading data values for fixed-point or enumerated types into workspace parameters.

**Uploading Variable-Size Signals**

External mode does not support uploading variable-size signals for the following targets:

- Simulink Real-Time
- Texas Instruments™ C2000™

**Signal Value Display in Simulation**

External mode does not support graphical display of signal values in models (described in “Displaying Signal Values in Model Diagrams” (Simulink)). For example, you cannot use the Data Display in Simulation menu selections *Show Value Labels When Hovering, Toggle Value Labels When Clicked*, and *Show Value Label of Selected Port*.

**Tunable Structure Parameters**

External mode does not support uploading or downloading tunable structure parameters.

**Archiving Data**

External mode supports the Scope and To Workspace blocks for archiving data to disk. However, external mode does not support scopes other than the Scope block for archiving.
data. For example, you cannot use Floating Scope blocks or Signal and Scope Manager viewer objects to archive data in external mode.

**Scopes in Referenced Models**

In a model hierarchy, if the top model simulates in external mode and a referenced model simulates in normal or accelerator mode, scopes in the referenced model are not displayed.

However, if the top model is changed to simulate in normal mode, the behavior of scopes in the referenced models differs between normal and accelerator mode. Scopes in a referenced model simulating in normal mode are displayed, while scopes in a referenced model simulating in accelerator mode are not displayed.

**Simulation Start Time**

External mode does not support nonzero simulation start times. In the Configuration Parameters dialog box, **Solver** pane, leave **Start time** set to the default value of 0.0.

**File-Scoped Data**

External mode does not support file-scope data, for example, data items to which you apply the built-in custom storage class **FileScope**. File-scope data are not externally accessible.

**Use of printf Statements**

External mode simulations support the use of `printf` calls to display error and information messages from the target program. For some target hardware, the use of `printf` statements can increase the external mode binary file size. To disable `printf` calls, specify the preprocessor macro definition `EXTMODE_DISABLEPRINTF` for your target program compiler.

**Command-Line Arguments**

External mode simulations support the use of command-line arguments for running target programs. These limitations apply:

- Parsing of the command-line arguments requires the `sscanf` function, which increases the program size for some target hardware.
- Some target programs do not accept command-line arguments.
To disable the processing of command-line arguments, specify the preprocessor macro definition `EXTMODE_DISABLE_ARGS_PROCESSING=1` for your target program compiler.

**Row-Major Code Generation**

External mode simulations do not support code generated with the row-major format.

This section helps you to connect your custom target by using external mode using your own low-level communications layer. The topics include:

- An overview of the design and operation of external mode
- A description of external mode source files
- Guidelines for modifying the external mode source files and building an executable to handle the tasks of the default ext_comm MEX-file

This section assumes that you are familiar with the execution of Simulink Coder programs, and with the basic operation of external mode.

**Design of External Mode**

External mode communication between the Simulink engine and a target system is based on a client/server architecture. The client (the Simulink engine) transmits messages requesting the server (target) to accept parameter changes or to upload signal data. The server responds by executing the request.

A low-level transport layer handles physical transmission of messages. Both the Simulink engine and the model code are independent of this layer. Both the transport layer and code directly interfacing to the transport layer are isolated in separate modules that format, transmit, and receive messages and data packets.

This design makes it possible for different targets to use different transport layers. The GRT, ERT, and RSim targets support host/target communication by using TCP/IP and RS-232 (serial) communication. The Simulink Desktop Real-Time target supports shared memory communication. The Wind River Systems Tornado® target supports TCP/IP only.
The Simulink Coder product provides full source code for both the client and server-side external mode modules, as used by the GRT, ERT, Rapid Simulation, and Tornado targets, and the Simulink Desktop Real-Time and Simulink Real-Time products. The main client-side module is `ext_comm.c`. The main server-side module is `ext_svr.c`.

These two modules call the specified transport layer through the following source files.

### Built-In Transport Layer Implementations

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Client or Server?</th>
<th>Source Files</th>
</tr>
</thead>
</table>
| TCP/IP    | Client (host)     | • `matlabroot/toolbox/coder/simulinkcoder_core/ext_mode/host/common/rtiostream_interface.c`
|           |                   | • `matlabroot/rtw/c/src/rtiostream/rtiostreamtcpip/rtiostream_tcpip.c`        |
|           | Server (target)   | • `matlabroot/rtw/c/src/rtiostream/rtiostreamtcpip/rtiostream_tcpip.c`        |
| Serial    | Client (host)     | • `matlabroot/toolbox/coder/simulinkcoder_core/ext_mode/host/serial/ext_serial_transport.c`
|           |                   | • `matlabroot/rtw/c/src/rtiostream/rtiostreamserial/rtiostream_serial.c`     |
|           | Server (target)   | • `matlabroot/rtw/c/src/rtiostream/rtiostreamserial/rtiostream_serial.c`     |

For serial communication, the modules `ext_serial_transport.c` and `rtiostream_serial.c` implement the client-side transport functions and the modules `ext_svr_serial_transport.c` and `rtiostream_serial.c` implement the corresponding server-side functions. For TCP/IP communication, the modules `rtiostream_interface.c` and `rtiostream_tcpip.c` implement both client-side and server-side functions. You can edit copies of these files (but do not modify the originals). You can support external mode using your own low-level communications layer by creating similar files using the following templates:
• Client (host) side: `matlabroot/rtw/c/src/rtiostream/rtiostreamtcpip/rtiostream_tcpip.c` (TCP/IP) or `matlabroot/rtw/c/src/rtiostream/rtiostreamserial/rtiostream_serial.c` (serial)

• Server (target) side: `matlabroot/rtw/c/src/rtiostream/rtiostreamtcpip/rtiostream_tcpip.c` (TCP/IP) or `matlabroot/rtw/c/src/rtiostream/rtiostreamserial/rtiostream_serial.c` (serial)

The file `rtiostream_interface.c` is an interface between the external mode protocol and an `rtiostream` communications channel. For more details on implementing an `rtiostream` communications channel, see “Communications `rtiostream` API” on page 67-48. Implement your `rtiostream` communications channel by using the documented interface to avoid having to make changes to the file `rtiostream_interface.c` or other external mode related files.

**Note** Do not modify working source files. Use the templates provided in the `/custom` or `/rtiostream` folder as starting points, guided by the comments within them.

You need only provide code that implements low-level communications. You need not be concerned with issues such as data conversions between host and target, or with the formatting of messages. The Simulink Coder software handles these functions.

On the client (Simulink engine) side, communications are handled by `ext_comm` (for TCP/IP) and `ext_serial_win32_comm` (for serial) MEX-files.

On the server (target) side, external mode modules are linked into the target executable. This takes place automatically if the **External mode** code generation option is selected at code generation time, based on the **External mode transport** option selected in the target code generation options dialog box. These modules, called from the main program and the model execution engine, are independent of the generated model code.

The general procedure for implementing your own client-side low-level transport protocol is as follows:

1. Edit the template `rtiostream_tcpip.c` to replace low-level communication calls with your own communication calls.
2. Generate a MEX-file executable for your custom transport.
3. Register your new transport layer with the Simulink software, so that the transport can be selected for a model using the **Interface** pane of the Configuration Parameters dialog box.
For more details, see “Create a Custom Client (Host) Transport Protocol” on page 44-99.

The general procedure for implementing your own server-side low-level transport protocol is as follows:

1. Edit the template rtiostream_tcpip.c to replace low-level communication calls with your own communication calls. Typically this involves writing or integrating device drivers for your target hardware.

2. Modify template makefiles to support the new transport.

For more details, see “Create a Custom Server (Target) Transport Protocol” on page 44-102.

**External Mode Communications Overview**

This section gives a high-level overview of how a Simulink Coder generated program communicates with Simulink external mode. This description is based on the TCP/IP version of external mode that ships with the Simulink Coder product.

For communication to take place, both the server (target) program and the Simulink software must be executing. This does not mean that the model code in the server system must be executing. The server can be waiting for the Simulink engine to issue a command to start model execution.

The client and server communicate by using bidirectional sockets carrying packets. Packets consist either of *messages* (commands, parameter downloads, and responses) or *data* (signal uploads).

If the target program was invoked with the `-w` command-line option, the program enters a wait state until it receives a message from the host. Otherwise, the program begins execution of the model. While the target program is in a wait state, the Simulink engine can download parameters to the target and configure data uploading.

When the user chooses the **Connect to Target** option from the **Simulation** menu, the host initiates a handshake by sending an EXT_CONNECT message. The server responds with information about itself. This information includes:

- Checksums. The host uses model checksums to determine that the target code is an exact representation of the current Simulink model.
- Data format information. The host uses this information when formatting data to be downloaded, or interpreting data that has been uploaded.
At this point, host and server are connected. The server is either executing the model or in the wait state. (In the latter case, the user can begin model execution by selecting Start Real-Time Code from the Simulation menu.)

During model execution, the message server runs as a background task. This task receives and processes messages such as parameter downloads.

Data uploading comprises both foreground execution and background servicing of the signal packets. As the target computes model outputs, it also copies signal values into data upload buffers. This occurs as part of the task associated with each task identifier (tid). Therefore, data collection occurs in the foreground. Transmission of the collected data, however, occurs as a background task. The background task sends the data in the collection buffers to the Simulink engine by using data packets.

The host initiates most exchanges as messages. The target usually sends a response confirming that it has received and processed the message. Examples of messages and commands are:

- Connection message / connection response
- Start target simulation / start response
- Parameter download / parameter download response
- Arm trigger for data uploading / arm trigger response
- Terminate target simulation / target shutdown response

Model execution terminates when the model reaches its final time, when the host sends a terminate command, or when a Stop Simulation block terminates execution. On termination, the server informs the host that model execution has stopped, and shuts down its socket. The host also shuts down its socket, and exits external mode.

**External Mode Source Files**

- “Client (Host) MEX-file Interface Source Files” on page 44-94
- “Server (Target) Source Files” on page 44-96
- “Other Files in the Server Folder” on page 44-98

**Client (Host) MEX-file Interface Source Files**

The source files for the MEX-file interface component are located in the folder `matlabroot/toolbox/coder/simulinkcoder_core/ext_mode/host (open)`, except as noted:
• common/ext_comm.c

This file is the core of external mode communication. It acts as a relay station between the target and the Simulink engine. ext_comm.c communicates to the Simulink engine by using a shared data structure, ExternalSim. It communicates to the target by using calls to the transport layer.

Tasks carried out by ext_comm.c include establishment of a connection with the target, downloading of parameters, and termination of the connection with the target.

• common/rtiostream_interface.c

This file is an interface between the external mode protocol and an rtiostream communications channel. For more details on implementing an rtiostream communications channel, see “Communications rtiostream API” on page 67-48. Implement your rtiostream communications channel using the documented interface to avoid having to change the file rtiostream_interface.c or other external mode related files.

• matlabroot/rtw/c/src/rtiostream/rtiostreamtcpip/rtiostream_tcpip.c

This file implements required TCP/IP transport layer functions. The version of rtiostream_tcpip.c shipped with the Simulink Coder software uses TCP/IP functions including recv(), send(), and socket().

• matlabroot/rtw/c/src/rtiostream/rtiostreamserial/rtiostream_serial.c

This file implements required serial transport layer functions. The version of rtiostream_serial.c shipped with the Simulink Coder software uses serial functions including ReadFile(), WriteFile(), and CreateFile().

• serial/ext_serial_transport.c

This file implements required serial transport layer functions. ext_serial_transport.c includes ext_serial_utils.c, which is located in matlabroot/rtw/c/src/ext_mode/serial (open) and contains functions common to client and server sides.

• common/ext_main.c

This file is a MEX-file wrapper for external mode. ext_main.c interfaces to the Simulink engine by using the standard mexFunction call. (See the mexFunction reference page and “MATLAB API for Other Languages” (MATLAB) for more...
information.) ext_main.c contains a function dispatcher, esGetAction, that sends requests from the Simulink engine to ext_comm.c.

- common/ext_convert.c and ext_convert.h

This file contains functions used for converting data from host to target formats (and vice versa). Functions include byte-swapping (big to little-endian), conversion from non-IEEE floats to IEEE doubles, and other conversions. These functions are called both by ext_comm.c and directly by the Simulink engine (by using function pointers).

**Note** You do not need to customize ext_convert to implement a custom transport layer. However, you might want to customize ext_convert for the intended target. For example, if the target represents the float data type in Texas Instruments format, ext_convert must be modified to perform a Texas Instruments to IEEE conversion.

- common/extsim.h

This file defines the ExternalSim data structure and access macros. This structure is used for communication between the Simulink engine and ext_comm.c.

- common/extutil.h

This file contains only conditionals for compilation of the assert macro.

- common/ext_transport.h

This file defines functions that must be implemented by the transport layer.

**Server (Target) Source Files**

These files are linked into the model.exe executable. They are located within matlabroot/rtw/c/src/ext_mode (open) except as noted.

- common/ext_svr.c

ext_svr.c is analogous to ext_comm.c on the host, but generally is responsible for more tasks. It acts as a relay station between the host and the generated code. Like ext_comm.c, ext_svr.c carries out tasks such as establishing and terminating connection with the host. ext_svr.c also contains the background task functions that either write downloaded parameters to the target model, or extract data from the target data buffers and send it back to the host.

- common/rtiostream_interface.c
This file is an interface between the external mode protocol and an rtiostream communications channel. For more details on implementing an rtiostream communications channel, see “Communications rtiostream API” on page 67-48. Implement your rtiostream communications channel by using the documented interface to avoid having to change the file rtiostream_interface.c or other external mode related files.

- **matlabroot/rtw/c/src/rtiostream/rtiostreamtcpip/rtiostream_tcpip.c**

  This file implements required TCP/IP transport layer functions. The version of rtiostream_tcpip.c shipped with the Simulink Coder software uses TCP/IP functions including recv(), send(), and socket().

- **matlabroot/rtw/c/src/rtiostream/rtiostreamserial/rtiostream_serial.c**

  This file implements required serial transport layer functions. The version of rtiostream_serial.c shipped with the software uses serial functions including ReadFile(), WriteFile(), and CreateFile().

- **matlabroot/rtw/c/src/rtiostream.h**

  This file defines the rtIOStream* functions implemented in rtiostream_tcpip.c.

- **serial/ext_svr_serial_transport.c**

  This file implements required serial transport layer functions. ext_svr_serial_transport.c includes serial/ext_serial_utils.c, which contains functions common to client and server sides.

- **common/updown.c**

  updown.c handles the details of interacting with the target model. During parameter downloads, updown.c does the work of installing the new parameters into the model's parameter vector. For data uploading, updown.c contains the functions that extract data from the model's blockio vector and write the data to the upload buffers. updown.c provides services both to ext_svr.c and to the model code (for example, grt_main.c). It contains code that is called by using the background tasks of ext_svr.c as well as code that is called as part of the higher priority model execution.

- **matlabroot/rtw/c/src/dt_info.h** (included by generated model build file model.h)
These files contain data type transition information that allows access to multi-data type structures across different computer architectures. This information is used in data conversions between host and target formats.

- **common/updown_util.h**

  This file contains only conditionals for compilation of the `assert` macro.

- **common/ext_svr_transport.h**

  This file defines the Ext* functions that must be implemented by the server (target) transport layer.

### Other Files in the Server Folder

- **common/ext_share.h**

  Contains message code definitions and other definitions required by both the host and target modules.

- **serial/ext_serial_utils.c**

  Contains functions and data structures for communication, MEX link, and generated code required by both the host and target modules of the transport layer for serial protocols.

  - The serial transport implementation includes the additional files
    - **serial/ext_serial_pkt.c** and **ext_serial_pkt.h**
    - **serial/ext_serial_port.h**

### Implement a Custom Transport Layer

- “Requirements for Custom Transport Layers” on page 44-99
- “Create a Custom Client (Host) Transport Protocol” on page 44-99
- “MATLAB Commands to Rebuild ext_comm and ext_serial_win32 MEX-Files” on page 44-100
- “Register a Custom Client (Host) Transport Protocol” on page 44-101
- “Create a Custom Server (Target) Transport Protocol” on page 44-102
- “Serial Receive Buffer Smaller than 64 Bytes” on page 44-104
Requirements for Custom Transport Layers

- By default, ext_svr.c and updown.c use malloc to allocate buffers in target memory for messages, data collection, and other purposes, although there is also an option to preallocate static memory. If your target uses another memory allocation scheme, you must modify these modules.
- The target is assumed to support both int32_T and uint32_T data types.

Create a Custom Client (Host) Transport Protocol

To implement the client (host) side of your low-level transport protocol,

1 Edit the template file matlabroot/rtw/c/src/rtiostream/rtiostreamtcpip/rtiostream_tcpip.c to replace low-level communication calls with your own communication calls.
   a Copy and rename the file to rtiostream_name.c (replacing name with a name meaningful to you).
   b Replace the functions rtiOStreamOpen, rtiOStreamClose, rtiOStreamSend, and rtiOStreamRecv with functions (of the same name) that call your low-level communication primitives. These functions are called from other external mode modules via rtiostream_interface.c. For more information, see “Communications rtiostream API” on page 67-48.
   c Build your rtiostream implementation into a shared library that exports the rtiOStreamOpen, rtiOStreamClose, rtiOStreamRecv and rtiOStreamSend functions.

2 Build the customized MEX-file executable using the MATLAB mex function. See “MATLAB Commands to Rebuild ext_comm and ext_serial_win32 MEX-Files” on page 44-100 for examples of mex invocations.

   Do not replace the existing ext_comm MEX-file if you want to preserve its existing function. Instead, use the -output option to name the resulting executable (for example, mex -output ext_myrtiostream_comm ... builds ext_myrtiostream_comm.mexext, on Windows platforms).

3 Register your new client transport layer with the Simulink software, so that the transport can be selected for a model using the Interface pane of the Configuration Parameters dialog box. For details, see “Register a Custom Client (Host) Transport Protocol” on page 44-101.
Sample commands for rebuilding external mode MEX-files are listed in “MATLAB Commands to Rebuild ext_comm and ext_serial_win32 MEX-Files” on page 44-100.

**MATLAB Commands to Rebuild ext_comm and ext_serial_win32 MEX-Files**

The following table lists the commands for building the standard ext_comm and ext_serial_win32 modules on PC and UNIX platforms.

<table>
<thead>
<tr>
<th>Platform</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Windows, TCP/IP</td>
<td><code>&gt;&gt; cd (matlabroot)</code>&lt;br&gt;<code>&gt;&gt; mex toolbox\simulinkcoder_core\ext_mode\host\common\ext_comm.c ...</code>&lt;br&gt;<code>toolbox\coder\simulinkcoder_core\ext_mode\host\common\ext_convert.c ...</code>&lt;br&gt;<code>toolbox\coder\simulinkcoder_core\ext_mode\host\common\rtiostream_interface.c ...</code>&lt;br&gt;<code>toolbox\coder\simulinkcoder_core\ext_mode\host\common\ext_util.c ...</code>&lt;br&gt;<code>-I\rtw\c\src -I\rtw\c\src\rtiostream\utils ...</code>&lt;br&gt;<code>-I\rtw\c\src\ext_mode\common ...</code>&lt;br&gt;<code>-I\toolbox\coder\simulinkcoder_core\ext_mode\host\common ...</code>&lt;br&gt;<code>-I\toolbox\coder\simulinkcoder_core\ext_mode\host\common\include ...</code>&lt;br&gt;<code>-lmwrtiostreamutils -lsl_services ...</code>&lt;br&gt;<code>-DEXTMODE_TCPIP_TRANSPORT ...</code>&lt;br&gt;<code>-DSL_EXT_DLL -output toolbox\coder\simulinkcoder_core\ext_comm</code></td>
</tr>
<tr>
<td>Note</td>
<td>The <code>rtiostream_interface.c</code> function defines <code>RTISTREAM_SHARED_LIB</code> as <code>libmwrtiostreamtcpip</code> and dynamically loads the MathWorks TCP/IP <code>rtiostream</code> shared library. Modify this file if you need to load a different <code>rtiostream</code> shared library.</td>
</tr>
<tr>
<td>Linux, TCP/IP</td>
<td>Use the Windows commands, with these changes:&lt;br&gt;  • Change <code>-DSL_EXT_DLL</code> to <code>-DSL_EXT_SO</code>.  • Change <code>-lsl_services</code> to <code>-lmwsl_services</code>.  • Replace backslashes with forward slashes.</td>
</tr>
<tr>
<td>Mac, TCP/IP</td>
<td>Use the Windows commands, with these changes:&lt;br&gt;  • Change <code>-DSL_EXT_DLL</code> to <code>-DSL_EXT_DYLIB</code>.  • Change <code>-lsl_services</code> to <code>-lmwsl_services</code>.  • Replace backslashes with forward slashes.</td>
</tr>
</tbody>
</table>
### Platform | Commands
---|---
Windows, serial | `>> cd (matlabroot)`  
`>> mex toolbox\coder\simulinkcoder_core\ext_mode\host\common\ext_comm.c ...`  
`toolbox\coder\simulinkcoder_core\ext_mode\host\common\ext_convert.c ...`  
`toolbox\coder\simulinkcoder_core\ext_mode\host\serial\ext_serial_transport.c ...`  
`toolbox\coder\simulinkcoder_core\ext_mode\host\serial\ext_serial_pkt.c ...`  
`toolbox\coder\simulinkcoder_core\ext_mode\host\serial\rtiostream_serial_interface.c ...`  
`toolbox\coder\simulinkcoder_core\ext_mode\host\common\ext_util.c ...`  
`-Irtw\c\src -Irtw\c\src\rtiostream\utils ...`  
`-Irtw\c\src\ext_mode\common ...`  
`-Irtw\c\src\ext_mode\serial ...`  
`-Itoolbox\coder\simulinkcoder_core\ext_mode\host\common ...`  
`-Itoolbox\coder\simulinkcoder_core\ext_mode\host\common\include ...`  
`-lmwrtiostreamutils -lsl_services ...`  
`-DEXTMODE_SERIAL_TRANSPORT -DSL_EXT_DLL ...`  
`-output toolbox\coder\simulinkcoder_core\ext_serial_win32_comm`

**Note** The `rtiostream_interface.c` function defines `RTIOSTREAM_SHARED_LIB` as `libmwrtiostreamserial` and dynamically loads the MathWorks serial `rtiostream` shared library. Modify this file if you need to load a different `rtiostream` shared library.

Linux, serial | Use the Windows commands, with these changes:
  - Change `-DSL_EXT_DLL` to `-DSL_EXT_SO`.
  - Change `-lsl_services` to `-lmwsl_services`.
  - Replace back slashes with forward slashes.

Mac, serial | Use the Windows commands, with these changes:
  - Change `-DSL_EXT_DLL` to `-DSL_EXT_DYLIB`.
  - Change `-lsl_services` to `-lmwsl_services`.
  - Replace back slashes with forward slashes.

**Note** `mex` requires a compiler supported by the MATLAB API. See the `mex` reference page and “MATLAB API for Other Languages” (MATLAB) for more information about the `mex` function.

### Register a Custom Client (Host) Transport Protocol

To register a custom client transport protocol with the Simulink software, you must add an entry of the following form to an `sl_customization.m` file on the MATLAB path:
function sl_customization(cm)
    cm.ExtModeTransports.add('stf.tlc', 'transport', 'mexfile', 'Level1');
end

where

- **stf.tlc** is the name of the system target file for which the transport will be registered (for example, 'grt.tlc')
- **transport** is the transport name to display in the **Transport layer** menu on the **Interface** pane of the Configuration Parameters dialog box (for example, 'mytcpip')
- **mexfile** is the name of the transport's associated external interface MEX-file (for example, 'ext_mytcpip_comm')

You can specify multiple targets and/or transports with additional `cm.ExtModeTransports.add` lines, for example:

```matlab
function sl_customization(cm)
    cm.ExtModeTransports.add('grt.tlc', 'mytcpip', 'ext_mytcpip_comm', 'Level1');
    cm.ExtModeTransports.add('ert.tlc', 'mytcpip', 'ext_mytcpip_comm', 'Level1');
end
```

If you place the `sl_customization.m` file containing the transport registration information on the MATLAB path, your custom client transport protocol will be registered with each subsequent Simulink session. The name of the transport will appear in the **Transport layer** menu on the **Interface** pane of the Configuration Parameters dialog box. When you select the transport for your model, the name of the associated external interface MEX-file will appear in the noneditable **MEX-file name** field, as shown in the following figure.

![External mode configuration](image)

**Create a Custom Server (Target) Transport Protocol**

The `rtIOStream*` function prototypes in `matlabroot/rtw/c/src/rtiostream.h` define the calling interface for both the server (target) and client (host) side transport layer functions.
- The TCP/IP implementations are in `matlabroot/rtw/c/src/rtiostream/rtiostreamtcpip/rtiostream_tcpip.c`.
- The serial implementations are in `matlabroot/rtw/c/src/rtiostream/rtiostreamserial/rtiostream_serial.c`.

**Note** The Ext* function prototypes in `matlabroot/rtw/c/src/ext_mode/common/ext_svr_transport.h` are implemented in `matlabroot/rtw/c/src/ext_mode/common/rtiostream_interface.c` or `matlabroot/rtw/c/src/ext_mode/serial/rtiostream_serial_interface.c`. In most cases you will not need to modify `rtiostream_interface.c` or `rtiostream_serial_interface.c` for your custom TCP/IP or serial transport layer.

To implement the server (target) side of your low-level TCP/IP or serial transport protocol:

1. Edit the template `matlabroot/rtw/c/src/rtiostream/rtiostreamtcpip/rtiostream_tcpip.c` or `matlabroot/rtw/c/src/rtiostream/rtiostreamserial/rtiostream_serial.c` to replace low-level communication calls with your own communication calls.

   a. Copy and rename the file to `rtiostream_name.c` (replacing `name` with a name meaningful to you).

   b. Replace the functions `rtIOStreamOpen`, `rtIOStreamClose`, `rtIOStreamSend`, and `rtIOStreamRecv` with functions (of the same name) that call your low-level communication drivers.

   You must implement the functions defined in `rtiostream.h`, and your implementations must conform to the prototypes defined in that file. Refer to the original `rtiostream_tcpip.c` or `rtiostream_serial.c` for guidance.

2. Incorporate the external mode source files for your transport layer into the model build process. Use a build process mechanism such as a post code generation command or a `before_make` hook function to make the transport files available to the build process. For more information on the build process mechanisms, see “Customize Post-Code-Generation Build Processing” (Simulink Coder), “Customize Build Process with STF_make_rtw_hook File” (Simulink Coder), and “Customize Build Process with sl_customization.m” (Simulink Coder).

   For example:
• Add the file created in the previous step to the build information:

`path/rtiostream_name.c`

• For TCP/IP, add the following file to the build information:

`matlabroot/rtw/c/src/ext_mode/common/rtiostream_interface.c`

• For serial, add the following files to the build information:

`matlabroot/rtw/c/src/ext_mode/serial/ext_serial_pkt.c`
`matlabroot/rtw/c/src/ext_mode/serial/rtiostream_serial_interface.c`
`matlabroot/rtw/c/src/ext_mode/serial/ext_svr_serial_transport.c`

**Note** For external mode, check that `rtIOStreamRecv` is not a blocking implementation. Otherwise, it might cause the external mode server to block until the host sends data through the `comm` layer.

**Serial Receive Buffer Smaller than 64 Bytes**

For serial communication, if the serial receive buffer of your target is smaller than 64 bytes:

1. Update the following macro with the actual target buffer size:

```
#define TARGET_SERIAL_RECEIVE_BUFFER_SIZE 64
```

Implement the change in the following files:

`matlabroot/rtw/c/src/ext_mode/serial/ext_serial_utils.c`
`matlabroot/toolbox/coder/simulinkcoder_core/ext_mode/host/serial/ext_serial_utils.c`

2. Run the command to rebuild the `ext_serial_win32` MEX-file. See “MATLAB Commands to Rebuild ext_comm and ext_serial_win32 MEX-Files” on page 44-100.

Logging in Simulink Coder
Log Program Execution Results

Multiple techniques are available by which a program generated by the Simulink Coder software can save data to a MAT-file for analysis. A generated executable can save system states, outputs, and simulation time at each model execution time step. The data is written to a MAT-file, named (by default) *model*.mat, where *model* is the name of your model. See “Log Data for Analysis” on page 45-2 for a data logging tutorial.

**Note** Data logging is available only for system target files that have access to a file system. In addition, only the RSim target executables are capable of accessing MATLAB workspace data.

For MAT-file logging limitations, see the configuration parameter “MAT-file logging” (Simulink Coder).

- “Data Logging from Generated Code” on page 45-7

### Set Up and Configure Model

This example shows how data generated by a copy of the model *slexAircraftExample* is logged to the file *myAircraftExample.mat*. Refer to “Build Process Workflow for Real-Time Systems” on page 43-32 for instructions on setting up a copy of *slexAircraftExample* as *myAircraftExample* in a working folder if you have not done so already.
**Note** When you configure the code generator to produce code that includes support for data logging during execution, the code generator can include text for block names in the block paths included in the log file. If the text includes characters that are unrepresented in the character set encoding for the model, the code generator replaces the characters with XML escape sequences. For example, the code generator replaces the Japanese full-width Katakana letter ｦ with the escape sequence \&#x30A2;. For more information, see “Internationalization and Code Generation” (Simulink Coder).

To configure data logging, open the Configuration Parameters dialog box and select the **Data Import/Export** pane. The process is the same as configuring a Simulink model to save output to the MATLAB workspace. For each workspace return variable you define and enable, the Simulink Coder software defines a parallel MAT-file variable. For example, if you save simulation time to the variable `tout`, your generated program logs the same data to a variable named `rt_tout`. You can change the prefix `rt_` to a suffix `(_rt)`, or eliminate it entirely. You do this by setting **Configuration Parameters > Code Generation > Interface > Advanced parameters > MAT-file variable name modifier**.

Simulink lets you log signal data from anywhere in a model. In the Simulink Editor, select the signals that you want to log and then in the **Simulation Data Inspector** button dropdown, select **Log Selected Signals**. However, the Simulink Coder software does not use this method of signal logging in generated code. To log signals in generated code, you must either use the **Data Import/Export** options described below or include To File or To Workspace blocks in your model.

**Note** If you enable MAT-file and signal logging (through the **Data Import/Export** pane) and select signals for logging (through the Simulink Editor), you see the following warning when you build the model:

Warning: MAT-file logging does not support signal logging.
When your model code executes, the signal logging variable 'rt_logsout' will not be saved to the MAT-file.

To avoid this warning, clear the **Data Import/Export > Signal logging** check box.

In this example, you modify the `myAircraftExample` model so that the generated program saves the simulation time and system outputs to the file `myAircraftExample.mat`. Then you load the data into the base workspace and plot simulation time against one of the outputs. The `myAircraftExample` model should be
configured as described in “Build Process Workflow for Real-Time Systems” on page 43-32.

**Data Logging During Simulation**

To use the data logging feature:

1. Open the myAircraftExample model if it is not already open.
2. Open the Configuration Parameters dialog box by selecting **Simulation > Model Configuration Parameters** from the model window.
3. Select the **Data Import/Export** pane. The **Data Import/Export** pane lets you specify which outport data is to be saved to the workspace and what variable names to use for it.
4. Set **Format** to **Structure with time**. When you select this format, Simulink saves the model states and outputs in structures that have their names specified in the **Save to workspace or file** area. By default, the structures are xout for states and yout for output. The structure used to save output has two top-level fields: time and signals. The time field contains a vector of simulation times and signals contains an array of substructures, each of which corresponds to a model output port.
5. Select the **Output** option. This tells Simulink to save output signal data during simulation as a variable named yout. Selecting **Output** enables the code generator to create code that logs the root Output block (alpha, rad) to a MAT-file.
6. Set **Decimation** to 1.
7. If other options are enabled, clear them. The figure below shows how the dialog box should appear.
Click **Apply** and **OK** to register your changes and close the dialog box.

Save the model.

In the model window, double-click the scope symbol next to the Aircraft Dynamics Model block, then run the model by choosing **Simulation** > **Run** in the model window. The resulting scope display is shown below.
11 Verify that the simulation time and outputs have been saved to the base workspace in MAT-files. At the MATLAB prompt, type:

```matlab
whos yout
```

Simulink displays:

```
Name        Size            Bytes  Class     Attributes
yout        1x1             10756  struct
```

12 Verify that \texttt{alpha, rad} was logged by plotting simulation time versus that variable. In the Command Window, type:

```matlab
plot(yout.time,yout.signals.values)
```

The resulting plot is shown below.
Data Logging from Generated Code

In the second part of this example, you build and run a Simulink Coder executable of the myAircraftExample model that outputs a MAT-file containing the simulation time and output you previously examined. Even though you have already generated code for the myAircraftExample model, you must now regenerate that code because you have changed the model by enabling data logging. The steps below explain this procedure.

To avoid overwriting workspace data with data from simulation runs, the code generator modifies identifiers for variables logged by Simulink. You can control these modifications.

1. Set Configuration Parameters > Code Generation > Interface > Advanced parameters > MAT-file variable name modifier to _rt. This adds the suffix _rt to each variable that you selected to be logged in the first part of this example.

2. Click Apply and OK to register your changes and close the dialog box.

3. Save the model.

4. Build an executable.

5. When the build concludes, run the executable with the command:

   `!myAircraftExample`

6. The program now produces two message lines, indicating that the MAT-file has been written.
** starting the model **
** created myAircraftExample.mat **

7 Load the MAT-file data created by the executable and look at the workspace variables from simulation and the generated program by typing:

```
load myAircraftExample.mat
whos yout*
```

Simulink displays:

<table>
<thead>
<tr>
<th>Name</th>
<th>Size</th>
<th>Bytes</th>
<th>Class</th>
<th>Attributes</th>
</tr>
</thead>
<tbody>
<tr>
<td>yout</td>
<td>1x1</td>
<td>10756</td>
<td>struct</td>
<td></td>
</tr>
<tr>
<td>yout_rt</td>
<td>1x1</td>
<td>10756</td>
<td>struct</td>
<td></td>
</tr>
</tbody>
</table>

Note the size and bytes of the structures resulting from the simulation run and generated code are the same.

8 Plot the generated code output by entering the following command in the Command Window:

```
plot(yout_rt.time,yout_rt.signals.values)
```

The plot should be identical to the plot that you produced in the previous part of this example.
**Tip** For UNIX platforms, run the executable in the Command Window with the syntax `!./executable_name`. If preferred, run the executable from an OS shell with the syntax `./executable_name`. For more information, see “Run External Commands, Scripts, and Programs” (MATLAB).

### Configure State, Time, and Output Logging

The **Data Import/Export** pane enables a generated program to save system states, outputs, and simulation time at each model execution time step. The data is written to a MAT-file, named (by default) `model.mat`.

Before using this data logging feature, you should learn how to configure a Simulink model to return output to the MATLAB workspace. This is discussed in “Export Simulation Data” (Simulink).

For each workspace return variable that you define and enable, the code generator defines a MAT-file variable. For example, if your model saves simulation time to the workspace variable `tout`, your generated program logs the same data to a variable named (by default) `rt_tout`.

The code generated by the code generator logs the following data:

- **Root Outport blocks**
  - The default MAT-file variable name for system outputs is `rt_yout`.
  - The sort order of the `rt_yout` array is based on the port number of the Outport block, starting with 1.

- **Continuous and discrete states in the model**
  - The default MAT-file variable name for system states is `rt_xout`.

- **Simulation time**
  - The default MAT-file variable name for simulation time is `rt_tout`.

### Override Default MAT-File Variable Names

By default, the code generation software prefixes the text `rt_` to the variable names for system outputs, states, and simulation time to form MAT-file variable names. To change
this prefix for a model, select a prefix (rt_), a suffix (_rt), or no modifier (none) for Configuration Parameters > Code Generation > Interface > Advanced parameters > MAT-file variable name modifier. Other system target files might not support this parameter.

Override Default MAT-File Name or Buffer Size

You can specify compiler options to override the following MAT-file attributes in generated code:

<table>
<thead>
<tr>
<th>MAT-File Attribute</th>
<th>Default</th>
<th>Compiler Option</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>model.mat</td>
<td>-DSAVEFILE=filename</td>
</tr>
<tr>
<td>Size of data logging buffer</td>
<td>1024 bytes</td>
<td>-DDefault_BUFFER_SIZE=n</td>
</tr>
</tbody>
</table>

**Note** Valid option syntax can vary among compilers. For example, Microsoft Visual C++ compilers typically accept /DSAVEFILE=filename as well as -DSAVEFILE=filename.

For a template makefile (TMF) based target, append the compiler option to the Make command field on the Code Generation pane of the Configuration Parameters dialog box. For example:

```
Make command:                       make_rtw OPTS="-DSAVEFILE=myCodeLog.mat"
```

For a toolchain-based target such as GRT or ERT, add the compiler option to the Build configuration settings on the Code Generation pane of the Configuration Parameters dialog box. Set Build configuration to Specify, and add the compiler option to the C Compiler row of the Tool/Options table. For example:

```
<table>
<thead>
<tr>
<th>Tool</th>
<th>Options</th>
</tr>
</thead>
<tbody>
<tr>
<td>C Compiler</td>
<td>$(cflags) $(CVARSFLAG) $(CFLAGS_ADDITIONAL) -DSAVEFILE=myCodeLog.mat /Od /Oy-</td>
</tr>
</tbody>
</table>
```

To add the compiler option to a custom toolchain, you can modify and reregister the custom toolchain using the procedures shown in the example “Adding a Custom Toolchain” (MATLAB Coder). For example, to add the compiler option to the MATLAB source file for the custom toolchain, you could define myCompilerOpts as follows:

```
optimsOffOpts = {'/c /Od'};
optimsOnOpts = {'/c /O2'};
```
Then you can add `myCompilerOpts` to the flags for each configuration and compiler to which it applies, for example:

```matlab
cfg = tc.getBuildConfiguration('Faster Builds');
cfg.setOption('C Compiler', horzcat(cCompilerOpts, myCompilerOpts, optimsOffOpts));
```

As shown in “Adding a Custom Toolchain” (MATLAB Coder), after modifying the custom toolchain, you save the configuration to a MAT-file and refresh the target registry.

## Log Data with Scope and To Workspace Blocks

The code generated by the code generator also logs data from these sources:

- Scope blocks that have the **Log data to workspace** parameter enabled
  
  You must specify the variable name and data format in each Scope block's dialog box.
- To Workspace blocks in the model
  
  You must specify the variable name and data format in each To Workspace block's dialog box.

The variables are written to `model.mat`, along with variables logged from the **Workspace I/O** pane.

## Log Data with To File Blocks

You can also log data to a To File block. The generated program creates a separate MAT-file (distinct from `model.mat`) for each To File block in the model. The file contains the block time and input variable(s). You must specify the filename, variable names, decimation, and sample time in the To File block dialog box.

**Note** Models referenced by Model blocks do not perform data logging in that context except for states, which you can include in the state logged for top models. Code generated by the Simulink Coder software for referenced models does not perform data logging to MAT-files.
Data Logging Differences Between Single- and Multitasking

When logging data in single-tasking and multitasking systems, you will notice differences in the logging of

- Noncontinuous root Outport blocks
- Discrete states

In multitasking mode, the logging of states and outputs is done after the first task execution (and not at the end of the first time step). In single-tasking mode, the code generated by the build procedure logs states and outputs after the first time step.

See DataLogging in Single-Tasking and Multitasking Model Execution (Simulink Coder) for more details on the differences between single-tasking and multitasking data logging.

Note The rapid simulation target (RSim) provides enhanced logging options. See “Accelerate, Refine, and Test Hybrid Dynamic System on Host Computer by Using RSim System Target File” (Simulink Coder) for more information.

Exchange Data Between Generated and External Code Using C API

Some Simulink Coder applications must interact with signals, states, root-level inputs/outputs, or parameters in the generated code for a model. For example, calibration applications monitor and modify parameters. Signal monitoring or data logging applications interface with signal, state, and root-level input/output data. Using the Simulink Coder C API, you can build target applications that log signals, states, and root-level inputs/outputs, monitor signals, states, and root-level inputs/outputs, and tune parameters, while the generated code executes.

The C API minimizes its memory footprint by sharing information common to signals, states, root-level inputs/outputs, and parameters in smaller structures. Signal, state, root-level input/output, and parameter structures include an index into the structure map, allowing multiple signals, states, root-level inputs/outputs, or parameters to share data.

To get started with an example, see “Use C API to Access Model Signals and States” on page 46-24 or “Use C API to Access Model Parameters” on page 46-30.

| “C API Limitations” on page 46-22 |

Generated C API Files

When you configure a model to use the C API, the Simulink Coder code generator generates two additional files, `model_capi.c` (or `.cpp`) and `model_capi.h`, where `model` is the name of the model. The code generator places the two C API files in the build folder, based on settings in the Configuration Parameters dialog box. The C API source code file contains information about global block output signals, states, root-level inputs/outputs, and global parameters defined in the generated code model source code. The C API header file is an interface header file between the model source code and the generated C API. You can use the information in these C API files to create your application. Among the files generated are those shown in the next figure.
**Generated Files with C API Selected**

*Note* When you configure the code generator to produce code that includes support for the C API interface and data logging, the code generator can include text for block names in the block paths logged to C API files `model_capi.c` (or `.cpp`) and `model_capi.h`. If the text includes characters that are unrepresented in the character set encoding for the model, the code generator replaces the characters with XML escape sequences. For example, the code generator replaces the Japanese full-width Katakana letter ㄞ with the escape sequence `\x30A2`. For more information, see “Internationalization and Code Generation” (Simulink Coder).

**Generate C API Files**

To generate C API files for your model:

1. Select the C API interface for your model. There are two ways to select the C API interface for your model, as described in the following sections.
   - “Select C API with Configuration Parameters Dialog” on page 46-4
   - “Select C API from the Command Line” on page 46-4

2. Generate code for your model.

After generating code, you can examine the files `model_capi.c` (or `.cpp`) and `model_capi.h` in the model build folder.
Select C API with Configuration Parameters Dialog

1. Open your model, and open the Configuration Parameters dialog box.
2. In the **Code Generation > Interface** pane, in the **Data exchange interface** subgroup, select one or more C API options. Based on the options you select, support for accessing signals, parameters, states, and root-level I/O will appear in the C API generated code.
   - If you want to generate C API code for global block output signals, select **Generate C API for: signals**.
   - If you want to generate C API code for global block parameters, select **Generate C API for: parameters**.
   - If you want to generate C API code for discrete and continuous states, select **Generate C API for: states**.
   - If you want to generate C API code for root-level inputs and outputs, select **Generate C API for: root-level I/O**.

Select C API from the Command Line

From the MATLAB command line, you can use the `set_param` function to select or clear the C API check boxes on the **Interface** pane of the Configuration Parameters dialog box. At the MATLAB command line, enter one or more of the following commands, where `modelname` is the name of your model.

To select **Generate C API for: signals**, enter:
```MATLAB
set_param('modelname','RTWCAPISignals','on')
```
To clear **Generate C API for: signals**, enter:
```MATLAB
set_param('modelname','RTWCAPISignals','off')
```
To select **Generate C API for: parameters**, enter:
```MATLAB
set_param('modelname','RTWCAPIParams','on')
```
To clear **Generate C API for: parameters**, enter:
```MATLAB
set_param('modelname','RTWCAPIParams','off')
```
To select **Generate C API for: states**, enter:
```MATLAB
set_param('modelname','RTWCAPISStates','on')
```
To clear **Generate C API for: states**, enter:

```c
set_param('modelname','RTWCAPIStates','off')
```

To select **Generate C API for: root-level I/O**, enter:

```c
set_param('modelname','RTWCAPIRootIO','on')
```

To clear **Generate C API for: root-level I/O**, enter:

```c
set_param('modelname','RTWCAPIRootIO','off')
```

**About C API Files**

The `model_capi.c` (or `.cpp`) file provides external applications with a consistent interface to model data. Depending on your configuration settings, the data could be a signal, state, root-level input or output, or parameter. In this document, the term data item refers to either a signal, a state, a root-level input or output, or a parameter. The C API uses structures that provide an interface to the data item properties. The interface packages the properties of each data item in a data structure. If the model contains multiple data items, the interface generates an array of data structures. The members of a data structure map to data properties.

To interface with data items, an application requires the following properties for each data item:

- Name
- Block path
- Port number (for signals and root-level inputs/outputs only)
- Address
- Data type information: native data type, data size, complexity, and other attributes
- Dimensions information: number of rows, number of columns, and data orientation (scalar, vector, matrix, or n-dimensional)
- Fixed-point information: slope, bias, scale type, word length, exponent, and other attributes
- Sample-time information (for signals, states, and root-level inputs/outputs only): sample time, task identifier, frames

As illustrated in the next figure, the properties of data item A, for example, are located in data structure DS_A. The properties of data item B are located in data structure DS_B.

Some property values can be unique to each data item, and there are some property values that several data items can share in common. Name, for example, has a unique value for each data item. The interface places the unique property values directly in the structure for the data item. The name value of data item A is in DS_A, and the name value of data item B is in DS_B.

But data type could be a property whose value several data items have in common. The ability of some data items to share a property allows the C API to have a reuse feature. In this case, the interface places only an index value in DS_A and an index value in DS_B. These indices point to a different data structure, DS_C, that contains the actual data type value. The next figure shows this scheme with more detail.
The figure shows three signals, signal1 and signal2 share the same data type, `double`. Instead of specifying this data type value in each signal data structure, the interface provides only an index value, 0, in the structure. "double" is described by entry 0 in the `rtDataTypeMap` array, which is referenced by both signals. Additionally, property values can be shared between signals, states, root-level inputs/outputs, and
parameters, so states, root-level inputs/outputs, and parameters also might reference the double entry in the rtDataTypeMap array. This reuse of information reduces the memory size of the generated interface.

**Structure Arrays Generated in C API Files**

As with data type, the interface maps other common properties (such as address, dimension, fixed-point scaling, and sample time) into separate structures and provides an index in the structure for the data item. For a complete list of structure definitions, refer to the file `matlabroot/rtw/c/src/rtw_capi.h`. This file also describes each member in a structure. The structure arrays generated in the `model_capi.c` (or `.cpp`) file are of structure types defined in the `rtw_capi.h` file. Here is a brief description of the structure arrays generated in `model_capi.c` (or `.cpp`):

- **rtBlockSignals** is an array of structures that contains information about global block output signals in the model. Each element in the array is of type struct `rtwCAPI_Signals`. The members of this structure provide the signal name, block path, block port number, address, and indices to the data type, dimension, fixed-point, and sample-time structure arrays.

- **rtBlockParameters** is an array of structures that contains information about the tunable block parameters in the model by block name and parameter name. Each element in the array is of type struct `rtwCAPI_BlockParameters`. The members of this structure provide the parameter name, block path, address, and indices to data type, dimension, and fixed-point structure arrays.

- **rtBlockStates** is an array of structures that contains information about discrete and continuous states in the model. Each element in the array is of type struct `rtwCAPI_States`. The members of this structure provide the state name, block path, type (continuous or discrete), and indices to the address, data type, dimension, fixed-point, and sample-time structure arrays.

- **rtRootInputs** is an array of structures that contains information about root-level inputs in the model. Each element in the array is of type struct `rtwCAPI_Signals`. The members of this structure provide the root-level input name, block path, block port number, address, and indices to the data type, dimension, fixed-point, and sample-time structure arrays.

- **rtRootOutputs** is an array of structures that contains information about root-level outputs in the model. Each element in the array is of type struct `rtwCAPI_Signals`. The members of this structure provide the root-level output name, block path, block port number, address, and indices to the data type, dimension, fixed-point, and sample-time structure arrays.
Exchange Data Between Generated and External Code Using C API

- **rtModelParameters** is an array of structures that contains information about workplace variables that one or more blocks or Stateflow charts in the model reference as block parameters. Each element in the array is of data type rtwCAPI_ModelParameters. The members of this structure provide the variable name, address, and indices to data type, dimension, and fixed-point structure arrays.

- **rtDataAddrMap** is an array of base addresses of signals, states, root-level inputs/outputs, and parameters that appear in the rtBlockSignals, rtBlockParameters, rtBlockStates, and rtModelParameters arrays. Each element of the rtDataAddrMap array is a pointer to void (void*).

- **rtDataTypeMap** is an array of structures that contains information about the various data types in the model. Each element of this array is of type struct rtwCAPI_DataTypeMap. The members of this structure provide the data type name, size of the data type, and information on whether or not the data is complex.

- **rtDimensionMap** is an array of structures that contains information about the various data dimensions in the model. Each element of this array is of type struct rtwCAPI_DimensionMap. The members of this structure provide information on the number of dimensions in the data, the orientation of the data (whether it is scalar, vector, or a matrix), and the actual dimensions of the data.

- **rtFixPtMap** is an array of structures that contains fixed-point information about the signals, states, root-level inputs/outputs, and parameters. Each element of this array is of type struct rtwCAPI_FixPtMap. The members of this structure provide information about the data scaling, bias, exponent, and whether or not the fixed-point data is signed. If the model does not have fixed-point data (signal, state, root-level input/output, or parameter), the Simulink Coder software assigns NULL or zero values to the elements of the rtFixPtMap array.

- **rtSampleTimeMap** is an array of structures that contains sampling information about the global signals, states, and root-level inputs/outputs in the model. (This array does not contain information about parameters.) Each element of this array is of type struct rtwCAPI_SampleTimeMap. The members of this structure provide information about the sample period, offset, and whether or not the data is frame-based or sample-based.

### Generate Example C API Files

Subtopics “C API Signals” on page 46-11, “C API States” on page 46-14, “C API Root-Level Inputs and Outputs” on page 46-15, and “C API Parameters“ on page 46-16 discuss generated C API structures using the example model rtwdemo_capi. To generate code from the example model, do the following:
1. Open the model by clicking the `rtwdemo_capi` link above or by typing `rtwdemo_capi` on the MATLAB command line.

2. If you want to generate C API structures for root-level inputs/outputs in `rtwdemo_capi`, open the Configuration Parameters dialog box, go to the **Code Generation > Interface** pane, and select **Generate C API for: root-level I/O**.

   **Note** The setting of **Generate C API for: root-level I/O** must match between the top model and the referenced model. If you modify the option, save the top model and the referenced model to the same writable work folder.

3. Generate code for the model by double-clicking **Generate Code Using Simulink Coder**.

   **Note** The C API code examples in the next subtopics are generated with C as the target language.

This model has three global block output signals that will appear in C API generated code:

- `top_sig1`, which is a test point at the output of the Gain1 block in the top model
- `sig2_eg`, which appears in the top model and is defined in the base workspace as a Simulink.Signal object having storage class `ExportedGlobal`
- `bot_sig1`, which appears in the referenced model `rtwdemo_capi_bot` and is defined as a Simulink.Signal object having storage class `Model default`

The model also has two discrete states that will appear in the C API generated code:

- `top_state`, which is defined for the Delay1 block in the top model
- `bot_state`, which is defined for the Discrete Filter block in the referenced model

The model has root-level inputs/outputs that will appear in the C API generated code if you select the option **Generate C API for: root-level I/O**:

- Four root-level inputs, `In1` through `In4`
- Six root-level outputs, `Out1` through `Out6`

Additionally, the model has five global block parameters that will appear in C API generated code:
• \(K_p\) (top model Gain1 block and referenced model Gain2 block share)
• \(K_i\) (referenced model Gain3 block)
• \(p_1\) (lookup table lu1d)
• \(p_2\) (lookup table lu2d)
• \(p_3\) (lookup table lu3d)

**C API Signals**

The `rtwCAPI_Signals` structure captures signal information including the signal name, address, block path, output port number, data type information, dimensions information, fixed-point information, and sample-time information.

Here is the section of code in `rtwdemo_capi_capi.c` that provides information on C API signals for the top model in `rtwdemo_capi`:

```c
/* Block output signal information */
static const rtwCAPI_Signals rtBlockSignals[] = {
    /* addrMapIndex, sysNum, blockPath, */
    /* signalName, portNumber, dataTypeIndex, dimIndex, fxpIndex, sTimeIndex */
    { 0, 0, "rtwdemo_capi/Gain1", "top_sig1", 0, 0, 0, 0, 0 },
    { 1, 0, "rtwdemo_capi/lu2d", "sig2_eg", 0, 0, 1, 0, 0 },

    { 0, 0, (NULL), (NULL), 0, 0, 0, 0, 0 },
};
```

**Note**  To better understand the code, read the comments in the file. For example, notice the comment that begins on the third line in the preceding code. This comment lists the members of the `rtwCAPI_Signals` structure, in order. This tells you the order in which the assigned values for each member appear for a signal. In this example, the comment tells you that `signalName` is the fourth member of the structure. The following lines describe the first signal:

```c
{ 0, 0, "rtwdemo_capi/Gain1", "top_sig1", 0, 0, 0, 0, 0 },
```

From these lines you infer that the name of the first signal is `top_sig1`. 

---

46-11
Each array element, except the last, describes one output port for a block signal. The final array element is a sentinel, with all elements set to null values. For example, examine the second signal, described by the following code:

```
{ 1, 0, "rtwdemo_capi/lu2d",
 "sig2_eg", 0, 0, 1, 0, 0 },
```

This signal, named `sig2_eg`, is the output signal of the first port of the block `rtwdemo_capi/lu2d`. (This port is the first port because the zero-based index for `portNumber` displayed on the second line is assigned the value 0.)

The address of this signal is given by `addrMapIndex`, which, in this example, is displayed on the first line as 1. This provides an index into the `rtDataAddrMap` array, found later in `rtwdemo_capi_capi.c`:

```c
/* Declare Data Addresses statically */
static void* rtDataAddrMap[] = {
    &rtwdemo_capi_B.top_sig1,            /* 0: Signal */
    &sig2_eg[0],                         /* 1: Signal */
    &rtwdemo_capi_DWork.top_state,       /* 2: Discrete State */
    &rtP_Ki,                             /* 3: Model Parameter */
    &rtP_Kp,                             /* 4: Model Parameter */
    &rtP_p1[0],                           /* 5: Model Parameter */
    &rtP_p2[0],                           /* 6: Model Parameter */
    &rtP_p3[0],                           /* 7: Model Parameter */
};
```

The index of 1 points to the second element in the `rtDataAddrMap` array. From the `rtDataAddrMap` array, you can infer that the address of this signal is `&sig2_eg[0]`.

This level of indirection supports multiple code instances of the same model. For multiple instances, the signal information remains constant, except for the address. In this case, the model is a single instance. Therefore, the `rtDataAddrMap` is declared statically. If you choose to generate reusable code, an initialize function is generated that initializes the addresses dynamically per instance. For details on generating reusable code, see “Configure Code Generation for Model Entry-Point Functions” (Simulink Coder) and see “Configure Code Reuse Support” on page 33-15.

The `dataTypeIndex` provides an index into the `rtDataTypeMap` array, found later in `rtwdemo_capi_capi.c`, indicating the data type of the signal:

```c
/* Data Type Map - use dataTypeMapIndex to access this structure */
static const rtwCAPI_DataTypeMap rtDataTypeMap[] = {
    /* cName, mwName, numElements, elemMapIndex, dataSize, slDataId, *
    * isComplex, isPointer */
    { "double", "real_T", 0, 0, sizeof(real_T), SS_DOUBLE, 0, 0 }
};
```
Because the index is 0 for sig2_eg, the index points to the first structure element in the array. You can infer that the data type of the signal is double. The value of isComplex is 0, indicating that the signal is not complex. Rather than providing the data type information directly in the rtwCAPI_Signals structure, a level of indirection is introduced. The indirection allows multiple signals that share the same data type to point to one map structure, saving memory for each signal.

The dimIndex (dimensions index) provides an index into the rtDimensionMap array, found later in rtwdemo_capi_capi.c, indicating the dimensions of the signal. Because this index is 1 for sig2_eg, the index points to the second element in the rtDimensionMap array:

```c
/* Dimension Map - use dimensionMapIndex to access elements of this structure*/
static const rtwCAPI_DimensionMap rtDimensionMap[] = {
    /* dataOrientation, dimArrayIndex, numDims, vardimsIndex */
    { rtwCAPI_SCALAR, 0, 2, 0 },
    { rtwCAPI_VECTOR, 2, 2, 0 },
    ...
};
```

From this structure, you can infer that this is a nonscalar signal having a dimension of 2. The dimArrayIndex value, 2, provides an index into rtDimensionArray, found later in rtwdemo_capi_capi.c:

```c
/* Dimension Array - use dimArrayIndex to access elements of this array */
static const uint_T rtDimensionArray[] = {
    1,  /* 0 */
    1,  /* 1 */
    2,  /* 2 */
    ...
};
```

The fxpIndex (fixed-point index) provides an index into the rtFixPtMap array, found later in rtwdemo_capi_capi.c, indicating fixed-point information about the signal. Your code can use the scaling information to compute the real-world value of the signal, using the equation \( V = SQ + B \), where \( V \) is “real-world” (that is, base-10) value, \( S \) is user-specified slope, \( Q \) is “quantized fixed-point value” or “stored integer,” and \( B \) is user-specified bias. For details, see “Scaling” (Fixed-Point Designer).

Because this index is 0 for sig2_eg, the signal does not have fixed-point information. A fixed-point map index of zero means that the signal does not have fixed-point information.

The sTimeIndex (sample-time index) provides the index to the rtSampleTimeMap array, found later in rtwdemo_capi_capi.c, indicating task information about the signal. If you log multirate signals or conditionally executed signals, the sampling information can be useful.
Note model_capi.c (or .cpp) includes rtw_capi.h. A source file that references the rtBlockSignals array also must include rtw_capi.h.

C API States

The rtwCAPI_States structure captures state information including the state name, address, block path, type (continuous or discrete), data type information, dimensions information, fixed-point information, and sample-time information.

Here is the section of code in rtwdemo_capi_capi.c that provides information on C API states for the top model in rtwdemo_capi:

```c
/* Block states information */
static const rtwCAPI_States rtBlockStates[] = {
  /* addrMapIndex, contStateStartIndex, blockPath,
     * stateName, pathAlias, dWorkIndex, dataTypeIndex, dimIndex,
     * fixPtIdx, sTimeIndex, isContinuous
     */
  { 2, -1, "rtwdemo_capi/Delay1",
     "top_state", ",", 0, 0, 0, 0 },

  { 0, -1, (NULL), (NULL), (NULL), 0, 0, 0, 0, 0
  }
};
```

Each array element, except the last, describes a state in the model. The final array element is a sentinel, with all elements set to null values. In this example, the C API code for the top model displays one state:

```
{ 2, -1, "rtwdemo_capi/Delay1",
   "top_state", ",", 0, 0, 0, 0, 0 },
```

This state, named top_state, is defined for the block rtwdemo_capi/Delay1. The value of isContinuous is zero, indicating that the state is discrete rather than continuous. The other fields correspond to the like-named signal equivalents described in “C API Signals” on page 46-11, as follows:

- The address of the signal is given by addrMapIndex, which, in this example, is 2. This is an index into the rtDataAddrMap array, found later in rtwdemo_capi_capi.c. Because the index is zero based, 2 corresponds to the third element in rtDataAddrMap, which is &rtwdemo_capi_DWork.top_state.
- The dataTypeIndex provides an index into the rtDataTypeMap array, found later in rtwdemo_capi_capi.c, indicating the data type of the parameter. The value 0 corresponds to a double, noncomplex parameter.
• The `dimIndex` (dimensions index) provides an index into the `rtDimensionMap` array, found later in `rtwdemo_capi_capi.c`. The value 0 corresponds to the first entry, which is `{ rtwCAPI_SCALAR, 0, 2, 0 }.

• The `fixPtIndex` (fixed-point index) provides an index into the `rtFixPtMap` array, found later in `rtwdemo_capi_capi.c`, indicating fixed-point information about the parameter. As with the corresponding signal attribute, a fixed-point map index of zero means that the parameter does not have fixed-point information.

### C API Root-Level Inputs and Outputs

The `rtwCAPI_Signals` structure captures root-level input/output information including the input/output name, address, block path, port number, data type information, dimensions information, fixed-point information, and sample-time information. (This structure also is used for block output signals, as previously described in “C API Signals” on page 46-11.)

Here is the section of code in `rtwdemo_capi_capi.c` that provides information on C API root-level inputs/outputs for the top model in `rtwdemo_capi`:

```c
/* Root Inputs information */
static const rtwCAPI_Signals rtRootInputs[] = {
    /* addrMapIndex, sysNum, blockPath, */
    /* signalName, portNumber, dataTypeIndex, dimIndex, fxpIndex, sTimeIndex */
    { 3, 0, "rtwdemo_capi/In1",
        "", 1, 0, 0, 0, 0 },
    { 4, 0, "rtwdemo_capi/In2",
        "", 2, 0, 0, 0, 0 },
    { 5, 0, "rtwdemo_capi/In3",
        "", 3, 0, 0, 0, 0 },
    { 6, 0, "rtwdemo_capi/In4",
        "", 4, 0, 0, 0, 0 },
    { 0, 0, (NULL), (NULL), 0, 0, 0, 0 },
};

/* Root Outputs information */
static const rtwCAPI_Signals rtRootOutputs[] = {
    /* addrMapIndex, sysNum, blockPath, */
    /* signalName, portNumber, dataTypeIndex, dimIndex, fxpIndex, sTimeIndex */
    { 7, 0, "rtwdemo_capi/Out1",
        "", 1, 0, 0, 0, 0 },
};
```
{ 8, 0, "rtwdemo_capi/Out2",
   "", 2, 0, 0, 0, 0 },

{ 9, 0, "rtwdemo_capi/Out3",
   "", 3, 0, 0, 0, 0 },

{ 10, 0, "rtwdemo_capi/Out4",
   "", 4, 0, 0, 0, 0 },

{ 11, 0, "rtwdemo_capi/Out5",
   "sig2_eg", 5, 0, 1, 0, 0 },

{ 12, 0, "rtwdemo_capi/Out6",
   "", 6, 0, 1, 0, 0 },

{ 0, 0, (NULL), (NULL), 0, 0, 0, 0 }
}

For information about interpreting the values in the rtwCAPI_Signals structure, see the previous section “C API Signals” on page 46-11.

C API Parameters

The rtwCAPI_BlockParameters and rtwCAPI_ModelParameters structures capture parameter information including the parameter name, block path (for block parameters), address, data type information, dimensions information, and fixed-point information.

The rtModelParameters array contains entries for workspace variables that are referenced as tunable Simulink block parameters or Stateflow data of machine scope. For example, tunable parameters include Simulink.Parameter objects that use a storage class other than Auto. The Simulink Coder software assigns its elements only NULL or zero values in the absence of such data.

The setting that you select for the model configuration parameter Default parameter behavior determines how information is generated into the rtBlockParameters array in model_capi.c (or .cpp).

- If you set Default parameter behavior to Tunable, the rtBlockParameters array contains an entry for every modifiable parameter of every block in the model. However, if you use a MATLAB variable or a tunable parameter to specify a block parameter, the block parameter does not appear in rtBlockParameters. Instead, the variable or tunable parameter appears in rtModelParameters.
- If you set Default parameter behavior to Inlined, the rtBlockParameters array is empty. The Simulink Coder software assigns its elements only NULL or zero values.
The last member of each array is a sentinel, with all elements set to null values.

Here is the `rtBlockParameters` array that is generated by default in `rtwdemo_capi_capi.c`:

```c
/* Individual block tuning is not valid when inline parameters is * 
* selected. An empty map is produced to provide a consistent     * 
* interface independent of inline parameters.                   */
static const rtwCAPI_BlockParameters rtBlockParameters[] = {
    /* addrMapIndex, blockPath, */
    /* paramName, dataTypeIndex, dimIndex, fixPtIdx */
    { 0, (NULL), (NULL), 0, 0, 0 },
};
```

In this example, only the final, sentinel array element is generated, with all members of the structure `rtwCAPI_BlockParameters` set to NULL and zero values. This is because `Default parameter behavior` is set to Inlined by default for the `rtwdemo_capi` example model. If you set `Default parameter behavior` to Tunable, the block parameters are generated in the `rtwCAPI_BlockParameters` structure. However, MATLAB variables and tunable parameters appear in the `rtwCAPI_ModelParameters` structure.

Here is the `rtModelParameters` array that is generated by default in `rtwdemo_capi_capi.c`:

```c
/* Tunable variable parameters */
static const rtwCAPI_ModelParameters rtModelParameters[] = {
    /* addrMapIndex, varName, dataTypeIndex, dimIndex, fixPtIndex */
    { 2, TARGET_STRING("Ki"), 0, 0, 0 },
    { 3, TARGET_STRING("Kp"), 0, 0, 0 },
    { 4, TARGET_STRING("p1"), 0, 2, 0 },
    { 5, TARGET_STRING("p2"), 0, 3, 0 },
    { 6, TARGET_STRING("p3"), 0, 4, 0 },
    { 0, (NULL), 0, 0, 0 }
};
```

In this example, the `rtModelParameters` array contains entries for each variable that is referenced as a tunable Simulink block parameter.
For example, the `varName` (variable name) of the fourth parameter is `p2`. The other fields correspond to the like-named signal equivalents described in “C API Signals” on page 46-11, as follows:

- The address of the fourth parameter is given by `addrMapIndex`, which, in this example, is 5. This is an index into the `rtDataAddrMap` array, found later in `rtwdemo_capi_capi.c`. Because the index is zero based, 5 corresponds to the sixth element in `rtDataAddrMap`, which is `rtP_p2`.
- The `dataTypeIndex` provides an index into the `rtDataTypeMap` array, found later in `rtwdemo_capi_capi.c`, indicating the data type of the parameter. The value 0 corresponds to a double, noncomplex parameter.
- The `dimIndex` (dimensions index) provides an index into the `rtDimensionMap` array, found later in `rtwdemo_capi_capi.c`. The value 3 corresponds to the fourth entry, which is `{ rtwCAPI_MATRIX_COL_MAJOR, 6, 2, 0 }`.
- The `fixPtIndex` (fixed-point index) provides an index into the `rtFixPtMap` array, found later in `rtwdemo_capi_capi.c`, indicating fixed-point information about the parameter. As with the corresponding signal attribute, a fixed-point map index of zero means that the parameter does not have fixed-point information.

For more information about tunable parameter storage in the generated code, see “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 22-50.

**Map C API Data Structures to rtModel**

The real-time model data structure encapsulates model data and associated information that describes the model fully. When you select the C API feature and generate code, the Simulink Coder code generator adds another member to the real-time model data structure generated in `model.h`:

```c
/*
 * DataMapInfo:
 * The following substructure contains information regarding
 * structures generated in the model's C API.
 */
struct {
    rtwCAPI_ModelMappingInfo mmi;
} DataMapInfo;
```

This member defines `mmi` (for model mapping information) of type `struct rtwCAPI_ModelMappingInfo`. The structure is located in `matlabroot/rtw/c/src/rtw_modelmap.h`. The `mmi` substructure defines the interface between the model and the
C API files. More specifically, members of mmi map the real-time model data structure to the structures in `model_capi.c` (or `.cpp`).

Initializing values of mmi members to the arrays accomplishes the mapping, as shown in "Map Model to C API Arrays of Structures" on page 46-20. Each member points to one of the arrays of structures in the generated C API file. For example, the address of the `rtBlockSignals` array of structures is allocated to the first member of the mmi substructure in `model.c` (or `.cpp`), using the following code in the `rtw_modelmap.h` file:

```c
/* signals */
struct {
    rtwCAPI_Signals const *signals;  /* Signals Array */
    uint_T                numSignals;   /* Num Signals   */
    rtwCAPI_Signals const *rootInputs; /* Root Inputs array */
    uint_T               numRootInputs; /* Num Root Inputs  */
    rtwCAPI_Signals const *rootOutputs; /* Root Outputs array */
    uint_T               numRootOutputs; /* Num Root Outputs  */
} Signals;
```

The model initialize function in `model.c` (or `.cpp`) performs the initializing by calling the C API initialize function. For example, the following code is generated in the model initialize function for example model `rtwdemo_capi`:

```c
/* Initialize DataMapInfo substructure containing ModelMap for C API */
rtwdemo_capi_InitializeDataMapInfo(rtwdemo_capi_M);
```
Map Model to C API Arrays of Structures

Note This figure lists the arrays in the order that their structures appear in rtw_modelmap.h, which differs slightly from their generated order in model_capi.c.

Generate C API Data Definition File for Exchanging Data with a Target System

This model illustrates the target-based C API for interfacing signals, parameters, and states in the generated code.
Open Example Model

Open the example model rtwdemo_capi.

```
open_system('rtwdemo_capi');
```

This model illustrates the target-based C API for interfacing signals, parameters and states in the generated code. The C API is useful for real-time interaction with the data, without having to stop execution or recompile the generated code. Typically, a client/server protocol is set up from a host to a target using serial, TCP/IP, or dual-port memory connection. The purpose of this example is not the client/server protocol. Rather, this model shows the necessary data interface required by the C client/server programs.

You can enable the C API by selecting one or more C API options on the "Code Generation > Interface" pane of the Configuration Parameters dialog box. Any signal or parameter or state with an addressable storage class is placed in the C API data structure in <model>_capi.c. Note that signals, states and parameters in the referenced model can be accessed using C-API. So make sure that C-API is enabled for the referenced model.

The C API is useful for real-time interaction with application data, without having to stop execution or recompile the generated code. Typically, a client/server protocol is set up from a host to a target using serial, TCP/IP, or dual-port memory connection. The purpose
of this example is not the client/server protocol. Rather, this model shows the necessary data interface required by the C client/server programs.

You enable the C API by selecting one or more C API options on the Code Generation > Interface pane of the Configuration Parameters dialog box. Any signal or parameter or state with an addressable storage class is placed in the C API data structure in model_capi.c. Note that signals, states, and parameters in the referenced model can be accessed using C API. So make sure that C API is enabled for the referenced model.

**C API Limitations**

The C API feature has the following limitations.

- The C API does not support the following values for the CodeFormat TLC variable:
  - S-Function
  - Accelerator_S-Function (for accelerated simulation)
- For ERT-based targets, the C API requires that support for floating-point code be enabled.
- Local block output signals are not supported.
- Local Stateflow parameters are not supported.
- The following custom storage class objects are not supported:
  - Objects without the package csc_registration file
  - Grouped custom storage classes
  - Objects defined by using macros
  - BitField objects
  - FileScope objects
- Customized data placement is disabled when you are using the C API. The interface looks for global data declaration in model.h and model_private.h. Declarations placed in any other file by customized data placement result in code that does not compile.

**Note** Custom Storage Class objects work in code generation, only if you use the ERT system target file and clear the model configuration parameter Ignore custom storage classes.

Use C API to Access Model Signals and States

This example helps you get started writing application code to interact with model signals and states. To get started writing application code to interact with model parameters, see “Use C API to Access Model Parameters” on page 46-30.

The C API provides you with the flexibility of writing your own application code to interact with model signals, states, root-level inputs/outputs, and parameters. Your target-based application code is compiled with the Simulink Coder generated code into an executable. The target-based application code accesses the C API structure arrays in `model_capi.c` (or `.cpp`). You might have host-based code that interacts with your target-based application code. Or, you might have other target-based code that interacts with your target-based application code. The files `rtw_modelmap.h` and `rtw_capi.h`, located in `matlabroot/rtw/c/src` (open), provide macros for accessing the structures in these arrays and their members.

Here is an example application that logs global signals and states in a model to a text file. This code is intended as a starting point for accessing signal and state addresses. You can extend the code to perform signal logging and monitoring, state logging and monitoring, or both.

This example uses the following macro and function interfaces:

- **rtmGetDataMapInfo macro**

  Accesses the model mapping information (MMI) substructure of the real-time model structure. In the following macro call, `rtM` is the pointer to the real-time model structure in `model.c` (or `.cpp`):

  ```c
  rtwCAPI_ModelMappingInfo* mmi = &(rtmGetDataMapInfo(rtM).mmi);
  ```

- **rtmGetTPtr macro**

  Accesses the absolute time information for the base rate from the timing substructure of the real-time model structure. In the following macro call, `rtM` is the pointer to the real-time model structure in `model.c` (or `.cpp`):

  ```c
  rtmGetTPtr(rtM)
  ```

- Custom functions `capi_StartLogging`, `capi_UpdateLogging`, and `capi_TerminateLogging`, provided via the files `rtwdemo_capi_datalog.h` and `rtwdemo_capi_datalog.c`. These files are located in `matlabroot/toolbox/rtw/rtwdemos` (open).
- `capi_StartLogging` initializes signal and state logging.
- `capi_UpdateLogging` logs a signal and state value at each time step.
- `capi_TerminateLogging` terminates signal and state logging and writes the logged values to a text file.

You can integrate these custom functions into generated model code using one or more of the following methods:

- **Code Generation > Custom Code** pane of the Configuration Parameters dialog box
- Custom Code library blocks
- TLC custom code functions

This tutorial uses the **Code Generation > Custom Code** pane and the System Outputs block from the Custom Code library to insert calls to the custom functions into `model.c` (or `.cpp`), as follows:

- `capi_StartLogging` is called in the `model_initialize` function.
- `capi_UpdateLogging` is called in the `model_step` function.
- `capi_TerminateLogging` is called in the `model_terminate` function.

The following excerpts of generated code from `model.c` (rearranged to reflect their order of execution) show how the function interfaces are used.

```c
void rtwdemo_capi_initialize(void)
{
    ...
    /* user code (Initialize function Body) */

    /* C API Custom Logging Function: Start Signal and State logging via C API. 
     * capi_StartLogging: Function prototype in rtwdemo_capi_datalog.h 
     */
    {
        rtwCAPI_ModelMappingInfo *MMI = rtmGetDataMapInfo(rtwdemo_capi_M).mmi;
        printf("** Started state/signal logging via C API **\n");
        capi_StartLogging(MMI, MAX_DATA_POINTS);
    }
    ...
}

/* Model step function */
void rtwdemo_capi_step(void)
{
    ...
    /* user code (Output function Trailer) */

    /* System '<Root>' */
```
The following procedure illustrates how you can use the C API macro and function interfaces to log global signals and states in a model to a text file.

1. At the MATLAB command line, enter `rtwdemo_capi` to open the example model.
2. Save the top model `rtwdemo_capi` and the referenced model `rtwdemo_capi_bot` to the same writable work folder.
3. Open the Configuration Parameters dialog box.
4. If you are licensed for Embedded Coder software and you want to use the `ert.tlc` system target file instead of the default `grt.tlc`, go to the Code Generation pane and use the System target file parameter to select an `ert.tlc` system target file. Make sure that you also select `ert.tlc` for the referenced model `rtwdemo_capi_bot`.
5. In the top model, go to the Code Generation > Interface pane. Confirm these model configuration parameter settings:
   a. Select Generate C API for signals, Generate C API for states, and Generate C API for parameters.
   b. If you are using the `ert.tlc` system target file, select Support complex numbers.
   c. Select MAT-file logging.
   d. Click Apply.
   e. Update configuration parameter settings in the referenced model, `rtwdemo_capi_bot`, to match changes you made in the top model.
6 Use the **Custom Code** pane to embed your custom application code in the generated code. Select the **Custom Code** pane, and then click **Include directories**. The **Include directories** input field is displayed.

7 In the **Include directories** field, type `matlabroot/toolbox/rtw/rtwdemos`, where `matlabroot` represents the root of your MATLAB installation folder. (If you are specifying a Windows path that contains a space, place the text inside double quotes.)

8 In the **Additional Build Information** subpane, click **Source files**, and type `rtwdemo_capi_datalog.c`.

9 In the **Include custom C code in generated** subpane, click **Source file**, and type or copy and paste the following include statement:

```
#include "rtwdemo_capi_datalog.h"
```

10 In the **Initialize function** field, type or copy and paste the following application code:

```c
/* C API Custom Logging Function: Start Signal and State logging via C API.
 * capi_StartLogging: Function prototype in rtwdemo_capi_datalog.h
 */
{
 rtwCAPI_ModelMappingInfo *MMI = &(rtmGetDataMapInfo(rtwdemo_capi_M).mmi);
 printf("** Started state/signal logging via C API **\n");
 capi_StartLogging(MMI, MAX_DATA_POINTS);
}
```

**Note** If you renamed the top model `rtwdemo_capi`, update the name `rtwdemo_capi_M` in the application code to reflect the new model name.

11 In the **Terminate function** field, type or copy and paste the following application code:

```c
/* C API Custom Logging Function: Dump Signal and State buffers into a text file.
 * capi_TerminateLogging: Function prototype in rtwdemo_capi_datalog.h
 */
{
```
capi_TerminateLogging("rtwdemo_capi_ModelLog.txt");
printf("** Finished state/signal logging. Created rtwdemo_capi_ModelLog.txt **\n");
}

Click **Apply**.

12 In the MATLAB Command Window, enter `custcode` to open the Simulink Coder Custom Code library. At the top level of the `rtwdemo_capi` model, add a System Outputs block.

13 Double-click the System Outputs block to open the System Outputs Function Custom Code dialog box. In the **System Outputs Function Exit Code** field, type or copy and paste the following application code:

```c
/* C API Custom Logging Function: Update Signal and State logging buffers.
 * capi_UpdateLogging: Function prototype in rtwdemo_capi_datalog.h
 */
{
    rtwCAPI_ModelMappingInfo *MMI = &(rtmGetDataMapInfo(rtwdemo_capi_M).mmi);
    capi_UpdateLogging(MMI, rtmGetTPtr(rtwdemo_capi_M));
}
```

**Note** If you renamed the top model `rtwdemo_capi`, update two instances of the name `rtwdemo_capi_M` in the application code to reflect the new model name.

Click **OK**.

14 On the **Code Generation** pane, verify that the **Generate code only** check box is cleared.

Build the model and generate an executable program. For example, on a Windows system, the build generates the executable file `rtwdemo_capi.exe` in your current working folder.

15 In the MATLAB Command Window, enter the command `!rtwdemo_capi` to run the executable file. During execution, signals and states are logged using the C API and then written to the text file `rtwdemo_capi_ModelLog.txt` in your current working folder.

```matlab
>> !rtwdemo_capi
```

** starting the model **
** Started state/signal logging via C API **
** Logging 2 signal(s) and 1 state(s). In this demo, only scalar named signals/states are logged **
** Finished state/signal logging. Created rtwdemo_capi_ModelLog.txt **

16 Examine the text file in the MATLAB editor or other text editor. Here is an excerpt of the signal and state logging output.
******** Signal Log File ********

Number of Signals Logged: 2
Number of points (time steps) logged: 51

Time           bot_sig1 (Referenced Model)             top_sig1

Use C API to Access Model Parameters

This example helps you get started writing application code to interact with model parameters. To get started writing application code to interact with model signals and states, see “Use C API to Access Model Signals and States” on page 46-24.

The C API provides you with the flexibility of writing your own application code to interact with model signals, states, root-level inputs/outputs, and parameters. Your target-based application code is compiled with generated code into an executable program. The target-based application code accesses the C API structure arrays in _model_capi.c (or .cpp). You might have host-based code that interacts with your target-based application code. Or, you might have other target-based code that interacts with your target-based application code. The files _rtw_modelmap.h and _rtw_capi.h, located in matlabroot/rtw/c/src (open), provide macros for accessing the structures in these arrays and their members.

Here is an example application that prints the parameter values of tunable parameters in a model to the standard output. This code is intended as a starting point for accessing parameter addresses. You can extend the code to perform parameter tuning. The application:

- Uses the _rtmGetDataMapInfo macro to access the mapping information in the _mmi substructure of the real-time model structure

  rtwCAPI_ModelMappingInfo* mmi = &(_rtmGetDataMapInfo(rtM).mmi);

  where _rtM is the pointer to the real-time model structure in _model.c (or .cpp).

- Uses _rtwCAPI_GetNumModelParameters to get the number of model parameters in mapped C API:

  uint_T nModelParams = rtwCAPI_GetNumModelParameters(mmi);

- Uses _rtwCAPI_GetModelParameters to access the array of model parameter structures mapped in C API:

  rtwCAPI_ModelParameters* capiModelParams = \
  _rtwCAPI_GetModelParameters(mmi);

- Loops over the capiModelParams array to access individual parameter structures. A call to the function _capi_PrintModelParameter displays the value of the parameter.

The example application code is provided below:
Get CAPI Mapping structure from Real-Time Model structure */
rtwCAPI_ModelMappingInfo* capiMap =
&(rtmGetDataMapInfo(rtwdemo_capi_M).mmi);

/* Get number of Model Parameters from capiMap */
uint_T nModelParams = rtwCAPI_GetNumModelParameters(capiMap);
printf("Number of Model Parameters: %d\n", nModelParams);

/* If the model has Model Parameters, print them using the 
application capi_PrintModelParameter */
if (nModelParams == 0) {
    printf("No Tunable Model Parameters in the model \n");
} else {
    unsigned int idx;
    for (idx=0; idx < nModelParams; idx++) {
        /* call print utility function */
        capi_PrintModelParameter(capiMap, idx);
    }
}

The print utility function is located in \textit{matlabroot}/rtw/c/src/ 
\textit{rtw_capi_examples.c}. This file contains utility functions for accessing the C API 
structures.

To become familiar with the example code, try building a model that displays the tunable 
block parameters and MATLAB variables. You can use \textit{rtwdemo_capi}, the C API example 
model. The following steps apply to both \textit{grt.tlc} and \textit{ert.tlc} system target files, 
unless otherwise indicated.

1. At the MATLAB command line, enter \textit{rtwdemo_capi} to open the example model.
2. Save the top model \textit{rtwdemo_capi} and the referenced model \textit{rtwdemo_capi_bot} 
to the same writable work folder.
3. If you are licensed for Embedded Coder software and you want to use the \textit{ert.tlc} 
system target tile instead of the default \textit{grt.tlc}, go to the \textbf{Code Generation} pane 
of the Configuration Parameters dialog box and use the \textbf{System target file} 
parameter to select an \textit{ert.tlc} system target file. Make sure that you also select 
\textit{ert.tlc} for the referenced model \textit{rtwdemo_capi_bot}.
4. Confirm these model configuration parameter settings:
a Select **Generate C API for parameters**.

b If you are using the `ert.tlc` system target file, select **Support complex numbers**.

c Select **MAT-file logging**.

d Click **Apply**.

e Update configuration parameter settings in the referenced model, `rtwdemo_capi_bot`, to match changes you made in the top model.

5 Use the **Custom Code** pane to embed your custom application code in the generated code. Select the **Custom Code** pane, and then click **Initialize function**. The **Initialize function** input field is displayed.

6 In the **Initialize function** input field, type or copy and paste the example application code shown above step 1. This embeds the application code in the `model_initialize` function.

---

**Note** If you renamed the top model `rtwdemo_capi`, update the name `rtwdemo_capi_M` in the application code to reflect the new model name.

7 Click **Include directories**, and type `matlabroot/rtw/c/src`, where `matlabroot` represents the root of your MATLAB installation folder. (If you are specifying a Windows path that contains a space, place the text inside double quotes.)

8 In the **Additional Build Information** subpane, click **Source files**, and type `rtw_capi_examples.c`. 

Click Apply.

9 On the Code Generation pane, verify that the Generate code only check box is cleared.

Build the model and generate an executable program. For example, on a Windows system, the build generates the executable file `rtwdemo_capi.exe` in your current working folder.

10 In the MATLAB Command Window, enter `!rtwdemo_capi` to run the executable file. Running the program displays parameter information in the Command Window.

```matlab
%!rtwdemo_capi

** starting the model **
Number of Model Parameters: 5
Ki =
  7
Kp =
  4
p1 =
  0.15
  0.36
  0.81
p2 =
  0.09  0.75  0.57
```
p3 =
ans(:,:,1) =
   0.23   0.82   0.04   0.64
   0.35   0.01   0.16   0.73
ans(:,:,2) =
   0.64   0.54   0.74   0.68
   0.45   0.29   0.18   0.18

ASAP2 Data Measurement and Calibration in Simulink Coder
Export ASAP2 File for Data Measurement and Calibration

The ASAM MCD-2 MC standard, also known as ASAP2, is a data definition standard proposed by the Association for Standardization of Automation and Measuring Systems (ASAM). ASAP2 is a non-object-oriented description of the data used for measurement, calibration, and diagnostic systems. For more information on ASAM and the ASAM MCD-2 MC (ASAP2) standard, see the ASAM Web site at http://www.asam.net.

The code generator lets you export an ASAP2 file containing information about your model during the code generation process.

You can run an interactive example of ASAP2 file generation. To open the example at the MATLAB command prompt, enter the following command:

rtwdemo_asap2

**Note** Simulink Coder support for ASAP2 file generation is version-neutral. By default, the software generates ASAP2 version 1.31 format, but the generated model information is generally compatible with all ASAP2 versions. ASAP2 file generation also is neutral with respect to the specific needs of ASAP2 measurement and calibration tools. The software provides customization APIs that you can use to customize ASAP2 file generation to generate any ASAP2 version and to meet the specific needs of your ASAP2 tools.

In this section...

- “Create a Host-Based ASAM-ASAP2 Data Definition File for Data Measurement and Calibration” on page 47-13
What You Should Know

To make use of ASAP2 file generation, you should become familiar with the following topics:

- ASAM and the ASAP2 standard and terminology. See the ASAM Web site at http://www.asam.net.
- Simulink data objects. Data objects are used to supply information not contained in the model. For an overview, see “Data Objects” (Simulink).
- Storage and representation of signals and parameters in generated code. See “Data Access for Prototyping and Debugging” (Simulink Coder).
- If you are licensed for Embedded Coder, see also the Embedded Coder topic “Data Representation and Access”.

Targets Supporting ASAP2

ASAP2 file generation is available to all code generator system target file configurations. For example,

- Generic Real-Time Target (grt.tlc) lets you generate an ASAP2 file as part of the code generation and build process.
- Embedded Coder (ert.tlc) system target file selections also let you generate an ASAP2 file as part of the code generation and build process.
- ASAM-ASAP2 Data Definition Target (asap2.tlc) lets you generate only an ASAP2 file, without building an executable program.

Procedures for generating ASAP2 files by using these target configurations are given in “Generate an ASAP2 File” on page 47-9.

Define ASAP2 Information

- “Define ASAP2 Information for Parameters and Signals” on page 47-4
- “Memory Address Attribute” on page 47-5
- “Automatic ECU Address Replacement for ASAP2 Files (Embedded Coder)” on page 47-6
- “Define ASAP2 Information for Lookup Tables” on page 47-7
Define ASAP2 Information for Parameters and Signals

The ASAP2 file generation process requires information about parameters and signals in your model. Some of this information is contained in the model itself. You must supply the rest by using Simulink data objects in a workspace or data dictionary. In some cases, the use of workspace objects is optional.

You can use the Model Data Editor and built-in Simulink data objects to provide the information. For example, you can use Simulink.Signal objects to provide MEASUREMENT information and Simulink.Parameter objects to provide CHARACTERISTIC information. Also, you can use data objects from data classes that are derived from Simulink.Signal and Simulink.Parameter to provide the information. For information about data objects, see “Data Objects” (Simulink). For information about the Model Data Editor, see “Configure Data Properties by Using the Model Data Editor” (Simulink).

The following table contains the minimum set of data attributes required for ASAP2 file generation. Some data attributes are defined in the model; others are supplied in the properties of objects. For attributes that are defined in Simulink.Signal or Simulink.Parameter objects, the table gives the associated property name.

<table>
<thead>
<tr>
<th>Data Attribute</th>
<th>Defined In</th>
<th>Property Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name (symbol)</td>
<td>Model and data object</td>
<td>Inherited from the handle of the data object to which parameter or signal name resolves</td>
</tr>
<tr>
<td>Description</td>
<td>Data object</td>
<td>Description</td>
</tr>
<tr>
<td>Data type</td>
<td>Model or data object</td>
<td>DataType</td>
</tr>
<tr>
<td>Scaling (if fixed-point data type)</td>
<td>Model or data object</td>
<td>DataType</td>
</tr>
<tr>
<td>Minimum allowable value</td>
<td>Model or data object</td>
<td>Min</td>
</tr>
<tr>
<td>Maximum allowable value</td>
<td>Model or data object</td>
<td>Max</td>
</tr>
<tr>
<td>Unit</td>
<td>Model or data object</td>
<td>Unit</td>
</tr>
<tr>
<td>Memory address (optional)</td>
<td>Model or data object</td>
<td>MemoryAddress_ASAP2 (optional; see “Memory Address Attribute” on page 47-5.)</td>
</tr>
</tbody>
</table>
**Memory Address Attribute**

If the memory address attribute is unknown before code generation, the code generator inserts ECU Address placeholder text in the generated ASAP2 file. You can substitute an actual address for the placeholder by postprocessing the generated file. See the file `matlabroot/toolbox/rtw/targets/asap2/asap2/asap2post.m` for an example. `asap2post.m` parses through the linker map file that you provide and replaces the ECU Address placeholders in the ASAP2 file with the actual memory addresses. Since linker map files vary from compiler to compiler, you might need to modify the regular expression code in `asap2post.m` to match the format of the linker map you use.

**Note** If Embedded Coder is licensed and installed on your system, and if you are generating ELF (Executable and Linkable Format) files for your embedded target, you can use the `rtw.asap2SetAddress` function to automate ECU address replacement. For more information, see “Automatic ECU Address Replacement for ASAP2 Files (Embedded Coder)” on page 47-6.

If the memory address attribute is known before code generation, it can be defined in the data item or data object. By default, the `MemoryAddress_ASAP2` property does not exist in the `Simulink.Signal` or `Simulink.Parameter` data object classes. If you want to add the attribute, add a property called `MemoryAddress_ASAP2` to a custom class that is a subclass of the `Simulink` or `ASAP2` class. For information on subclassing Simulink data classes, see “Define Data Classes” (Simulink).

**Note** In previous releases, for ASAP2 file generation, you had to define objects explicitly as `ASAP2.Signal` and `ASAP2.Parameter`. This is no longer a limitation. As explained above, you can use built-in Simulink objects for generating an ASAP2 file. If you have been using an earlier release, you can continue to use the ASAP2 objects. If one of these ASAP2 objects was created in the previous release, and you use it in this release, the MATLAB Command Window displays a warning the first time the objects are loaded.

The following table indicates the Simulink object properties that have replaced the ASAP2 object properties of the previous release:
Differences Between ASAP2 and Simulink Parameter and Signal Object Properties

<table>
<thead>
<tr>
<th>ASAP2 Object Properties (Previous)</th>
<th>Simulink Object Properties (Current)</th>
</tr>
</thead>
<tbody>
<tr>
<td>LONGIG_ASAP2</td>
<td>Description</td>
</tr>
<tr>
<td>PhysicalMin_ASAP2</td>
<td>Min</td>
</tr>
<tr>
<td>PhysicalMax_ASAP2</td>
<td>Max</td>
</tr>
<tr>
<td>Units_ASAP2</td>
<td>Unit</td>
</tr>
</tbody>
</table>

Automatic ECU Address Replacement for ASAP2 Files (Embedded Coder)

If Embedded Coder is licensed and installed on your system, and if you are generating ELF (Executable and Linkable Format) files for your embedded target, you can use the `rtw.asap2SetAddress` function to automate the replacement of ECU Address placeholder memory address values with actual addresses in the generated ASAP2 file.

If the memory address attribute is unknown before code generation, the code generator inserts ECU Address placeholder text in the generated ASAP2 file, as shown in the example below.

```plaintext
/begin CHARACTERISTIC
   /* Name            */ Ki
   /* Long Identifier */ ""
   /* Type            */ VALUE
   /* ECU Address     */ 0x0
   /*ECU_Address@Ki@ */

To substitute actual addresses for the ECU Address placeholders, process the generated ASAP2 file using the `rtw.asap2SetAddress` function. The general syntax is as follows:

```plaintext
rtw.asap2SetAddress(ASAP2File, InfoFile)
```

where the arguments are character vectors specifying the name of the generated ASAP2 file and the name of the generated executable ELF file or DWARF debug information file for the model. When called, `rtw.asap2SetAddress` extracts the actual ECU address from the specified ELF or DWARF file and replaces the placeholder in the ASAP2 file with the actual address, for example:

```plaintext
/begin CHARACTERISTIC
   /* Name            */ Ki
   /* Long Identifier */ ""
```
/* Type            */ VALUE
/* ECU Address     */ 0x40009E60

**Define ASAP2 Information for Lookup Tables**

Simulink Coder software generates ASAP2 descriptions for lookup table data and its breakpoints. The software represents 1-D table data as CURVE information, 2-D table data as MAP information, and breakpoints as AXIS_DESCR and AXIS_PTS information. You can model lookup tables using one of the following Simulink Lookup Table blocks:

- Direct Lookup Table (n-D) — 1 and 2 dimensions
- Interpolation Using Prelookup — 1 and 2 dimensions
- 1-D Lookup Table
- 2-D Lookup Table
- n-D Lookup Table — 1 and 2 dimensions

The software supports the following types of lookup table breakpoints (axis points):

<table>
<thead>
<tr>
<th>Breakpoint Type</th>
<th>Generates</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tunable and shared among multiple table axes (common axis)</td>
<td>COM_AXIS</td>
</tr>
<tr>
<td>Fixed and nontunable (fixed axis)</td>
<td>One of these variants of FIX_AXIS:</td>
</tr>
<tr>
<td></td>
<td>• FIX_AXIS_PAR if breakpoints are integers with equidistant spacing and the equidistant spacing is a power of two</td>
</tr>
<tr>
<td></td>
<td>• FIX_AXIS_PAR_DIST if breakpoints are integers with equidistant spacing</td>
</tr>
<tr>
<td></td>
<td>• FIX_AXIS_PAR_LIST if breakpoints are integers with non-equidistant spacing</td>
</tr>
<tr>
<td>Tunable but not shared among multiple tables (standard axis)</td>
<td>STD_AXIS</td>
</tr>
</tbody>
</table>

When you configure the blocks for ASAP2 code generation:

- For table data, use a Simulink.Parameter data object with a non-Auto storage class.
• For tunable breakpoint data that is shared among multiple table axes (COM_AXIS), use a `Simulink.Parameter` data object with a non-Auto storage class.

• For fixed, nontunable breakpoint data (FIX_AXIS), use workspace variables or arrays specified in the block parameters dialog box. The breakpoints should be stored as integers in the code, so the data type should be a built-in integer type (`int8`, `int16`, `int32`, `uint8`, `uint16`, or `uint32`), a fixed-point data type, or an equivalent alias type.

• For tunable breakpoint data that is not shared among multiple tables (STD_AXIS):

  1. Create a `Simulink.Bus` object to define the struct packaging (names and order of the fields). The fields of the parameter structure must correspond to the lookup table data and each axis of the lookup table block. For example, in an n-D Lookup Table block with 2 dimensions, the structure must contain only three fields. This bus object describes the record layout for the lookup characteristic.

  2. Create a `Simulink.Parameter` object to represent a tunable parameter.

  3. Create table and axis values.

  4. Optionally, specify the **Units**, **Minimum**, and **Maximum** properties for the parameter object. The properties will be applied to table data only.

Here is an example of an n-D Lookup Table record generated into an ASAP2 file in Standard Axis format:

```
/begin CHARACTERISTIC
   /* Name */   STDAxisParam
   ...
   /* Record Layout */   Lookup1D_X_WORD_Y_FLOAT32_IEEE
   ...
   begin AXIS_DESCR
      /* Description of X-Axis Points */
      /* Axis Type */   STD_AXIS
      ...
   /end AXIS_DESCR
/begin CHARACTERISTIC
```

```
/begin RECORD_LAYOUT Lookup1D_X_WORD_Y_FLOAT32_IEEE
   AXIS_PTS X 1 WORD INDEX INCR DIRECT
   FNC_VALUES 2 FLOAT32_IEEE COLUMN_DIR DIRECT
/end RECORD_LAYOUT
```
The example model `rtwdemo_asap2` illustrates ASAP2 file generation for Lookup Table blocks, including both tunable (COM_AXIS) and fixed (FIX_AXIS) lookup table breakpoints.

**Generate an ASAP2 File**

- “About Generating ASAP2 Files” on page 47-9
- “Use GRT or ERT System Target File” on page 47-9
- “Use the ASAM-ASAP2 Data Definition Target” on page 47-10
- “Generate ASAP2 Files for Referenced Models” on page 47-11
- “Merge ASAP2 Files for Top and Referenced Models” on page 47-11

**About Generating ASAP2 Files**

You can generate an ASAP2 file from your model in one of the following ways:

- Use the Generic Real-Time Target or a Embedded Coder target to generate an ASAP2 file as part of the code generation and build process.
- Use the ASAM-ASAP2 Data Definition Target to generate only an ASAP2 file, without building an executable.

This section discusses how to generate an ASAP2 file by using the targets that have built-in ASAP2 support. For an example, see the ASAP2 example model `rtwdemo_asap2`.

**Use GRT or ERT System Target File**

The procedure for generating the ASAP2 data definition for a model using the Generic Real-Time Target or Embedded Coder system target file is as follows:

1. Use the Model Data Editor (View > Model Data Editor) to apply storage classes to signals, block states, and block parameters as described in “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 22-81. Use signal and state names to refer to corresponding MEASUREMENT records and parameter object names to refer to CHARACTERISTIC records.

   Use any storage class or custom storage class other than Auto, FileScope, or, if you set the default storage class of the corresponding data category to Default in the Code Mapping Editor (the default setting), Model default. For example, using ExportedGlobal configures the data item as an unstructured global variable in the generated code.
The data item is not represented in the ASAP2 file if any of the following conditions exist:

- You apply one of the storage classes Auto, FileScope, or Default (through Model default).
- You apply a custom storage class that causes the code generator to generate a macro or non-addressable variable.

2 Use the Model Data Editor to configure the remaining properties as desired for each data item.

3 On the Code Generation pane, click Browse to open the System Target File Browser. In the browser, select grt.tlc or an ERT based target file and click OK.

4 On the Code Generation > Interface pane, in the Data exchange interface subgroup, select ASAP2 interface.

5 Select the Generate code only check box on the Code Generation pane.

6 Click Apply.

7 Build the model.

The code generator writes the ASAP2 file to the build folder. By default, the file is named model.a2l, where model is the name of the model. The ASAP2 setup file controls the ASAP2 file name. For details, see “Customize Generated ASAP2 File” on page 72-2.

Use the ASAM-ASAP2 Data Definition Target

The procedure for generating the ASAP2 data definition for a model using the ASAM-ASAP2 Data Definition Target is as follows:

1 Use the Model Data Editor (View > Model Data Editor) to apply storage classes to signals, block states, and block parameters as described in “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 22-81. Use signal and state names to refer to corresponding MEASUREMENT records and parameter object names to refer to CHARACTERISTIC records.

Use any storage class or custom storage class other than Auto, FileScope, or, if you set the default storage class of the corresponding data category to Default in the Code Mapping Editor (the default setting), Model default. For example, using ExportedGlobal configures the data item as an unstructured global variable in the generated code.
**Note** The data item is not represented in the ASAP2 file if any of the following conditions exist:

- You apply one of the storage classes `Auto`, `FileScope`, or `Default` (through `Model default`).
- You apply a custom storage class that causes the code generator to generate a macro or non-addressable variable.

2 Use the Model Data Editor to configure the remaining properties as desired for each data item.

3 On the **Code Generation** pane, click **Browse** to open the System Target File Browser. In the browser, select `asap2.tlc` and click **OK**.

4 Select the **Generate code only** check box on the **Code Generation** pane.

5 Click **Apply**.

6 Build the model.

The Simulink Coder code generator writes the ASAP2 file to the build folder. By default, the file is named `model.a2l`, where `model` is the name of the model. The ASAP2 setup file controls the ASAP2 file name. For details, see “Customize Generated ASAP2 File” on page 72-2.

**Generate ASAP2 Files for Referenced Models**

The build process can generate an ASAP2 file for each referenced model in a model reference hierarchy. In the generated ASAP2 file, MEASUREMENT records represent signals and states inside the referenced model.

To generate ASAP2 files for referenced models, select ASAP2 file generation for the top model and for each referenced model in the reference hierarchy. For example, if you are using the Generic Real-Time Target or an Embedded Coder target, follow the procedure described in “Use GRT or ERT System Target File” on page 47-9 for the top model and each referenced model.

**Merge ASAP2 Files for Top and Referenced Models**

Use function `rtw.asap2MergeMdlRefs` to merge the ASAP2 files generated for top and referenced models. The function has the following syntax:

```matlab
[status,info]=rtw.asap2MergeMdlRefs(topModelName,asap2FileName)
```
• `topModelName` is the name of the model containing one or more referenced models.
• `asap2FileName` is the name you specify for the merged ASAP2 file.
• *Optional*: `status` returns false (logical 0) if the merge completes and true (logical 1) otherwise.
• *Optional*: `info` returns additional information about merge failure if `status` is true. Otherwise, it returns an empty character vector.

Consider the following example.

```matlab
[status,info]=rtw.asap2MergeMdlRefs('myTopMdl','merged.a2l')
```

This command merges the ASAP2 files generated for the top model `myTopMdl` and its referenced models in the file `merged.a2l`.

The example model `rtwdemo_asap2` includes an example of merging ASAP2 files.

### Structure of the ASAP2 File

The following table outlines the basic structure of the ASAP2 file and describes the Target Language Compiler (TLC) functions and files used to create each part of the file:

- Static parts of the ASAP2 file are shown in **bold**.
- Function calls are indicated by `%<FunctionName()>.

<table>
<thead>
<tr>

### Create a Host-Based ASAM-ASAP2 Data Definition File for Data Measurement and Calibration

This model shows ASAP2 data export. ASAP2 is a data definition standard proposed by the Association for Standardization of Automation and Measuring Systems (ASAM).

**Open Example Model**

Open the example model `rtwdemo_asap2`.

```matlab
open_system('rtwdemo_asap2');
```
ASAP2 is a non-object-oriented description of the data used for measurement, calibration, and diagnostics systems. For more information on ASAM and the ASAP2 standard, see the ASAM Web site: http://www.asam.de.

ASAP2 data definition is achieved with Simulink® data objects and test point signals. Using the Target Language Compiler (TLC), you can create highly customized solutions for your application. See the Simulink Coder® documentation for details on ASAP2 file generation.

You can configure ASAP2 file generation from "Code Generation > Interface > ASAP2 interface" in the Configuration Parameters dialog box.

ASAP2 is a non-object-oriented description of the data used for measurement, calibration, and diagnostics systems. For more information on ASAM and the ASAP2 standard, see the ASAM Web site: http://www.asam.de.

ASAP2 data definition is achieved with Simulink® data objects and test point signals. Using the Target Language Compiler (TLC), you can create highly customized solutions for your application. See the Simulink Coder® documentation for details on ASAP2 file generation.
You can configure ASAP2 file generation by selecting **ASAP2 interface** on the **Code Generation > Interface** pane of the Configuration Parameters dialog box.

Direct Memory Access to Generated Code for Simulink Coder
Access Memory in Generated Code Using Global Data Map

Simulink Coder provides a Target Language Compiler (TLC) function library that lets you create a global data map record. The global data map record, when generated, is added to the CompiledModel structure in the model.rtw file. The global data map record is a database containing information required for accessing memory in the generated code, including

- Signals (Block I/O)
- Parameters
- Data type work vectors (DWork)
- External inputs
- External outputs

Use of the global data map requires knowledge of the Target Language Compiler and of the structure of the model.rtw file. See “Target Language Compiler Overview” (Simulink Coder) for information on these topics.

The TLC functions that are required to generate and access the global data map record are contained in matlabroot/rtw/c/tlc/mw/globalmaplib.tlc. The comments in the source code fully document the global data map structures and the library functions.

The global data map structures and functions might be modified or enhanced in future releases.

Accelerate, Refine, and Test Hybrid Dynamic System on Host Computer by Using RSim System Target File

After you create a model, you can use the rapid simulation (RSim) system target file to characterize model behavior. The executable program that results from the build process is for non-real-time execution on your development computer. The executable program is highly optimized for simulating models of hybrid dynamic systems, including models that use variable-step solvers and zero-crossing detection. The speed of the generated code makes the RSim system target file ideal for building programs for batch or Monte Carlo simulations.

About Rapid Simulation

Use the RSim target to generate an executable that runs fast, standalone simulations. You can repeat simulations with varying data sets, interactively or programmatically with scripts, without rebuilding the model. This can accelerate the characterization and tuning of model behavior and code generation testing.

Using command-line options:

- Define parameter values and input signals in one or more MAT-files that you can load and reload at the start of simulations without rebuilding your model.
- Redirect logging data to one or more MAT-files that you can then analyze and compare.
- Control simulation time.
- Specify external mode options.

Note To run an RSim executable, configure your computer to run MATLAB and have the MATLAB and Simulink installation folders accessible. To deploy a standalone host executable (i.e., without MATLAB and Simulink installed), consider using the Host-Based Shared Library target (ert_shrlib).

Rapid Simulation Advantage

The advantage that you gain from rapid simulation varies. Larger simulations achieve speed improvements of up to 10 times faster than standard Simulink simulations. Some models might not show noticeable improvement in simulation speed. To determine the
speed difference for your model, time your standard Simulink simulation and compare the results with a rapid simulation. In addition, test the model simulation in Rapid Accelerator simulation mode.

**General Rapid Simulation Workflow**

Like other stages of Model-Based Design, characterization and tuning of model behavior is an iterative process, as shown in the general workflow diagram in the figure. Tasks in the workflow are:

1. Identify your rapid simulation requirements. on page 49-4
2. Configure Inport blocks on page 49-6 that provide input source data for rapid simulations.
3. Configure the model on page 49-6 for rapid simulation.
4. Set up simulation input data. on page 49-8
5. Run the rapid simulations. on page 49-19
Identify Rapid Simulation Requirements

The first step to setting up a rapid simulation is to identify your simulation requirements.

Configure Inports to Provide Simulation Source Data

You can use Inport blocks as a source of input data for rapid simulations. To do so, configure the blocks so that they can import data from external MAT-files. By default, the Inport block inherits parameter settings from downstream blocks. In most cases, to import data from an external MAT-file, you must explicitly set the following parameters to match the source data in the MAT-file.

- **Main > Interpolate data**
- **Signal Attributes > Port dimensions**
- **Signal Attributes > Data type**
- **Signal Attributes > Signal type**

If you do not have control over the model content, you might need to modify the data in the MAT-file to conform to what the model expects for input. Input data characteristics and specifications of the Inport block that receives the data must match.

For details on adjusting these parameters and on creating a MAT-file for use with an Inport block, see “Create a MAT-File for an Inport Block” on page 49-14. For descriptions of the preceding block parameters, see the block description of Inport.

Configure and Build Model for Rapid Simulation

After you identify your rapid simulation requirements, configure the model for rapid simulation.

1. Open the Configuration Parameters dialog box.
2. Go to the Code Generation pane.
4. Select rsim.tlc (Rapid Simulation Target) and click OK.
On the **Code Generation** pane, the code generator populates the **Make command** and "Template makefile" (Simulink Coder) fields with default settings and adds the **RSim Target** pane under **Code Generation**.

5  
Click **RSim Target** to view the **RSim Target** pane.

6  
Set the RSim target configuration parameters to your rapid simulation requirements.

<table>
<thead>
<tr>
<th>If You Want to...</th>
<th>Then...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Generate code that allows the RSim executable to load parameters from a MAT-file</td>
<td>Select <strong>Enable RSim executable to load parameters from a MAT-file</strong> (default).</td>
</tr>
<tr>
<td>Let the target choose a solver based on the solver already configured for the model</td>
<td>Set <strong>Solver selection</strong> to auto (default). The code generator uses a built-in solver if a fixed-step solver is specified on the <strong>Solver</strong> pane or calls the Simulink solver module (a shared library) if a variable-step solver is specified.</td>
</tr>
<tr>
<td>Explicitly instruct the target to use a fixed-step solver</td>
<td>Set <strong>Solver selection</strong> to Use fixed-step solvers. In the Configuration Parameters dialog box, on the <strong>Solver</strong> pane, specify a fixed-step solver.</td>
</tr>
<tr>
<td>Explicitly instruct the target to use a variable-step solver</td>
<td>Set <strong>Solver selection</strong> to Use Simulink solver module. In the Configuration Parameters dialog box, on the <strong>Solver</strong> pane, specify a variable-step solver.</td>
</tr>
<tr>
<td>Force storage classes to Auto for flexible custom code interfacing</td>
<td>Select <strong>Force storage classes to AUTO</strong> (default).</td>
</tr>
</tbody>
</table>
If You Want to... | Then...
--- | ---
Retain storage class settings, such as ExportedGlobal or ImportedExtern, due to application requirements | Clear **Force storage classes to AUTO**.

7 Set up data import and export options. On the **Data Import/Export** pane, in the **Save to Workspace** section, select the **Time, States, Outputs**, and **Final States** options, as they apply. By default, the code generator saves simulation logging results to a file named `model.mat`. For more information, see “Export Simulation Data” (Simulink).

8 If you are using external mode communication, set up the interface, using the **Code Generation > Interface** pane. See “Host-Target Communication with External Mode Simulation” (Simulink Coder) for details.

9 Press **Ctrl+B**. The code generator builds a highly optimized executable program that you can run on your development computer with varying data, without rebuilding.

For more information on compilers that are compatible with the Simulink Coder product, see “Select and Configure C or C++ Compiler or IDE” on page 43-3 and “Template Makefiles and Make Options” on page 43-26.

### Set Up Rapid Simulation Input Data

- “About Rapid Simulation Data Setup” on page 49-8
- “Create a MAT-File That Includes a Model Parameter Structure” on page 49-9
- “Create a MAT-File for a From File Block” on page 49-13
- “Create a MAT-File for an Inport Block” on page 49-14

### About Rapid Simulation Data Setup

The format and setup of input data for a rapid simulation depends on your requirements.

<table>
<thead>
<tr>
<th>If the Input Data Source Is...</th>
<th>Then...</th>
</tr>
</thead>
<tbody>
<tr>
<td>The model's global parameter vector <em>(model_P)</em></td>
<td>Use the <code>rsimgetrtp</code> function to get the vector content and then save it to a MAT-file.</td>
</tr>
<tr>
<td>The model's global parameter vector and you want a mapping between the vector and tunable parameters</td>
<td>Call the <code>rsimgetrtp</code> function to get the global parameter structure and then save it to a MAT-file.</td>
</tr>
</tbody>
</table>
If the Input Data Source Is... | Then...
---|---
Provided by a From File block | Create a MAT-file that a From File block can read.
Provided by an Inport block | Create a MAT-file that adheres to one of the three data file formats that the Inport block can read.
Provided by a From Workspace block | Create structure variables in the MATLAB workspace.

The RSim target requires that MAT-files used as input for From File and Inport blocks contain data. The grt target inserts MAT-file data directly into the generated code, which is then compiled and linked as an executable. In contrast, RSim allows you to replace data sets for each successive simulation. A MAT-file containing From File or Inport block data must be present if a From File block or Inport block exists in your model.

**Create a MAT-File That Includes a Model Parameter Structure**

To create a MAT-file that includes a model global parameter structure (model_P),

1. Get the structure by calling the function rsimgetrtp.
2. Save the parameter structure to a MAT-file.

If you want to run simulations over varying data sets, consider converting the parameter structure to a cell array and saving the parameter variations to a single MAT-file.

**Get the Parameter Structure for a Model**

Get the global parameter structure (model_P) for a model by calling the function rsimgetrtp.

```matlab
param_struct = rsimgetrtp('model')
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>model</code></td>
<td>The model for which you are running the rapid simulations.</td>
</tr>
</tbody>
</table>

The rsimgetrtp function forces an update diagram action for the specified model and returns a structure that contains the following fields.
### Field Description

**modelChecksum**

A four-element vector that encodes the structure of the model. The code generator uses the checksum to check whether the structure of the model has changed since the RSim executable was generated. If you delete or add a block, and then generate a new `model_P` vector, the new checksum does not match the original checksum anymore. The RSim executable detects this incompatibility in parameter vectors and exits to avoid returning incorrect simulation results. If the model structure changes, you must regenerate the code for the model.

**parameters**

A structure that contains the model’s global parameters.

The parameter structure contains the following information.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dataTypeName</code></td>
<td>The name of the parameter data type, for example, <code>double</code></td>
</tr>
<tr>
<td><code>dataTypeID</code></td>
<td>Internal data type identifier used by the code generator</td>
</tr>
<tr>
<td><code>complex</code></td>
<td>The value 0 if real; 1 if complex</td>
</tr>
<tr>
<td><code>dtTransIdx</code></td>
<td>Internal data index used by the code generator</td>
</tr>
<tr>
<td><code>values</code></td>
<td>A vector of the parameter values associated with this structure</td>
</tr>
<tr>
<td><code>map</code></td>
<td>This field contains the mapping information that correlates the 'values' to the tunable parameters of the model. This mapping information, in conjunction with <code>rsimsetrtparam</code>, is useful for creating subsequent rtP structures without compiling the block diagram.</td>
</tr>
</tbody>
</table>

The code generator reports a tunable fixed-point parameter according to its stored value. For example, an `sfix(16)` parameter value of 1.4 with a scaling of $2^{-8}$ has a value of 358 as an `int16`.

In the following example, `rsimgetrtpp` returns the parameter structure for the example model `rtwdemo_rsimtf` to `param_struct`.

```plaintext
param_struct = rsimgetrtpp('rtwdemo_rsimtf')
param_struct =

modelChecksum: [1.7165e+009 3.0726e+009 2.6061e+009 2.3064e+009]
parameters: [1x1 struct]
```
Save the Parameter Structure to a MAT-File

After you issue a call to `rsimgetrtp`, save the return value of the function call to a MAT-file. Using a command-line option, you can then specify that MAT-file as input for rapid simulations.

The following example saves the parameter structure returned for `rtwdemo_rsimtf` to the MAT-file `myrsimdemo.mat`.

```matlab
save myrsimdemo.mat param_struct;
```

For information on using command-line options to specify required files, see “Run Rapid Simulations” on page 49-19.

Convert the Parameter Structure for Running Simulations on Varying Data Sets

To use rapid simulations to test changes to specific parameters, you can convert the model parameter structure to a cell array. You can then access a specific parameter set by using the `@` operator to specify the index for a specific parameter set in the file.

To convert the structure to a cell array:

1. Use the function `rsimgetrtp` to get a structure containing parameter information for the example model `rtwdemo_rsimtf`. Store the structure in a variable `param_struct`.

   ```matlab
   param_struct = rsimgetrtp('rtwdemo_rsimtf');
   ```

   The `parameters` field of the structure is a substructure that contains parameter information. The `values` field of the `parameters` substructure contains the numeric values of the parameters that you can tune during execution of the simulation code.

2. Use the function `rsimsetrtpparam` to expand the structure so that it contains more parameter sets. In this case, create two more parameter sets (for a total of three sets).

   ```matlab
   param_struct = rsimsetrtpparam(param_struct,3);
   ```

   The function converts the `parameters` field to a cell array with three elements. Each element contains information for a single parameter set. By default, the function creates the second and third elements of the cell array by copying the first element. Therefore, all of the parameter sets use the same parameter values.

3. Specify new values for the parameters in the second and third parameter sets.
param_struct.parameters{2}.values = [-150 -5000 0 4950];
param_struct.parameters{3}.values = [-170 -5500 0 5100];

4 Save the structure containing the parameter set information to a MAT-file.

save rtwdemo_rsimtf.mat param_struct;

Alternatively, you can modify the block parameters in the model, and use rsimgetrtp to create multiple parameter sets:

1 Use the function rsimgetrtp to get a structure containing parameter information for the example model rtwdemo_rsimtf. Store the structure in a variable param_struct.

param_struct = rsimgetrtp('rtwdemo_rsimtf');

2 Use the function rsimsetrtpparam to expand the structure so that it contains more parameter sets. In this case, create two more parameter sets (for a total of three sets).

param_struct = rsimsetrtpparam(param_struct,3);

The function converts the parameters field to a cell array with three elements. Each element contains information for a single parameter set. By default, the function creates the second and third elements of the cell array by copying the first element. Therefore, all of the parameter sets use the same parameter values.

3 Change the values of block parameters or workspace variables. For example, change the value of the variable w from 70 to 72.

w = 72;

4 Use rsimgetrtp to get another structure containing parameter information. Store the structure in a temporary variable rtp_temp.

rtp_temp = rsimgetrtp('rtwdemo_rsimtf');

5 Assign the value of the parameters field of rtp_temp to the structure param_struct as a second parameter set.

param_struct.parameters{2} = rtp_temp.parameters;

6 Change the value of the variable w from 72 to 75.

w = 75;

7 Use rsimgetrtp to get another structure containing parameter information. Then, assign the value of the parameters field to param_struct as a third parameter set.
```matlab
rtp_temp = rsimgetrtp('rtwdemo_rsimtf');
param_struct.parameters{3} = rtp_temp.parameters;
```

8. Save the structure containing the parameter set information to a MAT-file.

```matlab
save rtwdemo_rsimtf.mat param_struct;
```

For more information on how to specify each parameter set when you run the simulations, see “Change Block Parameters for an RSim Simulation” on page 49-28.

### Create a MAT-File for a From File Block

You can use a MAT-file as the input data source for a From File block. The format of the data in the MAT-file must match the data format expected by that block. For example, if you are using a matrix as an input for the MAT file, this cannot be different from the matrix size for the executable.

To create a MAT-file for a From File block:

1. For array format data, in the workspace create a matrix that consists of two or more rows. The first row must contain monotonically increasing time points. Other rows contain data points that correspond to the time point in that column. The time and data points must be data of type double.

For example:

```matlab
t=[0:0.1:2*pi]';
Ina1=[2*sin(t) 2*cos(t)];
Ina2=sin(2*t);
Ina3=[0.5*sin(3*t) 0.5*cos(3*t)];
var_matrix=[t Ina1 Ina2 Ina3]';
```

For other supported data types, such as int16 or fixed-point, the time data points must be of type double, just as for array format data. However, the sample data can be of any dimension.

For more information on setting up the input data, see the block description of From File.

2. Save the matrix to a MAT-file.

The following example saves the matrix `var_matrix` to the MAT-file `myrsimdemo.mat` in Version 7.3 format.

```matlab
save '-v7.3' myrsimdemo.mat var_matrix;
```
Using a command-line option, you can then specify that MAT-file as input for rapid simulations.

**Create a MAT-File for an Inport Block**

You can use a MAT-file as the input data source for an Inport block.

The format of the data in the MAT-file must adhere to one of the three column-based formats listed in the following table. The table lists the formats in order from least flexible to most flexible.

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
</table>
| Single time/data matrix     | • Least flexible.  
                          | • One variable.  
                          | • Two or more *columns*. Number of columns must equal the sum of the dimensions of all root Inport blocks plus 1. First column must contain monotonically increasing time points. Other columns contain data points that correspond to the time point in a given row.  
                          | • Data of type double.  
<p>|                             | For an example, see <strong>Single time/data matrix</strong> in the following procedure, step 4. For more information, see “Loading Data Arrays to Root-Level Inputs” (Simulink). |</p>
<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
</table>
| Signal-and-time structure | • More flexible than the single time/data matrix format.  
   • One variable.  
   • Must contain two top-level fields: time and signals. The time field contains a column vector of the simulation times. The signals field contains an array of substructures, each of which corresponds to an Inport block. The substructure index corresponds to the Inport block number. Each signals substructure must contain a field named values. The values field must contain an array of inputs for the corresponding Inport block, where each input corresponds to a time point specified by the time field.  
   • If the time field is set to an empty value, clear the check box for the Inport block Interpolate data parameter.  
   • Data type must match Inport block settings.  
   
For an example, see **Signal-and-time structure** in the following procedure, step 4. For more information on this format, see “Loading Data Structures to Root-Level Inputs” (Simulink). |
### Format Description

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
</table>
| Per-port structure | • Most flexible  
|                  | • Multiple variables. Number of variables must equal the number of Inport blocks.  
|                  | • Consists of a separate structure-with-time or structure-without-time for each Inport block. Each Inport block data structure has only one **signals** field. To use this format, in the **Input** text field, enter the names of the structures as a comma-separated list, **in1**, **in2**, ..., **inN**, where **in1** is the data for your model's first port, **in2** for the second port, and so on.  
|                  | • Each variable can have a different time vector.  
|                  | • If the **time** field is set to an empty value, clear the check box for the Inport block **Interpolate data** parameter.  
|                  | • Data type must match Inport block settings.  
|                  | • To save multiple variables to the same data file, you must save them in the order expected by the model, using the **-append** option. |

For an example, see **Per-port structure** in the following procedure, step 4. For more information, see “Loading Data Structures to Root-Level Inputs” (Simulink).

The supported formats and the following procedure are illustrated in `rtwdemo_rsim_i`.

To create a MAT-file for an Inport block:

1. Choose one of the preceding data file formats.
2. Update Inport block parameter settings and specifications to match specifications of the data to be supplied by the MAT-file.

By default, the Inport block inherits parameter settings from downstream blocks. To import data from an external MAT-file, explicitly set the following parameters to match the source data in the MAT-file.

- **Main > Interpolate data**
- **Signal Attributes > Port dimensions**
- **Signal Attributes > Data type**
- **Signal Attributes > Signal type**
If you choose to use a structure format for workspace variables and the time field is empty, you must clear **Interpolate data** or modify the field so that it is set to a nonempty value. Interpolation requires time data.

For descriptions of the preceding block parameters, see the block description of **Inport**.

3 Build an RSim executable program for the model. The build process creates and calculates a structural checksum for the model and embeds it in the generated executable. The RSim target uses the checksum to verify that data being passed into the model is consistent with what the model executable expects.

4 Create the MAT-file that provides the source data for the rapid simulations. You can create the MAT-file from a workspace variable. Using the specifications in the preceding format comparison table, create the workspace variables for your simulations.

An example of each format follows:

**Single time/data matrix**

```matlab
t=[0:0.1:2*pi]';
Ina1=[2*sin(t) 2*cos(t)];
Ina2=sin(2*t);
Ina3=[0.5*sin(3*t) 0.5*cos(3*t)];
var_matrix=[t Ina1 Ina2 Ina3];
```

**Signal-and-time structure**

```matlab
t=[0:0.1:2*pi]';
var_single_struct.time=t;
var_single_struct.signals(1).values(:,1)=2*sin(t);
var_single_struct.signals(1).values(:,2)=2*cos(t);
var_single_struct.signals(2).values=sin(2*t);
var_single_struct.signals(3).values(:,1)=0.5*sin(3*t);
var_single_struct.signals(3).values(:,2)=0.5*cos(3*t);
v=[var_single_struct.signals(1).values... var_single_struct.signals(2).values... var_single_struct.signals(3).values];
```

**Per-port structure**

```matlab
t=[0:0.1:2*pi]';
Inb1.time=t;
Inb1.signals.values(:,1)=2*sin(t);
```
Inb1.signals.values(:,2)=2*cos(t);
t=[0:0.2:2*pi]';
Inb2.time=t;
Inb2.signals.values(:,1)=sin(2*t);
t=[0:0.1:2*pi]';
Inb3.time=t;
Inb3.signals.values(:,1)=0.5*sin(3*t);
Inb3.signals.values(:,2)=0.5*cos(3*t);

Save the workspace variables to a MAT-file.

**Single time/data matrix**

The following example saves the workspace variable var_matrix to the MAT-file rsim_i_matrix.mat.

```matlab
save rsim_i_matrix.mat var_matrix;
```

**Signal-and-time structure**

The following example saves the workspace structure variable var_single_struct to the MAT-file rsim_i_single_struct.mat.

```matlab
save rsim_i_single_struct.mat var_single_struct;
```

**Per-port structure**

To order data when saving per-port structure variables to a single MAT-file, use the `save` command’s `-append` option. Be sure to append the data in the order that the model expects it.

```
The following example saves the workspace variables Inb1, Inb2, and Inb3 to MAT-file rsim_i_multi_struct.mat.

```matlab
save rsim_i_multi_struct.mat Inb1;
save rsim_i_multi_struct.mat Inb2 -append;
save rsim_i_multi_struct.mat Inb3 -append;
```

The `save` command does not preserve the order in which you specify your workspace variables in the command line when saving data to a MAT-file. For example, if you specify the variables v1, v2, and v3, in that order, the order of the variables in the MAT-file could be v2 v1 v3.

Using a command-line option, you can then specify the MAT-files as input for rapid simulations.
Scripts for Batch and Monte Carlo Simulations

The RSim target is for batch simulations in which parameters and input signals vary for multiple simulations. New output file names allow you to run new simulations without overwriting prior simulation results. You can set up a series of simulations to run by creating a .bat file for use on a Microsoft Windows platform.

Create a file for the Windows platform with a text editor and execute it by typing the file name, for example, mybatch, where the name of the text file is mybatch.bat.

```
rtwdemo_rsimtf -f rtwdemo_rsimtf.mat=run1.mat -o results1.mat -tf 10.0
rtwdemo_rsimtf -f rtwdemo_rsimtf.mat=run2.mat -o results2.mat -tf 10.0
rtwdemo_rsimtf -f rtwdemo_rsimtf.mat=run3.mat -o results3.mat -tf 10.0
rtwdemo_rsimtf -f rtwdemo_rsimtf.mat=run4.mat -o results4.mat -tf 10.0
```

In this case, batch simulations run using four sets of input data in files run1.mat, run2.mat, and so on. The RSim executable saves the data to the files specified with the -o option.

The variable names containing simulation results in each of the files are identical. Therefore, loading consecutive sets of data without renaming the data once it is in the MATLAB workspace results in overwriting the prior workspace variable with new data. To avoid overwriting, you can copy the result to a new MATLAB variable before loading the next set of data.

You can also write MATLAB scripts to create new signals and new parameter structures, as well as to save data and perform batch runs using the bang command (!).

For details on running simulations and available command-line options, see “Run Rapid Simulations” on page 49-19. For an example of a rapid simulation batch script, see the example “Run Batch Simulations Without Recompiling Generated Code” (Simulink Coder).

Run Rapid Simulations

- “Rapid Simulations” on page 49-20
- “Requirements for Running Rapid Simulations” on page 49-21
- “Set a Clock Time Limit for a Rapid Simulation” on page 49-22
- “Override a Model Simulation Stop Time” on page 49-22
- “Read the Parameter Vector into a Rapid Simulation” on page 49-23
Rapid Simulations

Using the RSim target, you can build a model once and run multiple simulations to study effects of varying parameter settings and input signals. You can run a simulation directly from your operating system command line, redirect the command from the MATLAB command line by using the bang (!) character, or execute commands from a script.

From the operating system command line, use

```
rtwdemo_rsimtf
```

From the MATLAB command line, use

```
!rtwdemo_rsimtf
```

The following table lists ways you can use RSim target command-line options to control a simulation.

<table>
<thead>
<tr>
<th>To...</th>
<th>Use...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Read input data for a From File block from a MAT-file other than the MAT-file used for the previous simulation</td>
<td><code>model -f oldfilename.mat=newfilename.mat</code></td>
</tr>
<tr>
<td>Print a summary of the options for RSim executable targets</td>
<td><code>executable filename -h</code></td>
</tr>
<tr>
<td>Read input data for an Inport block from a MAT-file</td>
<td><code>model -i filename.mat</code></td>
</tr>
<tr>
<td>Time out after $n$ clock time seconds, where $n$ is a positive integer value</td>
<td><code>model -L n</code></td>
</tr>
<tr>
<td>Write MAT-file logging data to file <code>filename.mat</code></td>
<td><code>model -o filename.mat</code></td>
</tr>
<tr>
<td>Read a parameter vector from file <code>filename.mat</code></td>
<td><code>model -p filename.mat</code></td>

<tr>
<td>Override the default TCP port (17725) for external mode</td>
<td><code>model -port TCPport</code></td>
</tr>
<tr>
<td>Write MAT-file logging data to a MAT-file other than the MAT-file used for the previous simulation</td>
<td><code>model -t oldfilename.mat=newfilename.mat</code></td>
</tr>
<tr>
<td>Run the simulation until the time value <code>stoptime</code> is reached</td>
<td><code>model -tf stoptime</code></td>
</tr>
<tr>
<td>Run in verbose mode</td>
<td><code>model -v</code></td>
</tr>
<tr>
<td>Wait for the Simulink engine to start the model in external mode</td>
<td><code>model -w</code></td>
</tr>
</tbody>
</table>

The following sections use the `rtwdemo_rsimtf` example model in examples to illustrate some of these command-line options. In each case, the example assumes you have already done the following:

- Created or changed to a working folder.
- Opened the example model.
- Copied the data file `matlabroot/toolbox/rtw/rtwdemos/rsimdemos/rsim_tfdata.mat` to your working folder. You can perform this operation using the command:

  ```
  copyfile(fullfile(matlabroot,'toolbox','rtw','rtwdemos','... 'rsimdemos','rsim_tfdata.mat'),pwd);
  ```

### Requirements for Running Rapid Simulations

The following requirements apply to both fixed and variable step executables.

- You must run the RSim executable on a computer configured to run MATLAB. Also, the `RSim.exe` file must be able to access the MATLAB and Simulink installation folders on this machine. To obtain that access, your PATH environment variable must include `/bin` and `/bin/($ARCH)`, where ($ARCH) represents your operating system architecture. For example, for a personal computer running on a Windows platform, ($ARCH) is “win64”, whereas for a Linux machine, ($ARCH) is “glnxa64”.
- On GNU Linux platforms, to run an RSim executable, define the `LD_LIBRARY_PATH` environment variable to provide the path to the MATLAB installation folder, as follows:

  ```
  % setenv LD_LIBRARY_PATH /matlab/sys/os/glnx64:$LD_LIBRARY_PATH
  ```
• On the Apple Macintosh OS X platform, to run RSim target executables, you must define the environment variable `DYLD_LIBRARY_PATH` to include the folders `bin/mac` and `sys/os/mac` under the MATLAB installation folder. For example, if your MATLAB installation is under `/MATLAB`, add `/MATLAB/bin/mac` and `/MATLAB/sys/os/mac` to the definition for `DYLD_LIBRARY_PATH`.

**Set a Clock Time Limit for a Rapid Simulation**

If a model experiences frequent zero crossings and the model's minor step size is small, consider setting a time limit for a rapid simulation. To set a time limit, specify the `-L` option with a positive integer value. The simulation aborts after running for the specified amount of clock time (not simulation time). For example,

```bash
rtdemo_rsimtf -L 20
```

Based on your clock, after the executable runs for 20 seconds, the program terminates. You see a message similar to one of the following:

• On a Microsoft Windows platform,
  
  Exiting program, time limit exceeded
  Logging available data ...

• On The Open Group UNIX platform,
  
  ** Received SIGALRM (Alarm) signal @ Fri Jul 25 15:43:23 2003
  ** Exiting model 'vdp' @ Fri Jul 25 15:43:23 2003

You do not need to do anything to your model or to its configuration to use this option.

**Override a Model Simulation Stop Time**

By default, a rapid simulation runs until the simulation time reaches the time specified the Configuration Parameters dialog box, on the **Solver** pane. You can override the model simulation stop time by using the `-tf` option. For example, the following simulation runs until the time reaches 6.0 seconds.

```bash
rtdemo_rsimtf -tf 6.0
```

The RSim target stops and logs output data using MAT-file data logging rules.

If the model includes a From File block, the end of the simulation is regulated by the stop time setting specified in the Configuration Parameters dialog box, on the **Solver** pane, or with the RSim target option `-tf`. The values in the block's time vector are ignored.
However, if the simulation time exceeds the endpoints of the time and signal matrix (if the final time is greater than the final time value of the data matrix), the signal data is extrapolated to the final time value.

**Read the Parameter Vector into a Rapid Simulation**

To read the model parameter vector into a rapid simulation, you must first create a MAT-file that includes the parameter structure as described in “Create a MAT-File That Includes a Model Parameter Structure” on page 49-9. You can then specify the MAT-file in the command line with the -p option.

For example:

1. Build an RSim executable for the example model `rtwdemo_rsimtf`.
2. Modify parameters in your model and save the parameter structure.
   ```matlab
   param_struct = rsimgetrtp('rtwdemo_rsimtf');
   save myrsimdata.mat param_struct
   ``
3. Run the executable with the new parameter set.
   ```bash
   !rtwdemo_rsimtf -p myrsimdata.mat
   ** Starting model 'rtwdemo_rsimtf' @ Tue Dec 27 12:30:16 2005**
   ** created rtwdemo_rsimtf.mat **
   ``
4. Load workspace variables and plot the simulation results by entering the following commands:
   ```matlab
   load myrsimdata.mat
   plot(rt_yout)
   ```

**Specify New Signal Data File for a From File Block**

If your model's input data source is a From File block, you can feed the block with input data during simulation from a single MAT-file or you can change the MAT-file from one simulation to the next. Each MAT-file must adhere to the format described in “Create a MAT-File for a From File Block” on page 49-13.

To change the MAT-file after an initial simulation, you specify the executable with the -f option and an `oldfile.mat=newfile.mat` parameter, as shown in the following example.

1. Set some parameters in the MATLAB workspace. For example:
\[ w = 100; \]
\[ \theta = 0.5; \]

2 Build an RSIm executable for the example model `rtwdemo_rsimtf`.

3 Run the executable.

\![rtwdemo_rsimtf]

The RSIm executable runs a set of simulations and creates output MAT-files containing the specific simulation result.

4 Load the workspace variables and plot the simulation results by entering the following commands:

```matlab
load rtwdemo_rsimtf.mat
plot(rt_yout)
```

The resulting plot shows simulation results based on default input data.

5 Create a new data file, `newfrom.mat`, that includes the following data:

```matlab
t=[0:.001:1];
u=sin(100*t.*t);
```
tu=[t;u];
save newfrom.mat tu;

6 Run a rapid simulation with the new data by using the -f option to replace the original file, rsim_tfdata.mat, with newfrom.mat.

!rtw.demo_rsimtf -f rsim.tfdata.mat=newfrom.mat

7 Load the data and plot the new results by entering the following commands:

load rtw.demo_rsimtf.mat
plot(rt_yout)

The next figure shows the resulting plot.

From File blocks require input data of type double. If you need to import signal data of a data type other than double, use an Inport block (see “Create a MAT-File for an Inport Block” on page 49-14) or a From Workspace block with the data specified as a structure.

Workspace data must be in the format:

variable.time
variable.signals.values
If you have more than one signal, use the following format:

`variable.time`
`variable.signals(1).values`
`variable.signals(2).values`

**Specify Signal Data File for an Inport Block**

If your model's input data source is an Inport block, you can feed the block with input data during simulation from a single MAT-file or you can change the MAT-file from one simulation to the next. Each MAT-file must adhere to one of the three formats described in “Create a MAT-File for an Inport Block” on page 49-14.

To specify the MAT-file after a simulation, you specify the executable with the `-i` option and the name of the MAT-file that contains the input data. For example:

1. Open the model `rtwdemo_rsim_i`.
2. Check the Inport block parameter settings. The following Inport block data parameter settings and specifications that you specify for the workspace variables must match settings in the MAT-file, as indicated in “Configure Inports to Provide Simulation Source Data” on page 49-6:
   - **Main > Interpolate data**
   - **Signal Attributes > Port dimensions**
   - **Signal Attributes > Data type**
   - **Signal Attributes > Signal type**
3. Build the model.
4. Set up the input signals. For example:

   ```
   t=[0:0.01:2*pi]';
   s1=[2*sin(t) 2*cos(t)];
   s2=sin(2*t);
   s3=[0.5*sin(3*t) 0.5*cos(3*t)];
   plot(t, [s1 s2 s3])
   ```
5 Prepare the MAT-file by using one of the three available file formats described in “Create a MAT-File for an Inport Block” on page 49-14. The following example defines a signal-and-time structure in the workspace and names it `var_single_struct`.

```matlab
t=[0:0.1:2*pi]';
var_single_struct.time=t;
var_single_struct.signals(1).values(:,1)=2*sin(t);
var_single_struct.signals(1).values(:,2)=2*cos(t);
var_single_struct.signals(2).values=sin(2*t);
var_single_struct.signals(3).values(:,1)=0.5*sin(3*t);
var_single_struct.signals(3).values(:,2)=0.5*cos(3*t);
v=[var_single_struct.signals(1).values...
   var_single_struct.signals(2).values...
   var_single_struct.signals(3).values];
```

6 Save the workspace variable `var_single_struct` to MAT-file `rsim_i_single_struct.mat`.

```matlab
save rsim_i_single_struct.mat var_single_struct;
```

7 Run a rapid simulation with the input data by using the `-i` option. Load and plot the results.

```bash
!rtwdemo_rsim_i -i rsim_i_single_struct.mat
```
8 Load and plot the results.

```matlab
load rtwdemo_rsim_i.mat
plot(rt_tout, rt_yout);
```

**Change Block Parameters for an RSim Simulation**

As described in “Create a MAT-File That Includes a Model Parameter Structure” on page 49-9, after you alter one or more parameters in a Simulink block diagram, you can extract the parameter vector, `model_P`, for the entire model. You can then save the parameter vector, along with a model checksum, to a MAT-file. This MAT-file can be read directly by the standalone RSim executable, allowing you to replace the entire parameter vector or individual parameter values, for running studies of variations of parameter values representing coefficients, new data for input signals, and so on.

RSim can read the MAT-file and replace the entire `model_P` structure whenever you change one or more parameters, without recompiling the entire model.
For example, assume that you changed one or more parameters in your model, generated the new $model_P$ vector, and saved $model_P$ to a new MAT-file called mymatfile.mat. To run the same rtwdemo_rsimtf model and use these new parameter values, use the -p option, as shown in the following example:

```
!rtwdemo_rsimtf -p mymatfile.mat
load rtwdemo_rsimtf
plot(rt_yout)
```

If you have converted the parameter structure to a cell array for running simulations on varying data sets, as described in “Convert the Parameter Structure for Running Simulations on Varying Data Sets” on page 49-11, you must add an @n suffix to the MAT-file specification. n is the element of the cell array that contains the specific input that you want to use for the simulation.

The following example converts param_struct to a cell array, changes parameter values, saves the changes to MAT-file mymatfile.mat, and then runs the executable using the parameter values in the second element of the cell array as input.

```
param_struct = rsimgetrtp('rtwdemo_rsimtf');
param_struct = rsimsetrtpparam(param_struct,2);
param_struct.parameters{1}
ans =
    dataTypeName: 'double'
    dataTypeId: 0
    complex: 0
    dtTransIdx: 0
    values: [-140 -4900 0 4900]
    map: []
    structParamInfo: []

param_struct.parameters{2}.values=[-150 -5000 0 4950];
save mymatfile.mat param_struct;
!rtwdemo_rsimtf -p mymatfile.mat@2 -o rsim2.mat
```

**Specify a New Output File Name for a Simulation**

If you have specified one or more of the Save to Workspace options — Time, States, Outputs, or Final States — in the Configuration Parameters dialog box, on the Data Import/Export pane, the default is to save simulation logging results to the file model.mat. For example, the example model rtwdemo_rsimtf normally saves data to rtwdemo_rsimtf.mat, as follows:
You can specify a new output file name for data logging by using the \texttt{-o} option when you run an executable.

\texttt{rtwdemo_rsimtf -o rsim1.mat}

In this case, the set of parameters provided at the time of code generation, including From File block data parameters, is run.

**Specify New Output File Names for To File Blocks**

In much the same way as you can specify a new system output file name, you can also provide new output file names for data saved from one or more To File blocks. To do this, specify the original file name at the time of code generation with a new name, as shown in the following example:

\texttt{rtwdemo_rsimtf -t rtwdemo_rsimtf_data.mat=mynewrsimdata.mat}

In this case, assume that the original model wrote data to the output file \texttt{rtwdemo_rsimtf_data.mat}. Specifying a new file name forces RSim to write to the file \texttt{mynewrsimdata.mat}. With this technique, you can avoid overwriting an existing simulation run.

**Tune Parameters Interactively During Rapid Simulation**

The RSim target was designed to let you run batch simulations at the fastest possible speed. Using variable-step or fixed-step solvers with RSim combined with the use of a tunable parameter data structure, whether you set \texttt{Default parameter behavior} to Tunable or to Inlined, you can create multiple parameter sets to run with the RSim target's standalone executable file (.exe on Windows) generated using Simulink Coder. Each invocation of the executable allows specification of the file name to use for results.

For this example, \texttt{Default parameter behavior} is set to Inlined. The model declares workspace variables as tunable parameters. To use RSim with \texttt{Default parameter behavior} set to Tunable, and without explicitly declaring tunable parameters, see “Run Batch Simulations Without Recompiling Generated Code” (Simulink Coder).

**Open Example Model**

Open the example model \texttt{rtwdemo_rsim_param_tuning}. 

```
!rtwdemo_rsimtf
created rtwdemo_rsimtf.mat

You can specify a new output file name for data logging by using the \texttt{-o} option when you run an executable.

!rtwdemo_rsimtf -o rsim1.mat

In this case, the set of parameters provided at the time of code generation, including From File block data parameters, is run.

**Specify New Output File Names for To File Blocks**

In much the same way as you can specify a new system output file name, you can also provide new output file names for data saved from one or more To File blocks. To do this, specify the original file name at the time of code generation with a new name, as shown in the following example:

!rtwdemo_rsimtf -t rtwdemo_rsimtf_data.mat=mynewrsimdata.mat

In this case, assume that the original model wrote data to the output file rtwdemo_rsimtf_data.mat. Specifying a new file name forces RSim to write to the file mynewrsimdata.mat. With this technique, you can avoid overwriting an existing simulation run.

**Tune Parameters Interactively During Rapid Simulation**

The RSim target was designed to let you run batch simulations at the fastest possible speed. Using variable-step or fixed-step solvers with RSim combined with the use of a tunable parameter data structure, whether you set \texttt{Default parameter behavior} to Tunable or to Inlined, you can create multiple parameter sets to run with the RSim target's standalone executable file (.exe on Windows) generated using Simulink Coder. Each invocation of the executable allows specification of the file name to use for results.

For this example, \texttt{Default parameter behavior} is set to Inlined. The model declares workspace variables as tunable parameters. To use RSim with \texttt{Default parameter behavior} set to Tunable, and without explicitly declaring tunable parameters, see “Run Batch Simulations Without Recompiling Generated Code” (Simulink Coder).

**Open Example Model**

Open the example model rtwdemo_rsim_param_tuning.
open_system('rtwdemo_rsim_param_tuning');
The RSim target was designed to let you run batch simulations at the fastest possible speed. Using variable-step or fixed-step solvers with RSim combined with the use of a tunable parameter data structure, you can create multiple parameter sets to run with the RSim target's standalone executable file (.exe on Windows) generated using Simulink Coder. Each invocation of the executable allows specification of the filename to use for results.

This model uses the RSim target to allow a non-real-time executable to be passed new data without the need to recompile the Simulink model. This feature allows you to easily get a map of the tunable parameters declared in a model and save it in a MAT-file. You can then create your own MATLAB GUI or a standalone GUI (independent of MATLAB) to read and write the MAT-file and rerun the executable to produce new output files.

Double-click the buttons at the upper right sequentially to run the example. To review the code used to create both the MATLAB GUI and standalone GUI, double-click the View MATLAB programs button.

For more information, you can also refer to the "Rapid Simulation Target" section in the Simulink Coder documentation.
This model uses the RSim target and the `rsimgetrtp` function to allow a non real time executable to be passed new data without the need to recompile the Simulink model. This feature allows you to get a map of the tunable parameters declared in a model and save it in a MAT-file. You can then create your own MATLAB GUI or a standalone GUI (independent of MATLAB) to read and write the MAT-file and rerun the executable to produce new output files.

### Rapid Simulation Target Limitations

The RSim target has the following limitations:

- Does not support algebraic loops.
- Does not support Interpreted MATLAB Function blocks.
- Does not support noninlined MATLAB language or Fortran S-functions.
- If an RSim build includes referenced models (by using Model blocks), set up these models to use fixed-step solvers to generate code for them. The top model, however, can use a variable-step solver as long as the blocks in the referenced models are discrete.
- In certain cases, changing block parameters can result in structural changes to your model that change the model checksum. An example of such a change is changing the number of delays in a DSP simulation. In such cases, you must regenerate the code for the model.

Run Rapid Simulations Over Range of Parameter Values

This example shows how to use the RSim target to run simulations over a range of parameter values. The example uses the Van der Pol oscillator and performs a parameter sweep over a range of initial state values to obtain the phase diagram of a nonlinear system.

It is very easy to customize this example for your own application by modifying the MATLAB® script used to build this example. Click the link in the top left corner of this page to edit the MATLAB® script. Click the link in the top right corner to run this example from MATLAB®. When running this example, make sure you are in a writable directory. The example creates files that you may want to investigate later.

For this example, Default parameter behavior is set to Inlined. In the example, you create Simulink.Parameter objects as tunable parameters. To use RSim with Default parameter behavior set to Tunable, and without explicitly declaring tunable parameters, see “Run Batch Simulations Without Recompiling Generated Code” (Simulink Coder).

To quickly run multiple simulations in the Simulink environment, consider using rapid accelerator instead of RSim. For information about rapid accelerator, see “What Is Acceleration?” (Simulink). To sweep parameter values, see “Optimize, Estimate, and Sweep Block Parameter Values” (Simulink).

**Step 1. Preparation**

Make sure the current directory is writable because this example will be creating files.

```matlab
[stat, fa] = fileattrib(pwd);
if ~fa.UserWrite
    disp('This script must be run in a writable directory');
    return
end
```

Open the model and configure it to use the RSim target. For more information on doing this graphically and setting up other RSim target related options, look here.

```matlab
mdlName = 'rtwdemo_rsim_vdp';
open_system(mdlName);
cs = getActiveConfigSet(mdlName);
cs.switchTarget('rsim.tlc',[]);
```
Specify as Tunable the variables INIT_X1 (the initial condition for state x1), INIT_X2 (the initial condition for state x2), and MU (the gain value). To create tunable parameters, convert the variables to Simulink.Parameter objects, and use a storage class other than Auto for each object. In this example we will be investigating how the state trajectories evolve from different initial values for the states x1 and x2 in the model.

```matlab
INIT_X1 = Simulink.Parameter(INIT_X1);
INIT_X1.StorageClass = 'Model default';

INIT_X2 = Simulink.Parameter(INIT_X2);
INIT_X2.StorageClass = 'Model default';

MU = Simulink.Parameter(MU);
MU.StorageClass = 'Model default';
```

Define the names of files that will be created during this example.

```matlab
prmFileName = [mdlName, '_prm_sets.mat'];
logFileName = [mdlName, '_run_scr.log'];
batFileName = [mdlName, '_run_scr'];
exeFileName = mdlName;
if ispc
    exeFileName = [exeFileName, '.exe'];
    batFileName = [batFileName, '.bat'];
end
```
aggDataFile = [mdlName, '_results'];
startTime = cputime;

**Step 2. Build the Model**

Build the RSim executable for the model. During the build process, a structural checksum is calculated for the model and embedded into the generated executable. This checksum is used to check that a parameter set passed to the executable is compatible with it.

rtwbuild(mdlName);

### Starting build procedure for model: rtwdemo_rsim_vdp
### Successful completion of build procedure for model: rtwdemo_rsim_vdp

**Step 3. Get the Default Parameter Set for the Model**

Get the default rtP structure (parameter set) for the model. The modelChecksum field in the rtP structure is the structural checksum of the model. This must match the checksum embedded in the RSim executable (generated in step 2 above). If the two checksums do not match, the executable will generate an error. `rsimgetrtp` generates an rtP structure with entries for the named tunable variables INIT_X1, INIT_X2 and MU in the model.

rtp = rsimgetrtp(mdlName)

rtp =

```
struct with fields:

    modelChecksum: [1.5936e+09 1.0250e+09 283187421 2.0458e+09]
    parameters: [1x1 struct]
    globalParameterInfo: [1x1 struct]
```

**Step 4. Create Parameter Sets**

Using the rtP structure from step 4, we build a structure array with different values for the tunable variables in the model. As mentioned earlier, in this example we want to see how the state trajectories evolve for different initial values for the states x1 and x2 in the model. Hence we generate different parameter sets with different values for INIT_X1 and INIT_X2 and leave the tunable variable MU at the default value.

```
INIT_X1_vals = -5:1:5;
INIT_X2_vals = -5:1:5;
```
MU_vals = 1;
nPrmSets = length(INIT_X1_vals)*length(INIT_X2_vals)*length(MU_vals)

nPrmSets = 121

Note that in this example we have nPrmSets parameter sets, i.e., we need to run that many simulations. Initialize aggData, which is a structure array used to hold the parameter set and the corresponding results.

aggData = struct('tout', [], 'yout', [], ... 'prms', struct('INIT_X1',[],'INIT_X2',[], 'MU', []))
aggData = repmat(aggData, nPrmSets, 1);

aggData =

struct with fields:
    tout: []
    yout: []
    prms: [1x1 struct]

The utility function rsimsetrtpparam is a convenient way to build the rtP structure by adding parameter sets one at a time with different parameters values.

idx = 1;
for iX1 = INIT_X1_vals
    for iX2 = INIT_X2_vals
        for iMU = MU_vals
            rtp = rsimsetrtpparam(rtp,idx,'INIT_X1',iX1,'INIT_X2',iX2,'MU',iMU);
            aggData(idx).prms.INIT_X1 = iX1;
            aggData(idx).prms.INIT_X2 = iX2;
            aggData(idx).prms.MU      = iMU;
            idx = idx + 1;
        end
    end
end

Save the rtP structure array with the parameter sets to a MAT-file.
save(prmFileName,'rtp');
Step 5. Create a Batch File

We create a batch/script file to run the RSim executable over the parameter sets. Each run reads the specified parameter set from the parameter MAT-file and writes the results to the specified output MAT-file. Note that we use the time out option so that if a particular run were to hang (because the model may have a singularity for that particular parameter set), we abort the run after the specified time limit is exceeded and proceed to the next run.

For example, the command (on Windows®)

```
model.exe -p prm.mat@3 -o run3.mat -L 3600 2>&1>> run.log
```

specifies using the third parameter set from the rtP structure in prm.mat, writing the results to run3.mat, and aborting execution if a run takes longer than 3600 seconds of CPU time. In addition, messages from model.exe while it is running are piped to run.log. In case of problems, we can look at run.log to help debug.

```matlab
fid = fopen(batFileName, 'w');
idx = 1;
for iX1 = INIT_X1_vals
    for iX2 = INIT_X2_vals
        for iMU = MU_vals
            outMatFile = [mdlName, '_run', num2str(idx),'.mat';
            cmd = [exeFileName, ...
                ' -p ', prmFileName, '@', int2str(idx), ...
                ' -o ', outMatFile, ...
                ' -L 3600';
            if ispc
                cmd  = [cmd, ' 2>&1>> ', logFileName];
            else % (unix)
                cmd  = ['.' filesep cmd, ' 1> ', logFileName, ' 2>&1'];
            end
            fprintf(fid, ['echo ",', cmd, ""]);
            fprintf(fid, [cmd, "\n)];
            idx = idx + 1;
        end
    end
end
if isunix,
    system(['touch ', logFileName]);
    system(['chmod +x ', batFileName]);
end
fclose(fid);
Creating a batch file to run the simulations enables us to call the system command once to run the simulations (or even run the batch script outside MATLAB®) instead of calling the system command in a loop for each simulation. This results in a performance improvement because the system command has significant overhead.

**Step 6. Execute Batch File to Run Simulations**

Run the batch/script file, which runs the RSim executable once for each parameter set and saves the results to a different MAT-file each time. Note that this batch file can be run from outside MATLAB®.

```matlab
[stat, res] = system(['.' filesep batFileName]);
if stat ~= 0
    error(['Error running batch file ''', batFileName, ''' :', res]);
end
```

In this example we put the simulation runs into one batch file, ran the batch file to sequentially run 'n' simulations over 'n' parameter sets. For your application this script can be modified to generate multiple batch files, and these batch files are run in parallel by distributing them across multiple computers. Also the batch files can be run without launching MATLAB®.

**Step 7. Load Output MAT-files and Collate the Results**

Here we collect the simulation results from the output MAT-files into the aggData structure. If the output MAT-file corresponding to a particular run is not found, we set the results corresponding to that run to be NaN (not a number). This situation can occur if a simulation run with a particular set of parameters encounters singularities in the model.

```matlab
idx = 1;
for iX1 = INIT_X1_vals
    for iX2 = INIT_X2_vals
        for iMU = MU_vals
            outMatFile = [mdlName, '_run', num2str(idx), '.mat'];
            if exist(outMatFile, 'file')
                load(outMatFile);
                aggData(idx).tout = rt_tout;
                aggData(idx).yout = rt_yout;
            else
                aggData(idx).tout = nan;
                aggData(idx).yout = nan;
            end
            idx = idx + 1;
        end
    end
end
```
Save the aggData structure to the results MAT-file. At this point, you can delete the other MAT-files, as the aggData data structure contains the aggregation of input (parameters sets) and output data (simulation results).

```matlab
save(aggDataFile,'aggData');
disp(['Took ', num2str(cputime-startTime), ...
    ' seconds to generate results from ', ...
    num2str(nPrmSets), ' simulation runs (Steps 2 to 7).']);
```

Took 11.875 seconds to generate results from 121 simulation runs (Steps 2 to 7).

**Step 8. Analyze Simulation Results**

We now have data to plot the phase diagram (X2 versus X1) with different initial values for x1 and x2. The diagram shows that, irrespective of the initial condition, the Van der Pol oscillator converges to its natural oscillator mode.

```matlab
colors = {'b','g','r','c','m','y','k'}; nColors = length(colors);
for idx = 1:nPrmSets
    col = colors{idx - nColors*floor(idx/nColors) + 1};
    plot(aggData(idx).prms.INIT_X1, aggData(idx).prms.INIT_X2, [col,'x'], ...
         aggData(idx).yout(:,1), aggData(idx).yout(:,2),col);
    hold on
end
grid on
xlabel('X1');
ylabel('X2');
axis('square');
title('Phase diagram for Van der Pol equation');
```
Phase diagram for Van der Pol equation
Run Batch Simulations Without Recompiling Generated Code

This example shows how to run batch simulations without recompiling the generated code. The example modifies input signal data and model parameters by reading data from a MAT-file. In the first part (steps 1-5), ten parameter sets are created from the Simulink® model by changing the transfer function damping factor. The ten parameter sets are saved to a MAT-file, and the RSim executable reads the specified parameter set from the file. In the second part (step 6-7) of this example, five sets of signal data chirps are created with increasingly high frequencies. In both parts, the RSim executable runs the set of simulations and creates output MAT-files containing the specific simulation result. Finally, a composite of runs appears in a MATLAB® figure.

To quickly run multiple simulations in the Simulink environment, consider using rapid accelerator instead of RSim. See “What Is Acceleration?” (Simulink).

**Step 1. Preparation**

Make sure the current directory is writable because this example will be creating files.

```matlab
[stat, fa] = fileattrib(pwd);
if ~fa.UserWrite
    disp('This script must be run in a writable directory');
    return;
end
```

Open the model and configure it to use the RSim target. For more information on doing this graphically and setting up other RSim target related options, look here.

```matlab
mdlName = 'rtwdemo_rsimtf';
open_system(mdlName);
cs = getActiveConfigSet(mdlName);
cs.switchTarget('rsim.tlc',[]);
```
The MAT-file `rsim_tfdata.mat` is required in the local directory.

```matlab
if ~isempty(dir('rsim_tfdata.mat')),
    delete('rsim_tfdata.mat');
end
str1 = fullfile(matlabroot,'toolbox','rtw','rtwdemos','rsimdemos','rsim_tfdata.mat');
str2 = ['copyfile(''', str1, ''',''rsim_tfdata.mat'',''writable'')'];
eval(str2);
```

**Step 2. Build the Model**

Build the RSim executable for the model. During the build process, a structural checksum is calculated for the model and embedded into the generated executable. This checksum is used to check that a parameter set passed to the executable is compatible with it.

```matlab
evalin('base','w = 70;')
evalin('base','theta = 1.0;')
disp('Building compiled RSim simulation.')
rtwbuild(mdlName);
```

Building compiled RSim simulation.
### Starting build procedure for model: rtwdemo_rsimtf
### Successful completion of build procedure for model: rtwdemo_rsimtf

**Step 3. Get the Default Parameter Set and Create 10 Parameters Sets**

```matlab
disp('Creating rtP data files')
for i=1:10
    % Extract current rtP structure using new damping factor.
    [rtpstruct]=evalin('base','rsimgetrtp(''rtwdemo_rsimtf'');');
    savestr = strcat('save params',num2str(i),'.mat rtpstruct');
```
eval(savestr);
evalin('base','theta = theta - .1;');
end
disp('Finished creating parameter data files.')

Creating rtP data files
Finished creating parameter data files.

**Step 4. Run 10 RSim Simulations Using New Parameter Sets and Plot the Results**

```matlab
figure
for i=1:10
    % Bang out and run a simulation using new parameter data
    runstr = ['.', filesep, 'rtwdemo_rsimtf -p params',num2str(i),'.mat', ' -v'];
    [status, result] = system(runstr);
    if status ~= 0, error(result); end
    % Load simulation data into MATLAB for plotting.
    load rtwdemo_rsimtf.mat;
    axis([0 1 0 2]);
    plot(rt_tout, rt_yout)
    hold on
end
```

49-45
The plot shows 10 simulations, each using a different damping factor.

**Step 5. Set Up a Time Vector and an Initial Frequency Vector**

The time vector has 4096 points in the event we want to do windowing and spectral analysis on simulation results.

```matlab
dt = .001;
nn = [0:1:4095];
t = dt*nn; [m,n] = size(t);
wlo = 1; whi = 4;
omega = [wlo:((whi-wlo)/n):whi - (whi-wlo)/n];
```
### Step 6. Create 5 Sets of Signal Data in MAT Files

Creating .mat files with chirp data.

```matlab
disp('This part of the example illustrates a sequence of 5 plots. Each')
disp('plot shows an input chirp signal of certain frequency range.')
for i = 1:5
    wlo = whi; whi = 3*whi; % keep increasing frequencies
    omega = [wlo:((whi-wlo)/n):whi - (whi-wlo)/n];
    % In a real application we recommend shaping the chirp using
    % a windowing function (hamming or hanning window, etc.)
    % This example does not use a windowing function.
    u = sin(omega.*t);
    tudata = [t;u];
    % At each pass, save one more set of tudata to the next
    % .mat file.
    savestr = strcat('save sweep',num2str(i),'.mat tudata');
    eval(savestr);
    % Display each chirp. Note that this is only input data.
    % Simulations have not been run yet.
    plotstr = strcat('subplot(5,1,',num2str(i),');');
    eval(plotstr);
    plot(t,u)
    pause(0.3)
end
```

This part of the example illustrates a sequence of 5 plots. Each plot shows an input chirp signal of certain frequency range.
Step 7. Run the RSim Compiled Simulation Using New Signal Data

Replace the original signal data (rsim_tfdata.mat) with the files sweep1.mat, sweep2.mat, and so on.

```matlab
disp('Starting batch simulations.')
for i = 1:5
    % Bang out and run the next set of data with RSim
    runstr = ['.\', filesep, 'rtwdemo_rsimtf -f rsim_tfdata.mat=sweep', ...
              num2str(i),'.mat -v -tf 4.096'];
    [status, result] = system(runstr);
    if status ~= 0, error(result); end
    % Load the data to MATLAB and plot the results.
    load rtwdemo_rsimtf.mat
```
plotstr = strcat('subplot(5,1,',num2str(i),');');
eval(plotstr);
plot(rt_tout, rt_yout); axis([0 4.1 -3 3]);
end

zoom on
%
cleanup
evalin('base','clear w theta')
disp('This part of the example illustrates a sequence of 5 plots. Each plot')
disp('shows the simulation results for the next frequency range. Using the')
disp('mouse, zoom in on each signal to observe signal amplitudes.')
close_system(mdlName, 0);

Starting batch simulations.
This part of the example illustrates a sequence of 5 plots. Each plot shows the simulation results for the next frequency range. Using the mouse, zoom in on each signal to observe signal amplitudes.
Use MAT-Files to Feed Data to Inport Blocks for Rapid Simulations

This example shows how the RSim -i option in Simulink® Coder™ lets you use a MAT-file as the input data source for Inport blocks for rapid simulations. The data in such a MAT-file can be presented in any of the following formats:

1. One variable that defines a time/input data matrix of double values.
2. One variable that defines a structure that uses a combination of Simulink® data types.
3. Multiple variables, each defining a structure that uses a combination of Simulink® data types.

This flexibility lends itself well to applications for which you must run simulations over a range of input data stored in different data files. This example explains how to use this feature.

To quickly run multiple simulations in the Simulink environment, consider using rapid accelerator instead of RSim. See “What Is Acceleration?” (Simulink).

**Step 1. Preparation**

Open the model and configure it to use the Simulink® Coder™ RSim target. For more information on doing this graphically and setting up other RSim target related options, look here.

```matlab
mdlName = 'rtwdemo_rsim_i';
open_system(mdlName);
cs = getActiveConfigSet(mdlName);
cs.switchTarget('rsim.tlc',[]);
```
Step 2. Configure the Inport Blocks

To use the RSim -i option, you must configure each Inport block properly. You can double-click an Inport block to view its properties. By default, Inport blocks inherit their properties from downstream blocks. Before you can import data from external MAT-files, you must set the parameters of each Inport block to match the data in the MAT file. In most cases, the following parameters of an Inport block must be set: Interpolate Data, Port Dimensions, Data Type, and Signal Type. For more information on these parameters, click the Help button. In this example model, three Inport blocks exist. We want Inport 1 and Inport 2 to interpolate between data, and Inport 3 to not interpolate. The dimension of the Inport blocks are 2, 1, and 2, respectively. Signals are real. The settings are as follows:

```matlab
for i = 1:3
    portName = ['In', num2str(i)];
    Interp = get_param(strcat(mdlName, portName), 'Interpolate');
    PortDimension = get_param(strcat(mdlName, portName), 'PortDimensions');
    DataType = get_param(strcat(mdlName, portName), 'OutDataTypeStr');
```

Copyright 2005-2011 The MathWorks, Inc.
SignalType    = get_param(strcat(mdlName,portName), 'SignalType');
s1 = sprintf('For inport %s ', portName(2:4));
disp('---------------------------------');
disp(s1);
s2 = sprintf('The interpolation flag is %s', Interp);
disp(s2);
s3 = sprintf('    The port dimension is %s', PortDimension);
disp(s3);
s4 = sprintf('        The data type  is %s', DataType);
disp(s4);
s5 = sprintf('       The signal type is %s
', SignalType);
disp(s5);
end

---------------------------------
For inport In1
The interpolation flag is on
    The port dimension is 2
        The data type  is double
       The signal type is real

---------------------------------
For inport In2
The interpolation flag is on
    The port dimension is 1
        The data type  is double
       The signal type is real

---------------------------------
For inport In3
The interpolation flag is off
    The port dimension is 2
        The data type  is double
       The signal type is real

**Step 3. Build the Model**

Build the RSim executable for the model. During the build process, a structural checksum is calculated for the model and embedded into the generated executable. This checksum is used to check that a parameter set passed to the executable is compatible with it.

`evalc('rtwbuild(mdlName)');`
Step 4. The Input Signals

Once the Inport block is configured, the data file should be prepared based on the Inport blocks. The following figure shows the input signals to be used.

```matlab
t=[0:0.01:2*pi]';
s1 = [2*sin(t) 2*cos(t)];
s2 = sin(2*t);
s3 = [0.5*sin(3*t) 0.5*cos(3*t)];
figure;
plot(t, [s1 s2 s3]);
disp('The following figure displays the input signals.');
```

The following figure displays the input signals.
**Step 5. Prepare the MAT-File**

Generally, the MAT-file can be created from a workspace variable. The RSim -i option supports three data file formats:

1) The MAT-file contains one variable in TU matrix format of doubles. For this format, the first column is the time vector and the remaining columns are input vectors. The number of columns in the TU matrix equals the sum of the dimensions of the root Inport blocks plus 1. The following MATLAB® code generates a MAT-file containing one variable `var_matrix` in TU matrix format. Note that you can use this format only if the input ports in your model have the same data type.

```matlab
% Example code for generating a MAT-file

t=[0:0.1:2*pi]';
Ina1 = [2*sin(t) 2*cos(t)];
Ina2 = sin(2*t);
Ina3 = [0.5*sin(3*t) 0.5*cos(3*t)];
var_matrix = [ t Ina1 Ina2 Ina3];
save rsim_i_matrix.mat var_matrix;
disp('rsim_i_matrix.mat contains one variable var_matrix in TU matrix format.');
```

2) The MAT-file contains one variable in structure format. For this format, the variable must contain two fields called time and signals. If one of the Inport block sets Interpolate Data to On, then the time field of the variable must not be an empty vector. Also, the width of the signals must equal the total width of the Inport blocks. The following code generates a MAT-file that contains one variable `var_matrix` in signal variable structure format. This format is more flexible than the TU matrix format because it can support input ports with different data types.

```matlab
% Example code for generating a MAT-file in structure format

t= [0:0.1:2*pi]';
var_single_struct.time = t;
var_single_struct.signals(1).values(:,1) = 2*sin(t);
var_single_struct.signals(1).values(:,2) = 2*cos(t);
var_single_struct.signals(2).values = sin(2*t);
var_single_struct.signals(3).values(:,1) = 0.5*sin(3*t) ;
var_single_struct.signals(3).values(:,2) = 0.5*cos(3*t) ;
v=[var_single_struct.signals(1).values var_single_struct.signals(2).values ...
   var_single_struct.signals(3).values ];
save rsim_i_single_struct.mat var_single_struct;
disp('rsim_i_single_struct.mat contains one variable var_single_struct in')
disp('struct format.');
```
rsim_i_single_struct.mat contains one variable var_single_struct in struct format.

3) The MAT-file contains multiple variables in structure format. For this format, the number of variables equals the number of Inport blocks. Different variables can have different time vectors. The following code generates a MAT-file that contains multiple variables, each in structure format. This is the most flexible format because it allows each Inport block to have its own time vector.

t = [0:0.1:2*pi]';
Inb1.time = t;
Inb1.signals.values(:,1) = 2*sin(t);
Inb1.signals.values(:,2) = 2*cos(t);
t = [0:0.2:2*pi]';
Inb2.time = t;
Inb2.signals.values(:,1) = sin(2*t);
t = [0:0.1:2*pi]';
Inb3.time = t;
Inb3.signals.values(:,1) = 0.5*sin(3*t);
Inb3.signals.values(:,2) = 0.5*cos(3*t);
save rsim_i_multi_struct.mat Inb1;
save rsim_i_multi_struct.mat Inb2 -append;
save rsim_i_multi_struct.mat Inb3 -append;
disp('rsim_i_multi_struct.mat contains three variables Inb1\Inb2\Inb3');
disp('in struct format. Note that command save -append option must be');
disp('used to generate the MAT-file to preserve the order of the');
disp('variables in the MAT-file generated. The command:');
disp('save rsim_i_multi_struct.mat Inb1 Inb2 Inb3 might not preserve');
disp('the order of the variables in the MAT-file and you should not use it');
disp('to generate the MAT-file. ');

rsim_i_multi_struct.mat contains three variables Inb1\Inb2\Inb3 in struct format. Note that command save -append option must be used to generate the MAT-file to preserve the order of the variables in the MAT-file generated. The command: save rsim_i_multi_struct.mat Inb1 Inb2 Inb3 might not preserve the order of the variables in the MAT-file and you should not use it to generate the MAT-file.

**Step 6. Run 3 RSim Simulations Using Different Files and Plot the Results**

RSim -i options can also be used for batch mode simulation. Prepare different MAT-files and run the RSim target with them.
figure
fileName = ({'rsim_i_matrix', 'rsim_i_single_struct', 'rsim_i_multi_struct'});
for i=1:3
   % bang out and run a simulation using new parameter data
   name = fileName(i);
   runstr = ['.', filesep, 'rtwdemo_rsim_i -i ',char(name),'.mat', ' -v'];
   evalc('system(runstr)');
   pause(0.5);
% load simulation data into MATLAB(R) for plotting.
load rtwdemo_rsim_i.mat;
subplot(3,1,i);
axis([0,6, -5, 5]);
plot(rt_tout, rt_yout);
hold on
end

disp('This part of the example illustrates a sequence of 3 plots. Each plot');
disp('shows the simulation results by using input MAT-file with different');
disp('variable format. Notice that the model is compiled only once.');
close_system(mdlName, 0);

This part of the example illustrates a sequence of 3 plots. Each plot shows the simulation results by using input MAT-file with different variable format. Notice that the model is compiled only once.
Accelerate Simulation, Reuse Code, or Protect Intellectual Property by Using S-Function Target

S-functions are an important class of system target file for which the code generator can produce code. The ability to encapsulate a subsystem into an S-function allows you to increase its execution efficiency and facilitate code reuse.

The following sections describe the properties of S-function targets and illustrate how to generate them. For more details on the structure of S-functions, see “S-Functions” (Simulink).

<td>“S-Function Target Limitations” on page 49-70</td>
</tr>
</tbody>
</table>

About the S-Function Target

Using the S-function target, you can build an S-function component and use it as an S-Function block in another model. The following sections describe deployment considerations for the S-function target.

- “Required Files for S-Function Deployment” on page 49-60
- “Sample Time Propagation in Generated S-Functions” on page 49-61
- “Choose a Solver Type” on page 49-61
- “Solver Type Overrides” on page 49-62

The 'S-Function' value for CodeFormat TLC variable used by the S-function target generates code that conforms to the Simulink C MEX S-function application programming interface (API). Applications of this format include
• Conversion of a model to a component. You can generate an S-Function block for a model, \( m_1 \). Then, you can place the generated S-Function block in another model, \( m_2 \). Regenerating code for \( m_2 \) does not require regenerating code for \( m_1 \).

• Conversion of a subsystem to a component. By extracting a subsystem to a separate model and generating an S-Function block from that model, you can create a reusable component from the subsystem. See “Create S-Function Blocks from a Subsystem” on page 49-63 for an example of this procedure.

• Speeding up simulation. Often, an S-function generated from a model performs more efficiently than the original model.

• Code reuse. You can incorporate multiple instances of one model inside another without replicating the code for each instance. Each instance continues to maintain its own unique data.

You can place a generated S-function block into another model from which you can generate another S-function. This approach allows any level of nested S-functions. For limitations related to nesting, see “Limitations on Nesting S-Functions” on page 49-74.

**Note** While the S-function target provides a means to deploy an application component for reuse while shielding its internal logic from inspection and modification, the preferred solutions for protecting intellectual property in distributed components are:

• The protected model, a referenced model that hides all block and line information. For more information, see “Simulate Protected Models from Third Parties” (Simulink).

• The shared library system target file, used to generate a shared library for a model or subsystem for use in a system simulation external to Simulink. For more information, see “Package Generated Code as Shared Libraries” on page 50-2.

**Required Files for S-Function Deployment**

There are different files required to deploy a generated S-Function block for simulation versus code generation.

To deploy your generated S-Function block for inclusion in other models *for simulation*, you need only provide the binary MEX-file object that was generated in the current working folder when the S-Function block was created. The required file is:

• \( \text{subsys}_\text{sf}.\text{mexext} \)
where `subsys` is the subsystem name and `mexext` is a platform-dependent MEX-file extension (see `mexext`). For example, `SourceSubsys_sf.mexw64`.

To deploy your generated S-Function block for inclusion in other models for code generation, you must provide all of the files that were generated in the current working folder when the S-Function block was created. The required files are:

- `subsys_sf.c` or `cpp`, where `subsys` is the subsystem name (for example, `SourceSubsys_sf.c`)
- `subsys_sf.h`
- `subsys_sf.mexext`, where `mexext` is a platform-dependent MEX-file extension (see `mexext`)
- Subfolder `subsys_sfcn_rtw` and its contents

**Note** The generated S-function code uses **Configuration Parameters > Hardware Implementation** parameter values that match the host system on which the function was built. When you use the S-function in a model for code generation, make sure that these parameter values for the model match the parameter values of the S-function.

### Sample Time Propagation in Generated S-Functions

A generated S-Function block can inherit its sample time from the model in which it is placed if certain criteria are met. Conditions that govern sample time propagation for both Model blocks and generated S-Function blocks are described in “Inherit Sample Times for Model Referencing” (Simulink) and “Inherited Sample Time for Referenced Models” on page 4-25.

To generate an S-Function block that meets the criteria for inheriting sample time, you must constrain the solver for the model from which the S-Function block is generated. On the **Solver** configuration parameters dialog box pane, set **Type** to **Fixed-step** and **Periodic sample time constraint** to **Ensure sample time independent**. If the model is unable to inherit sample times, this setting causes the Simulink software to display an error message when building the model. For more information about this option, see “Periodic sample time constraint” (Simulink).

### Choose a Solver Type

The table shows the possible combinations of top-level model solver types as these types relate to subsystem build types and solver types for generated S-functions.
## Top-level Model Solver Options and Subsystem Build Types

<table>
<thead>
<tr>
<th>Subsystem Build Type</th>
<th>Solver options, Type: Variable-step</th>
<th>Solver options, Type: Fixed-step</th>
</tr>
</thead>
<tbody>
<tr>
<td>Build This Subsystem</td>
<td>Generated S-function does NOT require variable-step solver</td>
<td>Generated S-function does NOT require variable-step solver</td>
</tr>
<tr>
<td>Generate S-Function</td>
<td>Generated S-function requires variable-step solver</td>
<td>Generated S-function does NOT require variable-step solver</td>
</tr>
</tbody>
</table>

**Note** S-functions generated from a subsystem have parameters that are hard coded into the block. Simulink calculates parameters such as sample time when it generates the block, not during simulation run time. Hence, it is important to verify whether the generated S-Function block works as expected in the destination model.

## Solver Type Overrides

There are instances when the subsystem build type selection produces an override of the subsystem solver type. The table summarizes the relationships between subsystem build types and the applied subsystem solver types.

## Top-level Model Solver Type Overrides of Subsystem Solver Types by Build Type

<table>
<thead>
<tr>
<th>Subsystem Build Type</th>
<th>Model Configuration Parameters: top-level model configuration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Build This Subsystem</td>
<td>Subsystem uses fixed-step solver type</td>
</tr>
<tr>
<td>Generate S-Function</td>
<td>Subsystem uses variable-step solver type</td>
</tr>
</tbody>
</table>
Create S-Function Blocks from a Subsystem

This section illustrates how to extract a subsystem from a model and generate a reusable S-function component from it.

The next figure shows SourceModel, a simple model that inputs signals to a subsystem. The subsequent figure shows the subsystem, SourceSubsys. The signals, which have different widths and sample times, are:

- A Step block with sample time 1
- A Sine Wave block with sample time 0.5
- A Constant block whose value is the vector [-2 3]

SourceModel
The objective is to extract SourceSubsys from the model and build an S-Function block from it, using the S-function target. The S-Function block must perform identically to the subsystem from which it was generated.

In this model, SourceSubsys inherits sample times and signal widths from its input signals. However, S-Function blocks created from a model using the S-function target has all signal attributes (such as signal widths or sample times) hard-wired. (The sole exception to this rule concerns sample times, as described in “Sample Time Propagation in Generated S-Functions” on page 49-61.)

In this example, you want the S-Function block to retain the properties of SourceSubsys as it exists in SourceModel. Therefore, before you build the subsystem as a separate S-function component, you must set the inport sample times and widths explicitly. In addition, the solver parameters of the S-function component must be the same as those parameters of the original model. The generated S-function component operates identically to the original subsystem (see “Choose a Solver Type” on page 49-61 for more information).

To build SourceSubsys as an S-function component,

1. Create a new model and copy/paste the SourceSubsys block into the empty window.
2. Set the signal widths and sample times of inports inside SourceSubsys such that they match those of the signals in the original model. Inport 1, Filter, has a width of 1 and a sample time of 1. Inport 2, Xferfcn, has a width of 1 and a sample time of 0.5. Inport 3, offsets, has a width of 2 and a sample time of 0.5.
3 The generated S-Function block should have three inports and one outport. Connect inports and an outport to SourceSubsys, as shown in the next figure.

4 Set the solver type, mode, and other solver parameters such that they are identical to those of the source model. This is easiest to do if you use Model Explorer.

5 In the Configuration Parameters dialog box, go to the Code Generation pane.

6 Click Browse to open the System Target File Browser.

7 In the System Target File Browser, select the S-function target, rtwsfcn.tlc, and click OK.

8 Select the S-Function Target pane. Make sure that Create new model is selected, as shown in the next figure:

   ![Create new model checkbox selected]

   When this option is selected, the build process creates a new model after it builds the S-function component. The new model contains an S-Function block, linked to the S-function component.

   Click Apply.

9 Save the new model containing your subsystem, for example as SourceSubsys.

10 Build the model.
The build process produces the S-function component in the working folder. After the build, a new model window is displayed.

Optionally you can save the generated model, for example as `SourceSubsys_Sfunction`.

You can now copy the S-Function block generated from the new model and use it in other models or in a library.

**Note** For a list of files required to deploy your S-Function block for simulation or code generation, see “Required Files for S-Function Deployment” on page 49-60.

The next figure shows the S-Function block plugged into the original model. Given identical input signals, the S-Function block performs identically to the original subsystem.

**Generated S-Function Configured Like SourceModel**

The speed at which the S-Function block executes is typically faster than the original model. This difference in speed is more pronounced for larger and more complicated models. By using generated S-functions, you can increase the efficiency of your modeling process.
**Tunable Parameters in Generated S-Functions**

You can use tunable parameters in generated S-functions in two ways:

- Use the **Generate S-function** feature (see “Generate S-Function from Subsystem” on page 11-62).

  or

- Use the Model Parameter Configuration dialog box (see “Declare Workspace Variables as Tunable Parameters Using the Model Parameter Configuration Dialog Box” (Simulink Coder)) to declare desired block parameters tunable.

Block parameters that are declared tunable with the **auto** storage class in the source model become tunable parameters of the generated S-function. These parameters do not become part of a generated `model_P` (formerly `rtP`) parameter data structure, as they would in code generated from other targets. Instead, the generated code accesses these parameters by using MEX API calls such as `mxGetPr` or `mxGetData`. Your code should access these parameters in the same way.

For more information on MEX API calls, see “About C S-Functions” (Simulink) and “MATLAB API for Other Languages” (MATLAB).

S-Function blocks created by using the S-function target are automatically masked. The mask displays each tunable parameter in an edit field. By default, the edit field displays the parameter by variable name, as in the following example.
You can choose to display the value of the parameter rather than its variable name by selecting **Use value for tunable parameters** on the **Code Generation > S-Function Target** pane of the Configuration Parameters dialog box.

When this option is chosen, the value of the variable (at code generation time) is displayed in the edit field, as in the following example.

![Block Parameters: Generated S-Function](image)

**System Target File**

The `rtwsfcn.tlc` system target file is provided for use with the S-function target.

**Checksums and the S-Function Target**

The code generator creates a checksum for a model and uses the checksum during the build process for code reuse, model reference, and external mode features.

The code generator calculates a model checksum by
Calculating a checksum for each subsystem in the model. A subsystem's checksum is the combination of properties (data type, complexity, sample time, port dimensions, and so forth) of the subsystem's blocks.

Combining the subsystem checksums and other model-level information.

An S-function can add additional information, not captured during the block property analysis, to a checksum by calling the function `ssSetChecksumVal`. For the S-Function target, the value that gets added to the checksum is the checksum of the model or subsystem from which the S-function is generated.

The code generator applies the subsystem and model checksums as follows:

- Code reuse — If two subsystems in a model have the same checksum, the code generator produces code for one function only.
- Model reference — If the current model checksum matches the checksum when the model was built, the build process does not rebuild referenced models.
- External mode — If the current model checksum does not match the checksum of the code that is running on the target hardware, the build process generates an error.

**Generated S-Function Compatibility**

When you build a MEX S-function from your model, the code generator builds a level 2 noninlined S-function. Cross-release usage limitations on the generated code and binary MEX file (for example, `*.mexw64`) include:

- S-function target generated code from previous MATLAB release software is not compatible with newer releases. Do not recompile the generated code from a previous release with newer MATLAB release software. Use the same MATLAB release software to generate code for the S-function target and compile the code into a MEX file.
- You can use binary S-function MEX files generated from previous MATLAB release software with the same or newer releases with the same compatibility considerations as handwritten S-functions. For more information, see “S-Function Compatibility” (Simulink).
- The code generator can generate code and build an executable from a model that contains generated S-functions. This support requires that the S-functions are built with the same MATLAB release software that builds the model. It is not possible to incorporate a generated S-function MEX file from previous MATLAB release software into a model and build the model with newer releases.
S-Function Target Limitations

- “Data Store Access” on page 49-75
- “Cannot Specify Inport or Outport Block Parameters Through Subsystem Mask” on page 49-75

Limitations on Using Tunable Variables in Expressions

Certain limitations apply to the use of tunable variables in expressions. When the code generator encounters an unsupported expression while producing code, a warning appears and the equivalent numeric value is generated in the code. For a list of the limitations, see “Tunable Expression Limitations” on page 22-135.

Parameter Tuning

The S-Function block does not support tuning of tunable parameters with:

- Complex values.
- Values or data types that are transformed to a constant (by setting the model configuration parameter Optimization > Default parameter behavior to Inlined).
- Data types that are not built-in.
If you select these tunable parameters (through the Generate S-Function for Subsystem dialog box):

- The software produces warnings during the build process.
- The generated S-Function block mask does not display these parameters.

**Run-Time Parameters and S-Function Compatibility Diagnostics**

If you set the *S-function upgrades needed* option on the **Diagnostics > Compatibility** pane of the Configuration Parameters dialog box to *warning* or *error*, the code generator instructs you to upgrade S-functions that you create with the **Generate S-function** feature. This is because the S-function system target file does not register run-time parameters. Run-time parameters are only supported for inlined S-Functions and the generated S-Function supports features that prevent it from being inlined (for example, it can call or contain other noninlined S-functions).

You can work around this limitation by setting the *S-function upgrades needed* option to *none*.

**Limitations on Using Goto and From Block**

When using the S-function system target file, the code generator restricts I/O to correspond to the root model Inport and Outport blocks (or the Inport and Outport blocks of the Subsystem block from which the S-function target was generated). No code is generated for Goto or From blocks.

To work around this restriction, create your model and subsystem with the required Inport and Outport blocks, instead of using Goto and From blocks to pass data between the root model and subsystem. In the model that incorporates the generated S-function, you would then add Goto and From blocks.

**Example Before Work Around**

- Root model with a From block and subsystem, *Subsystem1*
• Subsystem1 with a Goto block, which has global visibility and passes its input to the From block in the root model

![Diagram of Subsystem1 with a Goto block](image1)

• Subsystem1 replaced with an S-function generated with the S-Function target — a warning results when you run the model because the generated S-function does not implement the Goto block

![Diagram of Generated S-Function](image2)

**Example After Work Around**

An Outport block replaces the GoTo block in Subsystem1. When you plug the generated S-function into the root model, its output connects directly to the To Workspace block.

![Diagram of Example After Work Around](image3)

**Limitations on Building and Updating S-Functions**

The following limitations apply to building and updating S-functions using the S-function system target file:
• You cannot build models that contain Model blocks using the S-function system target file. This also means that you cannot build a subsystem module by right-clicking (or by using Code > C/C++ Code > Build Selected Subsystem) if the subsystem contains Model blocks. This restriction applies only to S-functions generated using the S-function target, not to ERT S-functions.

• If you modify the model that generated an S-Function block, the build process does not automatically rebuild models containing the generated S-Function block. This is in contrast to the practice of automatically rebuilding models referenced by Model blocks when they are modified (depending on the Model Reference Rebuild configuration setting).

• Handwritten S-functions without corresponding TLC files must contain exception-free code. For more information on exception-free code, see “Exception Free Code” (Simulink).

Unsupported Blocks

The S-function format does not support the following built-in blocks:

• Interpreted MATLAB Function block
• S-Function blocks containing any of the following:
  • MATLAB language S-functions (unless you supply a TLC file for C code generation)
  • Fortran S-functions (unless you supply a TLC file for C code generation)
  • C/C++ MEX S-functions that call into the MATLAB environment
• Scope block
• To Workspace block

The S-function format does not support blocks from the embeddedtargetslib block library.

SimState Not Supported for Code Generation

You can use SimState within C-MEX and Level-2 MATLAB language S-functions to save and restore the simulation state. See “S-Function Compliance with the SimState” (Simulink). However, SimState is not supported for code generation, including with the S-function system target file.
Profiling Code Performance with TLC Hook Function Not Supported

Profiling the performance of generated code using the Target Language Compiler (TLC) hook function interface described in “Profile Code Performance” (Simulink Coder) is not supported for the S-function target.

Note
If you have an Embedded Coder license, see “Code Execution Profiling” for an alternative and simpler approach based on software-in-the-loop (SIL) or processor-in-the-loop (PIL) simulations.

Limitations on Nesting S-Functions

The following limitations apply to nesting a generated S-Function block in a model or subsystem from which you generate another S-function:

- The software does not support nonvirtual bus input and output signals for a nested S-function.
- You should avoid nesting an S-function in a model or subsystem having the same name as the S-function (possibly several levels apart). In such situations, the S-function can be called recursively. The software currently does not detect such loops in S-function dependency, which can result in aborting or hanging your MATLAB session. To prevent this from happening, be sure to name the subsystem or model to be generated as an S-function target uniquely, to avoid duplicating existing MEX filenames on the MATLAB path.

Limitations on User-Defined Data Types

The S-function system target file does not support the HeaderFile property that can be specified on user-defined data types, including those based on Simulink.AliasType, Simulink.Bus, and Simulink.NumericType objects. If a user-defined data type in your model uses the HeaderFile property to specify an associated header file, code generation with the S-function system target file disregards the value and does not generate a corresponding include statement.

Limitation on Right-Click Generation of an S-Function Target

If you generate an S-function target by right-clicking a Function-Call Subsystem block, the original subsystem and the generated S-function might not be consistent. An inconsistency occurs when the States when enabling parameter of the Trigger Port
block inside the Function-Call Subsystem block is set to **inherit**. You must set the **States when enabling** parameter to **reset** or **held**, otherwise Simulink reports an error.

**Limitation on S-Functions with Bus I/O Signals**

If an S-function generated using the S-function target has bus input or output signals, the generated bus data structures might include padding to align fields of the bus elements with the Simulink representation used during simulation. However, if you insert the S-function in a model and generate code using a model target such as grt.tlc, the bus structure alignment generated for the model build might be incompatible with the padding generated for the S-function and might affect the numerical results of code execution. To make the structure alignment consistent between model simulation and execution of the model code, for each Simulink.Bus object, you can modify the **HeaderFile** property to remove the unpadded bus structure header file. This will cause the bus typedefs generated for the S-function to be reused in the model code.

**Limitation on Subsystems with Function-Call I/O Signals**

The S-function target does not support creating an S-Function block from a subsystem that has a function-call trigger input or a function-call output.

**Data Store Access**

When an S-Function in your model accesses a data store during simulation, Simulink disables data store diagnostics.

- If you created the S-Function from a model, the diagnostic is disabled for global data stores as well.
- If you created the S-Function from a subsystem, the diagnostic is disabled for the following data stores:
  - Global data stores
  - Data stores placed outside the subsystem, but accessed by Data Store Read or Data Store Write blocks.

**Cannot Specify Inport or Outport Block Parameters Through Subsystem Mask**

You cannot specify any Inport or Outport block parameters through subsystem mask variables if you want to generate an S-Function block from the subsystem. The software produces an error when you try to run a simulation that uses the S-Function block, for example:
Invalid setting in 'testSystem/Subsystem/__OutputSSForSFun__/Out2' for parameter 'PortDimensions'
...

Desksops in Embedded Coder
Package Generated Code as Shared Libraries

If you have an Embedded Coder license, you can package generated source code from a model component for easy distribution and shared use by building the code as a shared library—Windows dynamic link library (.dll), UNIX shared object (.so), or Macintosh OS X dynamic library (.dylib). You or others can integrate the shared library into an application that runs on a Windows, UNIX, or Macintosh OS X development computer. The generated .dll, .so, or .dylib file is shareable among different applications and upgradeable without having to recompile the applications that use it.

About Generated Shared Libraries

You build a shared library by configuring the code generator to use the system target file ert_shrlib.tlc. Code generation for that system target file exports:

• Variables and signals of type ExportedGlobal as data
• Real-time model structure (model_M) as data
• Functions essential to executing your model code

To view a list of symbols contained in a generated shared library:

• On Windows, use the Dependency Walker utility, downloadable from http://www.dependencywalker.com
• On UNIX, use nm -D model.so
• On Macintosh OS X, use nm -g model.dylib

To generate and use a shared library:

1. Generate a shared library version of your model code
2. Create application code to load and use your shared library file

Generate Shared Library Version of Model Code

To generate a shared library version of your model code:

1. Open your model and configure it to use the ert_shrlib.tlc system target file.
Selecting the ert_shrlib.tlc system target file causes the build process to generate a shared library version of your model code into your current working folder. The selection does not change the code that the code generator produces for your model.

2 Build the model.

3 After the build completes, examine the generated code in the model subfolder and examine the .dll, .so, or .dylib file in your current folder.

**Create Application Code to Use Shared Library**

To illustrate how application code can load a shared library file and access its functions and data, MathWorks provides the model rtwdemo_shrlib.

**Note** Change directory to a writable working folder before running the rtwdemo_shrlib script.

In the model, click the blue button to run a script. The script:

1 Builds a shared library file from the model (for example, rtwdemo_shrlib_win64.dll on 64-bit Windows).

2 Compiles and links an example application, rtwdemo_shrlib_app, that loads and uses the shared library file.

3Executes the example application.

**Tip** Explicit linking is preferred for portability. But, on Windows systems, the ert_shrlib system target file generates and retains the .lib file to support implicit linking.
To use implicit linking, the generated \textit{model.h} file needs a small modification for you to use it with the generated \textit{ert_main.c}. For example, if you are using Visual C++, declare \texttt{\_declspec(dllimport)} in front of data to be imported implicitly from the shared library file.

The model uses the following example application files, which are located in the folder \texttt{matlabroot/toolbox/rtw/rtwdemos/shrlib_demo} (open).

<table>
<thead>
<tr>
<th>File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rtwdemo_shrlib_app.h</td>
<td>Example application header file</td>
</tr>
<tr>
<td>rtwdemo_shrlib_app.c</td>
<td>Example application that loads and uses the shared library file generated</td>
</tr>
<tr>
<td>run_rtwdemo_shrlib_app.m</td>
<td>Script to compile, link, and execute the example application</td>
</tr>
</tbody>
</table>

You can view each of these files by clicking white buttons in the model window. Additionally, running the script places the relevant source and generated code files in your current folder. The files can be used as templates for writing application code for your own ERT shared library files.

The following sections present key excerpts of the example application files.

**Example Application Header File**

The example application header file \textit{rtwdemo_shrlib_app.h} contains type declarations for the model's external input and output.

```c
#ifndef _APP_MAIN_HEADER_
define _APP_MAIN_HEADER_

typedef struct {
    int32_T Input;
} ExternalInputs_rtwdemo_shrlib;

typedef struct {
    int32_T Output;
} ExternalOutputs_rtwdemo_shrlib;
#endif /*_APP_MAIN_HEADER_*/
```
Example Application C Code

The example application `rtwdemo_shrlib_app.c` includes the following code for dynamically loading the shared library file. Notice that, depending on platform, the code invokes Windows or UNIX library commands.

```c
#include <windows.h>
#define GETSYMBOLADDR GetProcAddress
#define LOADLIB LoadLibrary
#define CLOSELIB FreeLibrary

#include <dlfcn.h>
#define GETSYMBOLADDR dlsym
#define LOADLIB dlopen
#define CLOSELIB dlclose

int main()
{
    void* handleLib;
    ...
    #if defined(_WIN64)
        handleLib = LOADLIB("./rtwdemo_shrlib_win64.dll");
    #elif defined(_WIN32)
        handleLib = LOADLIB("./rtwdemo_shrlib_win32.dll");
    #else /* UNIX */
        handleLib = LOADLIB("./rtwdemo_shrlib.so", RTLD_LAZY);
    #endif
    ...
    return(CLOSELIB(handleLib));
}
```

The following code excerpt shows how the C application accesses the model's exported data and functions. Notice the hooks for adding user-defined initialization, step, and termination code.

```c
int32_T i;
...
    void (*mdl_initialize)(boolean_T);
    void (*mdl_step)(void);
    void (*mdl_terminate)(void);

    ExternalInputs_rtwdemo_shrlib (*mdl_Uptr);
    ExternalOutputs_rtwdemo_shrlib (*mdl_Yptr);
    uint8_T (*sum_outptr);
    ...
#if (defined(LCCDLL)||defined(BORLANDCDLL))
```
/* Exported symbols contain leading underscores when DLL is linked with
LCC or BORLANDC */
mdl_initialize =(void(*)(boolean_T))GETSYMBOLADDR(handleLib ,
"_rtwdemo_shrlib_initialize");
mdl_step =(void(*)(void))GETSYMBOLADDR(handleLib ,
"_rtwdemo_shrlib_step");
mdl_terminate =(void(*)(void))GETSYMBOLADDR(handleLib ,
"_rtwdemo_shrlib_terminate");
mdl_Uptr =(ExternalInputs_rtwdemo_shrlib*)GETSYMBOLADDR(handleLib ,
"_rtwdemo_shrlib_U");
mdl_Yptr =(ExternalOutputs_rtwdemo_shrlib*)GETSYMBOLADDR(handleLib ,
"_rtwdemo_shrlib_Y");
sum_outptr =(uint8_T*)GETSYMBOLADDR(handleLib ,"_sum_out");
#else
mdl_initialize =(void(*)(boolean_T))GETSYMBOLADDR(handleLib ,
"rtwdemo_shrlib_initialize");
mdl_step =(void(*)(void))GETSYMBOLADDR(handleLib ,
"rtwdemo_shrlib_step");
mdl_terminate =(void(*)(void))GETSYMBOLADDR(handleLib ,
"rtwdemo_shrlib_terminate");
mdl_Uptr =(ExternalInputs_rtwdemo_shrlib*)GETSYMBOLADDR(handleLib ,
"rtwdemo_shrlib_U");
mdl_Yptr =(ExternalOutputs_rtwdemo_shrlib*)GETSYMBOLADDR(handleLib ,
"rtwdemo_shrlib_Y");
sum_outptr =(uint8_T*)GETSYMBOLADDR(handleLib ,"sum_out");
#endif
if ((mdl_initialize && mdl_step && mdl_terminate && mdl_Uptr && mdl_Yptr &&
sum_outptr)) {
    /* === user application initialization function === */
    mdl_initialize(1);
    /* insert other user defined application initialization code here */
    /* === user application step function === */
    for(i=0;i<=12;i++){
        mdl_Uptr->Input = i;
        mdl_step();
        printf("Counter out(sum out): %d\tAmplifier in(Input): %d\tout(Output): %d\n",
            *sum_outptr, i, mdl_Yptr->Output);
        /* insert other user defined application step function code here */
    }
    /* === user application terminate function === */
    mdl_terminate();
    /* insert other user defined application termination code here */
} else {
    printf("Cannot locate the specified reference(s) in the shared library.\n");
    return(-1);
}
**Example Application Script**

The application script `run_rtwdemo_shrlib_app` loads and rebuilds the model, and then compiles, links, and executes the model's shared library target file. You can view the script source file by opening `rtwdemo_shrlib` and clicking a white button to view source code. The script constructs platform-dependent command character vectors for compilation, linking, and execution that may apply to your development environment. To run the script, click the blue button.

**Note** To run the `run_rtwdemo_shrlib_app` script without first opening the `rtwdemo_shrlib` model, change directory to a writable working folder and issue the following MATLAB command:

```
addpath(fullfile(matlabroot,'toolbox','rtw','rtwdemos','shrlib_demo'))
```

**Shared Library Limitations**

The following limitations apply to building shared libraries:

- Code generation for the `ert_shrlib.tlc` system target file exports the following as data:
  - Variables and signals of type `ExportedGlobal`
  - Real-time model structure (`model_M`)
- Code generation for the `ert_shrlib.tlc` system target file supports the C language only (not C++). When you select `ert_shrlib.tlc`, language selection is greyed out on the **Code Generation** pane of the Configuration Parameters dialog box.
- To reconstruct a model simulation using a generated shared library, the application author must maintain the timing between system and shared library function calls in the original application. The timing needs to be consistent so that you can compare the simulation and integration results. Additional simulation considerations apply if generating a shared library from a model that enables parameters **Support: continuous time** and **Single output/update function**. For more information, see “Single output/update function” (Simulink Coder) dependencies.

Deploy Algorithm Model for Real-Time Rapid Prototyping

Use the code generator to deploy algorithm models for real-time rapid prototyping.

In this section...

“About Real-Time Rapid Prototyping” on page 51-2
“Goals of Real-Time Rapid Prototyping” on page 51-2
“Refine Code With Real-Time Rapid Prototyping” on page 51-3

About Real-Time Rapid Prototyping

Real-time rapid prototyping requires the use of a real-time simulator, potentially connected to system hardware (for example, physical plant or vehicle) being controlled. You generate, deploy, and tune code as it runs on the real-time simulator or embedded microprocessor. This design step is crucial for verifying whether a component can adequately control the system, and allows you to assess, interact with, and optimize code.

The following figure shows a typical approach for real-time rapid prototyping.

Goals of Real-Time Rapid Prototyping

Assuming that you have documented functional requirements, refined concept models, system hardware for the physical plant or vehicle being controlled, and access to target
products you intend to use (for example, the Simulink Real-Time or Simulink Desktop Real-Time product), you can use real-time prototyping to:

- Refine component and environment model designs by rapidly iterating between algorithm design and prototyping
- Validate whether a component can adequately control the physical system in real time
- Evaluate system performance before laying out hardware, coding production software, or committing to a fixed design
- Test hardware

**Refine Code With Real-Time Rapid Prototyping**

To perform real-time rapid prototyping:

1. Create or acquire a real-time system that runs in real time on rapid prototyping hardware. The Simulink Real-Time product facilitates real-time rapid prototyping. This product provides a real-time operating system that makes PCs run in real time. It also provides device driver blocks for numerous hardware I/O cards. You can then create a rapid prototyping system using inexpensive commercial-off-the-shelf (COTS) hardware. In addition, third-party vendors offer products based on the Simulink Real-Time product or other code generation technology that you can integrate into a development environment.

2. Use provided system target files to generate code that you can deploy onto a real-time simulator. See the following information.

Deploy Environment Model for Real-Time Hardware-In-the-Loop (HIL) Simulation

About Hardware-In-the-Loop Simulation

Hardware-in-the-loop (HIL) simulation tests and verifies an embedded system or control unit in the context of a software test platform. Examples of test platforms include real-time target systems and instruction set simulators (IISs). You use Simulink software to develop and verify a model that represents the test environment. Using the code generator, you produce, build, and download an executable program for the model to the HIL simulation platform. After you set up the environment, you can run the executable to validate the embedded system or control unit in real time.

During HIL simulation, you gradually replace parts of a system environment with hardware components as you refine and fabricate the components. HIL simulation offers an efficient design process that eliminates costly iterations of part fabrication.

The code that you build for the system simulator provides real-time system capabilities. For example, the code can include VxWorks from Wind River or another real-time operating system (RTOS).

The following figure shows a typical HIL setup.
The HIL platform available from MathWorks is the Simulink Real-Time product. Several third-party products are also available for use as HIL platforms. The Simulink Real-Time product offers hard real-time performance for PCs with Intel or AMD® 32-bit processors functioning as your real-time target. The Simulink Real-Time product enables you to add I/O interface blocks to your models and automatically generate code with code generation technology. The Simulink Real-Time product can download the code to a second PC running the Simulink Real-Time real-time kernel. System integrator solutions that are based on Simulink Real-Time are also available.

Set Up and Run HIL Simulations

To set up and run HIL simulations iterate through the following steps:

1. Develop a model that represents the environment or system under development.
   For more information, see “Compare System Target File Support” (Simulink Coder).
2. Generate an executable for the environment model.
3. Download the executable for the environment model to the HIL simulation platform.
4. Replace software representing a system component with corresponding hardware.
5. Test the hardware in the context of the HIL system.
6. Repeat steps 4 and 5 until you can simulate the system after including components that require testing.

Deploy Generated Standalone Executable Programs To Target Hardware

By default, the Embedded Coder software generates standalone executable programs that do not require an external real-time executive or operating system. A standalone program requires minimal modification to be adapted to the target hardware. The standalone program architecture supports execution of models with either single or multiple sample rates.

In this section...

Generate a Standalone Program

To generate a standalone program:

1. In the Custom templates section of the Code Generation > Templates pane of the Configuration Parameters dialog box, select the Generate an example main program option (which is on by default). This enables the Target operating system menu.

2. From the Target operating system menu, select BareBoardExample (the default selection).

3. Generate the code.

Different code is generated for multirate models depending on the following factors:

- Whether the model executes in single-tasking or multitasking mode.
- Whether or not reusable code is being generated.
These factors affect the scheduling algorithms used in generated code, and in some cases affect the API for the model entry point functions. The following sections discuss these variants.

Standalone Program Components

The core of a standalone program is the main loop. On each iteration, the main loop executes a background or null task and checks for a termination condition.

The main loop is periodically interrupted by a timer. The function rt_OneStep is either installed as a timer interrupt service routine (ISR), or called from a timer ISR at each clock step.

The execution driver, rt_OneStep, sequences calls to the model_step functions. The operation of rt_OneStep differs depending on whether the generating model is single-rate or multirate. In a single-rate model, rt_OneStep simply calls the model_step function. In a multirate model, rt_OneStep prioritizes and schedules execution of blocks according to the rates at which they run.

Main Program

• “Overview of Operation” on page 52-3
• “Guidelines for Modifying the Main Program” on page 52-4

Overview of Operation

The following pseudocode shows the execution of a main program.

```c
main()
{
    Initialization (including installation of rt_OneStep as an interrupt service routine for a real-time clock)
    Initialize and start timer hardware
    Enable interrupts
    While(not Error) and (time < final time)
        Background task
    EndWhile
    Disable interrupts (Disable rt_OneStep from executing)
    Complete any background tasks
    Shutdown
}
```
The pseudocode is a design for a harness program to drive your model. The main program only partially implements this design. You must modify it according to your specifications.

**Guidelines for Modifying the Main Program**

This section describes the minimal modifications you should make in your production version of the main program module to implement your harness program.

1. Call `model_initialize`
2. Initialize target-specific data structures and hardware, such as ADCs or DACs.
3. Install `rt_OneStep` as a timer ISR.
4. Initialize timer hardware.
5. Enable timer interrupts and start the timer.

**Note** `rtModel` is not in a valid state until `model_initialize` has been called. Servicing of timer interrupts should not begin until `model_initialize` has been called.

6. Optionally, insert background task calls in the main loop.
7. On termination of the main loop (if applicable):
   
   - Disable timer interrupts.
   - Perform target-specific cleanup such as zeroing DACs.
   - Detect and handle errors. Note that even if your program is designed to run indefinitely, you may need to handle severe error conditions, such as timer interrupt overruns.

   You can use the macros `rtmGetErrorStatus` and `rtmSetErrorStatus` to detect and signal errors.

- “Multirate Multitasking Operation” on page 52-6
- “Multirate Single-Tasking Operation” on page 52-9
- “Guidelines for Modifying rt_OneStep” on page 52-9
Overview of Operation

The operation of rt_OneStep depends upon

- Whether your model is single-rate or multirate. In a single-rate model, the sample times of all blocks in the model, and the model's fixed step size, are the same. A model in which the sample times and step size do not meet these conditions is termed multirate.

- Your model's solver mode (SingleTasking versus MultiTasking)

Permitted Solver Modes for Embedded Real-Time System Target Files summarizes the permitted solver modes for single-rate and multirate models. Note that for a single-rate model, only SingleTasking solver mode is allowed.

<td>(defaults to SingleTasking)</td>
<td>(defaults to MultiTasking)</td>
</tr>
</tbody>
</table>

The generated code for rt_OneStep (and associated timing data structures and support functions) is tailored to the number of rates in the model and to the solver mode. The following sections discuss each possible case.

Single-Rate Single-Tasking Operation

The only valid solver mode for a single-rate model is SingleTasking. Such models run in “single-rate” operation.

The following pseudocode shows the design of rt_OneStep in a single-rate program.

```
rt_OneStep()
{
    Check for interrupt overflow or other error
    Enable "rt_OneStep" (timer) interrupt
    Model_Step() -- Time step combines output, logging, update
}
```
For the single-rate case, the generated `model_step` function is

```c
void model_step(void)
```

Single-rate `rt_OneStep` is designed to execute `model_step` within a single clock period. To enforce this timing constraint, `rt_OneStep` maintains and checks a timer overrun flag. On entry, timer interrupts are disabled until the overrun flag and other error conditions have been checked. If the overrun flag is clear, `rt_OneStep` sets the flag, and proceeds with timer interrupts enabled.

The overrun flag is cleared only upon successful return from `model_step`. Therefore, if `rt_OneStep` is reinterrupted before completing `model_step`, the reinterruption is detected through the overrun flag.

Reinterruption of `rt_OneStep` by the timer is an error condition. If this condition is detected `rt_OneStep` signals an error and returns immediately. (Note that you can change this behavior if you want to handle the condition differently.)

Note that the design of `rt_OneStep` assumes that interrupts are disabled before `rt_OneStep` is called. `rt_OneStep` should be noninterruptible until the interrupt overflow flag has been checked.

**Multirate Multitasking Operation**

In a multirate multitasking system, code generation uses a prioritized, preemptive multitasking scheme to execute the different sample rates in your model.

The following pseudocode shows the design of `rt_OneStep` in a multirate multitasking program.

```c
rt_OneStep()
{
    Check for base-rate interrupt overrun
    Enable "rt_OneStep" interrupt
    Determine which rates need to run this time step

    Model_Step0()        -- run base-rate time step code

    For N=1:NumTasks-1   -- iterate over sub-rate tasks
        If (sub-rate task N is scheduled)
            Check for sub-rate interrupt overrun
            Model_StepN()    -- run sub-rate time step code
        EndIf
}
```
Task Identifiers

The execution of blocks having different sample rates is broken into tasks. Each block that executes at a given sample rate is assigned a task identifier (tid), which associates it with a task that executes at that rate. Where there are NumTasks tasks in the system, the range of task identifiers is 0..NumTasks-1.

Prioritization of Base-Rate and Subrate Tasks

Tasks are prioritized, in descending order, by rate. The base-rate task is the task that runs at the fastest rate in the system (the hardware clock rate). The base-rate task has highest priority (tid 0). The next fastest task (tid 1) has the next highest priority, and so on down to the slowest, lowest priority task (tid NumTasks-1).

The slower tasks, running at multiples of the base rate, are called subrate tasks.

Rate Grouping and Rate-Specific model_step Functions

In a single-rate model, the block output computations are performed within a single function, model_step. For multirate, multitasking models, the code generator tries to use a different strategy. This strategy is called rate grouping. Rate grouping generates separate model_step functions for the base rate task and each subrate task in the model. The function naming convention for these functions is

model_stepN

where N is a task identifier. For example, for a model named my_model that has three rates, the following functions are generated:

```c
void my_model_step0 (void);
void my_model_step1 (void);
void my_model_step2 (void);
```

Each model_stepN function executes the blocks sharing tid N; in other words, the block code that executes within task N is grouped into the associated model_stepN function.

Scheduling model_stepN Execution

On each clock tick, rt_OneStep maintains scheduling counters and event flags for each subrate task. The counters are implemented as taskCounter arrays indexed on tid. The event flags are implemented as arrays indexed on tid.
The scheduling counters and task flags for sub-rates are maintained by `rt_OneStep`. The scheduling counters are basically clock rate dividers that count up the sample period associated with each sub-rate task. A pair of tasks that exchanges data maintains an interaction flag at the faster rate. Task interaction flags indicate that both fast and slow tasks are scheduled to run.

The event flags indicate whether or not a given task is scheduled for execution. `rt_OneStep` maintains the event flags based on a task counter that is maintained by code in the main program module for the model. When a counter indicates that a task's sample period has elapsed, the main code sets the event flag for that task.

On each invocation, `rt_OneStep` updates its scheduling data structures and steps the base-rate task (`rt_OneStep` calls `model_step0` because the base-rate task must execute on every clock step). Then, `rt_OneStep` iterates over the scheduling flags in `tid` order, unconditionally calling `model_stepN` for any task whose flag is set. The tasks are executed in order of priority.

**Preemption**

Note that the design of `rt_OneStep` assumes that interrupts are disabled before `rt_OneStep` is called. `rt_OneStep` should be noninterruptible until the base-rate interrupt overflow flag has been checked (see pseudocode above).

The event flag array and loop variables used by `rt_OneStep` are stored as local (stack) variables. Therefore, `rt_OneStep` is reentrant. If `rt_OneStep` is reinterrupted, higher priority tasks preempt lower priority tasks. Upon return from interrupt, lower priority tasks resume in the previously scheduled order.

**Overrun Detection**

Multirate `rt_OneStep` also maintains an array of timer overrun flags. `rt_OneStep` detects timer overrun, per task, by the same logic as single-rate `rt_OneStep`.

**Note** If you have developed multirate S-functions, or if you use a customized static main program module, see “Rate Grouping Compliance and Compatibility Issues” on page 52-17 for information about how to adapt your code for rate grouping compatibility. This adaptation lets your multirate, multitasking models generate more efficient code.
Multirate Single-Tasking Operation

In a multirate single-tasking program, by definition, sample times in the model must be an integer multiple of the model's fixed-step size.

In a multirate single-tasking program, blocks execute at different rates, but under the same task identifier. The operation of rt_OneStep, in this case, is a simplified version of multirate multitasking operation. Rate grouping is not used. The only task is the base-rate task. Therefore, only one model_step function is generated:

```c
void model_step(void)
```

On each clock tick, rt_OneStep checks the overrun flag and calls model_step. The scheduling function for a multirate single-tasking program is rate_scheduler (rather than rate_monotonic_scheduler). The scheduler maintains scheduling counters on each clock tick. There is one counter for each sample rate in the model. The counters are implemented in an array (indexed on tid) within the Timing structure within rtModel.

The counters are clock rate dividers that count up the sample period associated with each subrate task. When a counter indicates that a sample period for a given rate has elapsed, rate_scheduler clears the counter. This condition indicates that blocks running at that rate should execute on the next call to model_step, which is responsible for checking the counters.

Guidelines for Modifying rt_OneStep

rt_OneStep does not require extensive modification. The only required modification is to reenable interrupts after the overrun flags and error conditions have been checked. If applicable, you should also

- Save and restore your FPU context on entry and exit to rt_OneStep.
- Set model inputs associated with the base rate before calling model_step0.
- Get model outputs associated with the base rate after calling model_step0.

**Note** If you modify rt_OneStep to read a value from a continuous output port after each base-rate model step, see the relevant cautionary guideline below.

- In a multirate, multitasking model, set model inputs associated with subrates before calling model_stepN in the subrate loop.
- In a multirate, multitasking model, get model outputs associated with subrates after calling model_stepN in the subrate loop.
Comments in rt_OneStep indicate the place to add your code.

In multirate rt_OneStep, you can improve performance by unrolling for and while loops.

In addition, you may choose to modify the overrun behavior to continue execution after error recovery is complete.

Also observe the following cautionary guidelines:

• You should not modify the way in which the counters, event flags, or other timing data structures are set in rt_OneStep, or in functions called from rt_OneStep. The rt_OneStep timing data structures (including rtModel) and logic are critical to the operation of the generated program.

• If you have customized the main program module to read model outputs after each base-rate model step, be aware that selecting model options Support: continuous time and Single output/update function together may cause output values read from main for a continuous output port to differ slightly from the corresponding output values in the model's logged data. This is because, while logged data is a snapshot of output at major time steps, output read from main after the base-rate model step potentially reflects intervening minor time steps. To eliminate the discrepancy, either separate the generated output and update functions (clear the Single output/update function option) or place a Zero-Order Hold block before the continuous output port.

• It is possible to observe a mismatch between results from simulation and logged MAT file results from generated code if you do not set model inputs before each time you call the model step function. In the generated example main program, the following comments show the locations for setting the inputs and stepping the model with your code:

/* Set model inputs here */
/* Step the model */

If your model applies signal reuse and you are using MatFileLogging for comparing results from simulation against generated code, modify rt_OneStep to write model inputs in every time step as directed by these comments. Alternatively, you could “Choose a SIL or PIL Approach” on page 67-12 for verification.
Static Main Program Module

- “Overview” on page 52-11
- “Rate Grouping and the Static Main Program” on page 52-12
- “Modify the Static Main Program” on page 52-13
- “Modify Static Main to Allocate and Access Model Instance Data” on page 52-14

Overview

In most cases, the easiest strategy for deploying generated code is to use the Generate an example main program option to generate the ert_main.c or .cpp module (see “Generate a Standalone Program” on page 52-2).

However, if you turn the Generate an example main program option off, you can use a static main module as an example or template for developing your embedded applications. Static main modules provided by MathWorks include:

- `matlabroot/rtw/c/src/common/rt_main.c` — Supports Nonreusable function code interface packaging.
- `matlabroot/rtw/c/src/common/rt_malloc_main.c` — Supports Reusable function code interface packaging. The model option Use dynamic memory allocation for model initialization must be on and model parameter Pass root-level I/O as must be set to Part of model data structure.
- `matlabroot/rtw/c/src/common/rt_cppclass_main.cpp` — Supports C++ class code interface packaging.

The static main module is not part of the generated code; it is provided as a basis for your custom modifications, and for use in simulation. If your existing applications depend upon a static ert_main.c (developed in releases before R2012b), rt_main.c, rt_malloc_main.c, or rt_cppclass_main.cpp, you may need to continue using a static main program module.

When developing applications using a static main module, you should copy the module to your working folder and rename it before making modifications. For example, you could rename rt_main.c to `model_rt_main.c`. Also, you must modify the template makefile or toolchain settings such that the build process creates a corresponding object file, such as `model_rt_main.obj` (on UNIX, `model_rt_main.o`), in the build folder.

The static main module contains
- rt_OneStep, a timer interrupt service routine (ISR). rt_OneStep calls model_step to execute processing for one clock period of the model.

- A skeletal main function. As provided, main is useful in simulation only. You must modify main for real-time interrupt-driven execution.

For single-rate models, the operation of rt_OneStep and the main function are essentially the same in the static main module as they are in the automatically generated version described in “Deploy Generated Standalone Executable Programs To Target Hardware” on page 52-2. For multirate, multitasking models, however, the static and generated code are slightly different. The next section describes this case.

**Rate Grouping and the Static Main Program**

Targets based on the ERT target sometimes use a static main module and disallow use of the Generate an example main program option. This is done because target-specific modifications have been added to the static main module, and these modifications would not be preserved if the main program were regenerated.

Your static main module may or may not use rate grouping compatible model_stepN functions. If your main module is based on the static rt_main.c, rt_malloc_main.c, or rt_cppclass_main.cpp module, it does not use rate-specific model_stepN function calls. It uses the old-style model_step function, passing in a task identifier:

```c
void model_step(int_T tid);
```

By default, when the Generate an example main program option is off, the ERT target generates a model_step “wrapper” for multirate, multitasking models. The purpose of the wrapper is to interface the rate-specific model_stepN functions to the old-style call. The wrapper code dispatches to the model_stepN call with a switch statement, as in the following example:

```c
void mymodel_step(int_T tid) /* Sample time: */
{

    switch(tid) {
        case 0 :
            mymodel_step0();
            break;
        case 1 :
            mymodel_step1();
            break;
        case 2 :
            mymodel_step2();
            break;
    }

    /* Other cases */
}
```
mymodel_step2();
break;
default:
break;
}

The following pseudocode shows how rt_OneStep calls model_step from the static
main program in a multirate, multitasking model.

rt_OneStep()
{
    Check for base-rate interrupt overflow
    Enable "rt_OneStep" interrupt
    Determine which rates need to run this time step

    ModelStep(tid=0)    --base-rate time step

    For N=1:NumTasks-1   -- iterate over sub-rate tasks
        Check for sub-rate interrupt overflow
        If (sub-rate task N is scheduled)
            ModelStep(tid=N)   --sub-rate time step
        EndIf
    EndFor
}

You can use the TLC variable RateBasedStepFcn to specify that only the rate-based step
functions are generated, without the wrapper function. If your target calls the rate
grouping compatible model_stepN function directly, set RateBasedStepFcn to 1. In
this case, the wrapper function is not generated.

You should set RateBasedStepFcn prior to the %include "codegenentry.tlc"
statement in your system target file. Alternatively, you can set RateBasedStepFcn in
your target_settings.tlc file.

Modify the Static Main Program

As with the generated ert_main.c or .cpp, you should make a few modifications to the
main loop and rt_OneStep. See “Guidelines for Modifying the Main Program” on page
52-4 and “Guidelines for Modifying rt_OneStep” on page 52-9.

Also, you should replace the rt_OneStep call in the main loop with a background task
call or null statement.
Other modifications you may need to make are

- If applicable, follow comments in the code regarding where to add code for reading/writing model I/O and saving/restoring FPU context.

**Note** If you modify `rt_main.c`, `rt_malloc_main.c`, or `rt_cppclass_main.cpp` to read a value from a continuous output port after each base-rate model step, see the relevant cautionary guideline in “Guidelines for Modifying rt_OneStep” on page 52-9.

- When the **Generate an example main program** option is off, `rtmodel.h` is generated to provide an interface between the main module and generated model code. If you create your own static main program module, you would normally include `rtmodel.h`.

Alternatively, you can suppress generation of `rtmodel.h`, and include `model.h` directly in your main module. To suppress generation of `rtmodel.h`, use the following statement in your system target file:

```
%assign AutoBuildProcedure = 0
```

- If you have cleared the **Terminate function required** option, remove or comment out the following in your production version of `rt_main.c`, `rt_malloc_main.c`, or `rt_cppclass_main.cpp`:
  - The `#if TERMFCN...` compile-time error check
  - The call to `MODEL_TERMINATE`

- For `rt_main.c` (not applicable to `rt_cppclass_main.cpp`): If you do not want to combine output and update functions, clear the **Single output/update function** option and make the following changes in your production version of `rt_main.c`:
  - Replace calls to `MODEL_STEP` with calls to `MODEL_OUTPUT` and `MODEL_UPDATE`.
  - Remove the `#if ONESTEPFCN...` error check.
  - The static `rt_main.c` module does not support the **Reusable function code interface packaging**. The following error check raises a compile-time error if Reusable function code interface packaging is used illegally.

```
#if MULTI_Instance_CODE==1
```

**Modify Static Main to Allocate and Access Model Instance Data**

If you are using a static main program module, and your model is configured for **Reusable function code interface packaging**, but the model option **Use dynamic**
memory allocation for model initialization is not selected, model instance data must be allocated either statically or dynamically by the calling main code. Pointers to the individual model data structures (such as Block IO, DWork, and Parameters) must be set up in the top-level real-time model data structure.

To support main modifications, the build process generates a subset of the following real-time model (RTM) macros, based on the data requirements of your model, into model.h.

<table>
<thead>
<tr>
<th>RTM Macro Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rtmGetBlockIO(rtm)</td>
<td>Get the block I/O data structure</td>
</tr>
<tr>
<td>rtmSetBlockIO(rtm,val)</td>
<td>Set the block I/O data structure</td>
</tr>
<tr>
<td>rtmGetContStates(rtm)</td>
<td>Get the continuous states data structure</td>
</tr>
<tr>
<td>rtmSetContStates(rtm,val)</td>
<td>Set the continuous states data structure</td>
</tr>
<tr>
<td>rtmGetDefaultParam(rtm)</td>
<td>Get the default parameters data structure</td>
</tr>
<tr>
<td>rtmSetDefaultParam(rtm,val)</td>
<td>Set the default parameters data structure</td>
</tr>
<tr>
<td>rtmGetPrevZCSigState(rtm)</td>
<td>Get the previous zero-crossing signal state data structure</td>
</tr>
<tr>
<td>rtmSetPrevZCSigState(rtm,val)</td>
<td>Set the previous zero-crossing signal state data structure</td>
</tr>
<tr>
<td>rtmGetRootDWork(rtm)</td>
<td>Get the DWork data structure</td>
</tr>
<tr>
<td>rtmSetRootDWork(rtm,val)</td>
<td>Set the DWork data structure</td>
</tr>
<tr>
<td>rtmGetU(rtm)</td>
<td>Get the root inputs data structure (when root inputs are passed as part of the model data structure)</td>
</tr>
<tr>
<td>rtmSetU(rtm,val)</td>
<td>Set the root inputs data structure (when root inputs are passed as part of the model data structure)</td>
</tr>
<tr>
<td>rtmGetY(rtm)</td>
<td>Get the root outputs data structure (when root outputs are passed as part of the model data structure)</td>
</tr>
<tr>
<td>rtmSetY(rtm,val)</td>
<td>Set the root outputs data structure (when root outputs are passed as part of the model data structure)</td>
</tr>
</tbody>
</table>

Use these macros in your static main program to access individual model data structures within the RTM data structure. For example, suppose that the example model rtwdemo_reusable is configured with Reusable function code interface packaging,
Use dynamic memory allocation for model initialization cleared, Pass root-level I/O as set to Individual arguments, and Optimization pane option Remove root level I/O zero initialization cleared. Building the model generates the following model data structures and model entry-points into rtwdemo_reusable.h:

```c
/* Block states (auto storage) for system '<Root>' */
typedef struct {
    real_T Delay_DSTATE;               /* '<Root>/Delay' */
} D_Work;

/* Parameters (auto storage) */
struct Parameters_ {
    real_T k1;                           /* Variable: k1 
                                           * Referenced by: '<Root>/Gain'
    */
};

/* Model entry point functions */
extern void rtwdemo_reusable_initialize(RT_MODEL *const rtM, real_T *rtU_In1, real_T *rtU_In2, real_T *rtY_Out1);
extern void rtwdemo_reusable_step(RT_MODEL *const rtM, real_T rtU_In1, real_T rtU_In2, real_T *rtY_Out1);
```

Additionally, if Generate an example main program is not selected for the model, rtwdemo_reusable.h contains definitions for the RTM macros rtmGetDefaultParam, rtmsetDefaultParam, rtmGetRootDWork, and rtmSetRootDWork.

Also, for reference, the generated rtmmodel.h file contains an example parameter definition with initial values (non-executing code):

```c
#if 0
/* Example parameter data definition with initial values */
static Parameters rtP = {
    2.0                                  /* Variable: k1 
                                           * Referenced by: '<Root>/Gain'
    */
};                                     /* Modifiable parameters */
#endif
```

In the definitions section of your static main file, you could use the following code to statically allocate the real-time model data structures and arguments for the rtwdemo_reusable model:

```c
static RT_MODEL rtM_
static RT_MODEL *const rtM = &rtM_; /* Real-time model */
static Parameters rtP = {
    2.0                                  /* Variable: k1 
                                           * Referenced by: '<Root>/Gain'
    */
};
```
In the body of your main function, you could use the following RTM macro calls to set up the model parameters and DWork data in the real-time model data structure:

```c
int_T main(int_T argc, const char *argv[]) {
    
    /* Pack model data into RTM */
    rtmSetDefaultParam(rtM, &rtP);
    rtmSetRootDWork(rtM, &rtDWork);
    
    /* Initialize model */
    rtwdemo_reusable_initialize(rtM, &rtU_In1, &rtU_In2, &rtY_Out1);
}
```

Follow a similar approach to set up multiple instances of model data, where the real-time model data structure for each instance has its own data. In particular, the parameter structure (rtP) should be initialized, for each instance, to the desired values, either statically as part of the rtP data definition or at run time.

### Rate Grouping Compliance and Compatibility Issues

- “Main Program Compatibility” on page 52-17
- “Make Your S-Functions Rate Grouping Compliant” on page 52-17

#### Main Program Compatibility

When the Generate an example main program option is off, code generation produces slightly different rate grouping code, for compatibility with the older static ert_main.c module. See “Rate Grouping and the Static Main Program” on page 52-12 for details.

#### Make Your S-Functions Rate Grouping Compliant

Built-in Simulink blocks, as well as DSP System Toolbox blocks, are compliant with the requirements for generating rate grouping code. However, user-written multirate inlined
S-functions may not be rate grouping compliant. Noncompliant blocks generate less efficient code, but are otherwise compatible with rate grouping. To take full advantage of the efficiency of rate grouping, your multirate inlined S-functions must be upgraded to be fully rate grouping compliant. You should upgrade your TLC S-function implementations, as described in this section.

Use of noncompliant multirate blocks to generate rate-grouping code generates dead code. This can cause two problems:

- Reduced code efficiency.
- Warning messages issued at compile time. Such warnings are caused when dead code references temporary variables before initialization. Since the dead code does not run, this problem does not affect the run-time behavior of the generated code.

To make your S-functions rate grouping compliant, you can use the following TLC functions to generate ModelOutputs and ModelUpdate code, respectively:

```tcl
OutputsForTID(block, system, tid)
UpdateForTID(block, system, tid)
```

The code listings below illustrate generation of output computations without rate grouping (Listing 1) and with rate grouping (Listing 2). Note the following:

- The tid argument is a task identifier (0..NumTasks-1).
- Only code guarded by the tid passed in to OutputsForTID is generated. The if (%<LibIsSFcnSampleHit(portName)> test is not used in OutputsForTID.
- When generating rate grouping code, OutputsForTID and/or UpdateForTID is called during code generation. When generating non-rate-grouping code, Outputs and/or Update is called.
- In rate grouping compliant code, the top-level Outputs and/or Update functions call OutputsForTID and/or UpdateForTID functions for each rate (tid) involved in the block. The code returned by OutputsForTID and/or UpdateForTID must be guarded by the corresponding tid guard:

```tcl
if (%<LibIsSFcnSampleHit(portName)>)
```

as in Listing 2.

**Listing 1: Outputs Code Generation Without Rate Grouping**

```tcl
%% multirate_blk.tlc
```
Function: mdlOutputs

Abstract:

Compute the two outputs (input signal decimated by the specified parameter). The decimation is handled by sample times. The decimation is only performed if the block is enabled. Each port has a different rate.

Note, the usage of the enable should really be protected such that each task has its own enable state. In this example, the enable occurs immediately which may or may not be the expected behavior.

Listing 2: Outputs Code Generation With Rate Grouping
%% Function: mdlOutputs  ===================================================================================
%% Abstract:

  if (%<enabled>) {

Generate Code That Dereferences Data from a Literal Memory Address

This example shows how to generate code that reads the value of a signal by dereferencing a memory address that you specify. With this technique, you can generate a control algorithm that interacts with memory that your hardware populates (for example, memory that stores the output of an analog-to-digital converter in a microcontroller).

In this example, you generate an algorithm that acquires input data from a 16-bit block of memory at address 0x8675309. Assume that a hardware device asynchronously populates only the lower 10 bits of the address. The algorithm must treat the address as read-only (const), volatile (volatile) data, and ignore the upper 6 bits of the address.

The generated code can access the data by defining a macro that dereferences 0x8675309 and masks the unnecessary bits:

```c
#define A2D_INPUT (*((volatile const uint16_T *)0x8675309)&0x03FF)
```

To configure a model to generate code that defines and uses this macro, you must create an advanced custom storage class and write Target Language Compiler (TLC) code. For an example that shows how to use the Custom Storage Class Designer without writing TLC code, see “Create and Apply a Custom Storage Class” on page 26-26.

As an alternative to writing TLC code, you can use memory sections to generate code that includes pragmas. Depending on your build toolchain, you can use pragmas to specify a literal memory address for storing a global variable. For more information about memory sections, see “Control Data and Function Placement in Memory by Inserting Pragmas” on page 30-2.
**Derivation of Macro Syntax**

In this example, you configure the generated code to define and use the dereferencing macro. To determine the correct syntax for the macro, start by recording the target address.

0x8675309

Cast the address as a pointer to a 16-bit integer. Use the Simulink Coder data type name `uint16_T`.

`(uint16_T *)0x8675309`

Add the storage type qualifier `const` because the generated code must not write to the address. Add `volatile` because the hardware can populate the address at an arbitrary time.

`(volatile const uint16_T *)0x8675309`

Dereference the address.

`(*(volatile const uint16_T *)0x8675309)`

After the dereference operation, apply a mask to retain only the 10 bits that the hardware populates. Use explicit parentheses to control the order of operations.

`(*(volatile const uint16_T *)0x8675309)&0x03FF`

As a safe coding practice, wrap the entire construct in another layer of parentheses.

`((*(volatile const uint16_T *)0x8675309)&0x03FF)`

**Create Example Model**

Create the example model `ex_memmap_simple`.

For the Inport block, set the output data type to `uint16`. Name the signal as `A2D_INPUT`. The Inport block and the signal line represent the data that the hardware populates.
For the Gain block, set the output data type to double.

**Create Package to Contain Definitions of Data Class and Custom Storage Class**

In your current folder, create a folder named `MemoryMap`. The folder defines a package named `MemoryMap`.

To make the package available for use outside of your current folder, you can add the folder containing the `MemoryMap` folder to the MATLAB path.

**Create Custom Storage Class**

To generate code that defines and reads `A2D_INPUT` as a macro, you must create a custom storage class that you can apply to the signal line in the model. Later, you write TLC code that complements the custom storage class.

Open the Custom Storage Class designer in advanced mode. To design a custom storage class that operates through custom TLC code, you must use the advanced mode.

```matlab
cscdesigner('MemoryMap','-advanced');
```

In the Custom Storage Class Designer, click **New**. A new custom storage class, `NewCSC_1`, appears in the list of custom storage class definitions.

Rename the new custom storage class `MemoryMappedAddress`.

For `MemoryMappedAddress`, on the **General** tab, set:

- **Type** to *Other*. The custom storage class can operate through custom TLC code that you write later.
- **Data scope** to *Exported*. For data items that use this custom storage class, Simulink Coder generates the definition (for example, the `#define` statement that defines a macro).
- **Data initialization** to *None*. Simulink Coder does not generate code that initializes the data item. Use this setting because this custom storage class represents read-only data. You do not select *Macro* because the Custom Storage Class Designer does not allow you to use *Macro* for signal data.
- **Definition file** to *Specify* (leave the text box empty). For data items that consume memory in the generated code, **Definition file** specifies the `.c` source file that allocates the memory. However, this custom storage class yields a macro, which does not require memory. Typically, header files (.h), not `.c` files, define macros. Setting
**Definition file** to **Specify** instead of **Instance specific** prevents users of the custom storage class from unnecessarily specifying a definition file.

- **Header file** to **Instance specific**. To control the file placement of the macro definition, the user of the custom storage class must specify a header file for each data item that uses this custom storage class.

- **Owner** to **Specify** (leave the text box empty). **Owner** applies only to data items that consume memory.

After you finish selecting the settings, click **Apply** and **Save**.

Now, when you apply the custom storage class to a data item, such as the A2D_INPUT signal line, you can specify a header file to contain the generated macro definition. However, you cannot yet specify a memory address for the data item. To enable specification of a memory address, create a custom attributes class that you can associate with the **MemoryMappedAddress** custom storage class.

**Define Class to Store Custom Attributes for Custom Storage Class**

Define a MATLAB class to store additional information for data items that use the custom storage class. In this case, the additional information is the memory address.

In the **MemoryMap** package (the +MemoryMap folder), create a folder named @MemoryMapAttribs.

In the @MemoryMapAttribs folder, create a file named MemoryMapAttribs. The file defines a class that derives from the built-in class Simulink.CustomStorageClassAttributes.

```matlab
classdef MemoryMapAttribs < Simulink.CustomStorageClassAttributes
    properties( PropertyType = 'char' )
        MemoryAddress = '';
    end
end
```

Later, you associate this MATLAB class with the **MemoryMappedAddress** custom storage class. Then, when you apply the custom storage class to a data item, you can specify a memory address.
Write TLC Code That Emits Correct C Code

Write TLC code that uses the attributes of the custom storage class, such as HeaderFile and MemoryAddress, to generate correct C code for each data item.

In the +MemoryMap folder, create a folder named tlc.

Navigate to the new folder.

Inspect the built-in template TLC file, TEMPLATE_v1.tlc.

edit(fullfile(matlabroot,...
   'toolbox','rtw','targets','ecoder','csc_templates','TEMPLATE_v1.tlc'))

Save a copy of TEMPLATE_v1.tlc in the tlc folder. Rename the copy memory_map_csc.tlc.

In memory_map_csc.tlc, find the portion that controls the generation of C-code data declarations.

%case "declare"

   % LibDefaultCustomStorageDeclare is the default declare function to
   % declares a global variable whose identifier is the name of the data.
   %return "extern %<LibDefaultCustomStorageDeclare(record)>"
   %break

   %=================================

The declare case (%case) constructs a return value (%return), which the code generator emits into the header file that you specify for each data item. To control the C code that declares each data item, adjust the return value in the declare case.

Replace the existing %case content with this new code, which specifies a different return value:

%case "declare"

   % In TLC code, a 'record' is a data item (for example, a signal line).
   % 'LibGetRecordIdentifier' returns the name of the data item.
   %assign id = LibGetRecordIdentifier(record)
%assign dt = LibGetRecordCompositeDataTypeName(record)

%% The 'CoderInfo' property of a data item stores a 'Simulink.CoderInfo' object, which stores code generation settings such as the storage class or custom storage class that you specify for the item.
%assign ci = record.Object.ObjectProperties.CoderInfo
%% The 'ci' variable now stores the 'Simulink.CoderInfo' object.

%% By default, the 'CustomAttributes' property of a 'Simulink.CoderInfo' object stores a 'Simulink.CustomStorageClassAttributes' object.
%% This nested object stores specialized code generation settings such as the header file and definition file that you specify for the data item.
%%
%% The 'MemoryMap' package derives a new class, 'MemoryMapAttribs', from 'Simulink.CustomStorageClassAttributes'.
%% The new class adds a property named 'MemoryAddress'.
%% This TLC code determines the memory address of the data item by acquiring the value of the 'MemoryAddress' property.
%assign ca = ci.Object.ObjectPropertiesCustomAttributes
%assign address = ca.Object.ObjectProperties.MemoryAddress

%assign width = LibGetDataWidth(record)

%% This TLC code constructs the full macro, with correct C syntax, based on the values of TLC variables such as 'address' and 'dt'.
%% This TLC code also asserts that the data item must be a scalar.
%if width == 1
    %assign macro = ...
    "#define %<id> (*((volatile const %<dt>*)%<address>) & 0x03FF)"
%else
    %error( "Non scalars are not supported yet." )
%endif

%return "%<macro>"
%break

% ==============================================================

The new TLC code uses built-in, documented TLC functions, such as LibGetRecordIdentifier, and other TLC commands and operations to access information about the data item. Temporary variables such as dt and address store that
information. The TLC code constructs the full macro, with the correct C syntax, by expanding the variables, and stores the macro in the variable `macro`.

In the same file, find the portion that controls the generation of data definitions.

```plaintext
%case "define"
    % LibDefaultCustomStorageDefine is the default define function to define
    % a global variable whose identifier is the name of the data. If the
    % data is a parameter, the definition is also statically initialized to
    % its nominal value (as set in MATLAB).
    %return "%%<LibDefaultCustomStorageDefine(record)>"
%break
%
```

The `define` case derives a return value that the code generator emits into a `.c` file, which defines data items that consume memory.

Replace the existing `%case` content with this new content:

```plaintext
%case "define"
    %return ""
%break
%
```

MemoryMappedAddress yields a macro in the generated code, so you use the `declare` case instead of the `define` case to construct and emit the macro. To prevent the `define` case from emitting a duplicate macro definition, the new TLC code returns an empty string.

Find the portion that controls the generation of code that initializes data.

```plaintext
%case "initialize"
    % LibDefaultCustomStorageInitialize is the default initialization
    % function that initializes a scalar element of a global variable to 0.
    %return LibDefaultCustomStorageInitialize(record, idx, reim)
%break
%
```

```plaintext
%case "define"
    %return ""
%break
%
```
The **initialize** case generates code that initializes data items (for example, in the *model_initialize* function).

Replace the existing `%case` content with this new content:

```matlab
%case "initialize"
%return ""
%break
```

% MemoryMappedAddress yields a macro, so the generated code must not attempt to initialize the value of the macro. The new TLC code returns an empty string.

**Complete the Definition of the Custom Storage Class**

Your new MATLAB class, `MemoryMapAttribs`, can enable users of your new custom storage class, `MemoryMappedAddress`, to specify a memory address for each data item. To allow this specification, associate `MemoryMapAttribs` with `MemoryMappedAddress`. To generate correct C code based on the information that you specify for each data item, associate the customized TLC file, `memory_map_csc.tlc`, with `MemoryMappedAddress`.

Navigate to the folder that contains the `+MemoryMap` folder.

Open the Custom Storage Class Designer again.

cscdesigner('MemoryMap','-advanced');

For `MemoryMappedAddress`, on the **Other Attributes** tab, set:

- **TLC file name** to `memory_map_csc.tlc`.
- **CSC attributes class** to `MemoryMap.MemoryMapAttribs`.

Click **Apply** and **Save**.

**Define Signal Data Class**

To apply the custom storage class to a signal in a model, in the `MemoryMap` package, you must create a MATLAB class that derives from `Simulink.Signal`. When you configure the signal in the model, you select this new data class instead of the default class, `Simulink.Signal`.

In the `MemoryMap` package, create a folder named `@Signal`. 
In the @Signal folder, create a file named Signal.m.

```matlab
classdef Signal < Simulink.Signal
    methods
        function setupCoderInfo( this )
            useLocalCustomStorageClasses( this, 'MemoryMap' );
            return;
        end
    end
end
```

The file defines a class named MemoryMap.Signal. The class definition overrides the setupCoderInfo method, which the Simulink.Signal class already implements. The new implementation specifies that objects of the MemoryMap.Signal class use custom storage classes from the MemoryMap package (instead of custom storage classes from the Simulink package). When you configure a signal in a model by selecting the MemoryMap.Signal class, you can select the new custom storage class, MemoryMappedAddress.

**Apply Custom Storage Class to Signal Line**

Navigate to the folder that contains the example model and open the model.

In the model, select View > Property Inspector.

Click the signal named A2D_INPUT.

In the Property Inspector, under Code Generation, set Signal object class to MemoryMap.Signal. If you do not see MemoryMap.Signal, select Customize class lists and use the dialog box to enable the selection of MemoryMap.Signal.

In the Property Inspector, set Storage class to MemoryMappedAddress.

Set Header file to memory_mapped_addresses.h.

Set MemoryAddress to 0x8675309.

**Generate and Inspect Code**

Generate code from the model.
### Starting build procedure for model: ex_memmap_simple
### Successful completion of build procedure for model: ex_memmap_simple

Inspect the generated header file memory_mapped_addresses.h. The file defines the macro `A2D_INPUT`, which corresponds to the signal line in the model.

```c
/* Declaration of data with custom storage class MemoryMappedAddress */
#define A2D_INPUT                      ((*(volatile const uint16_T*)0x8675309) & 0x03FF)
```

Inspect the generated file `ex_memmap_simple.c`. The generated algorithmic code (which corresponds to the Gain block) calculates the model output, `rtY.Out1`, by operating on `A2D_INPUT`.

```c
/* Model step function */
void ex_memmap_simple_step(void)
{
    /* Outport: '<Root>/Out1' incorporates:
    *  Gain: '<Root>/Gain'
    *  Inport: '<Root>/In1'
    */
    rtY.Out1 = 42.0 * (real_T)A2D_INPUT;
}
```

Deploy Generated Component Software to Application Target Platforms

The code generator supports integration of generated code with operating systems and processors. For details, see “Embedded Coder Supported Hardware” on page 71-2.

Interface to an Example Real-Time Operating System (VxWorks®)

This example shows how to simulate and generate code for asynchronous events on an example RTOS (VxWorks).

The operating system integration techniques that are demonstrated in this example use one or more blocks the blocks in the vxlib1 library. These blocks provide starting point examples to help you develop custom blocks for your target environment.

Example Model

Open the rtwdemo_vxworks model.

```matlab
model = 'rtwdemo_vxworks';
open_system(model);
%```
Model Description

The example model contains two asynchronously executed subsystems, Count and Algorithm. Count executes at interrupt level. Algorithm executes in an asynchronous task. The generated code for these blocks is tailored for the VxWorks® operating system. However, you can modify the Async Interrupt and Task Sync blocks to generate code specific to your run-time environment whether you are using an operating system or not.
Multirate Modeling in Multitasking Mode (VxWorks® OS)

This example generates code for a multirate discrete-time model configured for a multitasking operating system target (VxWorks®). The model contains two sample times. Inport block 1 and Inport block 2 specify 1-second and 2-second sample times, respectively, which are enforced by the Periodic sample time constraint solver configuration parameter setting. The solver is set for multitasking operation, which means a Rate Transition block is required to ensure that data integrity is enforced when the 1-second task preempts the 2-second task. Simulink® and the code generator enforce proper rate transitions. This model specifies an explicit Rate Transition block. Alternatively, you can instruct Simulink® to insert this block for you by setting the model configuration parameter Automatically handle rate transition for data transfer.

The model is configured to display sample-time colors upon diagram update. Red represents the fastest discrete sample time in the model, green represents the second fastest, and yellow represents mixed sample times. Click the Display Sample Time Colors button to update the diagram and show sample-time colors.

Example Model

```matlab
model = 'rtwdemo_mrmtos';
open_system(model);
```
The model is configured to display sample-time colors upon diagram update. Red represents the fastest discrete sample time in the model, green represents the second fastest, and yellow represents mixed sample times. Click the yellow button to the right to update the diagram and show sample-time colors.

This model shows the code generated for a multirate discrete-time model configured for a multitasking operating system target (VxWorks). The model contains two sample times. Inport block 1 and Inport block 2 specify 1-second and 2-second sample times, respectively, which are enforced by the "Periodic sample time constraint" option on the Solver configuration page. The solver is set for multitasking operation, which means a rate transition block is required to ensure that data integrity is enforced when the 1-second task preempts the 2-second task. Proper rate transitions are always enforced by Simulink and SimulinkCoder. This model specifies an explicit rate transition block. Alternatively, this block could be automatically inserted by Simulink using the "Automatically handle data transfers between tasks" option on the Solver configuration page.

This example uses a Embedded Coder feature to generate an example VxWorks main (i.e., "Target operating system" on the Template configuration page.) Simulink Coder also supports VxWorks via the Tornado target.
Export Code Generated from Model to External Application in Embedded Coder

- “Control Generation of Function Interfaces” on page 53-2
- “Control Generation of C++ Class Interfaces” on page 53-4
Control Generation of Function Interfaces

The Embedded Coder software provides a **Configure Model Functions** button, located on the **Code Generation > Interface** pane of the Configuration Parameters dialog box, that allows you to control the model function interfaces that are generated for ERT-based models.

By default, the function prototype of an ERT-based model's generated `model_step` function resembles the following:

```c
void model_step(void);
```

The function prototype of an ERT-based model's generated `model_initialize` function resembles the following:

```c
void model_initialize(void);
```

(For more detailed information about the default calling interface for the `model_step` function, see the `model_step` reference page.)

The **Configure Model Functions** button on the **Interface** pane provides you flexible control over the model function interfaces that are generated for your model. Clicking **Configure Model Functions** launches a dialog box that you can use to customize and preview the function interfaces. Once you validate and apply your changes, you can generate code based on your modifications.

For more information about using the **Configure Model Functions** button and the Model Interface dialog box, see “Customize Generated C Function Interfaces” on page 29-2 and the example model `rtwdemo_fcnprotoctrl`, which is preconfigured to demonstrate function interface control.

Alternatively, you can use a programming interface to control model function interfaces. For more information, see “Configure C Initialize and Step Function Interfaces Programmatically” on page 29-19.

You can also control model function interfaces for nonvirtual subsystems, if you generate subsystem code using right-click build. To launch the **Model Interface for subsystem** dialog box, use the `RTW.configSubsystemBuild` function.

Right-click building the subsystem generates the step and initialization functions according to the customizations you make. For more information, see “Customize Function Interfaces for Nonvirtual Subsystems” on page 29-32.
For limitations that apply, see “Function Interface Customization Limitations for Rate-Based Models” on page 29-3.

Control Generation of C++ Class Interfaces

Using the Code interface packaging (Simulink Coder) option C++ class, on the Code Generation > Interface pane of the Configuration Parameters dialog box, you can generate a C++ class interface to model code. The generated interface encapsulates required model data into C++ class attributes and model entry point functions into C++ class methods. The benefits of C++ class encapsulation include:

- Greater control over access to model data
- Ability to multiply instantiate model classes
- Easier integration of model code into C++ programming environments

C++ class encapsulation also works for right-click builds of nonvirtual subsystems. (For information on requirements that apply, see “Configure C++ Class Interfaces for Nonvirtual Subsystems” on page 29-55.)

The general procedure for generating C++ class interfaces to model code is as follows:

1. Configure your model to use an ert.tlc system target file provided by MathWorks.
2. Select the C++ language for your model.
3. Select C++ class code interface packaging for your model.
4. Optionally, configure related C++ class interface settings for your model code, using either a graphical user interface (GUI) or application programming interface (API).
5. Generate model code and examine the results.

To get started with an example, see “Simple Use of C++ Class Control” on page 29-37. For more details about configuring C++ class interfaces for your model code, see “Customize C++ Class Interfaces Using Graphical Interfaces” on page 29-44 and “Customize C++ Class Interfaces Programmatically” on page 29-55. For limitations that apply, see “C++ Class Interface Control Limitations” on page 29-62.

*Note* For an example of C++ class code generation, see the example model rtwdemo_cppclass.

What Is Code Replacement Customization?

Customize how and when the code generator replaces C/C++ code that it generates by default for functions and operators by developing a custom code replacement library. You can develop libraries interactively with the Code Replacement Tool or programmatically.

- Develop libraries tailored to specific application requirements
- Add identifiers to the list of reserved keywords the code generator considers during code replacement
- Customize the code generator’s match and replacement process for functions

Code Replacement Match and Replacement Process

When the code generator encounters a call site for a function or operator, it:

1. Creates and partially populates a code replacement entry object with the function or operator name or key and conceptual arguments.

2. Uses the entry object to query the configured code replacement library for a conceptual representation match. The code generator searches the tables in a code replacement library for a match in the order that the tables appear in the library. When searching for a match, the code generator takes into account:
   - Conceptual name or key
   - Arguments, including quantity, type, type qualifiers, and complexity
   - Algorithm (computation method)
   - Fixed-point saturation and rounding modes
   - Priority

3. When a match exists, the code generator returns a code replacement object, fully populated with the conceptual representation, implementation representation, and priority. If the code generator finds multiple matches within a table, the entry priority determines the match. The priority can range from 0 to 100. The highest priority is 0. The code generator uses a higher-priority entry over a similar entry with a lower priority.
4 Uses the C or C++ replacement function prototype in the code replacement object to generate code.

**Code Replacement Customization Limitations**

- Code replacement verification — It is possible that code replacement behaves differently than you expect. For example, data types that you observe in code generator input might not match what the code generator uses as intermediate data types during an operation. Verify code replacements by examining generated code. See “Verify Code Replacements” on page 54-79.

- Tokens in file paths—You can include tokens in file paths when specifying build information for a code replacement entry by using the programming interface only. The ability to include tokens is not available from the Code Replacement Tool. See “Specify Build Information for Replacement Code” on page 54-61.

- Data alignment—
  - Not supported for
    - Arguments associated with a built-in custom storage class with DataScope set to Exported or the imported built-in custom storage class GetSet
    - Software-in-the-loop (SIL)
    - Processor-in-the-loop (PIL)
    - Model reference parameters
    - Exported functions in Stateflow charts
    - Replaced functions that are generated with C function prototype control or C++ class I/O arguments step method and that use root-level I/O variables
    - Replaced functions that are generated with the AUTOSAR system target file and that use root-level I/O or AUTOSAR inter-runnable access functions
  - If the following conditions exist, the code generator includes data alignment directives for root-level I/O variables in the ert_main.c or ert_main.cpp file it produces:
    - Compiler supports global variable alignment
    - Generate an example main program (select **Configuration Parameters** > Generate an example main program)
• Generate a reusable function interface for the model (set Configuration Parameters > Code Generation > Interface > Code interface packaging to Reusable function)

• Function uses root-level I/O variables that are passed in as individual arguments (set Configuration Parameters > Code Generation > Interface > Pass root-level I/O arguments to Individual arguments)

• Replaced function uses a root-level I/O variable

• Replaced function imposes alignment requirements

If you discard the generated example main program, align used root-level I/O variables correctly.

If you choose not to generate an example main program in this case, the code generator does not replace the function.

• If a replacement imposes alignment requirements on the shared utility interface arguments, the code generator does not honor data alignment. Under these conditions, replacement does not occur. Replacement is allowed if the registered data alignment type specification supports alignment of local variables, and the replacement involves only local variables.

• For Simulink.Bus:

  • If user registered alignment specifications do not support structure field alignment, aligning Simulink.Bus objects is not supported unless the Simulink.Bus is imported.

  • When aligning a Simulink.Bus data object, the elements in the bus object are aligned on the same boundary. The boundary is the lowest common multiple of the alignment requirements for each individual bus element.

• When you specify alignment for functions that occur in a model reference hierarchy, and multiple models in the hierarchy operate on the same function data, the bottommost model dictates alignment for the rest of the hierarchy. If the alignment requirement for a function in a model higher in the hierarchy cannot be honored due to the alignment set by a model lower in the hierarchy, the replacement in the higher model does not occur. In some cases, an error message is generated. To work around this issue, if the shared data is represented by a bus or signal object, manually set the alignment property on the shared data by setting the alignment property of the Simulink.Bus or Simulink.Signal object.

• It is your responsibility to honor the Alignment property setting for custom storage classes that you create.
See “Data Alignment for Code Replacement” on page 54-136.
• coder.replace function — See coder.replace for relevant limitations.

Code You Can Replace From Simulink Models

Code that the code generator replaces depends on the code replacement library (CRL) that you use. By default, the code generator does not apply a code replacement library. Your choice of libraries is dependent on product licensing and whether you have access to custom libraries.

For information on how to explore functions and operators that a code replacement library supports, see “Choose a Code Replacement Library” on page 41-8 license and want to develop a custom code replacement library, see Code Replacement Customization.

</tbody>
</table>
Function | Data Type Support | Scalar, Vector, Matrix Support | Real, Complex Support
--- | --- | --- | ---
tanh$^2$ | Floating point | Scalar Vector Matrix | Real Complex Complex input/complex output Real input/complex output

1 Wrap on integer overflow only.
2 For models involving vectors or matrices, the code generator replaces only functions coded in the MATLAB action language.
3 The code generator replaces only functions coded in the MATLAB action language.

### Memory Functions

Depending on code replacement libraries available in your development environment, you can configure the code generator to replace instances of the following memory functions with application-specific implementations.

<table>
<thead>
<tr>
<th>Function</th>
<th>Data Type Support</th>
<th>Scalar, Vector, Matrix Support</th>
<th>Real, Complex Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>memcmp</td>
<td>Void pointer (void*)</td>
<td>Scalar Vector Matrix</td>
<td>Real Complex</td>
</tr>
<tr>
<td>memcpy</td>
<td>Void pointer (void*)</td>
<td>Scalar Vector Matrix</td>
<td>Real Complex</td>
</tr>
<tr>
<td>memset</td>
<td>Void pointer (void*)</td>
<td>Scalar Vector Matrix</td>
<td>Real Complex</td>
</tr>
<tr>
<td>memset2zero</td>
<td>Void pointer (void*)</td>
<td>Scalar Vector Matrix</td>
<td>Real Complex</td>
</tr>
</tbody>
</table>
Some target processors provide optimized functions to set memory to zero. Use the code replacement library programming interface to replace the memset2zero function with more efficient target-specific functions.

**Nonfinite Functions**

Depending on code replacement libraries available in your development environment, you can configure the code generator to replace instances of the following nonfinite functions with application-specific implementations.

<table>
<thead>
<tr>
<th>Function</th>
<th>Data Type Support</th>
<th>Scalar, Vector, Matrix Support</th>
<th>Real, Complex Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>getInf</td>
<td>Floating point</td>
<td>Scalar</td>
<td>Real</td>
</tr>
<tr>
<td>getMinusInf</td>
<td>Floating point</td>
<td>Scalar</td>
<td>Real</td>
</tr>
<tr>
<td>getNaN</td>
<td>Floating point</td>
<td>Scalar</td>
<td>Real</td>
</tr>
<tr>
<td>rtIsInf</td>
<td>Floating point</td>
<td>Scalar</td>
<td>Real Complex</td>
</tr>
<tr>
<td>rtIsNaN</td>
<td>Floating point</td>
<td>Scalar</td>
<td>Real Complex</td>
</tr>
</tbody>
</table>

**Mutex and Semaphore Functions**

Mutex and semaphore functions control access to resources shared by multiple processes in multicore target environments. MathWorks provides code replacement libraries that support mutex and semaphore replacement for Rate Transition and Task Transition blocks on Windows, Linux, Mac, and VxWorks platforms.

Generated mutex and semaphore code typically consists of:

- In model initialization code, an initialization function call to create a mutex or semaphore to control entry to a critical section of code.
- In model step code:
  - Before code for a data transfer between tasks enters the critical section, mutex lock or semaphore wait function calls to reserve a critical section of code.
  - After code for a data transfer between tasks finishes executing the critical section, mutex unlock or semaphore post function calls to release the critical section of code.
• In model termination code, an optional destroy function call to explicitly delete the mutex or semaphore.

Depending on code replacement libraries available in your development environment, you can configure the code generator to replace instances of the following mutex and semaphore functions with application-specific implementations.

<table>
<thead>
<tr>
<th>Function</th>
<th>Key</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mutex Destroy</td>
<td>RTW_MUTEX_DESTROY</td>
</tr>
<tr>
<td>Mutex Init</td>
<td>RTW_MUTEX_INIT</td>
</tr>
<tr>
<td>Mutex Lock</td>
<td>RTW_MUTEX_LOCK</td>
</tr>
<tr>
<td>Mutex Unlock</td>
<td>RTW_MUTEX_UNLOCK</td>
</tr>
<tr>
<td>Semaphore Destroy</td>
<td>RTW_SEM_DESTROY</td>
</tr>
<tr>
<td>Semaphore Init</td>
<td>RTW_SEM_INIT</td>
</tr>
<tr>
<td>Semaphore Post</td>
<td>RTW_SEM_POST</td>
</tr>
<tr>
<td>Semaphore Wait</td>
<td>RTW_SEM_WAIT</td>
</tr>
</tbody>
</table>

**Operators**

When generating C/C++ code from a Simulink model, depending on code replacement libraries available in your development environment, you can configure the code generator to replace instances of the following operators with application-specific implementations.

Mixed data type support indicates that you can specify different data types for different inputs.

<table>
<thead>
<tr>
<th>Operator</th>
<th>Key</th>
<th>Data Type Support</th>
<th>Scalar, Vector, Matrix Support</th>
<th>Real, Complex Support</th>
</tr>
</thead>
<tbody>
<tr>

</tbody>
</table>

1. See “Addition and Subtraction Operator Code Replacement” on page 54-177 for details to consider when defining mappings for addition and subtraction code replacements.

2. Can map to Basic Linear Algebra Subroutine (BLAS) multiplication functions.

3. Scaled floating point is not supported.

4. Shift operator replacement with matrix data is supported for shift values that you specify with an input port. Replacement is not supported for shift values that you specify in a block parameter dialog.

5. The code generator converts some arithmetic shift rights to logical shift rights. To avoid unexpected results, when creating a code replacement library that includes a table entry for an arithmetic shift right implementation, also include an entry for a logical shift right implementation.

6. Use the multiplication (*) operator (RTW_0P_MUL) for scalar multiplication.

7. Requires scalar, real, or fixed-point data types with zero bias; output type of the multiplication operation to accommodate all possible output values; shift operand is an unsigned integer; and net slope is equal to 1 (U1_slope * U2_slope == Mul_output_slope and Mul_output_slope == output_slope_of_shift_operation).

8. Requires scalar, real, or fixed-point data types with zero bias; output type of the multiplication operation to accommodate all possible output values; and net slope is equal to 1 (U1_slope * U2_slope == Mul_output_slope == U3_slope * Div_output_slope).

Develop a Code Replacement Library

Iterate through the following steps, as necessary, to develop a code replacement library:

1. “Identify Code Replacement Requirements” on page 54-39
2. “Prepare for Code Replacement Library Development” on page 54-42
3. “Define Code Replacement Mappings” on page 54-43
4. “Specify Build Information for Replacement Code” on page 54-61
5. “Register Code Replacement Mappings” on page 54-70
6. “Verify Code Replacements” on page 54-79

To get started, see “Identify Code Replacement Requirements” on page 54-39.

To experiment with the process and tools, see “Quick Start Code Replacement Library Development - Simulink®” on page 54-28.

- “What Is Code Replacement Customization?” on page 54-3
Quick Start Code Replacement Library Development - Simulink®

This example shows how to develop a code replacement library that includes an entry for generating replacement code for the math function \( \sin \). You use the Code Replacement Tool.

**Prerequisites**

To complete this example, install the following software:

- MATLAB®
- MATLAB Coder™
- Simulink®
- Simulink Coder™
- Embedded Coder®
- Compiler

For instructions on installing MathWorks® products, see the MATLAB installation documentation. If you have installed MATLAB and want to see what other MathWorks products are installed, in the Command Window, enter `ver`.

For a list of supported compilers, see [https://www.mathworks.com/support/compilers/current_release/](https://www.mathworks.com/support/compilers/current_release/).

**Open the Code Replacement Tool**

1. Start a MATLAB session.

2. Create or navigate (cd) to an empty folder.

3. At the command prompt, enter the `crtool` command. The Code Replacement Tool window opens.

**Create Code Replacement Table**

1. In the Code Replacement Tool window, select **File > New table**

2. In the right pane, name the table `crl_table_sinfcn` and click **Apply**. When you save the table, the tool saves it with the file name `crl_table_sinfcn.m`. 

Create Table Entry

Create a table entry that maps a sin function with double input and double output to a custom implementation function.

1. In the left pane, select table crl_table_sinfcn. Then, select File > New entry > Function. The entry appears in the middle pane, initially without a name.

2. In the middle pane, select the new entry.

3. In the right pane, on the Mapping Information tab, from the Function menu, select sin.

4. Leave Algorithm set to Unspecified, and leave parameters in the Conceptual function group set to default values.

5. In the Replacement function group, name the replacement function sin_dbl.

6. Leave the remaining parameters in the Replacement function group set to default values.
7. Click **Apply**. The tool updates the **Function signature preview** to reflect the specified replacement function name.

8. Scroll to the bottom of the **Mapping Information** tab and click **Validate entry**. The tool validates your entry.

The following figure shows the completed mapping information.
Specify Build Information for Replacement Code

1. On the **Build Information** tab, for the **Implementation header file** parameter, enter `sin_dbl.h`.
2. Leave the remaining parameters set to default values.
3. Click **Apply**.

4. Optionally, you can revalidate the entry. Return to the **Mapping Information** tab and click **Validate entry**.

Create Another Table Entry

Create an entry that maps a `sin` function with single input and double output to a custom implementation function named `sin_sgl`. Create the entry by copying and pasting the `sin_dbl` entry.

1. In the middle pane, select the `sin_dbl` entry.
2. Select **Edit > Copy**.
3. Select **Edit > Paste**.
4. On the **Mapping Information** tab, in the **Conceptual function** section, set the data type of input argument `u1` to single.
5. In the **Replacement function** section, name the function `sin_sgl`. Set the data type of input argument `u1` to single.
6. Click **Apply**. Note the changes that appear for the **Function signature preview**.
7. On the **Build Information** tab, for the **Implementation header file** parameter, enter `sin_sgl.h`. Leave the remaining parameters set to default values and click **Apply**.

**Validate the Code Replacement Table**

1. Select **Actions > Validate table**.

2. If the tool reports errors, fix them, and rerun the validation. Repeat fixing and validating errors until the tool does not report errors. The following figure shows a validation report.

![Validation Report](image)

**Save the Code Replacement Table**

Save the code replacement table to a MATLAB file in your working folder. Select **File > Save table**. By default, the tool uses the table name to name the file. For this example, the tool saves the table in the file `crl_table_sinfcn.m`.

**Review the Code Replacement Table Definition**

Consider reviewing the MATLAB code for your code replacement table definition. After using the tool to create an initial version of a table definition file, you can update, enhance, or copy the file in a text editor.

To review it, in MATLAB or another text editor, open the file `crl_table_sinfcn.m`.

**Generate a Registration File**

Before you can use your code replacement table, you must register it as part of a code replacement library. Use the Code Replacement Tool to generate a registration file.

1. In the Code Replacement Tool, select **File > Generate registration file**.

2. In the **Generate registration file** dialog box, edit the dialog box fields to match the following figure, and click **OK**.
3. In the **Select location to save the registration file** dialog box, specify a location for the registration file. The location must be on the MATLAB path or in the current working folder. Save the file. The tool saves the file as `rtwTargetInfo.m`.

**Register the Code Replacement Table**

At the command prompt, enter:

```matlab
RTW.TargetRegistry.getInstance('reset');
```

**Review and Test Code Replacements**

Apply your code replacement library. Verify that the code generator makes code replacements that you expect.

1. Check for errors. At the command line, invoke the table definition file. For example:

```matlab
|tbl = crl_table_sinfcn
tbl =
TflTable with properties:
    Version: '1.0'
    ReservedSymbols: []
```
If an error exists in the definition file, the invocation triggers a message. Fix the error and try again.

2. Use the Code Replacement Viewer to check your code replacement entries. For example:

```matlab
crviewer('Sin Function Example')
```

In the viewer, select entries in your table and verify that the content is what you expect. The viewer can help you detect issues such as:

- Incorrect argument order.
- Conceptual argument names that do not match what the code generator expects.
- Incorrect priority settings.

3. Identify existing model or create a model that includes a Trigonometric block that is set to the sin function. For example:

4. Open the model and configure it for code generation with an Embedded Coder (ERT-based) target.

5. See whether your library is listed as an available option for the Code Generation > Interface > Code replacement library model configuration parameter. If it is, select it.

If it is not listed, open the registration file, `rtwTargetInfo.m`. See whether you entered the correct code replacement table name when you created the file. If you hover the
cursor over the selected library, a tool tip appears. This tip contains information derived from your code replacement library registration file, such as the library description and the list of tables it contains.

6. To find parameters quickly, in the Configuration Parameters dialog box **Search** field, type the parameter name. Configure the code generation report for code replacement analysis by selecting the following parameters:

- **Create code generation report**
- **Open report automatically**
- **Code-to-model**
- **Model-to-code**
- **Summarize which blocks triggered code replacements**
- **Include comments**
- **Simulink block comments**
- **Simulink block descriptions**

7. Configure the model to generate code only. Before you build an executable program, confirm that the code generator is replacing code as expected.

8. Generate code for the model.

The report indicates that the code generator found a match and applied the replacement code for the function `sin_dbl`.

10. Review the code replacements. In the model window, right-click the Trigonometric Function block. Select C/C++ Code > Navigate to C/C++ Code. The code generation report opens and highlights the code replacement in `my_sin_func.c`. In this case, the code generator replaced `sin` with `sin_dbl`. 
Identify Code Replacement Requirements

The first step to developing a code replacement library is to consider the following types of requirements for the library.

Mapping Information Requirements

- Are you defining a code replacement mapping for the first time?
- Are you updating code replacement entries in an existing library? Or, are you creating a new library?
- Are you rapid prototyping code replacements?
- Can you base your mappings on existing mappings?
- What type of code do you want to replace? Options include:
  - Math operation
  - Function
  - BLAS operation
  - CBLAS operation
  - Net slope fixed-point operation
  - Semaphore or mutex functions
- Do you want to change the inline or nonfinite behavior for functions?
- What specific functions and operations do you want to replace?
- What input and output arguments does the function or operator that you are replacing take? For each argument, what is the data type, complexity, and dimensionality?
- What does the prototype for your replacement code look like?
  - What is the replacement function name?
  - What are the input and output arguments?
  - Are there return values?
  - What is the data type, complexity, and dimensionality of each argument and return value?
Build Information Requirements

• Does your replacement function implementation require a header file? If yes, specify the header file.
• If the replacement function implementation requires a header file, what is the path for that file?
• Is the source file for the replacement function in your working folder? If not, you can explicitly specify the source file name and extension. For example, if the file is required in the generated makefile or specified in a build information object, specify the source file.
• Does the replacement function use additional include files? If yes, what are they and what are the paths for those files?
• Does the replacement function use additional source files? If yes, what are they and what are the paths for those files?
• What compiler flags are required for compiling code that includes the replacement code?
• What linker flags are required for building an executable that includes the replacement code?
• Are the required header, source, and object files for building an executable that includes your replacement code in the working folder for your project? If not, before starting the build process, do you want the code generator to copy required files to the build folder?

Registration Information Requirements

• What do you want to name your code replacement library?
• What code replacement tables do you want to include in the library? What are the file names and paths for the tables?
• What is the purpose of the library? You can document the purpose as the library description.
• Does the library apply to specific hardware devices? If yes, what devices?
• Are you developing a hierarchy of code replacement libraries? Is the library that you are developing based (dependent) on another library? For example, you can specify a general TI device library as the base library for a more specific TI C28x device library.
Do you need to specify data alignment for the library? What data alignments are required? For each specification, what type of alignment is required and for what programming language?

Next, prepare for developing a library by reviewing a code replacement library development checklist.

- “Develop a Code Replacement Library” on page 54-27
- “Prepare for Code Replacement Library Development” on page 54-42
- “What Is Code Replacement Customization?” on page 54-3
Prepare for Code Replacement Library Development

After you identify your code replacement requirements, prepare for library development by reviewing this checklist:

• Get familiar with the library development process.
• Decide whether to define code replacement mappings and produce a registration file interactively with the Code Replacement Tool or programmatically.
• Identify or develop MATLAB code and Simulink models to test your code replacement library.
• Consider the hierarchy and organization of your library. A library can consist of multiple tables and each table can include multiple entries. How do you want to organize the library to optimize reuse of tables and entries? For example, a registration file can define code replacement tables organized in a hierarchy of code replacement libraries based on entries that increase in specificity:
  • Common entries
  • Entries for TI devices
  • Entries for TI C6xx devices
  • Entries specific to the TI C67x device
• If support files, such as header files, additional source files, and dynamically linked libraries are not in your current working folder, note their location. You need to specify the paths for such files.

Next, based on your requirements and preparation, define code replacement mappings.

• “What Is Code Replacement Customization?” on page 54-3
Define Code Replacement Mappings

After you prepare for library development, use your requirements to define code replacement mappings. A code replacement mapping associates a conceptual representation of a function or operator that is familiar to the code generator with a custom implementation representation that specifies a C or C++ replacement function prototype. You capture a mapping as an entry in a code replacement table:

- Interactively, by using the Code Replacement Tool.
- Programmatically, by using a MATLAB programming interface.

Choose an Approach for Defining Code Replacement Mappings

The following table lists situations to help you decide when to use the interactive or programmatic approach.

<table>
<thead>
<tr>
<th>Situation</th>
<th>Approach</th>
</tr>
</thead>
<tbody>
<tr>
<td>Defining mappings for the first time.</td>
<td>Code Replacement Tool.</td>
</tr>
<tr>
<td>Rapid prototyping mappings.</td>
<td>Code Replacement Tool to quickly generate, register, and test mappings.</td>
</tr>
<tr>
<td>Developing a mapping as a template or starting point for defining similar mappings.</td>
<td>Code Replacement Tool to generate definition code that you can copy and modify.</td>
</tr>
<tr>
<td>Modifying a registration file, including copying and pasting content.</td>
<td>MATLAB Editor to update the programming interface directly.</td>
</tr>
<tr>
<td>Defining mappings that specify attributes not available from the Code Replacement Tool (for example, sets of algorithm parameters).</td>
<td>Programming interface.</td>
</tr>
<tr>
<td>Reusing existing code for new mappings by copying, pasting, and editing existing mappings.</td>
<td>Programming interface.</td>
</tr>
</tbody>
</table>
Define Mappings Interactively with the Code Replacement Tool

This example shows how to use the Code Replacement Tool to develop code replacement mappings. The tool is ideal for getting started with developing mappings, rapid prototyping, and developing a mapping to use as a starting point for defining similar mappings.

Open the Code Replacement Tool

Do one of the following:

- In the Command Window, enter the command `crtool`.
- In the Configuration Parameters dialog box, navigate to Code Generation pane. In the Advanced parameters section, scroll down and click Custom CRL... button.

An Embedded Coder license is not required to create a custom code replacement library. However, you must have an Embedded Coder license to use a such a library.

By default, the tool displays, left to right, a root pane, a list pane, and a dialog pane. You can manipulate the display:

- Drag boundaries to widen, narrow, shorten, or lengthen panes, and to resize table columns.
- Select View > Show dialog pane to hide or display the right-most pane.
- Click a table column heading to sort the table based on contents of the selected column.
- Right-click a table column heading and select Hide to remove the column from the display. (You cannot hide the Name column.)

Create a Code Replacement Table

1. In the Code Replacement Tool window, select File > New table.
2. In the right pane, name the table and click Apply. Later, when you save the table, the tool uses the table name that you specify to name the file. For example, if you enter the name `my_sinfcn`, the tool names the file `my_sinfcn.m`.
Create Table Entries

Create one or more table entries. Each entry maps the conceptual representation of a function or operator to your implementation representation. The information that you enter depends on the type of entry you create. Enter the following information:

1. In the left pane, select the table to which you want to add the entry.
2. Select File > New entry > entry-type, where entry-type is one of:
   - Math Operation
   - Function
   - BLAS Operation
   - CBLAS Operation
   - Net Slope Fixed-Point Operation
   - Semaphore entry
   - Customization entry

The new entry appears in the middle pane, initially without a name.

3. In the middle pane, select the new entry.

4. In the right pane, on the Mapping Information tab, from the Function or Operation menu, select the function or operation that you want the code generator to replace. Regardless of the entry type, make a selection from this menu. Your selection determines what other information you specify.

   Except for customization entries, you also specify information for your replacement function prototype. You can also specify implementation attributes, such as the rounding modes to apply.

5. If prompted, specify additional entry information that you want the code generator to use when searching for a match. For example, when you select an addition or subtraction operation, the tool prompts you to specify an algorithm (Cast before operation or Cast after operation).

6. Review the conceptual argument information that the tool populates for the function or operation. Conceptual input and output arguments represent arguments for the function or operator being replaced. Conceptual arguments observe naming conventions (‘y1’, ‘u1’, ‘u2’, ...) and data types familiar to the code generator.
When validating the entry, the code generator validates that each conceptual argument has an I/O type that is compatible with the argument name. For example, an input must have IOType of RTW_IO_INPUT.

If you do not want the data types for your implementation to be the same as the conceptual argument types, clear the Make the conceptual and implementation argument types the same check box. For example, most ANSI-C functions operate on and return double data. Clear the check box if want to map a conceptual representation of the function to an implementation representation that specifies an argument and return value. For example, clear the check box to map the conceptual representation of the function \textit{sin} to an implementation representation that specifies an argument and return value of type single (single \textit{sin}(single)), of type double (double \textit{sin}(double)). In this case, the code generator produces the following code:

\[ y = \text{(single) } \text{sin}(u1); \]

If you select Custom for a function entry, specify only conceptual argument information.

Specify the name and argument information for your replacement function. As you enter the information and click Apply, the tool updates the Function signature preview.

When validating the entry, the code generator validates that each implementation argument has an I/O type that is compatible with the conceptual argument to which it is mapped. For example, an conceptual argument of type RTW_IO_OUTPUT requires a compatible implementation argument of type RTW_IO_OUTPUT or RTW_IO_INPUT_OUTPUT. The default I/O type is RTW_IO_INPUT.

Specify additional implementation attributes that apply. For example, depending on the type and name of the entry that you specify, the tool prompts you to specify:

- Integer saturation mode
- Rounding modes
- Whether to allow inputs that include expressions
- Whether a function modifies internal or global state

Click Apply.

\textbf{Validate Tables and Entries}

The Code Replacement Tool provides a way to validate the syntax of code replacement tables and table entries as you define them. If the tool finds validation errors, you can
address them and retry the validation. Repeat the process until the tool does not report errors.

<table>
<thead>
<tr>
<th>To</th>
<th>Do</th>
</tr>
</thead>
<tbody>
<tr>
<td>Validate table entries</td>
<td>Select an entry, scroll to the bottom of the <strong>Mapping Information</strong> tab, and click <strong>Validate entry</strong>. Alternatively, select one or more entries, right-click, and select <strong>Validate entries</strong>.</td>
</tr>
<tr>
<td>Validate a table</td>
<td>Select the table. Then, select <strong>Actions &gt; Validate table</strong>.</td>
</tr>
</tbody>
</table>

**Save a Table**

When you save a table, the tool validates unvalidated content.

1. Select **File > Save table**.
2. In the Browse For Folder dialog box, specify a location and name for the file. Typically, you select a location on the MATLAB path. By default, the tool names the file using the name that you specify for the table with the extension `.m`.
3. Click **Save**.

**Open and Modify Tables**

After saving a code replacement table, to make changes in the table:

1. Select **File > Open table**.
2. In the Import file dialog box, browse to the MATLAB file that contains the table.

Repeat the sequence to open and work on multiple tables.

If you open multiple tables, you can manage the tables together. For example, use the tool to:

- Create new table entries.
- Delete entries.
- Copy and paste or cut and paste information between tables.

**Define Mappings Programmatically**

This example shows how to define a code replacement mapping programmatically. The programming interface for defining code replacement table mappings is ideal for
• Modifying tables that you create with the Code Replacement Tool.
• Defining mappings for specialized entries that you cannot create with the Code Replacement Tool.
• Replicating and modifying similar entries and tables.

Steps for defining a mapping programmatically are:

• “Create Code Replacement Table” on page 54-48
• “Create Table Entry” on page 54-48
• “Set Entry Parameters” on page 54-50
• “Create Conceptual Arguments” on page 54-52
• “Create Implementation Arguments” on page 54-54
• “Add Entry to Table” on page 54-58
• “Validate Entry” on page 54-58
• “Save Table” on page 54-59

Create Code Replacement Table

1. Create a table definition file that contains a function definition. For example:
   
   ```
   function hTable = crl_table_sinfcn()
   ``

2. Within the function body, create the table by calling the function `RTW.TflTable`.
   
   ```
   hTable = RTW.TflTable;
   ```

Create Table Entry

For each function or operator that you want the code generator to replace, map a conceptual representation of the function or operator to an implementation representation as a table entry.

1. Within the body of a table definition file, create a code replacement entry object. Call one of the following functions.

<table>
<thead>
<tr>
<th>Entry Type</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>Math operation</td>
<td><code>RTW.TflCOperationEntry</code></td>
</tr>
<tr>
<td>Function</td>
<td><code>RTW.TflCFunctionEntry</code></td>
</tr>
<tr>
<td>BLAS operation</td>
<td><code>RTW.TflBlasEntryGenerator</code></td>
</tr>
<tr>
<td>Entry Type</td>
<td>Function</td>
</tr>
<tr>
<td>------------------------------------------------</td>
<td>--------------------------------------------------------</td>
</tr>
<tr>
<td>CBLAS operation</td>
<td>RTW.TflCBlasEntryGenerator</td>
</tr>
<tr>
<td>Fixed-point addition and subtraction operations (support for SlopesMustBeTheSame and MustHaveZeroNetBias parameters)</td>
<td>RTW.TflCOperationEntryGenerator</td>
</tr>
<tr>
<td>Net slope fixed-point operation</td>
<td>RTW.TflCOperationEntryGenerator_NetSlope</td>
</tr>
<tr>
<td>Semaphore or mutex entry</td>
<td>RTW.TflCSemaphoreEntry</td>
</tr>
<tr>
<td>Custom function entry</td>
<td>MyCustomFunctionEntry (where MyCustomFunctionEntry is a class derived from RTW.TflCFunctionEntryML)</td>
</tr>
<tr>
<td>Custom operation entry</td>
<td>MyCustomOperationEntry (where MyCustomOperationEntry is a class derived from RTW.TflCOperationEntryML)</td>
</tr>
</tbody>
</table>

For example:

```c
hEnt = RTW.TflCFuncti
```

You can combine steps of creating the entry, setting entry parameters, creating conceptual and implementation arguments, and adding the entry to a table with a single function call to registerCFunctionEntry, registerCPPFunctionEntry, or registerCPromotableMacroEntry if you are creating an entry for a function and the function implementation meets the following criteria:

- Implementation argument names and order match the names and order of corresponding conceptual arguments.
- Input arguments are of the same type.
- The return and input argument names follow the code generator’s default naming conventions:
  - Return argument is y1.
  - Input arguments are u1, u2, ..., un.

For example:
As another alternative, you can significantly reduce the amount of code that you write by combining the steps of creating the entry and conceptual and implementation arguments with a call to the `createCRLEntry` function. In this case, specify the conceptual and implementation information as character vector specifications.

For example:

```matlab
hEnt = createCRLEntry(hTable, ...
    'double y1 = sin(double u1)', ...
    'mySin');
```

This approach does not support:

- C++ implementations
- Data alignment
- Operator replacement with net slope arguments
- Entry parameter specifications (for example, priority, algorithm, building information)
- Semaphore and mutex function replacements

### Set Entry Parameters

Set entry parameters, such as the priority, algorithm information, and implementation (replacement) function name. Call the function listed in the following table for the entry type that you created.

<table>
<thead>
<tr>
<th>Entry Type</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>Math operation</td>
<td><code>setTflCOperationEntryParameters</code></td>
</tr>
<tr>
<td>Function</td>
<td><code>setTflCFFunctionEntryParameters</code></td>
</tr>
<tr>
<td>BLAS operation</td>
<td><code>setTflCOperationEntryParameters</code></td>
</tr>
<tr>
<td>CBLAS operation</td>
<td><code>setTflCOperationEntryParameters</code></td>
</tr>
<tr>
<td>Entry Type</td>
<td>Function</td>
</tr>
<tr>
<td>------------</td>
<td>----------</td>
</tr>
<tr>
<td>Fixed-point addition and subtraction operations where there is a many-to-one mapping, such as a mapping for a range of fixed-point types to the same replacement function (support for SlopesMustBeTheSame and MustHaveZeroNetBias parameters)</td>
<td>setTflCOperationEntryParameters</td>
</tr>
<tr>
<td>Net slope fixed-point operation</td>
<td>setTflCOperationEntryParameters</td>
</tr>
<tr>
<td>Semaphore or mutex entry</td>
<td>setTflCSemaphoreEntryParameters</td>
</tr>
<tr>
<td>Custom function entry</td>
<td>setTflCFunctionEntryParameters</td>
</tr>
<tr>
<td>Custom operation entry</td>
<td>setTflCOperationEntryParameters</td>
</tr>
</tbody>
</table>

To see a list of the parameters that you can set, at the command line, create a new entry and omit the semicolon at the end of the command. For example:

```matlab
hEnt = RTW.TflCFunctionEntry
```

```matlab
hEnt =

TflCFunctionEntry with properties:

    Implementation: [1x1 RTW.CImplementation]
    SlopesMustBeTheSame: 0
    BiasMustBeTheSame: 0
    AlgorithmParams: []
    ImplType: 'FCN IMPL FUNCT'
    AdditionalHeaderFiles: {0x1 cell}
    AdditionalSourceFiles: {0x1 cell}
    AdditionalIncludePaths: {0x1 cell}
    AdditionalSourcePaths: {0x1 cell}
    AdditionalLinkObjs: {0x1 cell}
    AdditionalLinkObjsPaths: {0x1 cell}
    AdditionalLinkFlags: {0x1 cell}
    AdditionalCompileFlags: {0x1 cell}
    SearchPaths: {0x1 cell}
    Key: ''
    Priority: 100
    ArrayLayout: 'COLUMN_MAJOR'
    ConceptualArgs: [0x1 handle]
    EntryInfo: []
```
To see the implementation parameters, enter:

```matlab
hEnt.Implementation
```

ans =

```matlab
CImplementation with properties:

    HeaderFile: ''
    SourceFile: ''
    HeaderPath: ''
    SourcePath: ''
    Return: []
    StructFieldMap: []
    Name: ''
    Arguments: [0x1 RTW.Argument]
    ArgumentDescriptor: []
```

For example, to set entry parameters for the `sin` function and name your replacement function `sin_dbl`, use the following function call:

```matlab
setTflCFunctionEntryParameters(hEnt, ...
    'Key', 'sin', ...
    'ImplementationName', 'sin_dbl');
```

### Create Conceptual Arguments

Create conceptual arguments and add them to the entry's array of conceptual arguments.

- Specify output arguments before input arguments.
- Specify argument names that comply with code generator argument naming conventions:
• y1 for a return argument
• u1, u2, ..., un for input arguments

Specify data types that are familiar to the code generator.
The function signature, including argument naming, order, and attributes, must fulfill the signature match sought by function or operator callers.
The code generator determines the size of the value for an argument with an unsized type, such as integer, based on hardware implementation configuration settings.

For each argument:

1 Identify whether the argument is for input or output, the name, and data type. If you do not know what arguments to specify for a supported function or operation, use the Code Replacement Tool to find them. For example, to find the conceptual arguments for the sin function, open the tool, create a table, create a function entry, and in the Function menu select sin.

When validating the entry, the code generator validates that each conceptual argument has an I/O type that is compatible with the argument name. For example, an input must have IOType of RTW_IO_INPUT.

2 Create and add the conceptual argument to an entry. You can choose a method from the methods listed in this table.

<table>
<thead>
<tr>
<th>If</th>
<th>Then</th>
</tr>
</thead>
<tbody>
<tr>
<td>You want simpler code or want to explicitly specify whether the argument is scalar or nonscalar (vector or matrix).</td>
<td>Call the function createAndAddConceptualArg. For example:</td>
</tr>
</tbody>
</table>
|                                                                  | createAndAddConceptualArg(hEnt, ...
|                                                                  |   'RTW.TflArgNumeric', ...
|                                                                  |   'Name', 'y1',...
|                                                                  |   'IOType', 'RTW_IO_OUTPUT',...
|                                                                  |   'DataTypeMode', 'double');                                           |
|                                                                  | The second argument specifies whether the argument is scalar (RTW.TflArgNumeric or RTW.TflArgMatrix). |
If | Then
---|---
You want to create an argument based on a built-in argument definition (for example, scalar or nonscalar). | Call `getTflArgFromString` to create the argument. Then, call `addConceptualArg` to add the argument to the entry.

```matlab
arg = getTflArgFromString(hEnt, 'y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEnt, arg);
```

You need to define several similar mappings, you want to minimize the code to write, and the entries do not require data alignment, use net slope arguments, or involve semaphore or mutex replacements. | Call `createCRLEntry` to create the entry and specify conceptual and implementation arguments in a single function call.

```matlab
hEnt = createCRLEntry(hTable, ...
   'double y1 = sin(double u1)', ...
   'mySin');
```

The following code shows the second approach listed in the table for specifying the conceptual output and input argument definitions for the `sin` function.

```matlab
% Conceptual Args

arg = getTflArgFromString(hEnt, 'y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEnt, arg);

arg = getTflArgFromString(hEnt, 'u1','double');
addConceptualArg(hEnt, arg);

Create Implementation Arguments

Create implementation arguments for the C or C++ replacement function and add them to the entry.

- When replacing code, the code generator uses the argument names to determine how it passes data to the implementation function.
- For function replacements, the order of implementation argument names must match the order of the conceptual argument names.
• For operator replacements, the order of implementation argument names do not have to match the order of the conceptual argument names. For example, for an operator replacement for addition, \( y_1 = u_1 + u_2 \), the conceptual arguments are \( y_1, u_1, \) and \( u_2 \), in that order. If the signature of your implementation function is \( t \ myAdd(t \ u_2, t \ u_1) \), where \( t \) is a valid C type, based on the argument name matches, the code generator passes the value of the first conceptual argument, \( u_1 \), to the second implementation argument of \( myAdd \). The code generator passes the value of the second conceptual argument, \( u_2 \), to the first implementation argument of \( myAdd \).

• For operator replacements, you can remap operator output arguments to implementation function input arguments.

For each argument:

1. Identify whether the argument is for input or output, the name, and the data type.

   When validating the entry, the code generator validates that each implementation argument has an I/O type that is compatible with the conceptual argument to which it is mapped. For example, an conceptual argument of type \( \text{RTW}_\text{IO\_OUTPUT} \) requires a compatible implementation argument of type \( \text{RTW}_\text{IO\_OUTPUT} \) or \( \text{RTW}_\text{IO\_INPUT\_OUTPUT} \). The default I/O type is \( \text{RTW}_\text{IO\_INPUT} \).

2. Create and add the implementation argument to an entry. You can choose a method from the methods listed in this table.

<table>
<thead>
<tr>
<th>If</th>
<th>Then</th>
</tr>
</thead>
<tbody>
<tr>
<td>You want to populate implementation arguments as copies of previously created matching conceptual arguments</td>
<td>Call the function ( \text{copyConceptualArgsToImplementation} ). For example: ( \text{copyConceptualArgsToImplementation}(\text{hEnt}); )</td>
</tr>
<tr>
<td>If</td>
<td>Then</td>
</tr>
<tr>
<td>----</td>
<td>------</td>
</tr>
<tr>
<td>You want to create and add implementation arguments individually, or vary argument attributes, while maintaining conceptual argument order</td>
<td>Call functions createAndSetCImplementationReturn and createAndAddImplementationArg. For example:</td>
</tr>
</tbody>
</table>
| | createAndSetCImplementationReturn(hEnt, 'RTW.TflArgNumeric', ...
| | 'Name', 'y1', ...
| | 'IOType', 'RTW_IO_OUTPUT', ...
| | 'IsSigned', true, ...
| | 'WordLength', 32, ...
| | 'FractionLength', 0); |
| | createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric', ...
| | 'Name', 'u1', ...
| | 'IOType', 'RTW_IO_INPUT', ...
| | 'IsSigned', true, ...
| | 'WordLength', 32, ...
<p>| | 'FractionLength', 0 ); |</p>
<table>
<thead>
<tr>
<th><strong>If</strong></th>
<th><strong>Then</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>You want to minimize the amount of code, or specify constant arguments to pass to the implementation function</td>
<td>Create the argument with a call to the function <code>getTflArgFromString</code>. Then, use the convenience method <code>setReturn</code> or <code>addArgument</code> to specify whether an argument is a return value or argument and to add the argument to the entry’s array of implementation arguments. For example:</td>
</tr>
</tbody>
</table>
| | arg = `getTflArgFromString(hEnt,...
| |    'y1','double')`;
| | arg.IOType = 'RTW_IO_OUTPUT';
| | hEnt.Implementation.setReturn(arg); |
| | arg = `getTflArgFromString(hEnt,...
| |    'u1','double')`;
| | hEnt.Implementation.addArgument(arg); |
| The following call to `getTflArgFromString` passes the constant 0 to argument u2: | |
| | arg = `getTflArgFromString(hEnt,...
| |    'u2', 'int16', 0)`;
| | hEnt.Implementation.addArgument(arg); |
| For semaphore and mutex entries, use the functions `getTflDWorkFromString` and `addDWorkArg` to create and add a DWork argument to the entry. Then create implementation arguments as shown above with `getTflArgFromString` and the convenience methods `setReturn` and `addArgument`. For example: | | arg = `getTflDWorkFromString(...
| |    'd1', 'void*')`;
| | hEnt.addDWorkArg(arg); |
| | arg = hEnt.getTflArgFromString(...
| |    'y1', 'void');
| | arg.IOType = 'RTW_IO_OUTPUT';
| | hEnt.Implementation.setReturn(arg); |
| | arg = hEnt.getTflArgFromString(...
| |    'u1', 'integer');
<p>| | hEnt.Implementation.addArgument(arg); |</p>
<table>
<thead>
<tr>
<th>If</th>
<th>Then</th>
</tr>
</thead>
<tbody>
<tr>
<td>You need to define several similar mappings, you want to minimize the code to write, and the entries do not require data alignment, use net slope arguments, or involve semaphore or mutex replacements.</td>
<td>Call <code>createCRLEntry</code> to create the entry and specify conceptual and implementation arguments in a single function call.</td>
</tr>
<tr>
<td></td>
<td><code>hEnt = createCRLEntry(hTable, ... 'double y1 = sin(double u1)', ... 'mySin');</code></td>
</tr>
</tbody>
</table>

The following code shows the third approach listed in the table for specifying the implementation output and input argument definitions for the `sin` function:

```plaintext
% Implementation Args
arg = hEnt.getTflArgFromString('y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);

arg = hEnt.getTflArgFromString('u1','double');
hEnt.Implementation.addArgument(arg);
```

**Add Entry to Table**

Add an entry to a code replacement table by calling the function `addEntry`.

```plaintext
addEntry(hTable, hEnt);
```

**Validate Entry**

After you create or modify a code replacement table entry, validate it by invoking it at the MATLAB command line. For example:

```plaintext
hTbl = crl_table_sinfcn
```

```plaintext
hTbl =
```
If the table includes errors, MATLAB reports them. The following examples shows how MATLAB reports a typo in a data type name:

```matlab
tbl = crl_table_sinfcn
??? RTW_CORE:tfl:TflTable: Unsupported data type, 'dooble'.
Error in ==> crl_table_sinfcn at 7
tbl.registerCFunctionEntry(100, 1, 'sin', 'dooble', 'sin_dbl', ...)
```

**Save Table**

Save the table definition file. Use the name of the table definition function to name the file, for example, `crl_table_sinfcn.m`.

Next, from your requirements, determine whether you need to specify build information for your replacement code.

Specify Build Information for Replacement Code

After you define code replacement mappings, determine whether you need to specify build information for your replacement code. A code replacement table entry can specify build information for the code generator to use when replacing code for a match. For example, specify files for implementation replacement code if you are using a generated makefile and the code generation software compiles the code.

Add build information to an entry:

• Interactively, by using the **Build Information** tab in the **Code Replacement Tool**.
• Programmatically, by using a MATLAB programming interface.

**Build Information**

The build information can include:

• Paths and file names for header files
• Paths and file names for source files
• Paths and file names for object files
• Compile flags
• Link flags

**Choose an Approach for Specifying Build Information**

The following table lists situations to help you decide when to use an interactive or programmatic approach to specifying build information:

<table>
<thead>
<tr>
<th>Situation</th>
<th>Approach</th>
</tr>
</thead>
<tbody>
<tr>
<td>Creating code replacement entries for the first time.</td>
<td>Code Replacement Tool.</td>
</tr>
<tr>
<td>You used the Code Replacement Tool to create the entries for which the build information applies.</td>
<td>Code Replacement Tool to specify the build information quickly.</td>
</tr>
<tr>
<td>Situation</td>
<td>Approach</td>
</tr>
<tr>
<td>-----------</td>
<td>----------</td>
</tr>
<tr>
<td>Rapid prototyping entries.</td>
<td>Code Replacement Tool to generate, register, and test entries quickly.</td>
</tr>
<tr>
<td>Developing an entry to use as a template or starting point for defining similar entries.</td>
<td>Code Replacement Tool to generate entry code that you can copy and modify.</td>
</tr>
<tr>
<td>Modifying existing mappings.</td>
<td>MATLAB Editor to update the programming interface directly.</td>
</tr>
</tbody>
</table>

- If an entry uses header, source, or object files, consider whether to make the files accessible to the code generator. You can copy files to the build folder or you can specify individual file names and paths explicitly.
- If you specify additional header files/include paths or source files/paths and you copy files, the compiler and utilities such as `packNGo` might find duplicate instances of files (an instance in the build folder and an instance in the original folder).
- If you choose to copy files to the build folder and you are using the `packNGo` function to relocate static and generated code files to another development environment:
  - In the call to `packNGo`, specify the property-value pair `'minimalHeaders' true` (the default). That setting instructs the function to include the minimal header files required to build the code in the zip file.
  - Do not collocate files that you copy with files that you do not copy. If the `packNGo` function finds multiple instances of the same file, the function returns an error.
  - If you use the programming interface, paths that you specify can include tokens. A token is a variable defined as a character vector or cell array of character vectors in the MATLAB workspace that you enclose with dollar signs (`$variable$`). The code generator evaluates and replaces a token with the defined value. For example, consider the path `$myfolder$\folder1`, where `myfolder` is a character vector variable defined in the MATLAB workspace as `'d:\work\source\module1'`. The code generator generates the custom path as `d:\work\source\module1\folder1`.

**Specify Build Information Interactively with the Code Replacement Tool**

The Code Replacement Tool provides a quick, easy way for you to specify build information for code replacement table entries. It is ideal for getting started with defining a table entry, rapid prototyping, and developing table entries to use as a starting point for defining similar mappings.
1 Determine the information that you must specify.
2 Open the Code Replacement Tool.
3 Select the code replacement table entry for which you want to specify the build information. In the left pane, select the table that contains the entry. In the middle pane, select the entry that you want to modify.
4 In the right pane, select the **Build Information** tab.
5 On the **Build Information** tab, specify your build information.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Specify</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Implementation header file</strong></td>
<td>File name and extension for the header file the code generator needs to generate the replacement code. For example, <strong>sin_double.h</strong>.</td>
</tr>
<tr>
<td><strong>Implementation source file</strong></td>
<td>File name and extension for the C or C++ source file the code generator needs to generate the replacement code. For example, <strong>sin_double.c</strong>.</td>
</tr>
<tr>
<td><strong>Additional header files/include paths</strong></td>
<td>Paths and file names for additional header files the code generator needs to generate the replacement code. For example, <strong>C:\libs\headerFiles</strong> and <strong>C:\libs\headerFiles\common.h</strong>. This parameter adds <strong>-I</strong> to the compile line in the generated makefile.</td>
</tr>
<tr>
<td><strong>Additional source files/paths</strong></td>
<td>Paths and file names for additional source files the code generator needs to generate the replacement code. For example, <strong>C:\libs\srcFiles</strong> and <strong>C:\libs\srcFiles\common.c</strong>. This parameter adds <strong>-I</strong> to the compile line in the generated makefile.</td>
</tr>
<tr>
<td><strong>Additional object files/paths</strong></td>
<td>Paths and file names for additional object files the linker needs to build the replacement code. For example, <strong>C:\libs\objFiles</strong> and <strong>C:\libs\objFiles\common.obj</strong>.</td>
</tr>
<tr>
<td><strong>Additional link flags</strong></td>
<td>Flags the linker needs to generate an executable file for the replacement code.</td>
</tr>
<tr>
<td><strong>Additional compile flags</strong></td>
<td>Flags the compiler needs to generate object code for the replacement code.</td>
</tr>
</tbody>
</table>
Parameter | Specify
--- | ---
Copy files to build directory | Whether to copy header, source, or object files, which are required to generate replacement code, to the build folder before code generation. If you specify files with Additional header files/include paths or Additional source files/paths and you copy files, the compiler and utilities such as packNGo might find duplicate instances of files.

6 Click Apply.
7 Select the Mapping Information tab. Scroll to the bottom of that table and click Validate entry. The tool validates the changes that you made to the entry.
8 Save the table that includes the entry that you just modified.

Specify Build Information Programmatically

The programming interface for specifying build information for a code replacement entry is ideal for:

- Modifying entries created with the Code Replacement Tool.
- Replicating and then modifying similar entries and tables.

The basic workflow for specifying build information programmatically is:

1 Identify or create the code replacement entry that you want to specify the build information.
2 Determine what information to specify.
3 Specify your build information.
<table>
<thead>
<tr>
<th>Specify</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Implementation header file</td>
<td>Use one of the following:</td>
</tr>
<tr>
<td></td>
<td>• Set properties ImplementationHeaderFile and ImplementationHeaderPath in a call to setTflCFunctionEntryParameters, setTflCOperationEntryParameters, or setTflCSemaphoreEntryParameters. For example:</td>

<td>- <code>hEnt.AdditionalCompileFlags = {'-MD -Gy', '-T'};</code></td>
</tr>
</tbody>
</table>
### Specify Build Information for Replacement Code

<table>
<thead>
<tr>
<th>Specify</th>
<th>Action</th>
</tr>
</thead>
</table>
| Whether to copy header, source, or object files, which are required to generate replacement code, to the build folder before code generation | Use one of the following:  
- Set property GenCallback to 'RTW.copyFileToBuildDir' in a call to setTflCFunctionEntryParameters, setTflCOperationEntryParameters, or setTflCSemaphoreEntryParameters. For example:  
```c
setTflCFunctionEntryParameters(hEnt, ...  
    'ImplementationHeaderFile', 'sin_dbl.h', ...  
    'ImplementationHeaderPath', 'D:/lib/headerFiles'  
    'Key',                      'sin', ...  
    'ImplementationName',       'sin_dbl'  
    'GenCallback',              'RTW.copyFileToBuildDir');
```
- Set argument genCallback in a call to registerCFunctionEntry, registerCPPFunctionEntry, or registerCPromotableMacroEntry to 'RTW.copyFileToBuildDir'.  
If a match occurs for a table entry, a call to the function RTW.copyFileToBuildDir copies required files to the build folder.  
If you specify additional header files/include paths or additional source files/paths and you copy files, the compiler and utilities such as packNGo might find duplicate instances of files. |

4. Save the table that includes the entry that you added or modified.

The following example defines a table entry for an optimized multiplication function that takes signed 32-bit integers and returns a signed 32-bit integer, taking saturation into account. Multiplications in the generated code are replaced with calls to the optimized function. The optimized function does not reside in the build folder. For the code generator to access the files, copy them into the build folder to be compiled and linked into the application.

The table entry specifies the source and header file names and paths. To request the copy operation, the table entry sets the genCallback property to 'RTW.copyFileToBuildDir' in the call to the setTflCOperationEntryParameters function. In this example, the header file s32_mul.h contains an inlined function that invokes assembly functions contained in s32_mul.s. If a match occurs for the table entry,
the function RTW.copyFileToBuildDir copies the specified source and header files to
the build folder for use during the remainder of the build process.

function hTable = make_my_crl_table

hTable = RTW.TflTable;

op_entry = RTW.TflCOperationEntry;
setTflCOperationEntryParameters(op_entry, ...
    'Key',                       'RTW_OP_MUL', ...
    'Priority',                   100, ...
    'SaturationMode',             'RTW_SATURATE_ON_OVERFLOW', ...
    'RoundingModes',              '{'RTW_ROUND_UNSPECIFIED'}', ...
    'ImplementationName',         's32_mul_s32_s32_sat', ...
    'ImplementationHeaderFile',   's32_mul.h', ...
    'ImplementationSourceFile',   's32_mul.s', ...
    'ImplementationHeaderPath',   {fullfile('$(MATLAB_ROOT)','crl')}, ...
    'ImplementationSourcePath',   {fullfile('$(MATLAB_ROOT)','crl')}, ...
    'GenCallback',                'RTW.copyFileToBuildDir');

.
.
addEntry(hTable, op_entry);

The following example uses the functions addAdditionalHeaderFile,
addAdditionalIncludePath, addAdditionalSourceFile,
addAdditionalSourcePath, addAdditionalLinkObj, and
addAdditionalLinkObjPath in addition to the code generation callback function
RTW.copyFileToBuildDir.

hTable = RTW.TflTable;

% Path to external source, header, and object files
libdir = fullfile('$(MATLAB_ROOT)','..', '..', 'lib');

op_entry = RTW.TflCOperationEntry;
setTflCOperationEntryParameters(op_entry, ...
    'Key',                       'RTW_OP_ADD', ...
    'Priority',                   90, ...
    'SaturationMode',             'RTW_SATURATE_UNSPECIFIED', ...
    'RoundingModes',              '{'RTW_ROUND_UNSPECIFIED'}', ...
    'ImplementationName',         's32_add_s32_s32_sat', ...
    'ImplementationHeaderFile',   's32_add_s32_s32.h', ...
    'ImplementationSourceFile',   's32_add_s32_s32.c'...
    'GenCallback',                'RTW.copyFileToBuildDir');

addAdditionalHeaderFile(op_entry, 'all_additions.h');
addAdditionalIncludePath(op_entry, fullfile(libdir, 'include'));
addAdditionalSourceFile(op_entry, 'all_additions.c');
addAdditionalSourcePath(op_entry, fullfile(libdir, 'src'));
addAdditionalLinkObj(op_entry, 'addition.o');
addAdditionalLinkObjPath(op_entry, fullfile(libdir, 'bin'));

.
addEntry(hTable, op_entry);

Next, include your code replacement table in a code replacement library and register the library with the code generator.

- “Develop a Code Replacement Library” on page 54-27
- “What Is Code Replacement Customization?” on page 54-3
Register Code Replacement Mappings

After you define code replacement entries and specify build information in a code replacement table, you can include the table in a code replacement library that you register with the code generator. When registered, a library appears in the list of available code replacement libraries that you can choose from when configuring the code generator.

Register a code replacement table as a code replacement library:

- Interactively, by using the Code Replacement Tool
- Programmatically, by using a MATLAB programming interface

Choose an Approach for Creating the Registration File

The following table lists situations to help you decide when to use an interactive or programmatic approach to creating a registration file:

<table>
<thead>
<tr>
<th>If...</th>
<th>Then...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Registering a code replacement table for the first time</td>
<td>Use the Code Replacement Tool.</td>
</tr>
<tr>
<td>You used the Code Replacement Tool to create the table</td>
<td>Use the Code Replacement Tool to quickly register the table.</td>
</tr>
<tr>
<td>Rapid prototyping code replacement</td>
<td>Use the Code Replacement Tool to quickly generate, register, and test entries.</td>
</tr>
<tr>
<td>Creating registration file to use as a template or starting point for defining similar registration files</td>
<td>Use the Code Replacement Tool to generate code that you can copy and modify.</td>
</tr>
<tr>
<td>Modifying existing registration files</td>
<td>Use the MATLAB Editor to update the registration file.</td>
</tr>
<tr>
<td>Defining multiple code replacement libraries in one registration file</td>
<td>Use the MATLAB Editor to create a new or extend an existing registration file.</td>
</tr>
<tr>
<td>Defining code replacement library hierarchy in a registration file</td>
<td>Use the MATLAB Editor to create a new or extend an existing registration file.</td>
</tr>
</tbody>
</table>
Create Registration File Interactively with the Code Replacement Tool

The Code Replacement tool provides a quick, easy way for you to create a registration file for a code replacement table. It is ideal for getting started, rapid prototyping, and generating a registration file that you want to use as a starting point for similar registrations.

1. After you validate and save a code replacement table, select File > Generate registration file to open the Generate registration file dialog box.

2. Enter the registration information. Minimally, specify:

<table>
<thead>
<tr>
<th>For...</th>
<th>Specify...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Registry name</td>
<td>Text naming the code replacement library. For example, Sin Function Example.</td>
</tr>
</tbody>
</table>
For... | Specify...
--- | ---
Table list | Text naming one or more code replacement tables to include in the library. Specify each table as one of the following:

- Name of a table file on the MATLAB search path
- Absolute path to a table file
- Path to a table file relative to $(MATLAB_ROOT)$

You can specify multiple tables. If you do, separate the table specifications with a comma. For example:

crl_table_sinfcn, c:/work_crl/crl_table_muldiv

See “Registration Files That Define Multiple Code Replacement Libraries” on page 55-62 for examples of each type of table specification.

Optionally, you can specify:

<table>
<thead>
<tr>
<th>For...</th>
<th>Specify...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Description</td>
<td>Text that describes the purpose and content of the library.</td>
</tr>
<tr>
<td>Target HW device</td>
<td>Text naming one or more hardware devices the code replacement library supports. Separate names with a comma. To support all device types, enter an asterisk (*). For example, TI C28x, TI C62x.</td>
</tr>
<tr>
<td>Base CRL</td>
<td>Text naming a code replacement library that you want to serve as a base library for the library you are registering. Use this field to specify library hierarchies. For example, you can specify a general TI device library as the base library for a more specific TI C28x device library.</td>
</tr>
<tr>
<td>Generate data alignment specification</td>
<td>Flag that enables data alignment specification.</td>
</tr>
</tbody>
</table>
Create Registration File Programmatically

The programming interface for creating a registration file for a code replacement table is ideal for:

- Modifying registration files created with the Code Replacement Tool
- Replicating and modifying similar registration files
- Defining multiple code replacement libraries in one registration file

The basic workflow for creating a registration file programmatically consists of the following steps:

1. Define an `rtwTargetInfo` function. The code generator recognizes this function as a customization file. The function definition must include at least the following content:

   ```
   function rtwTargetInfo(cm)
   
   cm.registerTargetInfo(@loc_register_crl);
   
   function this = loc_register_crl
   
   this(1) = RTW.TflRegistry;
   this(1).Name = 'crl-name';
   this(1).TableList = {'table',...};
   ```

<table>
<thead>
<tr>
<th>For...</th>
<th>Replace...</th>
</tr>
</thead>
<tbody>
<tr>
<td>this(1).Name = 'crl-name';</td>
<td><code>crl-name</code> with text naming the code replacement library. For example, Sin Function Example.</td>
</tr>
</tbody>
</table>
For... | Replace...
---|---
this(1).TableList = {'table',...}; | *table* with text that identifies the code replacement table that contains your code replacement entries. Specify a table as one of the following:
- Name of a table file on the MATLAB search path
- Absolute path to a table file
- Path to a table file relative to $MATLAB_ROOT$

You can specify multiple tables. If you do, separate the table specifications with commas.

Optionally, you can specify:

For... | Replace...
---|---
this(1).Description = 'text' | *text* with text that describes the purpose and content of the library.

this(1).TargetHWDeviceType = {'device-type',...} | *device-type* with text that names a hardware device the code replacement library supports. You can specify multiple device types. Separate device types with a comma. For example, TI C28x, TI C62x. To support all device types, enter an asterisk (*).
<table>
<thead>
<tr>
<th>For...</th>
<th>Replace...</th>
</tr>
</thead>
<tbody>
<tr>
<td>this(1).BaseTfl = 'base-lib'</td>
<td><em>base-lib</em> with text that names a code replacement library that you want to serve as a base library for the library you are registering. Use this field to specify library hierarchies. For example, you can specify a general TI device library as the base library for a TI C28x device library. See “Registration Files That Define Code Replacement Library Hierarchies” on page 55-62 for an example.</td>
</tr>
</tbody>
</table>

For example:

```matlab
function rtwTargetInfo(cm)
    cm.registerTargetInfo(@loc_register_crl);

function this = loc_register_crl
    this(1) = RTW.TflRegistry;
    this(1).Name = 'Sin Function Example';
    this(1).TableList = {'crl_table_sinfnc'};
    this(1).TargetHWDeviceType = {'*'};
    this(1).Description = 'Example - sin function replacement';

Save the file with the name rtwTargetInfo.m.

Place the file on the MATLAB path. When the file is on the MATLAB path, the code generator reads the file after starting and applies the customizations during the current MATLAB session.

Register a Code Replacement Library

Before you can use the code replacement tables defined in a registration file, refresh Simulink customizations within the current MATLAB session. To initiate a refresh, enter the following command:

```matlab
sl_refresh_customizations
```
Register a Library that Includes Multiple Code Replacement Tables

Use the programming interface to create a registration file that defines a code replacement library that includes multiple code replacement tables. The following example defines a library that includes multiple tables. The TableList fields specify tables that reside at different locations. The tables reside on the MATLAB search path or at locations specified with a path.

```matlab
function rtwTargetInfo(cm)
    cm.registerTargetInfo(@locCrlRegFcn);

function thisCrl = locCrlRegFcn

% Register a code replacement library for use with model: rtwdemo_crladdsub
thisCrl(1) = RTW.TflRegistry;
thisCrl(1).Name = 'Addition & Subtraction Examples';
thisCrl(1).Description = 'Example of addition/subtraction op replacement';
thisCrl(1).TableList = {'crl_table_addsub'};
thisCrl(1).TargetHWDeviceType = {'*'};

% Register a code replacement library for use with model: rtwdemo_crlmuldiv
thisCrl(2) = RTW.TflRegistry;
thisCrl(2).Name = 'Multiplication & Division Examples';
thisCrl(2).Description = 'Example of mult/div op repl for built-in integers';
thisCrl(2).TableList = {'c:/work_crl/crl_table_muldiv'};
thisCrl(2).TargetHWDeviceType = {'*'};

% Register a code replacement library for use with model: rtwdemo_crlfixpt
thisCrl(3) = RTW.TflRegistry;
thisCrl(3).Name = 'Fixed-Point Examples';
thisCrl(3).Description = 'Example of fixed-point operator replacement';
thisCrl(3).TableList = {fullfile('$(MATLAB_ROOT)', ...
    'toolbox','rtw','rtwdemos','crl_demo','crl_table_fixpt')};
thisCrl(3).TargetHWDeviceType = {'*'};
```

Registration Files That Define Code Replacement Library Hierarchies

Using the programming interface, you can organize multiple code replacement libraries in a hierarchy. The following example shows a registration file that defines four code replacement tables organized in a hierarchy of four code replacement libraries. The tables include entries that increase in specificity: common entries, entries for TI devices, entries for TI C6xx devices, and entries specific to the TI C67x device.

```matlab
function rtwTargetInfo(cm)
```
after registering your code replacement mappings, verify that code replacements occur.

**More About**

- “Troubleshoot Code Replacement Library Registration” on page 54-78
- “Specify Build Information for Replacement Code” on page 54-61
- “Verify Code Replacements” on page 54-79
- “Develop a Code Replacement Library” on page 54-27
- “What Is Code Replacement Customization?” on page 54-3
Troubleshoot Code Replacement Library Registration

If a code replacement library is not listed as a configuration option or does not appear in the Code Replacement Viewer:

- Refresh the library registration information within the current MATLAB session (RTW.TargetRegistry.getInstance('reset'); or for the Simulink environment, sl_refresh_customizations).
- See whether the registration file, rtwTargetInfo.m, contains an error.

See Also

More About
- “Register Code Replacement Mappings” on page 54-70
Verify Code Replacements

After you create or modify and register a code replacement table, use the following techniques to examine and verify the table and its entries.

- Invoke the table definition file at the command prompt.
- Use the Code Replacement Viewer to examine libraries, tables, and entries.
- Trace code replacements from the source where you applied the code replacement library.
- Examine code replacement hits and misses logged during code generation.

Code Replacement Hits and Misses

The code generator logs code replacement table entries for which it finds and does not find matches in the hit cache and miss cache, respectively. When a code replacement entry match fails and code is not replaced, the code generator logs the call site object (CSO) for the miss in the miss cache. When an entry match succeeds, the code generator logs the matched entry in the hit cache.

The code generator overwrites the hit and miss cache data each time it produces code. The cache data reflects hits and misses for only the last application component (MATLAB code or Simulink model) for which you generate code.

You can use the Code Replacement Viewer to review trace information based on logged hit and miss trace data. The hit cache provides trace information that helps to verify code replacements.

The miss cache and related miss data collected and stored in code replacement tables provide trace information for misses. Use this information for misses to troubleshoot expected code replacements that do not occur. Trace information for a miss:

- Identifies the call site object.
- Provides a link to the relevant source location for the miss.
- Includes information about the reason for the miss.
Validate Table Definition File

After you create or modify a code replacement table definition file, validate it. At the command prompt, specify the name of the table in a call to the `isValid` function. For example:

```matlab
isValid(crl_table_sinfcn)
```

```matlab
ans =

1
```

MATLAB displays errors that occur. In the following example, MATLAB detects a typo in a data type name.

```matlab
isValid(crl_table_sinfcn)
```

```matlab
??? RTW_CORE:tfl:TflTable: Unsupported data type, 'dooble'.
```

```matlab
Error in ==> crl_table_sinfcn at 7
hTable.registerCFunctionEntry(100, 1, 'sin', 'dooble', 'sin_dbl', ...)
```

Review Library Content

After you create or modify a code replacement library, use the Code Replacement Viewer to review and verify the list of tables in the library and the entries in each table.

1. Open the viewer to display the contents of your library. At the command prompt, enter the following command:

```matlab
crviewer('library')
```

For example:

```matlab
crviewer('Addition & Subtraction Examples')
```
Review the list of tables in the left pane. Are tables missing? Are the tables listed in the correct relative order? By default, the viewer displays tables in search order.

In the left pane, click each table and review the list of entries in the center pane. Are entries missing? Does the list include extraneous or unexpected entries?
Review Table Content

After you create or modify a code replacement table, use the **Code Replacement Viewer** to review and verify table entries.

1. Open the viewer to display the contents of your table. At the command prompt, enter the following command. *table* is a MATLAB file that defines code replacement tables. The file must be in the current folder or on the MATLAB path.

   \[
   \text{crviewer(table)}
   \]

   For example:

   \[
   \text{crviewer(crl_table_addsub)}
   \]
2  Review the list of entries in the center pane. Are entries missing? Does the list include extraneous or unexpected entries? By default, the viewer displays entries in search order.

3  In the center pane, click each entry and verify the entry information in the right pane.
• Argument order is correct.
• Conceptual argument names match code generator naming conventions.
• Implementation argument names are correct.
• Algorithm properties (for example, saturation and rounding mode) are set correctly.
• Header or source file specification is not missing.
• I/O types are correct.
• Relative priority of entries is correct.

Review Code Replacements

After you review the content of your code replacement library and tables, generate code and a code generation report. Verify that the code generator replaces code as you expect.

The Code Replacements Report details the code replacement library functions that the code generator uses for code replacements. The report provides a mapping between each replacement instance and the model element that triggered the replacement.

The following example illustrates two complementary approaches to reviewing code replacements:

• Check the Code Replacements Report section of the code generation report for expected replacements.
• Trace code replacements.

For models that consist of model hierarchies, repeat the following procedure for each model in the hierarchy. Generate code for and review the trace information of each referenced model separately. Logged cache hit and miss information captured in the Code Replacement Viewer is valid for the last model for which code was generated. As you generate code for each model in the hierarchy, the code generator overwrites logged information.

1 Open the model where you anticipate that a function or operator replacement occurs. This example uses the model rtwdemo_crladdsub.
2 Configure the code generator to use your code replacement library. For this example, set the library to Addition & Subtraction Examples.
3 Configure the code generation report to include the Code Replacements Report. On the Code Generation > Report pane, select Create code generation report and Open report automatically. In the Advanced parameters section, select Model-to-code and Summarize which blocks triggered code replacements.
Configure comments for the generated code. On the Code Generation > Comments pane, select:

- **Include comments**
- Either or both of **Simulink block comments** and **Simulink block descriptions**

In the **Code Replacements Report**, these options include Simulink block information.

Configure the code generator to generate only code. Before you build an executable file, review your code replacements in the generated code.

Generate code and a report.

Open the **Code Replacements Report** section of the code generation report.

The report lists the replacement functions that the code generator used. It provides a mapping between each replacement instance and the Simulink block that triggered the replacement.
Review the report:

- Check whether expected function and operator code replacements occurred.
- In the replacements sections, click each block link to see the source that triggered the reported code replacement.

In the Simulink model window, use model-to-code highlighting to trace code replacements. Identify and right-click a block where you expected code replacement to occur. Select **C/C++ Code > Navigate to C/C++ Code**. The code generation report appears with the corresponding replacement code highlighted. In the example model `rtwdemo_crladdsub`, right-click the Add8 block and select **C/C++ Code > Navigate to C/C++ Code**.

```c
24 /* Real-time model */
25 RT_MODEL rtM;
26 RT_MODEL *const rtM = &rtM;
27
28 /* Model step function */
29 void rtwdemo_crladdsub_step(void)
30 {
31    /* Outport: '<Root>/Out1' incorporates:
32       * Inport: '<Root>/In1'
33       * Inport: '<Root>/In3'
34       * Sum: '<Root>/Add8'
35      */
36    rty.Out1 = u8_add_u8_u8(rtu.In1, rtU.In2);
37
38    /* Outport: '<Root>/Out2' incorporates:
39       * Inport: '<Root>/In3'
40       * Inport: '<Root>/In4'
41       * Sum: '<Root>/Add16'
42      */
43    rty.Out2 = u16_add_u16_u16(rtu.In3, rtU.In4);
```

Inspect the generated code to see if the function or operator replacement occurred as you expected.

If a function or operator is not replaced as expected, the code generator used a higher-priority (lower-priority value) match or did not find a match.
To analyze and troubleshoot code replacement misses, use the trace information that the Code Replacement Viewer provides. See “Troubleshoot Code Replacement Misses” on page 54-89.

Next, deploy your code replacement library for others to use.

More About

• “Troubleshoot Code Replacement Misses” on page 54-89
• “Register Code Replacement Mappings” on page 54-70
• “Deploy Code Replacement Library” on page 54-96
• “What Is Code Replacement Customization?” on page 54-3
Troubleshoot Code Replacement Misses

Use miss reason messages that appear in the Code Replacement Viewer to analyze and correct code replacement misses.

Miss Reason Messages

The Code Replacement Viewer displays miss reason messages in trace information for code replacement misses. A legend listing each message that appears in the miss report precedes the report details. A message consists of:

- Numeric identifier, which identifies the message in the report details.
- Message text, which in some cases includes placeholders for names of arguments, call site object values, table entry values, and property names.

For example:

1. Mismatched data types (argument name, CSO value, table entry value)

The parenthetical information represents placeholders for actual values that appear in the report details.

In the Miss Source Locations table that lists the miss details, the Reason column includes:

- The message identifier, as listed in the legend.
- The placeholder values for that instance of the miss reason message.

The following Reason details indicate a data type mismatch because the call site object specifies data type int8 for arguments y1, u1, and u2, while the code replacement table entry specifies uint32.

1. y1, int8, uint32
   u1, int8, uint32
   u2, int8, uint32

Depending on your situation and the reported miss reason, troubleshoot reported misses by looking for instances of the following:

- A typo in the code replacement table entry definition or a source parameter setting.
• Information missing from the code replacement table entry or a source parameter setting.
• Invalid or incorrect information in the code replacement table entry definition or a source parameter setting.
• Arguments incorrectly ordered in the code replacement table entry definition or the source being replaced with replacement code.
• Failed algorithm classification for an addition or subtraction operation due to:
  • An ideal accumulator not being calculated because the type of an input argument is not fixed-point or the slope adjustment factors of the input arguments are not equal.
  • Input or output casts with a floating-point cast type.
  • Input or output casts with cast types that have different slope adjustment factors or biases.
  • Output casts not being convertible to a single output cast.
  • Input casts resulting in loss of bits.

### Analyze and Correct Code Replacement Misses

The following example shows how to use Code Replacement Viewer trace information to troubleshoot code replacement misses. You must have already reviewed and tested code replacements for your model.

1. Review the code generated for a model element, looking for expected code replacements. For this example, examine the code generated for block Sub32 in model rtwdemo_crladdsub. Right-click the block and select **C/C++ Code > Navigate to C/C++ Code**.

   ```matlab
   63 /* Output: 'crladdsub/Sub32' incorporates:
   64 * Import: 'crladdsub/In10'
   65 * Import: 'crladdsub/In'
   66 * Sum: 'crladdsub/Sub1'
   67 */
   68 rtw.Out5 = rtw_sub_s32_s32(rtw.In9, rtw.In10);
   
   The Code Generation Report opens to the location of the generated code for that block.
   
   The code generator replaced code, but the replacement was for the signed version of the 32-bit subtraction operation. You expected an unsigned operation.
2 Regenerate or reopen the Code Replacements Report for your model. If you already generated the code generation report that includes the Code Replacements Report for model `rtwdemo_crladdsub`, open the file `rtwdemo_crladdsub_ert_rtw/html/rtwdemo_crladdsub_codegen_rpt.html`. For information on how to regenerate the report, see “Review Code Replacements” on page 54-85.

3 Click the link to open the Code Replacement Viewer.

4 In the viewer left pane, select your code replacement table. The following display shows entries for code replacement table `crl_table_addsub`.

5 In the middle pane, select table entry `RTW_OP_MINUS` with implementation function `u32_sub_u32_u32`.

6 In the right pane, select the **Trace Information** tab.
The **Trace Information** is a table that lists the following information for each miss:

- Call site object preview. The call site object is the conceptual representation of a subtraction operator. The code generator uses this object to query the code replacement library for a match.
- A link to the source location in the model for which the code generator considered replacing code.
- The reasons that the miss occurred. For the list of reasons that misses occur, see “Miss Reason Messages” on page 54-89.

For this example, the report shows misses for two blocks: Sub32 and Sub8.

7 Find that source in the trace information. Depending on your situation and the reported miss reason, consider looking for a condition such as a typo in the code replacement table entry definition or in a source parameter setting. “Miss Reason Messages” on page 54-89 lists conditions to consider.

For this example, determine why code for the Sub32 block was not replaced with code for an unsigned 32-bit subtraction operation. The miss reason for the Sub32 block indicates a data type mismatch. The data type in the call site object for the three arguments is a signed 32-bit integer. The code replacement entry specifies an unsigned 32-bit integer.

8 Correct the model or code replacement table entry. If the issue is in the model, use the source location link in the trace information to find the model element to correct. For this example, you expected an unsigned subtraction operation for the Sub32 block. Click the link in the trace report for the Sub32 block.

The model opens with the Sub32 block highlighted.
Change the data type setting for the two input signals and the output signal for the Sub32 block to `uint32`.

9. Regenerate code. Use the Code Replacement Viewer trace information to verify that your model or code replacement table entry corrects the code replacement issue. In the following display, the trace information shows a hit for block Sub32.

Deploy Code Replacement Library

After you verify code replacements and are ready to package and deploy a code replacement library for others to use:

1. Move your code replacement table files to an area that is on the MATLAB search path and that is accessible to and shared by other users.
2. Move the `rtwTargetInfo.m` registration file, to an area that is on the MATLAB search path and that is accessible to and shared by other users. If you are deploying a library to a folder in a development environment that already contains a `rtwTargetInfo.m` file, copy the registration code from your code replacement library version of `rtwTargetInfo.m` and paste it into the shared version of that file.
3. Register the library customizations or restart MATLAB.
4. Verify that the libraries are available for configuring the code generator and that code replacements occur as expected.
5. Inform users that the libraries are available and provide direction on when and how to apply them.

**Math Function Code Replacement**

This example shows how to define a code replacement mapping for a math function. The example defines a mapping for the `sin` function programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```matlab
   function hTable = crl_table_sinfcn2()
   %CRL_TABLE_SINFCN2 - Define function entry for code replacement table.
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```matlab
   hTable = RTW.TflTable;
   ```

3. Create an entry for the function mapping with a call to the `RTW.TflCFunctionEntry` function.

   ```matlab
   % Create entry for sin function replacement
   fcn_entry = RTW.TflCFunctionEntry;
   ```

4. Set function entry parameters with a call to the `setTflCFunctionEntryParameters` function.

   ```matlab
   setTflCFunctionEntryParameters(fcn_entry, ...
   'Key',                      'sin', ...
   'Priority',                 30, ...
   'ImplementationName',       'mySin', ...
   'ImplementationHeaderFile', 'basicMath.h',...
   'ImplementationSourceFile', 'basicMath.c');
   ```

5. Create conceptual arguments `y1` and `u1`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call.

   ```matlab
   createAndAddConceptualArg(fcn_entry, 'RTW.TflArgNumeric', ...
   'Name',         'y1',...
   'IOType',       'RTW_IO_OUTPUT',...
   'DataTypeMode', 'double');
   ```

   ```matlab
   createAndAddConceptualArg(fcn_entry, 'RTW.TflArgNumeric', ...
   'Name',         'u1',...
   'IOType',       'RTW_IO_INPUT',...
   'DataTypeMode', 'double');
   ```

6. Copy the conceptual arguments to the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses a call to the `copyConceptualArgsToImplementation` function to create and add implementation arguments to the entry by copying matching conceptual arguments.
copyConceptualArgsToImplementation(fcn_entry);

7 Add the entry to a code replacement table with a call to the addEntry function.

addEntry(hTable, fcn_entry);

8 Save the table definition file. Use the name of the table definition function to name the file.

Memory Function Code Replacement

This example shows how to define a code replacement mapping for a memory function. The example defines a mapping for the `memcpy` function programmatically. Alternatively, you can use the **Code Replacement Tool** to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```matlab
   function hTable = crl_table_memcpy()
   ``

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```matlab
   hTable = RTW.TflTable;
   ``

3. Create an entry for the function mapping with a call to the `RTW.TflCFunctionEntry` function.

   ```matlab
   % Create entry for void* memcpy(void*, void*, size_t)
   fcn_entry = RTW.TflCFunctionEntry;
   ``

4. Set function entry parameters with a call to the `setTflCFunctionEntryParameters` function.

   ```matlab
   setTflCFunctionEntryParameters(fcn_entry, ... 
   'Key',                      'memcpy', ... 
   'Priority',                 90, ... 
   'ImplementationName',       'memcpy_int', ... 
   'ImplementationHeaderFile', 'memcpy_int.h',... 
   'SideEffects',              true);
   ``

5. Create conceptual arguments `y1`, `u1`, `u2`, and `u3`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create and add the arguments.

   ```matlab
   arg = getTflArgFromString(hTable, 'y1', 'void*');
   arg.IOType = 'RTW_IO_OUTPUT';
   addConceptualArg(fcn_entry, arg);
   arg = getTflArgFromString(hTable, 'u1', 'void*');
   addConceptualArg(fcn_entry, arg);
   arg = getTflArgFromString(hTable, 'u2', 'void*');
   addConceptualArg(fcn_entry, arg);
   arg = getTflArgFromString(hTable, 'u3', 'size_t');
   addConceptualArg(fcn_entry, arg);
   ``

6. Copy the conceptual arguments to the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses a call to the
copyConceptualArgsToImplementation function to create and add implementation arguments to the entry by copying matching conceptual arguments.

copyConceptualArgsToImplementation(fcn_entry);

7 Add the entry to a code replacement table with a call to the `addEntry` function.

addEntry(hTable, fcn_entry);

8 Save the table definition file. Use the name of the table definition function to name the file.

To test this example:

1 Register the code replacement mapping.

2 Create a model that uses the `memcpy` function for vector assignments. For example, use In, Out, and Mux blocks to create the following model. (Alternatively, open the example model `rtwdemo_crlmath` and copy the contents of Subsystem1 to a new model.)

3 Select the diagram and use **Edit > Subsystem** to make it a subsystem.

4 Configure the subsystem with the following settings:

   • On the **Solver** pane, select a fixed-step solver.
   • On the **Optimization** pane, select **Use memcpy for vector assignment** and set **Memcpy threshold (bytes)** to 64.
   • On the **Code Generation** pane, select an ERT-based system target file.
   • On the **Code Generation > Interface** pane, select the code replacement library that contains your memory function entry.
5 In the Model Explorer, configure the **Signal Attributes** for the In1, In2, and In3 source blocks. For each, set **Port dimensions** to \([1, 100]\), and set **Data type** to int32. Apply the changes. Save the model.

6 Generate code and a code generation report.

7 Review the code replacements.

Nonfinite Function Code Replacement

This example shows how to define a code replacement mapping for nonfinite utility functions.

1. Create a table definition file that contains a function definition. For example:

```matlab
function hTable = crl_table_nonfinite()
```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

```matlab
hTable = RTW.TflTable;
```

3. Create entries for the function mappings. To minimize the size of this function, the example uses a local function, `locAddFcnEnt`, to group lines of code repeated for each entry. A call to the `RTW.TflCFunctionEntry` function creates an entry for the collection of local function entry definitions.

```matlab
%% Create entries for nonfinite utility functions
% locAddFcnEnt(hTable, key, implName, out, in1, hdr)
locAddFcnEnt(hTable, 'getNaN', 'getNaN', 'double', 'void', 'nonfin.h');
locAddFcnEnt(hTable, 'getNaN', 'getNaNF', 'single', 'void', 'nonfin.h');
locAddFcnEnt(hTable, 'getInf', 'getInf', 'double', 'void', 'nonfin.h');
locAddFcnEnt(hTable, 'getInf', 'getInfF', 'single', 'void', 'nonfin.h');
locAddFcnEnt(hTable, 'getMinusInf', 'getMinusInf', 'double', 'void', 'nonfin.h');
locAddFcnEnt(hTable, 'getMinusInf', 'getMinusInfF', 'single', 'void', 'nonfin.h');

%% Local Function
function locAddFcnEnt(hTable, key, implName, out, in1, hdr)
    if isempty(hTable)
        return;
    end
    fcn_entry = RTW.TflCFunctionEntry;
    setTflCFunctionEntryParameters(fcn_entry, ...
        'Key', key, ...
        'Priority', 90, ...
        'ImplementationName', implName, ...
        'ImplementationHeaderFile', hdr);

4. Set function entry parameters with a call to the `setTflCFunctionEntryParameters` function.

```matlab
setTflCFunctionEntryParameters(fcn_entry, ...
    'Key', key, ...
    'Priority', 90, ...
    'ImplementationName', implName, ...
    'ImplementationHeaderFile', hdr);
```

5. Create conceptual arguments `y1` and `u1`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create and add the arguments.

```matlab
arg = getTflArgFromString(hTable, 'y1', out);
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(fcn_entry, arg);
```
arg = getTflArgFromString(hTable, 'u1', in1);
addConceptualArg(fcn_entry, arg);

6 Copy the conceptual arguments to the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses a call to the copyConceptualArgsToImplementation function to create and add implementation arguments to the entry by copying matching conceptual arguments.

copyConceptualArgsToImplementation(fcn_entry);

7 Add the entry to a code replacement table with a call to the addEntry function.

addEntry(hTable, fcn_entry);

8 Save the table definition file. Use the name of the table definition function to name the file.

To test this example:

1 Register the code replacement mapping.

2 Create a model that uses a nonfinite function. For example, create a model that includes a Math Function block that is set to the rem function. For example:

3 Configure the model with the following settings:

   • On the Solver pane, select a fixed-step solver.
   • On the Code Generation pane, select an ERT-based system target file.
   • On the Code Generation > Interface pane, select the code replacement library that contains your memory function entry and select Support: non-finite numbers.

4 In the Model Explorer, configure the Signal Attributes for the In1 and Constant source blocks. For each source block, set Data type to double. Apply the changes. Save the model.

5 Generate code and a code generation report.

6 Review the code replacements.

Semaphore and Mutex Function Replacement

You can create a code replacement table for a custom target that supports concurrent execution. Create table entries that specify custom implementations of semaphore or mutex operations. The table must have four semaphore entries, four mutex entries, or both, and include the table in a custom code replacement library. (The semaphore or mutex entries are mutually dependent. Provide them in complete sets of four.)

Note A custom target that supports concurrent multitasking must set the target configuration parameter ConcurrentExecutionCompliant. For more information, see “Support Concurrent Execution of Multiple Tasks” (Simulink Coder).

If the build process generates semaphore or mutex function calls for data transfer between tasks during code generation for a multicore target environment, use a custom library. The library can specify code replacements for custom semaphore or mutex implementations that are optimal for your target environment. Using the Code Replacement Tool (crtool) or equivalent code replacement functions, you can:

- Configure code replacement table entries for custom semaphore or mutex functions. During system startup, execution of the code for data transfer between tasks, and system shutdown the generated code calls these functions.
- Configure DWork arguments that represent global data, which the semaphore or mutex functions access. A DWork pointer is passed to the model entry functions.

Generated mutex and semaphore code typically consists of these elements:

<table>
<thead>
<tr>
<th>Code</th>
<th>Generated Code</th>
</tr>
</thead>
<tbody>
<tr>
<td>Model initialization</td>
<td>Initialization function call that creates a mutex or semaphore function to control entry to a critical section of code.</td>
</tr>
</tbody>
</table>
| Model step            | - Before code for a data transfer between tasks enters the critical section, mutex lock or semaphore wait function calls reserve the critical section of code.  
                        | - After code for a data transfer between tasks finishes executing the critical section, mutex unlock or semaphore post function calls release the critical section of code. |
This example shows how to create code replacement table entries for a mutex replacement scenario. You configure a multicore target model for concurrent execution and for data transfer between tasks of differing rates, which Rate Transition blocks handle. In the generated code for the model, each Rate Transition block has a separate, unique mutex. Mutex lock and unlock operations within the Rate Transition block generated code share access to the same global data. They achieve this by using the unique mutex created for that Rate Transition block.

1. Open the Code Replacement Tool.
2. Create and open a new table.
3. Name the table `crl_table_rt_mutex`.
4. Create an entry for a mutex initialization function replacement.
   a. Select File > New entry > Semaphore entry to open a new table entry for configuring a semaphore or mutex replacement.
   b. In the Mapping Information tab, use the Function parameter to select Mutex Init. Initial default values for the table entry appear. In the Conceptual function section, typically you can leave the argument settings at their defaults.
   c. In the DWork attributes section, the Allocate DWork option is selected. The dialog box provides a unique entry tag for the DWork argument `d1`.

<table>
<thead>
<tr>
<th>Code</th>
<th>Generated Code</th>
</tr>
</thead>
<tbody>
<tr>
<td>Model termination</td>
<td>Optional destroy function call to delete the mutex or semaphore explicitly.</td>
</tr>
</tbody>
</table>
On the **DWork attributes** pane, configure a DWork argument to the replacement function. The DWork argument supports sharing of a semaphore or mutex between:

- Code that creates the semaphore or mutex
- Code that requests and relinquishes access
- Code that deletes the semaphore or mutex

In this example, the DWork argument for the **Mutex Init** function defines a unique entry tag, `entry_25576`. That function also defines DWork arguments for **Mutex Lock**, **Mutex Unlock**, and **Mutex Destroy**, which reference the entry tag to share the DWork data.

The only data type supported for the DWork **Data type** parameter is `void*`.

In the **Replacement function** section, enter a function name in the **Name** field. This example uses `myMutexCreate`. In the list of **Function arguments**, leave the DWork argument `d1` data type as `void**`.

The C function signature preview is:

```c
void myMutexCreate (void** d1);
```
e In the **Replacement function** section, select **Function modifies internal or global state**. This option instructs the code generator not to optimize away the implementation function described by this entry because it accesses global memory values. Click **Apply**. Optionally, you can click **Validate entry** to validate the information entered in the **Mapping Information** tab.

To create a sample table entry, configure the replacement function signature without the replacement function and its build information. If header and source files for these functions are available, select the **Build Information** table to specify them.

f The Mutex Init table entry is complete. Optionally, you can save the table to a file, and inspect the MATLAB code created for the table definition so far.

5 Repeat the following sequence to create the table entries for the mutex lock, unlock, and destroy function replacements. Each table entry references the DWork unique tag entry, entry_25576, defined in the Mutex Init table entry.

a Select **File > New entry > Semaphore entry**.

b In the **Mapping Information** tab, use the **Function** parameter to select Mutex Lock, Mutex Unlock, or Mutex Destroy. Initial default values for the table entry appear. In the **Conceptual function** section, typically you can leave the argument settings at their defaults.

c For a Rate Transition block mutex, the wait, post, and destroy functions operate on the DWork allocated at system startup by the mutex initialization function. In the **DWork attributes** section, verify that the **Allocate DWork** option is cleared. From the **DWork Allocator entry** drop-down list, select the entry tag matching the value in the Mutex Init table entry. In this example, the entry tag is entry_25576.

d In the **Replacement function** section, **Name** field, enter a function name. This example uses myMutexLock, myMutexUnlock, and myMutexDelete. In the list of **Function arguments**, leave the DWork argument d1 data type as **void**

```
In the **Implementation attributes** section, select the option **Function modifies internal or global state**. This option instructs the code generator not to optimize away the implementation function described by this entry because it accesses global memory values.

Optionally, supply build information for the replacement function on the **Build Information** tab.

Click **Apply**. In the middle pane, right-click the table entry and select **Validate entry(s)**.

When you have added the table entries for **Mutex Lock**, **Mutex Unlock**, and **Mutex Destroy** to the entry for **Mutex Init**, the rate transition mutex replacement table is complete. In the left-most pane, right-click the table name and select **Validate table**. Address errors and repeat the table validation.
Save the table to a MATLAB file in your working folder, for example, using File > Save table. The name of the saved file is the table name, `crl_table_rt_mutex`, with an `.m` extension. Optionally, you can open the saved file and examine the MATLAB code for the code replacement table definition.

To test this example:

1. Register the code replacement mapping.
2. Create a model that contains a rate transition for which the build process generates mutex function calls. For example:

3. Configure the model for a multicore target environment and the following settings:
   - On the Solver pane, select a fixed-step solver.
   - On the Code Generation pane, select an ERT-based system target file. 
   - On the Code Generation > Interface pane, select the code replacement library that contains your mutex entry.

Algorithm-Based Code Replacement

For some math function blocks, you can control code replacement based on the computation or approximation algorithm configured for that block. For example, you can configure:

- The Reciprocal Sqrt block to use the Newton-Raphson or Exact computation method.
- The Trigonometric Function block, with Function set to sin, cos, or sincos, to use the approximation method CORDIC or None.

You can define code replacement entries to replace these functions for one or all of the available computation methods. For example, you can define an entry to replace only Newton-Raphson instances of the rSqrt function.

To set the algorithm for a function in an entry definition, use the EntryInfoAlgorithm property in a call to the function setTflCFunctionEntryParameters. The following table lists arguments for specifying the computation method to match during code generation.

<table>
<thead>
<tr>
<th>Function</th>
<th>Argument</th>
</tr>
</thead>
</table>
| rSqrt    | • 'RTW_DEFAULT' (match the default computation method, Exact)  
|          | • 'RTW_NEWTON_RAPHSON'  
|          | • 'RTW_UNSPECIFIED' (match any computation method) |
| sin      | • 'RTW_CORDIC' |
| cos      | • 'RTW_DEFAULT' (match the default approximation method, None) |
| sincos   | • 'RTW_UNSPECIFIED' (match any approximation method) |

For example, to replace only Newton-Raphson instances of the rSqrt function, create an entry as follows:

1. Create a table definition file that contains a function definition. For example:

   ```matlab
   function hTable = crl_rsqrt()
   %CRL_TABLE_RSQRT - Define function entry for code replacement table.
   ```

2. Within the function body, create the table by calling the function RTW.TflTable.
3 Create an entry for the function mapping with a call to the RTW.TflCFunctionEntry function.

% Create entry for rsqrt function replacement
fcn_entry = RTW.TflCFunctionEntry;

4 Set function entry parameters with a call to the setTflCFunctionEntryParameters function.

setTflCFunctionEntryParameters(fcn_entry, ...
'Key',                      'rSqrt', ... 
'Priority',                 80, ... 
'ImplementationName',       'rsqrt_newton', ... 
'ImplementationHeaderFile', 'rsqrt.h', ... 
'EntryInfoAlgorithm',       'RTW_NEWTON_RAPHSON');

5 Create conceptual arguments y1 and u1. This example uses calls to the createAndAddConceptualArg function to create and add an argument with one function call.

createAndAddConceptualArg(fcn_entry, 'RTW.TflArgNumeric', ...
'Name',         'y1', ... 
'IOType',       'RTW_IO_OUTPUT', ... 
'DataTypeMode', 'double');

createAndAddConceptualArg(e, 'RTW.TflArgNumeric', ...
'Name',         'u1', ... 
'DataTypeMode', 'double');

6 Copy the conceptual arguments to the implementation arguments. This example uses a call to the copyConceptualArgsToImplementation function to create and add implementation arguments to the entry by copying matching conceptual arguments.

copyConceptualArgsToImplementation(fcn_entry);

7 Add the entry to a code replacement table with a call to the addEntry function.

addEntry(hTable, fcn_entry);

8 Save the table definition file. Use the name of the table definition function to name the file.

The generated code for a Newton-Raphson instance of the rSqrt function looks like the following code:

/* Model step function */
void mrsqrt_step(void) {

mrsqrt_Y.Out1 = rsqrt_newton(mrsqrt_U.In1);
}

Lookup Table Function Code Replacement

You can configure the algorithm for table lookup operations and index searches to better meet your application code requirements. Use the Algorithm tab of lookup table blocks. For example, you can specify the interpolation, extrapolation, and index search methods.

Lookup Table Algorithm Replacement

If the code generated for available algorithm options does not meet requirements for your application, create custom code replacement table entries to replace generated algorithm code. You can create the table entries programmatically or interactively by using the Code Replacement Tool.

For more information about using lookup table blocks, see “Nonlinearity” (Simulink).

Lookup Table Function Signatures

To create code replacement table entries for a function corresponding to a lookup table algorithm, you must have:

• Information about the conceptual function signature.
• Relevant algorithm parameters.

The following table provides the conceptual function signature information.

<table>
<thead>
<tr>
<th>Conceptual Function Signature</th>
<th>Argument Summary</th>
</tr>
</thead>
<tbody>
<tr>
<td>y1 = interp1D(u1, u2, u3, u4)</td>
<td>y1 - output</td>
</tr>
<tr>
<td></td>
<td>u1 - index</td>
</tr>
<tr>
<td></td>
<td>u2 - fraction</td>
</tr>
<tr>
<td></td>
<td>u3 - table data</td>
</tr>
<tr>
<td></td>
<td>u4 - table dimension length</td>
</tr>
<tr>
<td>y1 = interp2D(u1, u2, u3, u4, u5, u6, u7)</td>
<td>y1 - output</td>
</tr>
<tr>
<td></td>
<td>u1, u3 - index</td>
</tr>
<tr>
<td></td>
<td>u2, u4 - fraction</td>
</tr>
<tr>
<td></td>
<td>u5 - table data</td>
</tr>
<tr>
<td></td>
<td>u6, u7 - table dimension lengths</td>
</tr>
<tr>
<td>Conceptual Function Signature</td>
<td>Argument Summary</td>
</tr>
<tr>
<td>----------------------------------------------</td>
<td>-----------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| \( y_1 = \text{interp3D}(u_1, u_2, u_3, u_4, u_5, u_6, u_7, u_8, u_9, u_{10}) \) | \( y_1 \) – output  
   \( u_1, u_3, u_5 \) – index  
   \( u_2, u_4, u_6 \) – fraction  
   \( u_7 \) – table data  
   \( u_8, u_9, u_{10} \) – table dimension lengths |
| \( y_1 = \text{interp4D}(u_1, u_2, u_3, u_4, u_5, u_6, u_7, u_8, u_9, u_{10}, u_{11}, u_{12}, u_{13}) \) | \( y_1 \) – output  
   \( u_1, u_3, u_5, u_7 \) – index  
   \( u_2, u_4, u_6, u_8 \) – fraction  
   \( u_9 \) – table data  
   \( u_{10}, u_{11}, u_{12}, u_{13} \) – table dimension lengths |

</tbody>
</table>

When defining a table entry programmatically, you might also need to change the values of required (primary) and optional algorithm parameters.

- Set values for required parameters to achieve code replacement.
- If you do not set a value for an optional parameter, the algorithm parameter software applies don't care. The code replacement software ignores the parameter while searching for matches.

To look up algorithm parameter information for a lookup table function:

1. Create a table entry for a function.
   
   ```
   tableEntry = RTW.TflCFunctionEntry;
   ```
Identify the lookup table function in the table entry. Use the Key table entry parameter in a call to `setTflCFunctionEntryParameters`. The following example identifies an entry for the prelookup function.

```matlab
setTflCFunctionEntryParameters(tableEntry, ...
    'Key', 'prelookup', ...
    'Priority', 100, ...
    'ImplementationName', 'myPrelookup');
```

Get the algorithm parameter set for the entry with a call to `getAlgorithmParameters`.

```matlab
algParams = getAlgorithmParameters(tableEntry);
```

Examine information available for each parameter.

```matlab
algParams.ExtrapMethod
```

```matlab
ans =

ExtrapMethod with properties:

    Name: 'ExtrapMethod'
    Options: {'Linear' 'Clip'}
    Primary: 1
    Value: {'Linear'}
```

```matlab
algParams.RndMeth
```

```matlab
ans =

RndMeth with properties:

    Name: 'RndMeth'
    Options: {1x7 cell}
    Primary: 0
    Value: {1x7 cell}
```

```matlab
algParams.RndMeth.Value
```

```matlab
ans =

Columns 1 through 6

    'Ceiling'    'Convergent'    'Floor'    'Nearest'    'Round'    'Simplest'

Column 7

    'Zero'
```

```matlab
algParams.IndexSearchMethod
```
ans =

IndexSearchMethod with properties:
   Name: 'IndexSearchMethod'
   Options: {'Linear search' 'Binary search' 'Evenly spaced points'}
   Primary: 0
   Value: {'Binary search' 'Evenly spaced points' 'Linear search'}

algParams.UseLastBreakpoint
ans =

UseLastBreakpoint with properties:
   Name: 'UseLastBreakpoint'
   Options: {'off' 'on'}
   Primary: 0
   Value: {'off' 'on'}

algParams.RemoveProtectionInput
ans =

RemoveProtectionInput with properties:
   Name: 'RemoveProtectionInput'
   Options: {'off' 'on'}
   Primary: 0
   Value: {'off' 'on'}

Interactive Mapping with Code Replacement Tool

This example shows how to specify a code replacement table entry for a lookup table algorithm by using the Code Replacement Tool.

Open and Examine Example Replacement Function

Identify or create the C or C++ replacement function for the algorithm that you want to use in place of a Simulink software algorithm.

This example uses the following C replacement function header and source files, which are in the folder matlab/toolbox/rtw/rtwdemos/crl_demo:

- myLookup1D.h
- myLookup1D.c

Place a copy of these files in your working folder.

Open and examine the code for myLookup1D.h.

#include "rtwtypes.h"
real_T my Lookup1D_Repl(real_T u0, const real_T *bp0, const real_T *table, uint32_T tdl);
Open and examine the code in myLookup1D.c. Note the function signature. When you enter the implementation argument specification in the Code Replacement Tool, specify argument properties.

```c
#include "myLookup1D.h"

real_T my_Lookup1D_Repl(real_T u0, const real_T *bp0, const real_T *table, uint32_T tdl)
{
    real_T y;
    uint16_T frac;
    uint32_T bpIdx;
    uint32_T maxIndex=tdl-1;

    if (u0 <= bp0[0U]) {
        bpIdx = 0U;
        frac = 0U;
    } else if (u0 < bp0[maxIndex]) {
        bpIdx = maxIndex >> 1U;
        while ((u0 < bp0[bpIdx]) && (bpIdx > 0U)) {
            bpIdx--;
        }
        while ((bpIdx < maxIndex - 1U) && (u0 >= bp0[bpIdx + 1U])) {
            bpIdx++;
        }
        frac = (uint16_T)((u0 - bp0[bpIdx]) / (bp0[bpIdx + 1U] - bp0[bpIdx]) * 32768.0);
    } else {
        bpIdx = maxIndex;
        frac = 0U;
    }

    if (bpIdx == maxIndex) {
        y = table[bpIdx];
    } else {
        y = ((table[bpIdx + 1U] - table[bpIdx]) * ((real_T)frac * 3.0517578125E-5) + table[bpIdx]);
    }

    return y;
}
```

**Open and Examine the Example Model**

This example uses the model rtwdemo_crllookup1D to test your code replacement specification. Place a copy of the model in your working folder and name it my_lookup1d.slx.

Open and examine the model. Note input and output specifications and block parameter settings. To achieve a match, you must specify conceptual arguments based on how the 1-D Lookup Table block is configured in the example model.
Create Code Replacement Table

1. At the command prompt, enter `crtool` to open the Code Replacement Tool.
2. Add a new table, select that table, and add a new function entry.
3. On the **Mapping Information** tab, select **Custom** for the **Function** parameter.
4. Look up the call signature and algorithm parameter information for the lookup table function that you want to update with an algorithm replacement. See “Lookup Table Function Signatures” on page 54-115.

For this example, you replace the algorithm for the conceptual function associated with the 1-D Lookup Table block. The signature for that function is:

\[ y_1 = \text{lookup1D}(u_1, u_2, u_3, u_4) \]

Arguments \( u_1, u_2, u_3, u_4 \) represent input, breakpoint data, table data, and table dimension length, respectively. The function returns output to \( y_1 \).

5. To the right of the **Function** drop-down list, in the function-name text box, enter the name of the Simulink lookup table function. For this example, type the name `lookup1D`. Type the name exactly as it appears in the documented signature, including character casing. Press **Enter**.

The tool displays algorithm parameter settings that trigger a match for the 1-D Lookup Table block in the example model. Required parameters appear with only one value. For this example, do not change the values. Optional parameters appear with multiple values. Changes to optional parameters do not affect the match process.

6. Specify the conceptual arguments. Under the **Conceptual arguments** list box, click + to add the arguments that are in the documented function signature. The `lookup1D` function takes one output argument and four input arguments. Click + five times.
The tool creates an output argument \( y_1 \) and four input arguments \( u_1, u_2, u_3, \) and \( u_4. \) By default, the four arguments are scalars of type double.

You can adjust the conceptual argument properties. For this example, you do not make changes for \( y_1 \) and \( u_1. \) However, as the block parameter dialog box for the example model shows, you must adjust the argument properties for the breakpoint and table data arguments.

![Function Block Parameters: 1-D Lookup Table](image)

Adjust the conceptual argument properties by using the following table. Click **Apply**.

<table>
<thead>
<tr>
<th>Signature Argument Name</th>
<th>Conceptual Argument Name</th>
<th>Data type</th>
<th>I/O type</th>
<th>Argument type</th>
<th>Lower range</th>
<th>Upper range</th>
</tr>
</thead>
<tbody>
<tr>
<td>( y )</td>
<td>( y_1 )</td>
<td>double</td>
<td>OUTPUT</td>
<td>Scalar</td>
<td>Not applicable</td>
<td>Not applicable</td>
</tr>
<tr>
<td>( u_1 )</td>
<td>( u_1 )</td>
<td>double</td>
<td>INPUT</td>
<td>Scalar</td>
<td>Not applicable</td>
<td>Not applicable</td>
</tr>
<tr>
<td>( b_1 )</td>
<td>( u_2 )</td>
<td>double</td>
<td>INPUT</td>
<td>Matrix</td>
<td>([0 0])</td>
<td>([\text{Inf Inf}])</td>
</tr>
<tr>
<td>( \text{table} )</td>
<td>( u_3 )</td>
<td>double</td>
<td>INPUT</td>
<td>Matrix</td>
<td>([0 0])</td>
<td>([\text{Inf Inf}])</td>
</tr>
</tbody>
</table>
Enter information for the replacement function prototype. The prototype for the example function is:

```c
real_T my_Lookup1D_Repl(real_T u0, const real_T *bp0, const real_T *table, uint32_T tdl)
```

In the Replacement function > Function prototype section, type the function name `my_Lookup1D_Repl` in the Name text box.

Specify the arguments for the replacement function. Under the Function arguments list box, click + five times to add five implementation arguments.

You might need to adjust the function argument properties. As the replacement function signature shows, adjust the argument properties for the breakpoint, table data, and table dimension length arguments. For `u2` (breakpoints) and `u3` (table), select the Const check box. For `u4`, set Data type to uint32.

The function signature preview should appear as follows:

```c
double my_Lookup1D_Repl(double u1, const double* u2, const double* u3, uint32 u4)
```

Set relevant implementation attributes. Use the default settings.

Validate the entry. If the tool reports errors, fix them, and retry the validation. Repeat the procedure until the tool does not report errors.

Save the code replacement table in your working folder as `my_lookup_replacement_table.m`.

Specify Build Information

On the Build Information tab, specify information relevant to generating C or C++ code and building an executable from the model. Enter `myLookup1D.h` for Implementation Header File and `myLookup1D.c` for Implementation Source File.
If you copied the example files to a folder other than the working folder containing the test model, lookup1d.slx, specify the source and header file paths. Otherwise, leave the other Build Information parameters set to default values. Click Apply.

Test the Entry

To test this example:

1. Register the code replacement mapping.
2. Use the example model rtwdemo_crllookup1D.
3. Configure the model with the following settings:
   - On the Solver pane, select a fixed-step solver.
   - On the Code Generation pane, select an ERT-based system target file.
   - On the Code Generation > Interface pane, select the code replacement library that contains your lookup table function entry.

Programmatic Specification

This example shows how to specify code replacement table entries for lookup table functions programmatically.

Open and Examine Example Replacement Function

Identify or create the C or C++ replacement function for the algorithm that you want to use in place of a Simulink software algorithm.

This example uses the following C replacement function header and source files, which are in the folder matlab/toolbox/rtw/rtwdemos/crl_demo:

- myLookup1D.h
- myLookup1D.c

Place a copy of these files in your working folder.

Open and examine the code for myLookup1D.h.

#include "rtwtypes.h"
real_T my_Lookup1D_Repl(real_T u0, const real_T *bp0, const real_T *table, uint32_T tdl);
Open and examine the code in `myLookup1D.c`. Note the function signature. When you enter the implementation argument specification in the Code Replacement Tool, specify argument properties.

```c
#include "myLookup1D.h"
real_T my_Lookup1D_Repl(real_T u0, const real_T *bp0, const real_T *table, uint32_T tdl)
{
    real_T y;
    uint16_T frac;
    uint32_T bpIdx;
    uint32_T maxIndex=tdl-1;

    if (u0 <= bp0[0U]) {
        bpIdx = 0U;
        frac = 0U;
    } else if (u0 < bp0[maxIndex]) {
        bpIdx = maxIndex >> 1U;
        while ((u0 < bp0[bpIdx]) && (bpIdx > 0U)) {
            bpIdx--;
        }
        while ((bpIdx < maxIndex - 1U) && (u0 >= bp0[bpIdx + 1U])) {
            bpIdx++;
        }
        frac = (uint16_T)((u0 - bp0[bpIdx]) / (bp0[bpIdx + 1U] -
            bp0[bpIdx]) * 32768.0);
    } else {
        bpIdx = maxIndex;
        frac = 0U;
    }

    if (bpIdx == maxIndex) {
        y = table[bpIdx];
    } else {
        y = (table[bpIdx + 1U] - table[bpIdx]) * ((real_T)frac * 3.0517578125E-5) +
            table[bpIdx];
    }

    return y;
}
```

### Review Lookup Function Signature

Look up the call signature information for the lookup function that you want to update with an algorithm replacement. See “Lookup Table Function Signatures” on page 54-115.

Replace the algorithm for the function associated with the 1-D Lookup Table block. The signature for that function is:

\[ y_1 = \text{lookup1D}(u_1, u_2, u_3, u_4) \]

Arguments \( u_1, u_2, u_3, \) and \( u_4 \) represent input, breakpoint data, table data, and table dimension length, respectively. The function returns output to \( y_1 \).
Create Code Replacement Entry

Create a code replacement table file as a MATLAB function, that describes the lookup table function code replacement table entries. Place a copy of the file matlab/toolbox/rtw/rtwdeemos/crl_demo/crl_table_lookup1D.m in your working folder. This file defines a code replacement table for the C function my_Lookup1D_Repl.

Open crl_table_lookup1D.m and examine the definition.

1. Create a table definition file that contains a function definition. For example:

   function hLib = my_lookup_replacement_table

2. Within the function body, create the table by calling the function RTW.TflTable.

   hLib = RTW.TflTable;

3. Create an entry for the function mapping with a call to the RTW.TflCFunctionEntry function.

   hEnt = RTW.TflCFunctionEntry;

4. Set function entry parameters with a call to the setTflCFunctionEntryParameters function. The function key, implementation name, and header and source files in the function call identify the Simulink lookup table function name, lookup1D, and the following information for replacement function my_Lookup1D_Repl:

   • Function name
   • Header file
   • Source file

   Specify the Simulink lookup table function name exactly as it appears in the documented signature, including character casing (see “Lookup Table Function Signatures” on page 54-115). If you copied the example files to a folder other than the working folder that contains the test model, rtwdemo_crllookup1D, specify the source and header file paths.

   setTflCFunctionEntryParameters(hEnt, ...
      'Key',                      'lookup1D', ...
      'Priority',                 100, ...
      'ImplementationName',       'my_Lookup1D_Repl', ...
      'ImplementationHeaderFile', 'myLookup1D.h', ...
      'ImplementationSourceFile', 'myLookup1D.c', ...
      'GenCallback',              'RTW.copyFileToBuildDir');
Create conceptual arguments and add them to the entry. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create and add the arguments.

The example defines five conceptual arguments for the `lookup1D` function, one output argument `y1` and four input arguments `u1`, `u2`, `u3`, and `u4`. Arguments `y1` and `u1` are defined as scalar double data. Arguments `u2` and `u3` represent `bp1` and `table` in the signature and are defined as 1x10 matrices of double data. Argument `u4` represents `tdl` and is defined as scalar of `uint32` data. This definition triggers a match with the example model.

```matlab
arg = hEnt.getTflArgFromString('y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEnt, arg);

arg = hEnt.getTflArgFromString('u1','double');
addConceptualArg(hEnt, arg);

arg = RTW.TflArgMatrix('u2', 'RTW_IO_INPUT',  'double');
arg.DimRange = [0 0; Inf Inf];
addConceptualArg(hEnt, arg);

arg = RTW.TflArgMatrix('u3', 'RTW_IO_INPUT',  'double');
arg.DimRange = [0 0; Inf Inf];
addConceptualArg(hEnt, arg);

arg = hEnt.getTflArgFromString('u4','uint32');
addConceptualArg(hEnt, arg);
```

Review the algorithm parameter information for the lookup function that you want to update with an algorithm replacement. Use the `getAlgorithmParameters` function to display the parameter information.

```matlab
algParams = getAlgorithmParameters(hEnt)
```

Examine the information for each parameter. The `Options` property lists possible values. `Primary` indicates whether a parameter is required (1) or optional (0). The `Value` property specifies the current value. For required parameters, initially, `Value` is set to the default value for a given lookup table function.
algParams.InterpMethod
ans =

InterpMethod with properties:
Name: 'InterpMethod'
Options: {'Linear'  'Flat'  'Nearest'}
Primary: 1
Value: {'Linear'}

algParams.RndMeth
ans =

RndMeth with properties:
Name: 'RndMeth'
Options: {1x7 cell}
Primary: 0
Value: {1x7 cell}

algParams.RndMeth.Options
ans =

Columns 1 through 5
'Ceiling'    'Convergent'    'Floor'    'Nearest'    'Round'

Columns 6 through 7
'Simplest'    'Zero'

Set the algorithm properties for the `lookup1D` table entry. Assign a value to each parameter. Update the parameter settings for the entry by calling the function `setAlgorithmParameters`. The following parameter settings trigger a match with the example model.

algParams.InterpMethod = 'Linear';
algParams.ExtrapMethod = 'Clip';
algParams.RndMeth = 'Round';
algParams.IndexSearchMethod = 'Linear search';
algParams.UseLastTableValue = 'Evenly spaced point';
algParams.RemoveProtectionInput = 'off';
algParams.SaturateOnIntegerOverflow = 'off';
algParams.SupportTunableTableSize = 'off';
algParams.BPPower2Spacing = 'off';
setAlgorithmParameters(hEnt, algParams);

ans =

    RndMeth with properties:
    
        Name: 'RndMeth'
        Options: {1x7 cell}
        Primary: 0
            Value: {1x7 cell}

To verify your changes, call getAlgorithmParameters to get the parameter set for the table entry. Examine the value of each parameter.

getAlgorithmParameters(hEnt, algParams);
algParams.InterpMethod.Value

ans =

    'Linear'

algParams.ExtrapMethod.Value

ans =

    'Clip'

algParams.RndMeth.Value

ans =

    'Round'

Create the implementation arguments and add them to the entry. This example uses calls to the getTflArgFromString function to create five implementation arguments that map to arguments in the replacement function prototype: one output
argument \( y_1 \) and four input arguments \( u_1, u_2, u_3, \) and \( u_4 \). The convenience methods 
\texttt{setReturn} and \texttt{addArgument} specify whether an argument is a return value or argument. The \texttt{addArgument} function also adds each argument to the entry’s array of implementation arguments.

```matlab
arg = hEnt.getTflArgFromString('y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);

arg = hEnt.getTflArgFromString('u1','double');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u2','double*');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u3','double*');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u4','uint32');
hEnt.Implementation.addArgument(arg);
```

9 Add the entry to a code replacement table with a call to the \texttt{addEntry} function.

```matlab
addEntry(hLib, hEnt);
```

10 Save the table definition file. Use the name of the table definition function to name the file.

**Test the Entry**

To test this example:

1 Register the code replacement mapping.
2 Use the example model \texttt{rtwdemo_crllookup1D}.
3 Configure the model with the following settings:
   - On the \textbf{Solver} pane, select a fixed-step solver.
   - On the \textbf{Code Generation} pane, select an ERT-based system target file.
On the **Code Generation > Interface** pane, select the code replacement library that contains your lookup table function entry.

**Sample Code Replacement Definition for the lookup2D Function**

The following code shows a replacement definition for the lookup2D function.

```matlab
function hLib = my_2dlookup_replacement_table

hLib = RTW.TflTable;

hEnt = RTW.TflCFunctionEntry;
setTflCFunctionEntryParameters(hEnt, ...'Key', 'lookup2D', ...
'Priority', 100, ...
'ImplementationName', 'custom_lookup2d', ...
'ImplementationHeaderFile', 'custom_lookup2d.h', ...
'ImplementationSourceFile', 'custom_lookup2d.c', ...
'GenCallback', 'RTW.copyFileToBuildDir');

% Conceptual Args

arg = hEnt.getTflArgFromString('y1','double');
arg.IOType = 'RTW IO_OUTPUT';
addConceptualArg(hEnt, arg);

arg = hEnt.getTflArgFromString('u1','double');
addConceptualArg(hEnt, arg);

arg = hEnt.getTflArgFromString('u2','double');
addConceptualArg(hEnt, arg);

arg = RTW.TflArgMatrix('u3', 'RTW IO_INPUT', 'double');
arg.DimRange = [1 1; 10 1];
addConceptualArg(hEnt, arg);

arg = RTW.TflArgMatrix('u4', 'RTW IO_INPUT', 'double');
arg.DimRange = [1 1; 10 1];
addConceptualArg(hEnt, arg);

arg = RTW.TflArgMatrix('u5', 'RTW IO_INPUT', 'double');
```

54-133
arg.DimRange = [1 1; 10 1];
addConceptualArg(hEnt, arg);

arg = hEnt.getTflArgFromString('u6','uint32');
addConceptualArg(hEnt, arg);

arg = hEnt.getTflArgFromString('u7','uint32');
addConceptualArg(hEnt, arg);

% Algorithm Parameters
addAlgorithmProperty(hEnt, 'ExtrapMethod','Clip');
addAlgorithmProperty(hEnt, 'IndexSearchMethod','Linear search');
addAlgorithmProperty(hEnt, 'InterpMethod','Linear');
addAlgorithmProperty(hEnt, 'RemoveProtectionInput','off');
addAlgorithmProperty(hEnt, 'UseLastTableValue','on');

% Implementation Args
arg = hEnt.getTflArgFromString('y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);

arg = hEnt.getTflArgFromString('u1','double');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u2','double');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u3','double*');
arg.Type.BaseType.ReadOnly = true;
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u4','double*');
arg.Type.BaseType.ReadOnly = true;
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u5','double*');
arg.Type.BaseType.ReadOnly = true;
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u6','uint32');
hEnt.Implementation.addArgument(arg);
arg = hEnt.getTflArgFromString('u7','uint32');
hEnt.Implementation.addArgument(arg);

hLib.addEntry(hEnt);

Data Alignment for Code Replacement

Code replacement libraries can align data objects passed into a replacement function to a specified boundary.

Code Replacement Data Alignment

You can take advantage of function implementations that require aligned data to optimize application performance. To configure data alignment for a function implementation:

1. Specify the data alignment requirements in a code replacement entry. Specify alignment separately for each implementation function argument or collectively for all function arguments. See “Specify Data Alignment Requirements for Function Arguments” on page 54-136.

2. Specify the data alignment capabilities and syntax for one or more compilers. Include the alignment specifications in a library registration entry in the rtwTargetInfo.m file. See “Provide Data Alignment Specifications for Compilers” on page 54-138.

3. Register the library containing the table entry and alignment specification object.

4. Configure the code generator to use the code replacement library and generate code. Observe the results.

For examples, see “Basic Example of Code Replacement Data Alignment” on page 54-143 and the “Data Alignment for Function Implementations” section of the “Optimize Generated Code By Developing and Using Code Replacement Libraries - Simulink®” example page.

Specify Data Alignment Requirements for Function Arguments

To specify the data alignment requirement for an argument in a code replacement entry:

- If you are defining a replacement function in a code replacement table registration file, create an argument descriptor object (RTW.ArgumentDescriptor). Use its AlignmentBoundary property to specify the required alignment boundary and assign the object to the argument Descriptor property.

- If you are defining a replacement function using the Code Replacement Tool, on the Mapping Information tab, in the Argument properties section for the replacement function, enter a value for the Alignment value parameter.
The `AlignmentBoundary` property (or **Alignment value** parameter) specifies the alignment boundary for data passed to a function argument, in number of bytes. The `AlignmentBoundary` property is valid only for addressable objects, including matrix and pointer arguments. It is not applicable for value arguments. Valid values are:

- **-1** (default) — If the data is a `Simulink.Bus`, `Simulink.Signal`, or `Simulink.Parameter` object, specifies that the code generator determines an optimal alignment based on usage. Otherwise, specifies that there is not an alignment requirement for this argument.

- Positive integer that is a power of 2, not exceeding 128 — Specifies number of bytes in the boundary. The starting memory address for the data allocated for the function argument is a multiple of the specified value. If you specify an alignment boundary that is less than the natural alignment of the argument data type, the alignment directive is emitted in the generated code. However, the target compiler ignores the directive.

The following code specifies the `AlignmentBoundary` for an argument as 16 bytes.

```matlab
hLib = RTW.TflTable;
entry = RTW.TflCOperationEntry;
arg = getTflArgFromString(hLib, 'u1', 'single*');
desc = RTW.ArgumentDescriptor;
desc.AlignmentBoundary = 16;
arg.Descriptor = desc;
entry.Implementation.addArgument(arg);
```
The equivalent alignment boundary specification in the Code Replacement Tool dialog box is in this figure.

![Alignment boundary specification](image)

**Note** If your model imports `Simulink.Bus`, `Simulink.Parameter`, or `Simulink.Signal` objects, specify an alignment boundary in the object properties, using the **Alignment** property. For more information, see `Simulink.Bus`, `Simulink.Parameter`, and `Simulink.Signal`.

### Provide Data Alignment Specifications for Compilers

To support data alignment in generated code, describe the data alignment capabilities and syntax for your compilers in the code replacement library registration. Provide one or more alignment specifications for each compiler in a library registry entry.

To describe the data alignment capabilities and syntax for a compiler:

- If you are defining a code replacement library registration entry in a `rtwTargetInfo.m` customization file, add one or more `AlignmentSpecification` objects to an `RTW.DataAlignment` object. Attach the `RTW.DataAlignment` object to the `TargetCharacteristics` object of the registry entry.

The `RTW.DataAlignment` object also has the property `DefaultMallocAlignment`, which specifies the default alignment boundary, in bytes, that the compiler uses for dynamically allocated memory. If the code generator uses dynamic memory allocation for a data object involved in a code replacement, this value determines if the memory satisfies the alignment requirement of the replacement. If not, the code generator does not use the replacement. The default value for `DefaultMallocAlignment` is `-1`, indicating that the default alignment boundary used for dynamically allocated memory is unknown. In this case, the code generator uses the natural alignment of the data type to determine whether to allow a replacement.
Additionally, you can specify the alignment boundary for complex types by using the `addComplexTypeAlignment` function.

- If you are generating a customization file function using the Code Replacement Tool, fill out the following fields for each compiler.

Click the plus (+) symbol to add additional compiler specifications.

For each data alignment specification, provide the following information.
<table>
<thead>
<tr>
<th>Alignment-Specification Property</th>
<th>Dialog Box Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>AlignmentType</strong></td>
<td><strong>Alignment type</strong></td>
<td>Cell array of predefined enumerated strings, specifying which types of alignment this specification supports.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• DATA_ALIGNMENT_LOCAL_VAR — Local variables.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• DATA_ALIGNMENT_GLOBAL_VAR — Global variables.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• DATA_ALIGNMENT_STRUCT_FIELD — Individual structure fields.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• DATA_ALIGNMENT_WHOLE_STRUCT — Whole structure, with padding (individual structure field alignment, if specified, is favored and takes precedence over whole structure alignment).</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Each alignment specification must specify at least DATA_ALIGNMENT_GLOBAL_VAR and DATA_ALIGNMENT_STRUCT_FIELD.</td>
</tr>
<tr>
<td>Alignment-Specification Property</td>
<td>Dialog Box Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------</td>
<td>---------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>AlignmentPosition</td>
<td>Alignment position</td>
<td>Predefined enumerated string specifying the position in which you must place the compiler alignment directive for alignment type DATA_ALIGNMENT_WHOLE_STRUCT:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• DATA_ALIGNMENT_PREDIRECTIVE — The alignment directive is emitted before struct st_tag{...}, as part of the type definition statement (for example, MSVC).</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• DATA_ALIGNMENT_POSTDIRECTIVE — The alignment directive is emitted after struct st_tag{...}, as part of the type definition statement (for example, gcc).</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• DATA_ALIGNMENT_PRECEDING_STATEMENT — The alignment directive is emitted as a standalone statement immediately preceding the definition of the structure type. A semicolon (;) must terminate the registered alignment syntax.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• DATA_ALIGNMENT_FOLLOWING_STATEMENT — The alignment directive is emitted as a standalone statement immediately following the definition of the structure type. A semicolon (;) must terminate the registered alignment syntax.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>For alignment types other than DATA_ALIGNMENT_WHOLE_STRUCT, code generation uses alignment position DATA_ALIGNMENT_PREDIRECTIVE.</td>
</tr>
</tbody>
</table>
**Alignment-Specification Property** | **Dialog Box Parameter** | **Description**
--- | --- | ---
AlignmentSyntax-Template | Alignment syntax | Specifies the alignment directive string that the compiler supports. The string is registered as a syntax template that has placeholders in it. These placeholders are supported:
- `%n` — Replaced by the alignment boundary for the replacement function argument.
- `%s` — Replaced by the aligned symbol, usually the identifier of a variable.
For example, for the gcc compiler, you can specify `__attribute__((aligned(%n)))`, or for the MSVC compiler, `__declspec(align(%n))`.

| SupportedLanguages | Supported languages | Cell array specifying the languages to which this alignment specification applies, among c and c++. Sometimes alignment syntax and position differ between languages for a compiler.

Here is a data alignment specification for the GCC compiler:

```plaintext
da = RTW.DataAlignment;

as = RTW.AlignmentSpecification;
as.AlignmentType = {'DATA_ALIGNMENT_LOCAL_VAR', ...
   'DATA_ALIGNMENT_STRUCT_FIELD', ...
   'DATA_ALIGNMENT_GLOBAL_VAR'};
as.AlignmentSyntaxTemplate = '__attribute__((aligned(%n)))';
as.AlignmentPosition = 'DATA_ALIGNMENT_PREDIRECTIVE';
as.SupportedLanguages = {'c', 'c++'};
da.addAlignmentSpecification(as);

tc = RTW.TargetCharacteristics;
tc.DataAlignment = da;
```

Here is the corresponding specification in the **Generate customization** dialog box of the Code Replacement Tool.
Basic Example of Code Replacement Data Alignment

A simple example of the complete workflow for data alignment specified for code replacement is:

1. Create and save the following code replacement table definition file, `crl_table_mmul_4x4_single_align.m`. This table defines a replacement entry for the * (multiplication) operator, the single data type, and input dimensions [4,4]. The entry also specifies a data alignment boundary of 16 bytes for each replacement function argument. The entry expresses the requirement that the starting memory address for the data allocated for the function arguments during code generation is a multiple of 16.

```matlab
function hLib = crl_table_mmul_4x4_single_align
%CRL_TABLE_MMUL_4x4_SINGLE_ALIGN - Describe matrix operator entry with data alignment

hLib = RTW.TflTable;
entry = RTW.TflCOperationEntry;
setTflCOperationEntryParameters(entry, ...
'Key',                   'RTW_OP_MUL', ...
'Priority',              90, ...
'ImplementationName',    'matrix_mul_4x4_s');

% conceptual arguments
createAndAddConceptualArg(entry, 'RTW.TflArgMatrix',...
'Name', 'y1', ...
'IOType', 'RTW_IO_OUTPUT', ...
'BaseType', 'single', ...
'DimRange', [4 4]);
```
createAndAddConceptualArg(entry, 'RTW.TflArgMatrix', ...
    'Name', 'u1', ...
    'BaseType', 'single', ...
    'DimRange', [4 4]);

createAndAddConceptualArg(entry, 'RTW.TflArgMatrix', ...
    'Name', 'u2', ...
    'BaseType', 'single', ...
    'DimRange', [4 4]);

% implementation arguments
arg = getTflArgFromString(hLib, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
entry.Implementation.setReturn(arg);

arg = getTflArgFromString(hLib, 'y1', 'single*');
desc = RTW.ArgumentDescriptor;
desc.AlignmentBoundary = 16;
arg.Descriptor = desc;
entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hLib, 'u1', 'single*');
desc = RTW.ArgumentDescriptor;
desc.AlignmentBoundary = 16;
arg.Descriptor = desc;
entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hLib, 'u2', 'single*');
desc = RTW.ArgumentDescriptor;
desc.AlignmentBoundary = 16;
arg.Descriptor = desc;
entry.Implementation.addArgument(arg);

hLib.addEntry(entry);

Create and save the following registration file, rtwTargetInfo.m. If you want to compile the code generated in this example, first modify the AlignmentSyntaxTemplate property for the compiler that you use. For example, for the MSVC compiler, replace the gcc template character vector __attribute__((aligned(%n))) with __declspec(align(%n)).

function rtwTargetInfo(cm)
% rtwTargetInfo function to register a code replacement library (CRL)
% for use with code generation

    % Register the CRL defined in local function locCrlRegFcn
    cm.registerTargetInfo(@locCrlRegFcn);

end % End of RTWTARGETINFO

% Local function to define a CRL containing crl_table_mmul_4x4_single_align
function thisCrl = locCrlRegFcn

    % create an alignment specification object, assume gcc
as = RTW.AlignmentSpecification;
as.AlignmentType = {'DATA_ALIGNMENT_LOCAL_VAR', ...
    'DATA_ALIGNMENT_GLOBAL_VAR', ...
    'DATA_ALIGNMENT_STRUCT_FIELD'};
as.AlignmentSyntaxTemplate = '__attribute__((aligned(%n)))';
as.SupportedLanguages={'c', 'c++'};

% add the alignment specification object
da = RTW.DataAlignment;
da.addAlignmentSpecification(as);

% add the data alignment object to target characteristics
tc = RTW.TargetCharacteristics;
tc.DataAlignment = da;

% Instantiate a CRL registry entry
tc = RTW.TflRegistry;

% Define the CRL properties
tc.Name = 'Data Alignment Example';
tc.Description = 'Example of replacement with data alignment';
tc.TableList = {'crl_table_mmul_4x4_single_align'};
tc.TargetCharacteristics = tc;

end % End of LOCCRLREGFCN

3  To register your library with code generator without having to restart MATLAB, enter this command:

    RTW.TargetRegistry.getInstance('reset');

4  Configure the code generator to use your code replacement library.

5  Generate code and a code generation report.

6  Review the code replacements. For example, check whether a multiplication operation is
    replaced with a matrix_mul_4x4_s function call. In mmalign.h, check whether the gcc
    alignment directive __attribute__((aligned(16))) is generated to align the function variables.

Replace MATLAB Functions with Custom Code Using coder.replace

The coder.replace function provides the ability to replace a specified MATLAB function with a code replacement function in generated code. Use coder.replace in MATLAB code from which you want to generate C code using:

• MATLAB Coder
• MATLAB code in a Simulink MATLAB Function block

You can replace MATLAB functions that have:

• Single or multiple inputs
• Single or multiple outputs
• Scalar and matrix inputs and outputs

Supported types include:

• single, double (complex and noncomplex)
• int8, uint8 (complex and noncomplex)
• int16, uint16 (complex and noncomplex)
• int32, uint32 (complex and noncomplex)
• Fixed-point integers
• Mixed types (different type on each input)

Replace coder.ceval Calls to External Functions

The coder.ceval function calls external C/C++ functions from code generated from MATLAB code. The code replacement software supports replacement of the function that you specify in a call to coder.ceval. An application of this code replacement scenario is to write generic MATLAB code that you can customize for different platforms with code replacements. A code replacement library can define hardware-specific code replacements for the function call. Use coder.ceval in MATLAB code from which you want to generate C code using:

- MATLAB Coder
- MATLAB code in a Simulink MATLAB Function block

Example Files

For the examples in “Interactive External Function Call Replacement Specification with Code Replacement Tool” on page 55-107 and “Programmatic External Function Call Replacement Specification” on page 55-109 you must have set up the following:

- Custom C function my_add.c.

```c
/* my_add.c */
#include "my_add.h"

double my_add(double in1, double in2)
{
    return in1 + in2;
}
```

- Custom C header file my_add.h.

```c
/* my_add.h */
double my_add(double in1, double in2);
```

- MATLAB function call_my_add.m, which uses coder.ceval to invoke my_add.c.

```matlab
function y = call_my_add(in1, in2)  %#codegen
y=0.0;
if ~coder.target('Rtw')
```
Interactive External Function Call Replacement Specification with Code Replacement Tool

This example shows how to define a code replacement table entry for a MATLAB function that calls coder.ceval to invoke an external C function. The example shows how to define the entry interactively with the Code Replacement Tool.

1. Identify or create the C/C++ code and relevant header files, the MATLAB function that calls coder.ceval, a MATLAB test function, and the source and header files for
your replacement code. To follow along with this example, set up the files identified in “Example Files” on page 55-106.

2 In the Code Replacement Tool, add a table, select that table, and add a function entry. For more information, see “Define Code Replacement Mappings” on page 55-29.

3 On the Mapping Information tab, select Custom for the Function parameter.

4 In the function-name text box, type the custom function name. For this example, type the name my_add.

5 Under the Conceptual arguments list box, click + to add three arguments. By default, the tool creates an output argument y1 and input arguments u1 and u2 of type double.

6 In the Replacement function > Function prototype section, type the name my_add_replacement in the Name text box.

7 Under the Function arguments list box, click + to add three function implementation arguments. By default, the tool creates an output argument y1 and input arguments u1 and u2 of type double. Use the default settings.

8 In the Function signature preview box, if you see the expected function signature, click Apply. The function signature for this example, appears as:

   double my_add_replacement(double u1, double u2);

9 On the Build Information tab, specify my_add_replacement.h for the Implementation header file parameter and my_add_replacement.c for the Implementation source file.

10 Click Validate entry.

11 Save the code replacement table in the same folder as my_add_replacement.c. Name the file crl_table_my_add.m.

To test the example:

1 Register the table that contains the entry in a code replacement library.

2 Configure the code generator to use the code replacement library and to include the Code Replacements Report in the code generation report.

3 Generate code and the report.

4 Review the code replacements.
Programmatic External Function Call Replacement Specification

This example shows how to define a code replacement table entry for a MATLAB function that calls \texttt{coder.ceval} to invoke an external C function. The example shows how to define the entry programmatically.

1. Identify or create the C/C++ code and relevant header files, the MATLAB function that calls \texttt{coder.ceval} to invoke the C/C++ function, a MATLAB test function, and the source and header files for your replacement code. To follow along with this example, set up the files identified in “Example Files” on page 55-106.

2. Create a table definition file that contains a function definition. For example:

   ```matlab
   function hLib = crl_table_my_add
   ```

3. Within the function body, create the table by calling the function \texttt{RTW.TflTable}.

4. Create an entry for the function mapping with a call to the \texttt{RTW.TflCFunctionEntry} function.

   ```matlab
   hEnt = RTW.TflCFunctionEntry;
   ```

5. Set function entry parameters with a call to the \texttt{setTflCFunctionEntryParameters} function.

   ```matlab
   hEnt.setTflCFunctionEntryParameters( ...
               'Key', 'my_add', ...
               'Priority', 100, ...
               'ImplementationName', 'my_add_replacement', ...
               'ImplementationHeaderFile', 'my_add_replacement.h', ...
               'ImplementationSourceFile', 'my_add_replacement.c');
   ```

6. Create conceptual arguments y1, u1, and u2. This example uses calls to the \texttt{getTflArgFromString} and \texttt{addConceptualArg} functions to create and add the arguments.

   ```matlab
   arg = hEnt.getTflArgFromString('y1','double');
   arg.IOType = 'RTW_IO_OUTPUT';
   hEnt.addConceptualArg(arg);
   ```

   ```matlab
   arg = hEnt.getTflArgFromString('u1','double');
   hEnt.addConceptualArg(arg);
   ```

   ```matlab
   arg = hEnt.getTflArgFromString('u2','double');
   hEnt.addConceptualArg(arg);
   ```
Create the implementation arguments and add them to the entry. This example uses calls to the `getTflArgFromString` function to create implementation arguments. These functions map to arguments in the replacement function prototype: output argument `y1` and input arguments `u1` and `u2`. For each argument, the example uses the convenience method `setReturn` or `addArgument` to specify whether an argument is a return value or argument. For each argument, this example adds the argument to the entry array of implementation arguments.

```matlab
arg = hEnt.getTflArgFromString('y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);

arg = hEnt.getTflArgFromString('u1','double');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u2','double');
hEnt.Implementation.addArgument(arg);
```

Add the entry to a code replacement table with a call to the `addEntry` function.

```matlab
hLib.addEntry(hEnt);
```

Save the table definition file. Use the name of the table definition function to name the file.

To test the example:

1. Register the table that contains the entry in a code replacement library.
2. Configure the code generator to use the code replacement library and to include the Code Replacements Report in the code generation report.
3. Generate code and the report.
4. Review the code replacements.

Replace MATLAB Functions Specified in MATLAB Function Blocks

This example shows how to use code replacement to replace a MATLAB function specified in a MATLAB Function block.

1. Open the ex_replace model. At the command prompt, enter:
   ```
   addpath(fullfile(docroot,'toolbox','ecoder','examples'))
   ex_replace
   ```

2. View the MATLAB Function Block code. In the model, double-click the MATLAB Function block to view the code in the MATLAB editor.
   ```
   function y = customFcn(u1, u2) %#codegen
   % This block supports MATLAB for code generation.
   % Replace this MATLAB function with CRL replacement function and if no
   % CRL replacement is found, generate an error during code generation.
   coder.replace('-errorifnoreplacement');
   assert(isa(u1,'int32'));
   assert(isa(u2,'int32'));
   
   y = power(u1,u2);
   ```

   The `coder.replace('-errorifnoreplacement')` statement instructs the code generator to replace this MATLAB function with a code replacement library function. The code generator produces an error if it does not find a match.

3. Create a table definition file that contains a function definition. For example:
   ```
   function hTable = crl_table_coderreplace()
   ```

4. Within the function body, create the table by calling the function `RTW.TflTable`.
   ```
   hTable = RTW.TflTable;
   ```

5. Create an entry for the function mapping with a call to the `RTW.TflCFunctionEntry` function.
   ```
   hEnt = RTW.TflCFunctionEntry;
   ```

6. Set function entry parameters with a call to the `setTflCFunctionEntryParameters` function.
setTflCFunctionEntryParameters(hEnt, ...
    'Key',                      'customFcn', ...
    'Priority',                 100, ...
    'ImplementationName',       'scalarFcnReplacement', ...
    'ImplementationHeaderFile', 'MyMath.h', ...
    'ImplementationSourceFile', 'MyMath.c')

7  Create conceptual arguments \( y_1, u_1, \) and \( u_2 \). This example uses calls to the getTflArgFromString and addConceptualArg functions to create and add the arguments.

\[
\begin{align*}
\text{arg} &= \text{getTflArgFromString}(h\text{Ent}, 'y1','\text{int32}'); \\
\text{arg.IOType} &= '\text{RTW\_IO\_OUTPUT}'; \\
\text{addConceptualArg}(h\text{Ent}, \text{arg}); \\
\text{arg} &= \text{getTflArgFromString}(h\text{Ent}, 'u1','\text{int32}'); \\
\text{addConceptualArg}(h\text{Ent}, \text{arg}); \\
\text{arg} &= \text{getTflArgFromString}(h\text{Ent}, 'u2','\text{int32}'); \\
\text{addConceptualArg}(h\text{Ent}, \text{arg});
\end{align*}
\]

8  Create the implementation arguments and add them to the entry. This example uses calls to the getTflArgFromString function to create implementation arguments that map to arguments in the replacement function prototype: output argument \( \text{void} \), input arguments \( u_1 \) and \( u_2 \), and output argument \( y_1 \). The convenience methods setReturn and addArgument specify whether an argument is a return value or argument. The addArgument function also adds each argument to the entry’s array of implementation arguments.

\[
\begin{align*}
\text{arg} &= \text{getTflArgFromString}(h\text{Ent}, '\text{void}','\text{void}'); \\
\text{arg.IOType} &= '\text{RTW\_IO\_OUTPUT}'; \\
\h\text{Ent}.\text{Implementation}.\text{setReturn}(\text{arg}); \\
\text{arg} &= \text{getTflArgFromString}(h\text{Ent}, 'u1','\text{int32}'); \\
\h\text{Ent}.\text{Implementation}.\text{addArgument}(\text{arg}); \\
\text{arg} &= \text{getTflArgFromString}(h\text{Ent}, 'u2','\text{int32}'); \\
\h\text{Ent}.\text{Implementation}.\text{addArgument}(\text{arg}); \\
\text{arg} &= \text{getTflArgFromString}(h\text{Ent}, 'y1','\text{int32 *}'); \\
\text{arg.IOType} &= '\text{RTW\_IO\_OUTPUT}'; \\
\h\text{Ent}.\text{Implementation}.\text{addArgument}(\text{arg});
\end{align*}
\]

9  Add the entry to a code replacement table with a call to the addEntry function.

\[
\text{addEntry}(\text{hLib}, \text{hEnt});
\]

10 Save the table definition file. Use the name of the table definition function to name the file.
To test the example:

1. Register the code replacement mapping.
2. Create files `MyMath.c` and `MyMath.h` that define the replacement function, `scalarFcnReplacement`, which has two `int32` inputs and one `int32` output.

   **MyMath.c**
   ```c
   #include "MyMath.h"

   void scalarFcnReplacement(int32_T u1, int32_T u2, int32_T* y1) {
       *y1 = u1^u2;
   }
   
   **MyMath.h**
   ```c
   #ifndef _ScalarMath_h
   #define _ScalarMath_h
   
   #include "rtwtypes.h"
   
   #ifdef __cplusplus
   extern "C" {
   
   extern void scalarFcnReplacement(int32_T u1, int32_T u2, int32_T* y1);
   
   #ifdef __cplusplus
   } 
   
   #endif
   
   #endif
   
   #endif
   ```

3. Open the `ex_replace` model.
4. Configure the code generator to use the code replacement library and to include the Code Replacements Report in the code generation report.
5. Generate the replacement code and a code generation report.
6. Review the code replacements. In the code generation report, view the generated code for `ex_replace.c`.

   ```c
   void ex_replace_step(void) {
       int32_T y;
   }
   ```
```c
scalarFcnReplacement(ex_replace_U.In1, ex_replace_U.In2, &y);
ex_replace_Y.Out1 = y;
```

Reserved Identifiers and Code Replacement

The code generator and C programming language use, internally, reserved keywords for code generation. Do not use reserved keywords as identifiers or function names. Reserved keywords for code generation include many code replacement library identifiers, the majority of which are function names, such as acos.

To view a list of reserved identifiers for the code replacement library that you use to generate code, specify the name of the library in a call to the function RTW.TargetRegistry.getInstance.getTflReservedIdentifiers. For example:

crl_ids = RTW.TargetRegistry.getInstance.getTflReservedIdentifiers('GNU99 (GNU)')

In a code replacement table, the code generator registers each function implementation name defined by a table entry as a reserved identifier. You can register additional reserved identifiers for the table on a per-header-file basis. Providing additional reserved identifiers can help prevent duplicate symbols and other identifier-related compile and link issues.

To register additional code replacement reserved identifiers, use the setReservedIdentifiers function. This function registers specified reserved identifiers to be associated with a code replacement table.

You can register up to four reserved identifier structures in a code replacement table. You can associate one set of reserved identifiers with a code replacement library, while the other three (if present) must be associated with ANSI C. The following example shows a reserved identifier structure that specifies two identifiers and the associated header file.

d{1}.LibraryName = 'ANSI C';
d{1}.HeaderInfos{1}.HeaderName = 'math.h';
d{1}.HeaderInfos{1}.ReservedIds = {'y0', 'y1'};

The code generator adds the identifiers to the list of reserved identifiers and honors them during the build procedure.

Customize Match and Replacement Process

During the build process, the code generator uses:

- Preset match criteria to identify functions and operators for which application-specific implementations replace default implementations.
- Preset replacement function signatures.

It is possible that preset match criteria and preset replacement function signatures do not completely meet your function and operator replacement needs. For example:

- You want to replace an operator with a particular fixed-point implementation function only when fraction lengths are within a particular range.
- When a match occurs, you want to modify your replacement function signature based on compile-time information, such as passing fraction-length values into the function.

To add extra logic into the code replacement match and replacement process, create custom code replacement table entries. With custom entries, you can specify additional match criteria and modify the replacement function signature to meet application needs.

To create a custom code replacement entry:

1. Create a custom code replacement entry class, derived from RTW.TflCFunctionEntryML (for function replacement) or RTW.TflCOperationEntryML (for operator replacement).

2. In your derived class, implement a do_match method with a fixed preset signature as a MATLAB function. In your do_match method, provide either or both of the following customizations that instantiate the class:

   - Add match criteria that the base class does not provide. The base class provides a match based on:
     - Argument number
     - Argument name
     - Signedness
     - Word size
     - Slope (if not specified with wildcards)
     - Bias (if not specified with wildcards)
Math modes, such as saturation and rounding
Operator or function key
Modify the implementation signature by adding additional arguments or setting constant input argument values. You can inject a constant value, such as an input scaling value, as an additional argument to the replacement function.

3 Create code replacement entries that instantiate the custom entry class.
4 Register a library containing the code replacement table that includes your entries.

During code generation, the code replacement match process tries to match function or operator call sites with the base class of your derived entry class. If the process finds a match, the software calls your `do_match` method to execute your additional match logic (if any) and your replacement function customizations (if any).

### Customize Code Match and Replacement for Functions

This example shows how to use custom code replacement table entries to refine the match and replacement logic for functions. The example shows how to:

- Modify a sine function replacement only if the integer size on the current target platform is 32 bits.
- Change the replacement such that the implementation function passes in a degrees-versus-radians flag as an input argument.

1 To exercise the table entries that you create in this example, create an ERT-based model with a sine function block. For example:

In the Inport block parameters, set the signal **Data type** to `double`. If the value selected for **Configuration Parameters > Hardware Implementation > Device type** supports an integer size other than 32, do one of the following:

- Select a temporary target platform with a 32-bit integer size.
- Modify the code to match the integer size of your target platform.

2 Create a class, for example `TflCustomFunctionEntry`, that is derived from the base class `RTW.TflCFunctionEntryML`. The derived class defines a `do_match` method with the signature:
function ent = do_match(hThis, ...
    hCSo, ...
    targetBitPerChar, ...
    targetBitPerShort, ...
    targetBitPerInt, ...
    targetBitPerLong, ...
    targetBitPerLongLong)

In the do_match signature:

• ent is the return handle, which is returned either as empty (indicating that the match failed) or as a TflCFunctionEntry handle.
• hThis is a handle to the class instance.
• hCSo is a handle to an object that the code generator creates for querying the library for a replacement.
• Remaining arguments are the number of bits for various data types of the current target.

The do_match method:

• Adds required additional match criteria that the base class does not provide.
• Makes required modifications to the implementation signature.

In this case, the do_match method must match only targetBitPerInt, representing the number of bits in the C int data type for the current target, to the value 32. If the code generator finds a match, the method sets the return handle and creates and adds an input argument. The input argument represents whether units are expressed as degrees or radians, to the replacement function signature.

Alternatively, create and add the additional implementation function argument for passing a units flag in each code replacement table definition file that instantiates this class. In that case, this class definition code does not create the argument. That code sets only the argument value. For an example of creating and adding additional implementation function arguments in a table definition file, see “Customize Code Match and Replacement for Scalar Operations” on page 54-167.
targetBitPerLong, ... %#ok
targetBitPerLongLong) %#ok
% DO MATCH - Create a custom match function. The base class
% checks the types of the arguments prior to calling this
% method. This will check additional data and perhaps modify
% the implementation function.

ent = []; % default the return to empty, indicating the match failed.

% Match sine function only if the target int size is 32 bits
if targetBitPerInt == 32
  % Need to modify the default implementation, starting from a copy
  % of the standard TflCFunctionEntry.
  ent = RTW.TflCFunctionEntry(hThis);

  % If the target int size is 32 bits, the implementation function
  % takes an additional input flag argument indicating degress vs.
  % radians. The additional argument can be created and added either
  % in the CRL table definition file that instantiates this class, or
  % here in the class definition, as follows:
  createAndAddImplementationArg(ent, 'RTW.TflArgNumericConstant', ...
    'Name',           'u2', ...
    'IsSigned',       true, ...
    'WordLength',     32, ...
    'FractionLength', 0, ...
    'Value',          1);
end
end
end
end

Exit the class folder and return to the previous working folder.

3 Create and save the following code replacement table definition file,
crl_table_custom_sinfcn_double.m. This file defines a code replacement table
that contains a function table entry for sine with double input and output. This entry
instantiates the derived class from the previous step, TflCustomFunctionEntry.

function hTable = crl_table_custom_sinfcn_double

hTable = RTW.TflTable;

% Add TflCustomFunctionEntry
fcn_entry = TflCustomFunctionEntry;
setTflCFunctionEntryParameters(fcn_entry, ...
  'Key',           'sin', ...
  'Priority',      30, ...
  'ImplementationName', 'mySin', ...
  'ImplementationHeaderFile', 'mySin.h', ...
  'ImplementationSourceFile', 'mySin.c');

createAndAddConceptualArg(fcn_entry, 'RTW.TflArgNumeric', ...
  'Name',           'y1', ...
  'IOType',          'RTW_IO_OUTPUT', ...
customAndAddConceptualArg(fcn_entry, 'RTW.TflArgNumeric', ...
    'Name', 'u1', ...
    'IOType', 'RTW_IO_INPUT', ...
    'DataTypeMode', 'double');

% TflCustomFunctionEntry class do_match method will create and add
% an implementation function argument during code generation if
% the supported integer size on the current target is 32 bits.
copyConceptualArgsToImplementation(fcn_entry);
addEntry(hTable, fcn_entry);

4 Check the validity of the code replacement table entry.

• At the command prompt, invoke the table definition file.

    tbl = crl_table_custom_sinfcn_double

• In the Code Replacement Viewer, view the table definition file.

    crviewer(crl_table_custom_sinfcn_double)

**Customize Code Match and Replacement for Nonscalar Operations**

This example shows how to create custom code replacement entries that add logic to the code match and replacement process for a nonscalar operation. Custom entries specify additional match criteria or modify the replacement function signature to meet application needs.

This example restricts the match criteria for an element-wise multiplication replacement to entries with a specific dimension range. When a match occurs, the custom do_match method modifies the replacement signature to pass the number of elements into the function.

Files for developing and testing this code replacement library example are available in matlab/help/toolbox/ecoder/examples/code_replacement/custom_elemmult:

• do_match method — @MyElemMultEntry/MyElemMultEntry.m
• Replacement function source and header files — src/myMulImplLib.c and src/myMulImplLib.h
• Model — myElemMul.slx
To create custom code replacement entries that add logic to the code replacement match and replacement process:

1. Create a class, for example `MyElemMultEntry`, which is derived from the base class `RTW.TflCOperationEntryML`. The derived class defines a `do_match` method with the following signature:

```plaintext
function ent = do_match(hThis, ...
    hCSO, ...
    targetBitPerChar, ...
    targetBitPerShort, ...
    targetBitPerInt, ...
    targetBitPerLong, ...
    targetBitPerLongLong)
```

In the `do_match` signature:

- `ent` is the return handle, which is returned as empty (indicating that the match failed) or as a `TflCOperationEntry` handle.
- `hThis` is the handle to the derived instance.
- `hCSO` is a handle to an object that the code generator creates for querying the library for a replacement.
- Remaining arguments are the number of bits for various data types of the current target.

The `do_match` method:

- Adds match criteria that the base class does not provide.
- Makes changes to the implementation signature.

The `do_match` method relies on the base class for checking data types and dimension ranges. If the code generator finds a match, `do_match`:

- Sets the return handle.
- Uses the conceptual arguments to compute the number of elements in the array. In the replacement entry returned, sets the value of the constant implementation argument as the number of elements of the array.
• Updates the code replacement entry such that it matches CSOs that have the same argument dimensions.

```matlab
classdef MyElemMulyEntry < RTW.TflCOperationEntryML
    methods
        function obj = MyElemMultEntry(varargin)
            mlock;
            obj@RTW.TflCOperationEntryML(varargin{:});
        end

        function ent = do_match(hThis, ...
            hCSO, ... %#ok
            targetBitPerChar, ... %#ok
            targetBitPerShort, ... %#ok
            targetBitPerInt, ... %#ok
            targetBitPerLong, ... %#ok
            targetBitPerLongLong ) %#ok

            % Fourth implementation arg represents number of elements for producing matches.
            assert(strcmp(hThis.Implementation.Arguments(4).Name,'numElements'));

            ent = RTW.TflCOperationEntry(hThis);

            % Calculate number of elements and set value of injected constant.
            ent.Implementation.Arguments(4).Value = prod(hCSO.ConceptualArgs(1).DimRange(1,:));

            % Since implementation has been modified for specific DimRange, update
            % returned entry to match similar CSOs only.
            for idx =1:3
                ent.ConceptualArgs(idx).DimRange = hCSO.ConceptualArgs(idx).DimRange;
            end
        end
    end
end
```

2 Create and save the following code replacement table definition file, `myElemMultCrlTable.m`. This file defines a code replacement table that contains an operator entry generator for element-wise multiplication. The table entry:

• Instantiates the derived class `myElemMultEntry` from the previous step.
• Sets operator entry parameters with the call to the `setTflCOperationEntryParameters` function.
• Creates conceptual arguments `y1`, `u1`, and `u2`. The argument class `RTW.TflArgMatrix` specifies matrix arguments to match. The three arguments are set up to match 2-dimensional matrices with at least two elements in each dimension.
• Calls the `getTflArgFromString` function to create a return value and four implementation arguments. Arguments `u1` and `u2` are the operands, `y1` is the product, and the fourth argument is the number of elements.
Alternatively, the `do_match` method of the derived class `myElemMultEntry` can create and add the implementation arguments. When the number of additional implementation arguments required can vary based on compile-time information, use the alternative approach.

- Calls `addEntry` to add the entry to a code replacement table.

```matlab
function hLib = myElemMultCrlTable

libPath = fullfile(fileparts(which(mfilename)),'src');

hLib = RTW.TflTable;
%---------- entry: RTW_OP_ELEM_MUL -----------
hEnt = MyElemMultEntry;
heEnt.setTflCOperationEntryParameters( ...
    'Key', 'RTW_OP_ELEM_MUL', ...
    'Priority', 100, ...
    'SaturationMode', 'RTW_WRAP_ON_OVERFLOW', ...
    'ImplementationName', 'myElemMul_s32', ...
    'ImplementationSourceFile', 'myMulImplLib.c', ...
    'ImplementationSourcePath', libPath, ...
    'ImplementationHeaderFile', 'myMulImplLib.h', ...
    'ImplementationHeaderPath', libPath, ...
    'SideEffects', true, ...
    'GenCallback','RTW.copyFileToBuildDir');

% Conceptual Args
arg = RTW.TflArgMatrix('y1', 'RTW_IO_OUTPUT', 'int32');
arg.DimRange = [2 2; Inf Inf];
hEnt.addConceptualArg(arg);

arg = RTW.TflArgMatrix('u1', 'RTW_IO_INPUT', 'int32');
arg.DimRange = [2 2; Inf Inf];
hEnt.addConceptualArg(arg);

arg = RTW.TflArgMatrix('u2', 'RTW_IO_INPUT', 'int32');
arg.DimRange = [2 2; Inf Inf];
hEnt.addConceptualArg(arg);

% Implementation Args
arg = hEnt.getTflArgFromString('unused','void');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);
```
arg = hEnt.getTflArgFromString('u1','int32*');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u2','int32*');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('y1','int32*');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('numElements','uint32',0);
hEnt.Implementation.addArgument(arg);

hLib.addEntry( hEnt );

Check the validity of the code replacement table entry.

• At the command prompt, invoke the table definition file.
  tbl = myElemMultCrlTable
• In the Code Replacement Viewer, view the table definition file.
  crviewer(myElemMultCrlTable)

**Customize Code Match and Replacement for Scalar Operations**

This example shows how to create custom code replacement entries that add logic to the code match and replacement process for a scalar operation. Custom entries specify additional match criteria or modify the replacement function signature to meet application needs.

For example:

• When fraction lengths are within a specific range, replace an operator with a fixed-point implementation function.

• When a match occurs, modify the replacement function signature based on compile-time information, such as passing fraction-length values into the function.

This example modifies a fixed-point addition replacement such that the implementation function passes in the fraction lengths of the input and output data types as arguments.
To create custom code replacement entries that add logic to the code replacement match and replacement process:

1. Create a class, for example `TflCustomOperationEntry`, that is derived from the base class `RTW.TflCOperationEntryML`. The derived class defines a `do_match` method with the following signature:

```matlab
function ent = do_match(hThis, ...
    hCSO, ...
    targetBitPerChar, ...
    targetBitPerShort, ...
    targetBitPerInt, ...
    targetBitPerLong, ...
    targetBitPerLongLong)
```

In the `do_match` signature:

- `ent` is the return handle, which is returned as empty (indicating that the match failed) or as a `TflCOperationEntry` handle.
- `hThis` is the handle to the class instance.
- `hCSO` is a handle to an object that the code generator creates for querying the library for a replacement.
- Remaining arguments are the number of bits for various data types of the current target.

The `do_match` method adds match criteria that the base class does not provide. The method makes modifications to the implementation signature. In this case, the `do_match` method relies on the base class for checking word size and signedness.

`do_match` must match only the number of conceptual arguments to the value 3 (two inputs and one output) and the bias for each argument to value 0. If the code generator finds a match, `do_match`:

- Sets the return handle.
- Removes slope and bias wild cards from the conceptual arguments (the match is for specific slope and bias values).
- Writes fraction-length values for the inputs and output into replacement function arguments 3, 4, and 5.

You can create and add three additional implementation function arguments for passing fraction lengths in the class definition or in each code replacement entry definition that instantiates this class. This example creates the arguments, adds them...
to a code replacement table definition file, and sets them to specific values in the class definition code.

classdef TflCustomOperationEntry < RTW.TflCOperationEntryML
methods
    function ent = do_match(hThis, ...
        hCSO,... %#ok
        targetBitPerChar, ... %#ok
        targetBitPerShort, ... %#ok
        targetBitPerInt, ... %#ok
        targetBitPerLong, ... %#ok
        targetBitPerLongLong) %#ok

    % DO_MATCH - Create a custom match function. The base class
    % checks the types of the arguments prior to calling this
    % method. This class will check additional data and can
    % modify the implementation function.

    % The base class checks word size and signedness. Slopes and biases
    % have been wildcarded, so the only additional checking to do is
    % to check that the biases are zero and that there are only three
    % conceptual arguments (one output, two inputs)
    ent = []; % default the return to empty, indicating the match failed

    if length(hCSO.ConceptualArgs) == 3 && ...
        hCSO.ConceptualArgs(1).Type.Bias == 0 && ...
        hCSO.ConceptualArgs(2).Type.Bias == 0 && ...
        hCSO.ConceptualArgs(3).Type.Bias == 0

        % Modify the default implementation. Since this is a
        % generator entry, a concrete entry is created using this entry
        % as a template. The type of entry being created is a standard
        % TflCOperationEntry. Using the standard operation entry
        % provides required information, and you do not need
        % a custom match function.
        ent = RTW.TflCOperationEntry(hThis);

    % Since this entry is modifying the implementation for specific
    % fraction-length values (arguments 3, 4, and 5), the conceptual argument
    % wild cards must be removed (the wildcards were inherited from the
    % generator when it was used as a template for the concrete entry).
    % This concrete entry is now for a specific slope and bias.
    % hCSO holds the slope and bias values (created by the code generator).
    for idx=1:3
        ent.ConceptualArgs(idx).CheckSlope = true;
        ent.ConceptualArgs(idx).CheckBias = true;

        % Set the specific Slope and Biases
        ent.ConceptualArgs(idx).Type.Slope = hCSO.ConceptualArgs(idx).Type.Slope;
        ent.ConceptualArgs(idx).Type.Bias = 0;
    end

    % Set the fraction-length values in the implementation function.
    ent.Implementation.Arguments(3).Value = ...
Exit the class folder and return to the previous working folder.

2 Create and save the following code replacement table definition file, `crl_table_custom_sinfcn_double.m`. This file defines a code replacement table that contains a single operator entry, an entry generator for unsigned 32-bit fixed-point addition operations, with arbitrary fraction-length values on the inputs and the output. The table entry:

- Instantiates the derived class `TflCustomOperationEntry` from the previous step. If you want to replace word sizes and signedness attributes, you can use the same derived class, but not the same entry, because you cannot use a wild card with the `WordLength` and `IsSigned` arguments. For example, to support `uint8`, `int8`, `uint16`, `int16`, and `int32`, add five other distinct entries. To use different implementation functions for saturation and rounding modes other than overflow and round to floor, add entries for those match permutations.

- Sets operator entry parameters with the call to the `setTflCOperationEntryParameters` function.

- Calls the `createAndAddConceptualArg` function to create conceptual arguments `y1`, `u1`, and `u2`.

- Calls `createAndSetCImplementationReturn` and `createAndAddImplementationArg` to define the signature for the replacement function. Three of the calls to `createAndAddImplementationArg` create implementation arguments to hold the fraction-length values for the inputs and output. Alternatively, the entry can omit those argument definitions. Instead, the `do_match` method of the derived class `TflCustomOperationEntry` can create and add the three implementation arguments. When the number of additional implementation arguments required can vary based on compile-time information, use the alternative approach.

- Calls `addEntry` to add the entry to a code replacement table.

```matlab
function hTable = crl_table_custom_sinfcn_double

hTable = RTW.TflTable;
```
%% Add TflCustomOperationEntry

op_entry = TflCustomOperationEntry;

setTflCOperationEntryParameters(op_entry, ...
  'Key', 'RTW_OP_ADD', ...

Scalar Operator Code Replacement

This example shows how to define a code replacement mapping for a scalar operator. The example defines a mapping for the + (addition) operator programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```matlab
   function hTable = crl_table_add_uint8
   ```

2. Within the function body, create the table by calling the function RTW.TflTable.

   ```matlab
   hTable = RTW.TflTable;
   ```

3. Create an entry for the operator mapping with a call to the RTW.TflCOperationEntry function.

   ```matlab
   % Create operation entry
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set function entry parameters with a call to the setTflCOperationEntryParameters function.

   ```matlab
   % Define addition operation of built-in uint8 data type
   % Saturation on, Rounding unspecified
   setTflCOperationEntryParameters(op_entry, ...
       'Key',                      'RTW_OP_ADD', ...
       'Priority',                 90, ...
       'SaturationMode',           'RTW_SATURATE_ON_OVERFLOW', ...
       'RoundingModes',            {'RTW_ROUND_UNSPECIFIED'}, ...
       'ImplementationName',       'u8_add_u8_u8', ...
       'ImplementationHeaderFile', 'u8_add_u8_u8.h', ...
       'ImplementationSourceFile', 'u8_add_u8_u8.c' );
   ```

5. Create conceptual arguments y1, u1, and u2. There are multiple ways to set up the conceptual arguments. This example uses calls to the getTflArgFromString and addConceptualArg functions to create and add the arguments.

   ```matlab
   arg = getTflArgFromString(hTable, 'y1', 'uint8');
   arg.IOType = 'RTW_IO_OUTPUT';
   addConceptualArg(op_entry, arg);
   arg = getTflArgFromString(hTable, 'u1', 'uint8');
   addConceptualArg(op_entry, arg );
   arg = getTflArgFromString(hTable, 'u2', 'uint8');
   addConceptualArg(op_entry, arg );
   ```

6. Copy the conceptual arguments to the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses a call to the
copyConceptualArgsToImplementation function to create and add implementation arguments to the entry by copying matching conceptual arguments.

copyConceptualArgsToImplementation(op_entry);

7 Add the entry to a code replacement table with a call to the addEntry function.

addEntry(hTable, op_entry);

8 Save the table definition file. Use the name of the table definition function to name the file.

To test this example:

1 Register the code replacement mapping.
2 Create a model that includes an Add block, such as this model.

3 Configure the model with the following settings:
   • On the Solver pane, select a fixed-step solver.
   • On the Code Generation pane, select an ERT-based system target file.
   • On the Code Generation > Interface pane, select the code replacement library that contains your addition operation entry.

4 Generate code and a code generation report.
5 Review the code replacements.

Addition and Subtraction Operator Code Replacement

Consider the following when defining mappings for addition and subtraction operator code replacements.

Algorithm Options

When creating a code replacement table entry for an addition or subtraction operator, first determine the type of algorithm that your library function implements.

• Cast-before-operation (CBO), default — Prior to performing the addition or subtraction operation, the algorithm type casts input values to the output type. If the output data type cannot exactly represent the input values, losses can occur as a result of the cast to the output type. Additional loss can occur when the result of the operation is cast to the final output type.

• Cast-after-operation (CAO) — The algorithm computes the ideal result of the addition or subtraction operation of the two inputs. The algorithm then type casts the result to the output data type. Loss occurs during the type cast. This algorithm behaves similarly to the C language except when the signedness of the operands does not match. For example, when you add a signed long operand to an unsigned long operand, standard C language rules convert the signed long operand to an unsigned long operand. The result is a value that is not ideal.

Interactive Specification with Code Replacement Tool

When you use the Code Replacement Tool to create a code replacement table entry for an addition or subtraction operation, the tool displays an Algorithm menu. Use that menu to specify the Cast before operation or Cast after operation algorithm for that entry.
**Programmatic Specification**

Create a code replacement table file, as a MATLAB function, that describes the addition or subtraction code replacement table entry. In the call to `setTflCOperationEntryParameters`, set at least these parameters:

- **Key** to `RTW_OP_ADD` or `RTW_OP_MINUS`
- **ImplementationName** to the name of your replacement function
- **EntryInfoAlgorithm** to `RTW_CAST_BFORE_OP` (cast-before-operation) or `RTW_CAST_AFTER_OP` (cast-after-operation)

This example sets parameters for a code replacement operator entry for a cast-after-operation implementation of a `uint8` addition.

```matlab
op_entry = RTW.TflCOperationEntry;
setTflCOperationEntryParameters(op_entry, ...
    'Key',                      'RTW_OP_ADD', ...
    'EntryInfoAlgorithm',       'RTW_CAST_AFTER_OP', ...
    'ImplementationName',       'u8_add_u8_u8');
```

For more information, see `setTflCOperationEntryParameters`.

**Algorithm Classification**

During code generation, the code generator examines addition and subtraction operations, including adjacent type cast operations, to determine the type of algorithm to compute the expression result. Based on the data types in the expression and the type of the accumulator (type used to hold the result of the addition or subtraction operation), the code generator uses these rules.

- Floating-point types only

<table>
<thead>
<tr>
<th><strong>Input 1 Data Type</strong></th>
<th><strong>Input 2 Data Type</strong></th>
<th><strong>Accumulator Data Type</strong></th>
<th><strong>Output Data Type</strong></th>
<th><strong>Classification</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>double</td>
<td>double</td>
<td>double</td>
<td>double</td>
<td>CBO, CAO</td>
</tr>
<tr>
<td>double</td>
<td>double</td>
<td>double</td>
<td>single</td>
<td>—</td>
</tr>
<tr>
<td>double</td>
<td>single</td>
<td>double</td>
<td>double</td>
<td>—</td>
</tr>
<tr>
<td>double</td>
<td>single</td>
<td>single</td>
<td>single</td>
<td>CBO</td>
</tr>
<tr>
<td>double</td>
<td>single</td>
<td>double</td>
<td>double</td>
<td>CBO, CAO</td>
</tr>
</tbody>
</table>
### Floating-point and fixed-point types on the immediate addition or subtraction operation

<table>
<thead>
<tr>
<th>Algorithm</th>
<th>Conditions</th>
</tr>
</thead>
</table>
| CBO       | One of the following is true:  
  - Operation type is double.  
  - Operation type is single and input types are single or fixed-point. |
| CAO       | Operation type is a superset of input types—that is, output type can represent values of input types without loss of data. |

### Fixed-point types only

<table>
<thead>
<tr>
<th>Algorithm</th>
<th>Conditions</th>
</tr>
</thead>
</table>
| CBO       | At least one of the following is true:  
  - Accumulator type equals output type (Tacc == Tout).  
  - Output type is a superset of input types (Tacc >= {Tin1, Tin2}) and accumulator type is a superset of output type (Tacc >= Tout).  
  - Operation does not incur range or precision loss. |
<table>
<thead>
<tr>
<th>Algorithm</th>
<th>Conditions</th>
</tr>
</thead>
<tbody>
<tr>
<td>CAO</td>
<td>Net bias is zero and the data types in the expression have equal slope adjustment factors. For more information on net bias, see “Addition” or “Subtraction” in “Fixed-Point Operator Code Replacement” on page 55-149 (for MATLAB code) or “Fixed-Point Operator Code Replacement” on page 54-204 (for Simulink models).</td>
</tr>
</tbody>
</table>

In many cases, the numerical result of a CBO operation is equal to that of a CAO operation. For example, if the input and output types are such that the operation produces the ideal result, as in the case of `int8 + int8 -> int16`. To maximize the probability of code replacement occurring in such cases, set the algorithm to cast-after-operation.

**Limitations**

- The code generator does not replace operations with nonzero net bias.
- When classifying an operation as a CAO operation, the code generator includes the adjacent casts in the expression when the expression involves only fixed-point types. Otherwise, the code generator classifies and replaces only the immediate addition or subtraction operation. Casts that the code generator excludes from the classification appear in the generated code.
- To enable the code generator to include multiple cast operations, which follow an addition or subtraction of fixed-point data, in the classification of an expression, the rounding mode must be `simplest` or `floor`. Consider the expression `y=(cast A) (cast B)(u1+u2)`. If the rounding mode of `(cast A), (cast B), and the addition operator (+)` are set to `simplest` or `floor`, the code generator takes into account `(cast A)` and `(cast B)` when classifying the expression and performing the replacement only.

Small Matrix Operation to Processor Code Replacement

This example shows how to define code replacement mappings that replace nonscalar small matrix operations with processor-specific intrinsic functions. The example defines a table containing two matrix operator replacement entries for the + (addition) operator and the double data type. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```matlab
   function hTable = crl_table_matrix_add_double
   ```

2. Within the function body, create the table by calling the function RTW.TflTable.

   ```matlab
   hTable = RTW.TflTable;
   ```

3. Create the entry for the first operator mapping with a call to the RTW.TflCOperationEntry function.

   ```matlab
   % Create table entry for matrix_sum_2x2_double
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set operator entry parameters with a call to the setTflCOperationEntryParameters function. The code generator ignores saturation and rounding modes for floating-point nonscalar addition and subtraction. For code replacement entries for nonscalar addition and subtraction operations that do not involve fixed-point data, in the call to setTflCOperationEntryParameters, specify 'RTW_SATURATE_UNSPECIFIED' for the SaturationMode property and {'RTW_ROUND_UNSPECIFIED'} for RoundingModes.

   ```matlab
   setTflCOperationEntryParameters(op_entry, ...
   'Key',                      'RTW_OP_ADD', ... 
   'Priority',                 30, ... 
   'SaturationMode',           'RTW_WRAP_ON_OVERFLOW', ... 
   'ImplementationName',       'matrix_sum_2x2_double', ... 
   'ImplementationHeaderFile', 'MatrixMath.h', ... 
   'ImplementationSourceFile', 'MatrixMath.c', ... 
   'ImplementationHeaderPath', LibPath, ... 
   'ImplementationSourcePath', LibPath, ... 
   'AdditionalIncludePaths',   {LibPath}, ... 
   'GenCallback',              'RTW.copyFileToBuildDir', ... 
   'SideEffects',              true);
   ```

5. Create conceptual arguments y1, u1, and u2. There are multiple ways to set up the conceptual arguments. This example uses calls to the createAndAddConceptualArg function to create and add an argument with one function call. To specify a matrix argument in the function call, use the argument class RTW.TflArgMatrix. Specify the base type and the dimensions for which the
argument is valid. The first table entry specifies \([2 \ 2]\) and the second table entry specifies \([3 \ 3]\).

% Specify operands and result
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
    'Name',         'y1', ...
    'IOType',       'RTW_IO_OUTPUT', ...
    'BaseType',     'double', ...
    'DimRange',     [2 2]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix',...
    'Name',         'u1', ...
    'BaseType',     'double', ...
    'DimRange',     [2 2]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix',...
    'Name',         'u2', ...
    'BaseType',     'double', ...
    'DimRange',     [2 2]);

6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the getTflArgFromString to create the arguments. The convenience methods setReturn and addArgument specify whether an argument is a return value or argument and adds the argument to the entry's array of implementation arguments.

arg = getTflArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW IO_OUTPUT';
op_entry.Implementation.setReturn(arg);
arg = getTflArgFromString(hTable, 'u1', ['double' '*']);
op_entry.Implementation.addArgument(arg);
arg = getTflArgFromString(hTable, 'u2', ['double' '*']);
op_entry.Implementation.addArgument(arg);
arg = getTflArgFromString(hTable, 'y1', ['double' '*']);
arg.IOType = 'RTW IO_OUTPUT';
op_entry.Implementation.addArgument(arg);

7 Add the entry to a code replacement table with a call to the addEntry function.

addEntry(hTable, op_entry);

8 Create the entry for the second operator mapping.

% Create table entry for matrix_sum_3x3_double
op_entry = RTW.TflCOperationEntry;
setTflCOperationEntryParameters(op_entry, ...
    'Key',                      'RTW_OP_ADD', ...
    'Priority',                 30, ...
    'SaturationMode',           'RTW_WRAP_ON_OVERFLOW', ...
    'ImplementationName',       'matrix_sum_3x3_double', ...
    'ImplementationHeaderFile', 'MatrixMath.h', ...)
To test this example:

1. Register the code replacement mapping.
2. Create a model that includes an Add block.
3 Configure the model with the following settings:

- On the **Solver** pane, select a fixed-step, discrete solver with a fixed-step size such as 0.1.
- On the **Code Generation** pane, select an ERT-based system target file.
- On the **Code Generation > Interface** pane, select the code replacement library that contains your addition operation entry.

4 In the Model Explorer, configure the **Signal Attributes** for the In1 and In2 source blocks. For each source block, set **Port dimensions** to [3,3], and set **Data type** to double. Apply the changes. Save the model.

5 Generate code and a code generation report.

6 Review the code replacements. The code generator replaces the + operator with `matrix_sum_3x3_double` in the generated code.

7 Reconfigure **Port dimensions** for In1 and In2 to [2 2], regenerate code. Observe that code containing the + operator is replaced with `matrix_sum_2x2_double`.

Matrix Multiplication Operation to MathWorks BLAS Code Replacement

This example shows how to define code replacement mappings that replace nonscalar multiplication operations with Basic Linear Algebra Subroutine (BLAS) multiplication functions \( \times \text{gemm} \) and \( \times \text{gemv} \). The example defines code replacement entries that map floating-point matrix/matrix and matrix/vector multiplication operations to MathWorks BLAS library multiplication functions \( \text{dgemm} \) and \( \text{dgemv} \). The example defines the function mappings programmatically. Alternatively, you can use the Code Replacement Tool to define the same mappings.

BLAS libraries support matrix/matrix multiplication in the form of

\[
C = a(\text{op}(A) \times \text{op}(B)) + bC \quad \text{. op}(X) \text{ means X, transposition of X, or Hermitian transposition of X. However, code replacement libraries support only the limited case of}
\]

\[
C = \text{op}(A) \times \text{op}(B) \quad (a = 1.0, b = 0.0) \quad . \text{Correspondingly, although BLAS libraries support matrix/vector multiplication in the form of} \quad y = a(\text{op}(A) \times x) + by \quad \text{, code replacement libraries support only the limited case of} \quad y = \text{op}(A) \times x \quad (a = 1.0, b = 0.0).
\]

1 Create a table definition file that contains a function definition. For example:

```matlab
function hTable = crl_table_tmwblas_mmult_double
```

2 Within the function body, create the table by calling the function RTW.TflTable.

```matlab
hTable = RTW.TflTable;
```

3 Define the path for the BLAS function library. If your replacement functions are on the MATLAB search path or are in your working folder, you can skip this step.

```matlab
% Define library path for Windows or UNIX
arch = computer('arch');
if ~iscpc
    LibPath = fullfile('$(MATLAB_ROOT)', 'bin', arch);
else
    % Use Stateflow to get the compiler info
    compilerInfo = sf('Private', 'compilerman', 'get_compiler_info');
    compilerName = compilerInfo.compilerName;
    if strcmp(compilerName, 'msvc90') || ...
        strcmp(compilerName, 'msvc80') || ...
        strcmp(compilerName, 'msvc71') || ...
        strcmp(compilerName, 'msvc60'), ...
        compilerName = 'microsoft';
    end
end
```
LibPath = fullfile('$(MATLAB_ROOT)','extern','lib',arch,compilerName);

4 Create an entry for the first mapping with a call to the
RTW.TflBlasEntryGenerator function.

% Create table entry for dgemm32
op_entry = RTW.TflBlasEntryGenerator;

5 Set operator entry parameters with a call to the
setTflCFunctionEntryParameters function. The function call sets matrix
multiplication operator entry properties. The code generator ignores saturation and
rounding modes for floating-point nonscalar addition and subtraction. For code
replacement entries for nonscalar addition and subtraction operations that do not
involve fixed-point data, in the call to setTflCFunctionEntryParameters, specify
'RTW_SATURATE_UNSPECIFIED' for the SaturationMode property and
{'RTW_ROUND_UNSPECIFIED'} for RoundingModes.

if ispc
    libExt = 'lib';
else if ismac
    libExt = 'dylib';
else
    libExt = 'so';
end
setTflCOperationEntryParameters(op_entry,...
    'Key', 'RTW_OP_MUL', ...
    'Priority', 100, ...
    'ImplementationName', 'dgemm32', ...
    'ImplementationHeaderFile', 'blascompat32_crl.h', ...
    'ImplementationHeaderPath', fullfile('$(MATLAB_ROOT)','extern','include'), ...
    'AdditionalLinkObjs', {
        ['libmwblascompat32.' libExt], ...
    'AdditionalLinkObjsPaths', {LibPath}, ...
    'SideEffects', true);

6 Create conceptual arguments y1, u1, and u2. There are multiple ways to set up the
conceptual arguments. This example uses calls to the
createAndAddConceptualArg function to create and add an argument with one
function call. To specify a matrix argument in the function call, use the argument
class RTW.TflArgMatrix and specify the base type and the dimensions for which
the argument is valid. This type of table entry supports a range of dimensions
specified in the format [Dim1Min Dim2Min ... DimNMin; Dim1Max
Dim2Max ... DimNMax]. For example, [2 2; inf inf] means a two-dimensional
matrix of size 2x2 or larger. The conceptual output argument for the dgemm32 entry
for matrix/matrix multiplication replacement specifies dimensions [2 2; inf inf],
while the conceptual output argument for the dgemv32 entry for matrix/vector
multiplication replacement specifies dimensions [2 1; inf 1].

54-187
Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `getTflArgFromString` and `RTW.TflArgCharConstant` functions to create the arguments. The example code configures special implementation arguments that are required for `dgemm` and `dgemv` function replacements. The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument and adds the argument to the entry’s array of implementation arguments.

% Using RTW.TflBlasEntryGenerator for xgemm requires the following
% implementation signature:
% void f(char* TRANSA, char* TRANSB, int* M, int* N, int* K,
%        type* ALPHA, type* u1, int* LDA, type* u2, int* LDB,
%        type* BETA, type* y, int* LDC)
% When a match occurs, the code generator computes the
% values for M, N, K, LDA, LDB, and LDC and inserts them into the
% generated code. TRANSA and TRANSB are set to 'N'.

% Specify replacement function signature
arg = getTflArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);

arg = RTW.TflArgCharConstant('TRANSA');
% Possible values for PassByType property are
% RTW_PASSBY_AUTO, RTW_PASSBY_POINTER,
% RTW_PASSBY_VOID_POINTER, RTW_PASSBY_BASE_POINTER
arg.PassByType = 'RTW_PASSBY_POINTER';
op_entry.Implementation.addArgument(arg);

arg = RTW.TflArgCharConstant('TRANSB');
arg.PassByType = 'RTW_PASSBY_POINTER';
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'M', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
Add the entry to a code replacement table with a call to the addEntry function.

addEntry(hTable, op_entry);
54

Code Replacement Customization for Simulink Models in Embedded Coder

9

Create the entry for the second mapping.
% Create table entry for dgemv32
op_entry = RTW.TflBlasEntryGenerator;
if ispc
libExt = 'lib';
elseif ismac
libExt = 'dylib';
else
libExt = 'so';
end
setTflCOperationEntryParameters(op_entry, ...
'Key',
'RTW_OP_MUL', ...
'Priority',
100, ...
'ImplementationName',
'dgemv32', ...
'ImplementationHeaderFile', 'blascompat32_crl.h', ...
'ImplementationHeaderPath', fullfile('$(MATLAB_ROOT)','extern','include'), ...
'AdditionalLinkObjs',
{['libmwblascompat32.' libExt]}, ...
'AdditionalLinkObjsPaths', {LibPath},...
'SideEffects',
true);
% Specify operands and result
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...

Using RTW.TflBlasEntryGenerator for xgemv requires the following
implementation signature:
void f(char* TRANS, int* M, int* N,
type* ALPHA, type* u1, int* LDA, type* u2, int* INCX,
type* BETA, type* y, int* INCY)
Upon a match, the CRL entry will compute the
values for M, N, LDA, INCX, and INCY, and insert them into the
generated code. TRANS will be set to 'N'.

% Specify replacement function signature
arg = getTflArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);
arg = RTW.TflArgCharConstant('TRANS');
arg.PassByType = 'RTW_PASSBY_POINTER';

Matrix Multiplication Operation to MathWorks BLAS Code Replacement

```matlab
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'M', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'N', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'ALPHA', 'double', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u1', ['double' '*']);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDA', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u2', ['double' '*']);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'INCX','integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

addEntry(hTable, op_entry);
```
10 Save the table definition file. Use the name of the table definition function to name the file.

To test this example:

1 Register the code replacement mapping.
2 Create a model that includes two Product blocks.
3 For each Product block, set the block parameter `Multiplication` to the value `Matrix(*)`.
4 Configure the model with the following settings:
   • On the Solver pane, select a fixed-step, discrete solver with a fixed-step size such as 0.1.
   • On the Code Generation pane, select an ERT-based system target file.
   • On the Code Generation > Interface pane, select the code replacement library that contains your addition operation entry.
5 In the Model Explorer, configure the Signal Attributes for the In1, In2, and In3 source blocks. For In1 and In2, set Port dimensions to `[3 3]` and set the Data type to double. For In3, set Port dimensions to `[3 1]` and set the Data type to double.
6 Generate code and a code generation report.
7 Review the code replacements.

Matrix Multiplication Operation to ANSI/ISO C BLAS Code Replacement

This example shows how to define code replacement mappings that replace nonscalar multiplication operations with ANSI/ISO C BLAS multiplication functions \texttt{Xgemm} and \texttt{Xgemv}. The example defines code replacement entries that map floating-point matrix/matrix and matrix/vector multiplication operations to ANSI/ISO C BLAS library multiplication functions \texttt{Dgemm} and \texttt{Dgemv}. The example defines the function mappings programmatically. Alternatively, you can use the Code Replacement Tool to define the same mappings.

BLAS libraries support matrix/matrix multiplication in the form of
\[
    C = \text{a}(\text{op}(A) \ast \text{op}(B)) + \text{b}C
\]
where \text{op}(X) means \(X\), transposition of \(X\), or Hermitian transposition of \(X\). However, code replacement libraries support only the limited case of
\[
    C = \text{op}(A) \ast \text{op}(B) \quad (a = 1.0, \ b = 0.0)
\]
Correspondingly, although BLAS libraries support matrix/vector multiplication in the form of
\[
    y = \text{a}(\text{op}(A) \ast x) + \text{b}y
\]
libraries support only the limited case of
\[
    y = \text{op}(A) \ast x \quad (a = 1.0, \ b = 0.0)
\]

1. Create a table definition file that contains a function definition. For example:

   ```matlab
   function hTable = crl_table_cblas_mmult_double
   ```

2. Within the function body, create the table by calling the function \texttt{RTW.TflTable}.

   ```matlab
   hTable = RTW.TflTable;
   ```

3. Define the path for the CBLAS function library. For example:

   ```matlab
   LibPath = fullfile(matlabroot, 'toolbox', 'rtw', 'rtwdemos', 'crl_demo');
   ```

4. Create an entry for the first mapping with a call to the \texttt{RTW.TflBlasEntryGenerator} function.

   ```matlab
   % Create table entry for cblas_dgemm
   op_entry = RTW.TflCBlasEntryGenerator;
   ```

5. Set operator entry parameters with a call to the \texttt{setTflCOperationEntryParameters} function. The function call sets matrix multiplication operator entry properties. The code generator ignores saturation and rounding modes for floating-point nonscalar addition and subtraction.

   ```matlab
   setTflCOperationEntryParameters(op_entry, ...
         'Key', 'RTW_OP_MUL', ...
6 Create conceptual arguments y1, u1, and u2. There are multiple ways to set up the conceptual arguments. This example uses calls to the createAndAddConceptualArg function to create and add an argument with one function call. To specify a matrix argument in the function call, use the argument class RTW.TflArgMatrix and specify the base type and the dimensions for which the argument is valid. This type of table entry supports a range of dimensions specified in the format \[\text{Dim1Min} \text{ Dim2Min} \ldots \text{ DimNMin}; \text{ Dim1Max} \text{ Dim2Max} \ldots \text{ DimNMax}\]. For example, \[2 2; \text{inf inf}\] means a two-dimensional matrix of size 2x2 or larger. The conceptual output argument for the dgemm32 entry for matrix/matrix multiplication replacement specifies dimensions \[2 2; \text{inf inf}\]. The conceptual output argument for the dgemv32 entry for matrix/vector multiplication replacement specifies dimensions \[2 1; \text{inf 1}\].

% Specify operands and result
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
    'Name', 'y1', ...
    'IOType', 'RTW_IO_OUTPUT', ...
    'BaseType', 'double', ...
    'DimRange', [2 2; inf inf]);

createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
    'Name', 'u1', ...
    'BaseType', 'double', ...
    'DimRange', [2 2; inf inf]);

createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
    'Name', 'u2', ...
    'BaseType', 'double', ...
    'DimRange', [1 1; inf inf]);

7 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the getTflArgFromString function to create the arguments. The example code configures special implementation arguments that are required for dgemm and dgemv function replacements. The convenience methods setReturn and addArgument specify whether an argument is a return value or argument and adds the argument to the entry’s array of implementation arguments.

% Using RTW.TflCBlasEntryGenerator for xgemm requires the following
% implementation signature:
%
% void f(enum ORDER, enum TRANSA, enum TRANSB, int M, int N, int K,
%    type ALPHA, type* u1, int LDA, type* u2, int LDB,
%    type BETA, type* y, int LDC)
% Since CRLs do not have the ability to specify enums, you must
% use integer.  (This will cause problems with C++ code generation,
% so for C++, use a wrapper function to cast each int to the
% corresponding enumeration type.)
%
% When a match occurs, the code generator computes the
% values for M, N, K, LDA, LDB, and LDC and insert them into the
% generated code.

% Specify replacement function signature

arg = getTflArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW IO OUTPUT';
op_entry.Implementation.setReturn(arg);

arg = getTflArgFromString(hTable, 'ORDER', 'integer', 102);
% arg.Type.ReadOnly=true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'TRANSA', 'integer', 111);
% arg.Type.ReadOnly=true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'TRANSB', 'integer', 111);
% arg.Type.ReadOnly=true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'M', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'N', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'K', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'ALPHA', 'double', 1);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u1', ['double' '*']);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDA', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u2', ['double' '*']);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDB', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'BETA', 'double', 0);
op_entry.Implementation.addArgument(arg);
arg = getTflArgFromString(hTable, 'y1', ['double' '*']);
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDC', 'integer', 0);
op_entry.Implementation.addArgument(arg);

8 Add the entry to a code replacement table with a call to the addEntry function.

addEntry(hTable, op_entry);

9 Create the entry for the second mapping.

% Create table entry for cblas_dgemv
op_entry = RTW.TflCBlasEntryGenerator;
setTflCOperationEntryParameters(op_entry, ...
    'Key',                      'RTW_OP_MUL', ...
    'Priority',                 100, ...
    'ImplementationName',       'cblas_dgemv', ...
    'ImplementationHeaderFile', 'cblas.h', ...
    'ImplementationHeaderPath', LibPath, ...
    'AdditionalIncludePaths',   {LibPath}, ...
    'GenCallback',              'RTW.copyFileToBuildDir', ...
    'SideEffects',              true);

% Specify operands and result
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
    'Name',         'y1', ...
    'IOType',       'RTW_IO_OUTPUT', ...
    'BaseType',     'double', ...
    'DimRange',     [2 1; inf 1]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
    'Name',         'u1', ...
    'BaseType',     'double', ...
    'DimRange',     [2 2; inf inf]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix',...
    'Name',         'u2', ...
    'BaseType',     'double', ...
    'DimRange',     [1 1; inf 1]);

% Using RTW.TflCBlasEntryGenerator for xgemv requires the following
% implementation signature:
%
% void f(enum ORDER, enum TRANSA, int M, int N, 
%    type ALPHA, type* u1, int LDA, type* u2, int INCX, 
%    type BETA, type* y, int INCY)
%
% Since CRLs do not have the ability to specify enums, you must
% use integer. (This will cause problems with C++ code generation,
% so for C++, use a wrapper function to cast each int to the
% corresponding enumeration type.)
%
% Upon a match, the CRL entry will compute the
% values for M, N, LDA, INXC, and INCY and insert them into the
% generated code.
% Specify replacement function signature
arg = getTflArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);

arg = getTflArgFromString(hTable, 'ORDER', 'integer', 102);
% arg.Type.ReadOnly=true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'TRANSA', 'integer', 111);
% arg.Type.ReadOnly=true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'M', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'N', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'ALPHA', 'double', 1);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u1', ['double' '*']);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDA', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u2', ['double' '*']);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'INCX', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'BETA', 'double', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'y1', ['double' '*']);
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'INCY', 'integer', 0);
op_entry.Implementation.addArgument(arg);

addEntry(hTable, op_entry);

10 Save the table definition file. Use the name of the table definition function to name the file.

To test this example:

1 Register the code replacement mapping.
2 Create a model that includes two Product blocks.

3 Configure the model with the following settings:
   • On the **Solver** pane, select a fixed-step, discrete solver with a fixed-step size such as 0.1.
   • On the **Code Generation** pane, select an ERT-based system target file.
   • On the **Code Generation > Interface** pane, select the code replacement library that contains your addition operation entry.

4 For each Product block, set the block parameter **Multiplication** to the value **Matrix(*)**.

5 In the Model Explorer, configure the **Signal Attributes** for the In1, In2, and In3 source blocks. For In1 and In2, set **Port dimensions** to [3 3]. Set the **Data type** to double. For In3, set **Port dimensions** to [3 1]. Set the **Data type** to double.

6 Generate code and a code generation report.

7 Review the code replacements.

Remap Operator Output to Function Input

If your generated code must meet a specific coding pattern or you want more flexibility, for example, to further improve performance, you can remap operator outputs to input positions in an implementation function argument list.

**Note** Remapping outputs to implementation function inputs is supported only for operator replacement.

For example, for a sum operation, the code generator produces code similar to:

```plaintext
add8_Y.Out1 = u8_add_u8_u8(add8_U.In1, add8_U.In2);
```

If you remap the output to the first input, the code generator produces code similar to:

```plaintext
u8_add_u8_u8(&add8_Y.Out1;, add8_U.In1, add8_U.In2);
```

The following table definition file for a sum operation remaps operator output y1 as the first function input argument.

1. Create a table definition file that contains a function definition. For example:

   ```plaintext
   function hTable = crl_table_add_uint8
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```plaintext
   hTable = RTW.TflTable;
   ```

3. Create an entry for the operator mapping with a call to the `RTW.TflCOperationEntry` function.

   ```plaintext
   % Create operation entry
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. In the function call, set the property `SideEffects` to true.

   ```plaintext
   setTflCOperationEntryParameters(op_entry, ...
   'Key',                      'RTW_OP_ADD', ...,
   'Priority',                 90, ...,
   'ImplementationName',       'u8_add_u8_u8', ...,
   'ImplementationHeaderFile', 'u8_add_u8_u8.h', ...,
   'ImplementationSourceFile', 'u8_add_u8_u8.c', ...,
   'SideEffects',              true );
   ```
Create conceptual arguments \( y_1, u_1, \) and \( u_2. \) There are multiple ways to set up the conceptual arguments. This example uses calls to the getTflArgFromString and addConceptualArg functions to create and add the arguments.

\[
\begin{align*}
\text{arg} &= \text{getTflArgFromString}(hTable, 'y1', 'uint8'); \\
\text{arg.IOType} &= 'RTW_IO_OUTPUT'; \\
\text{addConceptualArg}(op_entry, \text{arg}); \\
\text{arg} &= \text{getTflArgFromString}(hTable, 'u1', 'uint8'); \\
\text{addConceptualArg}(op_entry, \text{arg}); \\
\text{arg} &= \text{getTflArgFromString}(hTable, 'u2', 'uint8'); \\
\text{addConceptualArg}(op_entry, \text{arg});
\end{align*}
\]

Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the getTflArgFromString function to create the arguments. When defining the implementation function return argument, create a new void output argument, for example, \( y_2. \) When defining the implementation function argument for the conceptual output argument (\( y_1 \)), set the operator output argument as an additional input argument. Mark its IOType as output. Make its type a pointer type. The convenience methods setReturn and addArgument specify whether an argument is a return value or argument and adds the argument to the entry’s array of implementation arguments.

\[
\begin{align*}
\% \text{ Create new void output } y_2 \\
\text{arg} &= \text{getTflArgFromString}(hTable, 'y2', 'void'); \\
\text{arg.IOType} &= 'RTW_IO_OUTPUT'; \\
\text{op_entry}.\text{Implementation}.\text{setReturn}(\text{arg}); \\
\% \text{ Set } y_1 \text{ as first input arg, mark IOType as output, and use pointer type} \\
\text{arg} &= \text{getTflArgFromString}(hTable, 'y1', 'uint8*'); \\
\text{arg.IOType} &= 'RTW_IO_OUTPUT'; \\
\text{op_entry}.\text{Implementation}.\text{addArgument}(\text{arg}); \\
\text{arg} &= \text{getTflArgFromString}(hTable, 'u1', 'uint8'); \\
\text{op_entry}.\text{Implementation}.\text{addArgument}(\text{arg}); \\
\text{arg} &= \text{getTflArgFromString}(hTable, 'u2', 'uint8'); \\
\text{op_entry}.\text{Implementation}.\text{addArgument}(\text{arg});
\end{align*}
\]

Add the entry to a code replacement table with a call to the addEntry function.

\[
\text{addEntry}(hTable, \text{op_entry});
\]

Save the table definition file. Use the name of the table definition function to name the file.

To test this example:

1. Register the code replacement mapping.
2 Create a model that includes an Add block.

3 Configure the model with the following settings:
   • On the **Solver** pane, select a fixed-step solver.
   • On the **Code Generation** pane, select an ERT-based system target file.
   • On the **Code Generation > Interface** pane, select the code replacement library that contains your addition operation entry.
   • Set the **Optimize global data access** parameter to **Use global to hold temporary results** to reduce data copies in the generated code.

4 Generate code and a code generation report.

5 Review the code replacements.

Fixed-Point Operator Code Replacement

If you have a Fixed-Point Designer license, you can define fixed-point operator code replacement entries to match:

- A binary-point-only scaling combination on the operator inputs and output.
- A slope bias scaling combination on the operator inputs and output.
- Relative scaling or net slope between multiplication or division operator inputs and output. Use one of these methods to map a range of slope and bias values to a replacement function for multiplication or division.
- Equal slope and zero net bias across addition or subtraction operator inputs and output. Use this method to disregard specific slope and bias values and map relative slope and bias values to a replacement function for addition or subtraction.

Common Ways to Match Fixed-Point Operator Entries

The following table maps common ways to match fixed-point operator code replacement entries with the associated fixed-point parameters that you specify in a code replacement table definition file.

<table>
<thead>

Fixed-Point Numbers and Arithmetic

Fixed-point numbers use integers and integer arithmetic to represent real numbers and arithmetic with the following encoding scheme:

\[ V = \bar{V} = SQ + B \]

- \( V \) is an arbitrarily precise real-world value.
- \( \bar{V} \) is the approximate real-world value that results from fixed-point representation.
- \( Q \) is an integer that encodes \( \bar{V} \), referred to as the quantized integer.
- \( S \) is a coefficient of \( Q \), referred to as the slope.
- \( B \) is an additive correction, referred to as the bias.

The general equation for an operation between fixed-point operands is:

\( (S_o Q_o + B_o) = (S_1 Q_1 + B_1) < op > (S_2 Q_2 + B_2) \)

The objective of fixed-point operator replacement is to replace an operator that accepts and returns fixed-point or integer inputs and output with a function that accepts and returns built-in C numeric data types. The following sections provide additional programming information for each supported operator.

**Addition**

The operation \( V_0 = V_1 + V_2 \) implies that

\[ Q_0 = \left( \frac{S_1}{S_0} \right) Q_1 + \left( \frac{S_2}{S_0} \right) Q_2 + \left( \frac{B_1 + B_2 - B_0}{S_0} \right) \]

If an addition replacement function is defined such that the scaling on the operands and sum are equal and the net bias
Subtraction

The operation $V_0 = V_1 - V_2$ implies that

$$Q_0 = \left( \frac{S_1}{S_0} \right) Q_1 - \left( \frac{S_2}{S_0} \right) Q_2 + \left( \frac{B_1 - B_2 - B_0}{S_0} \right)$$

If a subtraction replacement function is defined such that the scaling on the operands and difference are equal and the net bias

$$\left( \frac{B_1 - B_2 - B_0}{S_0} \right)$$

is zero (for example, a function `s8_sub_s8_s8` that subtracts two signed 8-bit values and produces a signed 8-bit result), then the operator entry must set the operator entry parameters `SlopesMustBeTheSame` and `MustHaveZeroNetBias` to `true`. To match for replacement, the slopes must be the same for all subtraction conceptual arguments. (For parameter descriptions, see the reference page for the function `setTflCOperationEntryParameters`.)

Multiplication

There are different ways to specify multiplication replacements. The most direct way is to specify an exact match of the input and output types. This is feasible if a model contains only a few (known) slope and bias combinations. Use the `TflCOperationEntry` class and specify the exact values of slope and bias on each argument. For scenarios where
there are numerous slope/bias combinations, it is not feasible to specify each value with a different entry. Use a net slope entry or create a custom entry.

The operation \( V_0 = V_1 \times V_2 \) implies, for binary-point-only scaling, that

\[
S_0Q_0 = (S_1Q_1)(S_2Q_2)
\]

\[
Q_0 = \left( \frac{S_1S_2}{S_0} \right)Q_1Q_2
\]

\[
Q_0 = S_nQ_1Q_2
\]

where \( S_n \) is the net slope.

It is common to replace all multiplication operations that have a net slope of 1.0 with a function that performs C-style multiplication. For example, to replace all signed 8-bit multiplications that have a net scaling of 1.0 with the `s8_mul_s8_u8_` replacement function, the operator entry must define a net slope factor, \( F^{E} \). You specify the values for \( F \) and \( E \) using operator entry parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`. For the `s8_mul_s8_u8` function, set `NetSlopeAdjustmentFactor` to 1 and `NetFixedExponent` to 0.0. Also, set the operator entry parameters `SlopesMustBeTheSame` and `MustHaveZeroNetBias` to true. To match for replacement, the biases must be zero for all multiplication conceptual arguments. (For parameter descriptions, see the reference page for the function `setTflCOperationEntryParameters`.)

**Note** When an operator entry specifies `NetSlopeAdjustmentFactor` and `NetFixedExponent`, matching entries must have arguments with zero bias.

### Division

There are different ways to specify division replacements. The most direct way is to specify an exact match of the input and output types. This is feasible if a model contains only a few (known) slope and bias combinations. For this, use the `TflCOperationEntry` class and specify the exact values of slope and bias on each argument. For scenarios where there are numerous slope/bias combinations, it is not feasible to specify each value with a different entry. For this, use a net slope entry or create a custom entry (see "Customize Match and Replacement Process" on page 54-159).
The operation $V_0 = (V_1 / V_2)$ implies, for binary-point-only scaling, that

$$S_0 Q_0 = \left( \frac{S_1 Q_1}{S_2 Q_2} \right)$$

$$Q_0 = S_n \left( \frac{Q_1}{Q_2} \right)$$

where $S_n$ is the net slope.

It is common to replace all division operations that have a net slope of 1.0 with a function that performs C-style division. For example, to replace all signed 8-bit divisions that have a net scaling of 1.0 with the `s8_mul_s8_u8_` replacement function, the operator entry must define a net slope factor, $F^{2E}$. You specify the values for $F$ and $E$ using operator entry parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`. For the `s16_netslope0p5_div_s16_s16` function, you would set `NetSlopeAdjustmentFactor` to 1 and `NetFixedExponent` to 0.0. Also, set the operator entry parameters `SlopesMustBeTheSame` and `MustHaveZeroNetBias` to true. To match for replacement, the biases must be zero for all division conceptual arguments. (For parameter descriptions, see the reference page for the function `setTflCOperationEntryParameters`.)

**Note** When an operator entry specifies `NetSlopeAdjustmentFactor` and `NetFixedExponent`, matching entries must have arguments with zero bias.

### Data Type Conversion (Cast)

The data type conversion operation $V_0 = V_1$ implies, for binary-point-only scaling, that

$$Q_0 = \left( \frac{S_1}{S_0} \right) Q_1$$

$$Q_0 = S_n Q_1$$

where $S_n$ is the net slope. Set the operator entry parameters `SlopesMustBeTheSame` and `MustHaveZeroNetBias` to true. To match for replacement, the biases must be zero for
all cast conceptual arguments. (For parameter descriptions, see the reference page for
the function setTflCOperationEntryParameters.)

Shift

The shift left or shift right operation \( V_0 = (V_1 / 2^n) \) implies, for binary-point-only scaling, that

\[
S_0Q_0 = \left( \frac{S_1Q_1}{2^n} \right)
\]

\[
Q_0 = \left( \frac{S_1}{S_0} \right) + \left( \frac{Q_1}{2^n} \right)
\]

\[
Q_0 = S_n \left( \frac{Q_1}{2^n} \right)
\]

where \( S_n \) is the net slope. Set the operator entry parameters SlopesMustBeTheSame and
MustHaveZeroNetBias to true. To match for replacement, the biases must be zero for
all shift conceptual arguments. (For parameter descriptions, see the reference page for
the function setTflCOperationEntryParameters.)

Binary-Point-Only Scaling Code Replacement

You can define code replacement entries for operations on fixed-point data types such that they match a binary-point-only scaling combination on operator inputs and output. These binary-point-only scaling entries can map the specified binary-point-scaling combination to a replacement function for addition, subtraction, multiplication, or division.

This example creates a code replacement entry for multiplication of fixed-point data types. You specify arguments using binary-point-only scaling. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_fixed_binptscale
   ```

2. Within the function body, create the table by calling the function RTW.TflTable.

   ```
   hTable = RTW.TflTable;
   ```

3. Create the entry for the operator mapping with a call to the RTW.TflCOperationEntry function.

   ```
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set operator entry parameters with a call to the setTflCOperationEntryParameters function. The parameters specify the type of operation as multiplication, the saturation mode as saturate on integer overflow, rounding modes as unspecified, and the name of the replacement function as s32_mul_s16_s16_binarypoint.

   ```
   setTflCOperationEntryParameters(op_entry, ...
   'Key',                      'RTW_OP_MUL', ...
   'Priority',                 90, ...
   'SaturationMode',           'RTW_SATURATE_ON_OVERFLOW', ...
   'RoundingModes',            {'RTW_ROUND_UNSPECIFIED'}, ...
   'ImplementationName',       's32_mul_s16_s16_binarypoint', ...
   'ImplementationHeaderFile', 's32_mul_s16_s16_binarypoint.h', ...
   'ImplementationSourceFile', 's32_mul_s16_s16_binarypoint.c');
   ```

5. Create conceptual arguments y1, u1, and u2. There are multiple ways to set up the conceptual arguments. This example uses calls to the createAndAddConceptualArg function to create and add an argument with one function call. Each argument specifies that the data type is fixed-point, the mode is binary-point-only scaling, and its derived slope and bias values must exactly match the call-site slope and bias values. The output argument is 32 bits, signed, with a
fraction length of 28. The input arguments are 16 bits, signed, with fraction lengths of 15 and 13.

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
'Name',           'y1', ...
'IOType',         'RTW_IO_OUTPUT', ...
'CheckSlope',     true, ...
'CheckBias',      true, ...
'DataTypeMode',   'Fixed-point: binary point scaling', ...
'IsSigned',       true, ...
'WordLength',     32, ...
'FractionLength', 28);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
'Name',           'u1', ...
'IOType',         'RTW_IO_INPUT', ...
'CheckSlope',     true, ...
'CheckBias',      true, ...
'DataTypeMode',   'Fixed-point: binary point scaling', ...
'IsSigned',       true, ...
'WordLength',     16, ...
'FractionLength', 15);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
'Name',           'u2', ...
'IOType',         'RTW_IO_INPUT', ...
'CheckSlope',     true, ...
'CheckBias',      true, ...
'DataTypeMode',   'Fixed-point: binary point scaling', ...
'IsSigned',       true, ...
'WordLength',     16, ...
'FractionLength', 13);

Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the createAndSetCImplementationReturn and createAndAddImplementationArg functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). In this case, the output argument is 32 bits and signed (int32). The input arguments are 16 bits and signed (int16).

createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...
'Name',           'y1', ...
'IOType',         'RTW_IO_OUTPUT', ...
'IsSigned',       true, ...
'WordLength',     32, ...
'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric', ...
'Name',           'u1', ...
'IOType',         'RTW_IO_INPUT', ...
'IsSigned',       true, ...
'WordLength',     16, ...
7 Add the entry to a code replacement table with a call to the `addEntry` function.

    addEntry(hTable, op_entry);

8 Save the table definition file. Use the name of the table definition function to name the file.

To test this example:

1 Register the code replacement mapping.

2 Create a model.

3 For this model:
   - Set the Inport 1 **Data type** to `fixdt(1,16,15)``.
   - Set the Inport 2 **Data type** to `fixdt(1,16,13)`.
   - In the Product block:
     - Set **Output data type** to `fixdt(1,32,28)`.
     - Select the option **Saturate on integer overflow**.

4 Configure the model with the following settings:
   - On the **Solver** pane, select a fixed-step, discrete solver.
   - On the **Code Generation** pane, select an ERT-based system target file.
   - On the **Code Generation > Interface** pane, select the code replacement library that contains your addition operation entry.

5 Generate code and a code generation report.
6 Review the code replacements.

Slope Bias Scaling Code Replacement

You can define code replacement for operations on fixed-point data types as matching a slope bias scaling combination on the operator inputs and output. The slope bias scaling entries can map the specified slope bias combination to a replacement function for addition, subtraction, multiplication, or division.

This example creates a code replacement entry for division of fixed-point data types. You specify arguments using slope bias scaling. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```matlab
   function hTable = crl_table_fixed_s16divslopebias
   ```

2. Within the function body, create the table by calling the function RTW.TflTable.

   ```matlab
   hTable = RTW.TflTable;
   ```

3. Create the entry for the operator mapping with a call to the RTW.TflCOperationEntry function.

   ```matlab
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set operator entry parameters with a call to the setTflCOperationEntryParameters function. The parameters specify the type of operation as division, the saturation mode as saturate on integer overflow, rounding modes as round to ceiling, and the name of the replacement function as s16_div_s16_s16_slopebias.

   ```matlab
   setTflCOperationEntryParameters(op_entry, ...
   'Key',                      'RTW_OP_DIV', ...
   'Priority',                 90, ...
   'SaturationMode',           'RTW_SATURATE_ON_OVERFLOW', ...
   'RoundingModes',            {'RTW_ROUND_CEILING'}, ...
   'ImplementationName',       's16_div_s16_s16_slopebias', ...
   'ImplementationHeaderFile', 's16_div_s16_s16_slopebias.h', ...
   'ImplementationSourceFile', 's16_div_s16_s16_slopebias.c');
   ```

5. Create conceptual arguments y1, u1, and u2. There are multiple ways to set up the conceptual arguments. This example uses calls to the createAndAddConceptualArg function to create and add an argument with one function call. Each argument specifies that the data type is fixed-point, the mode is slope bias scaling, and its specified slope and bias values must exactly match the call-site slope and bias values. The output argument and input arguments are 16 bits, signed, each with specific slope bias specifications.
Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `createAndSetCImplementationReturn` and `createAndAddImplementationArg` functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). In this case, the output and input arguments are 16 bits and signed (`int16`).

```matlab
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ... 'Name', 'y1', ...
'IOType', 'RTW_IO_OUTPUT', ...
'CheckSlope', true, ...
'CheckBias', true, ...
'DatatypeMode', 'Fixed-point: slope and bias scaling', ...
'IsSigned', true, ...
'WordLength', 16, ...
'Slope', 15, ...
'Bias', 2);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
'Name', 'u1', ...
'IOType', 'RTW_IO_INPUT', ...
'CheckSlope', true, ...
'CheckBias', true, ...
'DatatypeMode', 'Fixed-point: slope and bias scaling', ...
'IsSigned', true, ...
'WordLength', 16, ...
'Slope', 15, ...
'Bias', 2);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
'Name', 'u2', ...
'IOType', 'RTW_IO_INPUT', ...
'CheckSlope', true, ...
'CheckBias', true, ...
'DatatypeMode', 'Fixed-point: slope and bias scaling', ...
'IsSigned', true, ...
'WordLength', 16, ...
'Slope', 13, ...
'Bias', 5);
```
createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',
    'Name', 'u2',
    'IOType', 'RTW_IO_INPUT',
    'IsSigned', true,
    'WordLength', 16,
    'FractionLength', 0);

7 Add the entry to a code replacement table with a call to the addEntry function.

    addEntry(hTable, op_entry);

8 Save the table definition file. Use the name of the table definition function to name the file.

To test this example:

1 Register the code replacement mapping.
2 Create a model.

   ![Diagram of a model with Inports 1 and 2, Multiply and Divide blocks, and Outports]

3 For this model:
   • Set the Inport 1 **Data type** to fixdt(1,16,15,2).
   • Set the Inport 2 **Data type** to fixdt(1,16,13,5).
   • In the Divide block:
     • Set **Output data type** to Inherit: Inherit via back propagation.
     • Set **Integer rounding mode** to Ceiling.
     • Select the option **Saturate on integer overflow**.

4 Configure the model with the following settings:
   • On the **Solver** pane, select a fixed-step, discrete solver.
   • On the **Code Generation** pane, select an ERT-based system target file.
   • On the **Code Generation > Interface** pane, select the code replacement library that contains your addition operation entry.
5 Generate code and a code generation report.
6 Review the code replacements.

Net Slope Scaling Code Replacement

**Multiplication and Division with Saturation**

You can define code replacement entries for operations on fixed-point data types as matching net slope between operator inputs and output. The net slope entries can map a range of slope and bias values to a replacement function for multiplication or division.

This example creates a code replacement entry for division of fixed-point data types, using wrap on overflow saturation mode and a net slope. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_fixed_netslopesaturate
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntryGenerator_Netslope` function, which provides access to the fixed-point parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`.

   ```
   wv = [16,32];
   for iy = 1:2
       for inum = 1:2
           for iden = 1:2
               hTable = getDivOpEntry(hTable, ...
               fixdt(1,wv(iy)),fixdt(1,wv(inum)),fixdt(1,wv(iden)));
           end
       end
   end
   ```

   `%-----------------------------------------------------`

   ```
   function hTable = getDivOpEntry(hTable,dty,dtnum,dtden)
   %-----------------------------------------------------
   % Create an entry for division of fixed-point data types where
   % arguments are specified using Slope and Bias scaling
   % Saturation on, Rounding unspecified
   
   funcStr = sprintf('user_div_%s_%s_%s',...
       typeStrFunc(dty),...
       typeStrFunc(dtnum),...
       typeStrFunc(dtden));
   ```
Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as division, the saturation mode as wrap on overflow, rounding modes as unspecified, and the name of the replacement function as `user_div_*`.

NetSlopeAdjustmentFactor and NetFixedExponent specify the $F$ and $E$ parts of the net slope $F2^E$.

```matlab
setTflCOperationEntryParameters(op_entry, ...
    'Key',                      'RTW_OP_DIV', ...
    'Priority',                 90, ...
    'SaturationMode',           'RTW_WRAP_ON_OVERFLOW',...
    'RoundingModes',            {'RTW_ROUND_UNSPECIFIED'},...
    'NetSlopeAdjustmentFactor', 1.0, ...
    'NetFixedExponent',         0.0, ...
    'ImplementationName',       funcStr, ...
    'ImplementationHeaderFile', [funcStr,'.h'], ...
    'ImplementationSourceFile', [funcStr,'.c']);
```

Create conceptual arguments $y_1$, $u_1$, and $u_2$. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Specify each argument as fixed-point and signed. Also, for each argument, specify that code replacement request processing does not check for an exact match to the call-site slope and bias values.

```matlab
createAndAddConceptualArg(op_entry, ...
    'RTW.TflArgNumeric', ...
    'Name',           'y1', ...
    'IOType',         'RTW_IO_OUTPUT',...
    'CheckSlope',     false,...
    'CheckBias',      false,...
    'DataTypeMode',   'Fixed-point: slope and bias scaling',...
    'IsSigned',       dty.Signed,...
    'WordLength',     dty.WordLength,...
    'Bias',           0);
```

```matlab
createAndAddConceptualArg(op_entry, ...
    'RTW.TflArgNumeric', ...
    'Name',           'u1', ...
    'IOType',         'RTW_IO_INPUT',...
    'CheckSlope',     false,...
    'CheckBias',      false,...
    'DataTypeMode',   'Fixed-point: slope and bias scaling',...
    'IsSigned',       dttnum.Signed,...
    'WordLength',     dttnum.WordLength,...
    'Bias',           0);
```

```matlab
createAndAddConceptualArg(op_entry, ...
    'RTW.TflArgNumeric', ...
    'Name',           'u2', ...
    'IOType',         'RTW_IO_INPUT',...
    'CheckSlope',     false,...
    'CheckBias',      false,...
    'DataTypeMode',   'Fixed-point: slope and bias scaling',...
    'IsSigned',       dttnum.Signed,...
    'WordLength',     dttnum.WordLength,...
    'Bias',           0);
```
Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `getTflArgFromString` function to create the arguments. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument. These methods add the argument to the entry array of implementation arguments.

```
arg = getTflArgFromString(hTable, 'y1', typeStrBase(dty));
op_entry.Implementation.setReturn(arg);

arg = getTflArgFromString(hTable, 'u1', typeStrBase(dtnum));
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u2', typeStrBase(dtden));
op_entry.Implementation.addArgument(arg);
```

Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

Define functions that determine the data type word length.

```
function str = typeStrFunc(dt)
    if dt.Signed
        sstr = 's';
    else
        sstr = 'u';
    end
    str = sprintf('%s%d', sstr, dt.WordLength);

function str = typeStrBase(dt)
    if dt.Signed
        sstr = ;
    else
        sstr = 'u';
    end
    str = sprintf('%sint%d', sstr, dt.WordLength);
```
Save the table definition file. Use the name of the table definition function to name the file.

**Multiplication and Division with Rounding Mode and Additional Implementation Arguments**

You can define code replacement entries for multiplication and division operations on fixed-point data types such that they match the net slope between operator inputs and output. The net slope entries can map a range of slope and bias values to a replacement function for multiplication or division.

This example creates a code replacement entry for division of fixed-point data types, using the ceiling rounding mode and a net slope scaling factor. The example defines the function mapping programmatically. Alternatively, you can use the **Code Replacement Tool** to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```matlab
   function hTable = crl_table_fixed_netsloperound
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```matlab
   hTable = RTW.TflTable;
   ```

3. Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntryGenerator_NetSlope` function, which provides access to the fixed-point parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`.

   ```matlab
   op_entry = RTW.TflCOperationEntryGenerator_NetSlope;
   ```

4. Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as division, the saturation mode as saturation off, rounding modes as round to ceiling, and the name of the replacement function as `s16_div_s16_s16`. `NetSlopeAdjustmentFactor` and `NetFixedExponent` specify the $F$ and $E$ parts of the relative scaling factor $F2^E$.

   ```matlab
   setTflCOperationEntryParameters(op_entry, ...
   'Key',                           'RTW.OP_DIV', ...
   'Priority',                       90, ...
   'SaturationMode',                 'RTW.WRAP_ON_OVERFLOW', ...
   'RoundingModes',                  {'RTW_ROUND_CEILING'}, ...
   'NetSlopeAdjustmentFactor',       1.0, ...
   'NetFixedExponent',               0.0, ...
   ```
Create conceptual arguments $y_1$, $u_1$, and $u_2$. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Specify each argument as fixed-point, 16 bits, and signed. Also, for each argument, specify that code replacement request processing does not check for an exact match to the call-site slope and bias values.

```matlab
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'y1', ...
    'IOType',         'RTW_IO_OUTPUT', ...
    'CheckSlope',     false, ...
    'CheckBias',      false, ...
    'DataType',       'Fixed', ...
    'IsSigned',       true, ...
    'WordLength',     16);
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'u1', ...
    'IOType',         'RTW_IO_INPUT', ...
    'CheckSlope',     false, ...
    'CheckBias',      false, ...
    'DataType',       'Fixed', ...
    'IsSigned',       true, ...
    'WordLength',     16);
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'u2', ...
    'IOType',         'RTW_IO_INPUT', ...
    'CheckSlope',     false, ...
    'CheckBias',      false, ...
    'DataType',       'Fixed', ...
    'IsSigned',       true, ...
    'WordLength',     16);
```

Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `createAndSetCImplementationReturn` and `createAndAddImplementationArg` functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). In this case, the output and input arguments are 16 bits and signed (int16).

```matlab
createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'y1', ...
    'IOType',         'RTW_IO_OUTPUT', ...
    'IsSigned',       true, ...
    'WordLength',     16, ...
    'FractionLength', 0);
```
createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric', ...  
    'Name',       'u1',  ...  
    'IOType',     'RTW_IO_INPUT', ...  
    'IsSigned',   true, ...  
    'WordLength', 16, ...  
    'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric', ...  
    'Name',       'u2',  ...  
    'IOType',     'RTW_IO_INPUT', ...  
    'IsSigned',   true, ...  
    'WordLength', 16, ...  
    'FractionLength', 0);

7 Add the entry to a code replacement table with a call to the `addEntry` function.

    addEntry(hTable, op_entry);

8 Save the table definition file. Use the name of the table definition function to name the file.

To test this example:

1 Register the code replacement mapping.
2 Create a model.

3 For this model:
   • Set the Inport 1 Data type to int16.
   • Set the Inport 2 Data type to fixdt(1,16,-5).
   • In the Divide block:
      • Set Output data type to fixdt(1,16,-13).
      • Set Integer rounding mode to Ceiling.
4 Configure the model with the following settings:
   • On the Solver pane, select a fixed-step, discrete solver.
• On the Code Generation pane, select an ERT-based system target file.
• On the Code Generation > Interface pane, select the code replacement library that contains your addition operation entry.

5 Generate code and a code generation report.
6 Review the code replacements.

Equal Slope and Zero Net Bias Code Replacement

You can define code replacement entries for addition or subtraction of fixed-point data types such that they match relative slope and bias values (equal slope and zero net bias) across operator inputs and output. These entries allow you to disregard slope and bias values. Map relative slope and bias values to a replacement function for addition or subtraction.

This example creates a code replacement entry for addition of fixed-point data types. Slopes must be equal and net bias must be zero across the operator inputs and output. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1 Create a table definition file that contains a function definition. For example:

   ```matlab
   function hTable = crl_table_fixed_slopeseq_netbiaszero
   ```

2 Within the function body, create the table by calling the function RTW.TflTable.

   ```matlab
   hTable = RTW.TflTable;
   ```

3 Create the entry for the operator mapping with a call to the RTW.TflCOperationEntryGenerator function, which provides access to the fixed-point parameters SlopesMustBeTheSame and MustHaveZeroNetBias.

   ```matlab
   op_entry = RTW.TflCOperationEntryGenerator;
   ```

4 Set operator entry parameters with a call to the setTflCOperationEntryParameters function. The parameters specify the type of operation as addition, the saturation mode as saturation off, rounding modes as unspecified, and the name of the replacement function as u16_add_SameSlopeZeroBias. SlopesMustBeTheSame and MustHaveZeroNetBias are set to true, indicating that slopes must be equal and net bias must be zero across the addition inputs and output.

   ```matlab
   setTflCOperationEntryParameters(op_entry, ...
   'Key',                    'RTW_OP_ADD', ...
   'Priority',                90, ...  
   'SaturationMode',          'RTW_WRAP_ON_OVERFLOW', ... 
   'RoundingModes',           {'RTW_ROUND_UNSPECIFIED'}, ... 
   'SlopesMustBeTheSame',     true, ...  
   'MustHaveZeroNetBias',     true, ... 
   'ImplementationName',      'u16_add_SameSlopeZeroBias', ... 
   'ImplementationHeaderFile', 'u16_add_SameSlopeZeroBias.h',... 
   'ImplementationSourceFile', 'u16_add_SameSlopeZeroBias.c');
   ```

5 Create conceptual arguments y1, u1, and u2. There are multiple ways to set up the conceptual arguments. This example uses calls to the
createAndAddConceptualArg function to create and add an argument with one function call. Each argument is specified as 16 bits and unsigned. Each argument specifies that code replacement request processing does not check for an exact match to the call-site slope and bias values.

```matlab
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'y1', ...
    'IOType',         'RTW_IO_OUTPUT', ...
    'CheckSlope',     false, ...
    'CheckBias',      false, ...
    'IsSigned',       false, ...
    'WordLength',     16);
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'u1', ...
    'IOType',         'RTW_IO_INPUT', ...
    'CheckSlope',     false, ...
    'CheckBias',      false, ...
    'IsSigned',       false, ...
    'WordLength',     16);
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'u2', ...
    'IOType',         'RTW_IO_INPUT', ...
    'CheckSlope',     false, ...
    'CheckBias',      false, ...
    'IsSigned',       false, ...
    'WordLength',     16);
```

Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the createAndSetCImplementationReturn and createAndAddImplementationArg functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). In this case, the output and input arguments are 16 bits and unsigned (uint16).

```matlab
createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'y1', ...
    'IOType',         'RTW_IO_OUTPUT', ...
    'IsSigned',       false, ...
    'WordLength',     16, ...
    'FractionLength', 0);
createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',...
    'Name',           'u1', ...
    'IOType',         'RTW_IO_INPUT', ...
    'IsSigned',       false, ...
    'WordLength',     16, ...
    'FractionLength', 0);
createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',...
    'Name',           'u2', ...
    'IOType',         'RTW_IO_INPUT', ...
    'IsSigned',       false, ...
    'WordLength',     16, ...
    'FractionLength', 0);
```
7 Add the entry to a code replacement table with a call to the `addEntry` function.

```matlab
addEntry(hTable, op_entry);
```

8 Save the table definition file. Use the name of the table definition function to name the file.

To test this example:

1 Register the code replacement mapping.

2 Create a model.

3 For this model:

   - Set the Inport 1 **Data type** to `fixdt(0, 16, 13)`.
   - Set the Inport 2 **Data type** to `fixdt(0, 16, 13)`.
   - In the Add block:
     - Verify that **Output data type** is set to its default, `Inherit via internal rule`.
     - Set **Integer rounding mode** to Zero.

4 Configure the model with the following settings:

   - On the **Solver** pane, select a fixed-step, discrete solver.
   - On the **Code Generation** pane, select an ERT-based system target file.
   - On the **Code Generation > Interface** pane, select the code replacement library that contains your addition operation entry.

5 Generate code and a code generation report.

6 Review the code replacements.

Data Type Conversions (Casts) and Operator Code Replacement

You can use code replacement entries to replace code that the code generator produces for data type conversion (cast) operations.

Casts from int32 To int16

This example creates a code replacement entry that replaces int32 to int16 data type conversion (cast) operations. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ``` matlab
   function hTable = crl_table_cast_int32_to_int16
   end
   ```

2. Within the function body, create the table by calling the function RTW.TflTable.

   ``` matlab
   hTable = RTW.TflTable;
   ```

3. Create the entry for the operator mapping with a call to the RTW.TflCOperationEntry function.

   ``` matlab
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set operator entry parameters with a call to the setTflCOperationEntryParameters function. The parameters specify the type of operation as cast, the saturation mode as saturate on integer overflow, rounding modes as toward negative infinity, and the name of the replacement function as my_sat_cast.

   ``` matlab
   setTflCOperationEntryParameters(op_entry, ...
   'Key',                      'RTW_OP_CAST', ...
   'Priority',                 50, ...
   'ImplementationName',       'my_sat_cast', ...
   'SaturationMode',           'RTW_SATURATE_ON_OVERFLOW', ...
   'RoundingModes',            {'RTW_ROUND_FLOOR'}, ...
   'ImplementationHeaderFile', 'some_hdr.h', ...
   'ImplementationSourceFile', 'some_hdr.c');
   ```

5. Create the int16 argument as conceptual argument y1 and the implementation return value. There are multiple ways to set up the conceptual and implementation arguments. This example uses calls to the getTflArgFromString and addConceptualArg functions to create the conceptual argument and add it to the...
entry. Convenience method `setReturn` specifies the argument as the implementation return value.

```matlab
arg = getTflArgFromString(hTable, 'y1', 'int16');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(op_entry, arg);
setReturn(op_entry).Implementation.setReturn(arg);
```

6 Create the `int32` argument as conceptual and implementation argument `u1`. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create the conceptual argument and add it to the entry. Convenience method `addArgument` specifies the argument as implementation input argument.

```matlab
arg = getTflArgFromString(hTable, 'u1', 'int32');
addConceptualArg(op_entry, arg);
setReturn(op_entry).Implementation.addArgument(arg);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

```matlab
addEntry(hLib, hEnt);
```

8 Save the table definition file. Use the name of the table definition function to name the file.

**Casts Using Net Slope**

You can use code replacement entries to replace code that the code generator produces for data type conversion (cast) operations.

This example creates a code replacement entry to replace data type conversions (casts) of fixed-point data types by using a net slope. The example defines the function mapping programatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1 Create a table definition file that contains a function definition. For example:

```matlab
function hTable = crl_table_cast_fixpt_net_slope
```

2 Within the function body, create the table by calling the function `RTW.TflTable`.

```matlab
hTable = RTW.TflTable;
```

3 Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntryGenerator_Netslope` function, which provides access to the fixed-point parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`.

```matlab
op_entry = RTW.TflCOperationEntryGenerator_Netslope;
```
Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as cast, the saturation mode as saturate on integer overflow, rounding modes as toward negative infinity, and the name of the replacement function as `my_fxp_cast`. `NetSlopeAdjustmentFactor` and `NetFixedExponent` specify the $F$ and $E$ parts of the net slope $F2^E$.

```matlab
InFL = 2;
InWL = 16;
InSgn = true;
OutFL = 4;
OutWL = 32;
OutSgn = true;
setTflCOperationEntryParameters(op_entry, ...
    'Key',                       'RTW_OP_CAST', ...
    'Priority',                  50, ... 
    'SaturationMode',            'RTW_SATURATE_ON_OVERFLOW', ... 
    'RoundingModes',             {'RTW_ROUND_FLOOR'}, ... 
    'NetSlopeAdjustmentFactor',  1.0, ... 
    'NetFixedExponent',          (OutFL - InFL), ... 
    'ImplementationName',        'my_fxp_cast', ... 
    'ImplementationHeaderFile',  'some_hdr.h', ... 
    'ImplementationSourceFile',  'some_hdr.c');
```

Create conceptual arguments y1 and u1. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Each argument is specified as fixed-point and signed. Each argument specifies that code replacement request processing does not check for an exact match to the call-site slope and bias values.

```matlab
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',         'y1', ...
    'IOType',       'RTW_IO_OUTPUT', ...
    'CheckSlope',   false, ...
    'CheckBias',    false, ...
    'DataTypeMode', 'Fixed-point: binary point scaling', ... 
    'IsSigned',     OutSgn, ...
    'WordLength',   OutWL, ...
    'FractionLength',OutFL);
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',         'u1', ...
    'IOType',       'RTW_IO_INPUT', ...
    'CheckSlope',   false, ...
    'CheckBias',    false, ...
    'DataTypeMode', 'Fixed-point: binary point scaling', ... 
    'IsSigned',     InSgn, ...
    'WordLength',   InWL, ...
    'FractionLength',InFL);
```
Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the createAndSetCImplementationReturn and createAndAddImplementationArg functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types).

```matlab
createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...
     'Name',           'y1', ...
     'IOType',         'RTW_IO_OUTPUT', ...
     'IsSigned',       OutSgn, ...
     'WordLength',     OutWL, ...
     'FractionLength', 0);
createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',...
     'Name',           'u1', ...
     'IOType',         'RTW_IO_INPUT', ...
     'IsSigned',       InSgn, ...
     'WordLength',     InWL, ...
     'FractionLength', 0);
```

Add the entry to a code replacement table with a call to the addEntry function.

```matlab
addEntry(hTable, op_entry);
```

Save the table definition file. Use the name of the table definition function to name the file.

Shift Left Operations and Code Replacement

You can use code replacement entries to replace code that the code generator produces for shift (<<) operations.

Shift Lefts for int16 Data

This example creates a code replacement entry to replace shift left operations for int16 data. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```matlab
   function hTable = crl_table_shift_left_int16
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```matlab
   hTable = RTW.TflTable;
   ```

3. Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntry` function.

   ```matlab
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as shift left and the name of the replacement function as `my_shift_left`.

   ```matlab
   setTflCOperationEntryParameters(op_entry, ...
      'Key',                      'RTW_OP_SL', ...
      'Priority',                 50, ...
      'ImplementationName',       'my_shift_left', ...
      'ImplementationHeaderFile', 'some_hdr.h', ...
      'ImplementationSourceFile', 'some_hdr.c');
   ```

5. Create the int16 argument as conceptual argument `y1` and the implementation return value. There are multiple ways to set up the conceptual and implementation arguments. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create the conceptual argument and add it to the entry. Convenience method `setReturn` specifies the argument as the implementation return value.

   ```matlab
   arg = getTflArgFromString(hTable, 'y1', 'int16');
   arg.IOType = 'RTW_IO_OUTPUT';
   addConceptualArg(op_entry, arg);
   op_entry.Implementation.setReturn(arg);
   ```
6 Create the int16 argument as conceptual and implementation argument u1. This example uses calls to the getTflArgFromString and addConceptualArg functions to create the conceptual argument and add it to the entry. Convenience method addArgument specifies the argument as the implementation input argument.

```
arg = getTflArgFromString(hTable, 'u1', 'int16');
addConceptualArg(op_entry, arg);
op_entry.Implementation.addArgument(arg);
```

7 Create the int8 argument as conceptual and implementation argument u2. This example uses calls to the getTflArgFromString and addConceptualArg functions to create the conceptual argument and add it to the entry. This argument specifies the number of bits to shift the previous input argument. Because the argument type is not relevant, the example disables type checking by setting the CheckType property to false. Convenience method addArgument specifies the argument as implementation input argument.

```
arg = getTflArgFromString(hTable, 'u2', 'int8');
arg.CheckType = false;
addConceptualArg(op_entry, arg);
op_entry.Implementation.addArgument(arg);
```

- The function getTflArgFromString is called to create an int8 input argument. This argument is added to the operator entry both as the third conceptual argument and the second implementation input argument.
- Add the entry to a code replacement table with a call to the addEntry function.

```
addEntry(hTable, op_entry);
```
- Save the table definition file. Use the name of the table definition function to name the file.

## Shift Lefts Using Net Slope

You can use code replacement entries to replace code that the code generator produces for shift (<<) operations.

This example creates a code replacement entry to replace shift left operations for fixed-point data using a net slope. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1 Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_shift_left_fixpt_net_slope
```
Within the function body, create the table by calling the function `RTW.TflTable`.

```matlab
hTable = RTW.TflTable;
```

Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntryGenerator_NetSlope` function. This function provides access to the fixed-point parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`.

```matlab
op_entry = RTW.TflCOperationEntryGenerator_NetSlope;
```

Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as shift left, the saturation mode as saturate on integer overflow, rounding modes as toward negative infinity, and the name of the replacement function as `my_fxp_shift_left`. `NetSlopeAdjustmentFactor` and `NetFixedExponent` specify the F and E parts of the net slope $F2^E$.

```matlab
InFL = 2;
InWL = 16;
InSgn = true;
OutFL = 4;
OutWL = 32;
OutSgn = true;
setTflCOperationEntryParameters(op_entry, ...
    'Key',                       'RTW_OP_SL', ...
    'Priority',                  50, ...
    'SaturationMode',            'RTW_SATURATE_ON_OVERFLOW', ...
    'RoundingModes',             {'RTW_ROUND_FLOOR'}, ...
    'NetSlopeAdjustmentFactor',  1.0, ...
    'NetFixedExponent',          (OutFL - InFL),...
    'ImplementationName',        'my_fxp_shift_left', ...
    'ImplementationHeaderFile',  'some_hdr.h', ...
    'ImplementationSourceFile',  'some_hdr.c');
```

Create conceptual arguments $y1$ and $u1$. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Each argument is specified as fixed-point and signed. Each argument specifies that code replacement request processing does not check for an exact match to the call-site slope and bias values.

```matlab
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',         'y1', ...
    'IOType',       'RTW_IO_OUTPUT', ...
    'CheckSlope',   false, ...
    'CheckBias',    false, ...
    'DataTypeMode', 'Fixed-point: binary point scaling', ...
    'IsSigned',     OutSgn, ...
    'WordLength',   OutWL, ...
    'FractionLength',OutFL);
```
Create and add conceptual arguments:

```matlab
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name', 'u1', ...
    'IOType', 'RTW_IO_INPUT', ...
    'CheckSlope', false, ...
    'CheckBias', false, ...
    'DataTypeMode', 'Fixed-point: binary point scaling', ...
    'IsSigned', InSgn, ...
    'WordLength', InWL, ...
    'FractionLength', InFL);
```

6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `createAndSetCImplementationReturn` and `createAndAddImplementationArg` functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types).

```matlab
createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...
    'Name', 'y1', ...
    'IOType', 'RTW_IO_OUTPUT', ...
    'IsSigned', OutSgn, ...
    'WordLength', OutWL, ...
    'FractionLength', 0);
createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name', 'u1', ...
    'IOType', 'RTW_IO_INPUT', ...
    'IsSigned', InSgn, ...
    'WordLength', InWL, ...
    'FractionLength', 0);
```

7 Create the `int8` argument as conceptual and implementation argument `u2`. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create the conceptual argument and add it to the entry. This argument specifies the number of bits to shift the previous input argument. Because the argument type is not relevant, type checking is disabled by setting the `CheckType` property to false. Convenience method `addArgument` specifies the argument as implementation input argument.

```matlab
arg = getTflArgFromString(hTable, 'u2', 'uint8');
arg.CheckType = false;
addConceptualArg(op_entry, arg);
```

8 Add the entry to a code replacement table with a call to the `addEntry` function.

```matlab
addEntry(hTable, op_entry);
```

9 Save the table definition file. Use the name of the table definition function to name the file.

What Is Code Replacement Customization?

Customize how and when the code generator replaces C/C++ code that it generates by default for functions and operators by developing a custom code replacement library. You can develop libraries interactively with the Code Replacement Tool or programmatically.

- Develop libraries tailored to specific application requirements
- Add identifiers to the list of reserved keywords the code generator considers during code replacement
- Customize the code generator’s match and replacement process for functions

Code Replacement Match and Replacement Process

When the code generator encounters a call site for a function or operator, it:

1. Creates and partially populates a code replacement entry object with the function or operator name or key and conceptual arguments.
2. Uses the entry object to query the configured code replacement library for a conceptual representation match. The code generator searches the tables in a code replacement library for a match in the order that the tables appear in the library. When searching for a match, the code generator takes into account:
   - Conceptual name or key
   - Arguments, including quantity, type, type qualifiers, and complexity
   - Algorithm (computation method)
   - Fixed-point saturation and rounding modes
   - Priority
3. When a match exists, the code generator returns a code replacement object, fully populated with the conceptual representation, implementation representation, and priority. If the code generator finds multiple matches within a table, the entry priority determines the match. The priority can range from 0 to 100. The highest priority is 0. The code generator uses a higher-priority entry over a similar entry with a lower priority.
4 Uses the C or C++ replacement function prototype in the code replacement object to generate code.

**Code Replacement Customization Limitations**

- Code replacement verification — It is possible that code replacement behaves differently than you expect. For example, data types that you observe in code generator input might not match what the code generator uses as intermediate data types during an operation. Verify code replacements by examining generated code. See “Verify Code Replacements” on page 55-65.
- Tokens in file paths—You can include tokens in file paths when specifying build information for a code replacement entry by using the programming interface only. The ability to include tokens is not available from the Code Replacement Tool. See “Specify Build Information for Replacement Code” on page 55-47.
- `coder.replace` function — See `coder.replace` for relevant limitations.
- `coder.dataAlignment` function — See `coder.dataAlignment` for relevant limitations.

Code You Can Replace from MATLAB Code

Code that the code generator replaces depends on the code replacement library (CRL) that you use. By default, the code generator does not apply a code replacement library. Your choice of libraries is dependent on product licensing and whether you have access to custom libraries.

### Memory Functions

Depending on code replacement libraries available in your development environment, you can configure the code generator to replace instances of the following memory functions with application-specific implementations.

<table>
<thead>
<tr>
<th>Function</th>
<th>Data Type Support</th>
<th>Scalar, Vector, Matrix Support</th>
<th>Real, Complex Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>memcmp</td>
<td>Void pointer (void*)</td>
<td>Scalar</td>
<td>Real Complex</td>
</tr>
<tr>
<td>memcpy</td>
<td>Void pointer (void*)</td>
<td>Scalar</td>
<td>Real Complex</td>
</tr>
<tr>
<td>memset</td>
<td>Void pointer (void*)</td>
<td>Scalar</td>
<td>Real Complex</td>
</tr>
<tr>
<td>memset2zero</td>
<td>Void pointer (void*)</td>
<td>Scalar</td>
<td>Real Complex</td>
</tr>
</tbody>
</table>

Some target processors provide optimized functions to set memory to zero. Use the code replacement library programming interface to replace the `memset2zero` function with more efficient target-specific functions.

### Operators

When generating C/C++ code from MATLAB code, depending on code replacement libraries available in your development environment, you can configure the code
generator to replace instances of the following operators with application-specific implementations.

Mixed data type support indicates you can specify different data types of different inputs.

<table>
<thead>
<tr>
<th>Operator</th>
<th>Key</th>
<th>Data Type Support</th>
<th>Scalar, Vector, Matrix Support</th>
<th>Real, Complex Support</th>
</tr>
</thead>
<tbody>

### Operator

<table>
<thead>
<tr>
<th>Operator</th>
<th>Key</th>
<th>Data Type Support</th>
<th>Scalar, Vector, Matrix Support</th>
<th>Real, Complex Support</th>
</tr>
</thead>
</table>

1. See “Addition and Subtraction Operator Code Replacement” on page 55-123 for details to consider when defining mappings for addition and subtraction code replacements.

2. Can map to Basic Linear Algebra Subroutine (BLAS) multiplication functions.

3. Scaled floating point is not supported.

4. Code replacement libraries that provide arithmetic shift right implementations should also provide logical shift right implementations, because some arithmetic shift rights are converted to logical shift rights during code generation.

5. Use the multiplication (*) operator (RTW_OP_MUL) for scalar multiplication.

6. Requires scalar, real, or fixed-point data types with zero bias; output type of the multiplication operation to accommodate all possible output values; shift operand is an unsigned integer; and net slope is equal to 1 (U1_slope * U2_slope == Mul_output_slope and Mul_output_slope == output_slope_of_shift_operation).

7. Requires scalar, real, or fixed-point data types with zero bias; output type of the multiplication operation to accommodate all possible output values; and net slope is equal to 1 (U1_slope * U2_slope == Mul_output_slope == U3_slope * Div_output_slope).

Develop a Code Replacement Library

Iterate through the following steps, as necessary, to develop a code replacement library:

1. “Identify Code Replacement Requirements” on page 55-25
2. “Prepare for Code Replacement Library Development” on page 55-28
3. “Define Code Replacement Mappings” on page 55-29
4. “Specify Build Information for Replacement Code” on page 55-47
5. “Register Code Replacement Mappings” on page 55-56
6. “Verify Code Replacements” on page 55-65
7. “Deploy Code Replacement Library” on page 55-78

To get started, see “Identify Code Replacement Requirements” on page 55-25.

To experiment with the process and tools, see “Quick Start Library Development” on page 55-16.

More About

- “Identify Code Replacement Requirements” on page 55-25
- “Code You Can Replace from MATLAB Code” on page 55-5
- “Quick Start Library Development” on page 55-16
Quick Start Library Development

This example shows how to develop a code replacement library that includes an entry for generating replacement code for the math function \( \sin \). You use the Code Replacement Tool.

Prerequisites

To complete this example, install the following software:

- MATLAB
- MATLAB Coder
- Embedded Coder
- C compiler

For instructions on installing MathWorks products, see “Installation and Activation” (Installation, Licensing, and Activation). If you have installed MATLAB and want to see what other MathWorks products are installed, in the Command Window, enter `ver`.

For a list of supported compilers, see https://www.mathworks.com/support/compilers/current_release/.

Open the Code Replacement Tool

1. Start a new MATLAB session.
2. Create or navigate (cd) to an empty folder.
3. At the command prompt, enter the `crtool` command. The Code Replacement Tool window opens.

Create Code Replacement Table

1. In the Code Replacement Tool window, select File > New table.
2. In the right pane, name the table `crl_table_sinfcn` and click Apply. Later, when you save the table, the tool saves it with the file name `crl_table_sinfcn.m`. 
Create Table Entry

Create a table entry that maps a \( \sin \) function with double input and double output to a custom implementation function.

1. In the left pane, select table crl_table_sinfcn. Then, select **File > New entry > Function**. The new entry appears in the middle pane, initially without a name.
2. In the middle pane, select the new entry.
3. In the right pane, on the **Mapping Information** tab, from the **Function** menu, select \( \sin \).
4. Leave **Algorithm** set to Unspecified, and leave parameters in the **Conceptual function** group set to default values.
5. In the **Replacement function** group, name the replacement function sin_dbl.
6. Leave the remaining parameters in the **Replacement function** group set to default values.
7. Click **Apply**. The tool updates the **Function signature preview** to reflect the specified replacement function name.
8 Scroll to the bottom of the **Mapping Information** tab and click **Validate entry**. The tool validates your entry.

The following figure shows the completed mapping information.
Specify Build Information for Replacement Code

1. On the **Build Information** tab, for the **Implementation header file** parameter, enter `sin_dbl.h`.
2. Leave the remaining parameters set to default values.
3. Click **Apply**.

4. Optionally, you can revalidate the entry. Return to the **Mapping Information** tab and click **Validate entry**.

Create Another Table Entry

Create an entry that maps a `sin` function with single input and double output to a custom implementation function named `sin_sgl`. Create the entry by copying and pasting the `sin_dbl` entry.

1. In the middle pane, select the `sin_dbl` entry.
2. Select **Edit > Copy**
3. Select **Edit > Paste**
4. On the **Mapping Information** tab, in the **Conceptual function** section, set the data type of input argument `u1` to single.
5. In the **Replacement function** section, name the function `sin_sgl`. Set the data type of input argument `u1` to single.
6. Click **Apply**. Note the changes that appear for the **Function signature preview**.
7. On the **Build Information** tab, for the **Implementation header file** parameter, enter `sin_sgl.h`. Leave the remaining parameters set to default values and click **Apply**.

Validate the Code Replacement Table

1. Select **Actions > Validate table**.
2 If the tool reports errors, fix them, and rerun the validation. Repeat fixing and validating errors until the tool does not report errors. The following figure shows a validation report.

![Validation Report](image)

**Save the Code Replacement Table**

Save the code replacement table to a MATLAB file in your working folder. Select **File > Save table**. By default, the tool uses the table name to name the file. For this example, the tool saves the table in the file `crl_table_sinfcn.m`.

**Review the Code Replacement Table Definition**

Consider reviewing the MATLAB code for your code replacement table definition. After using the tool to create an initial version of a table definition file, you can update, enhance, or copy the file in a text editor.

To review it, in MATLAB or another text editor, open the file `crl_table_sinfcn.m`.

**Generate a Registration File**

Before you can use your code replacement table, you must register it as part of a code replacement library. Use the Code Replacement Tool to generate a registration file.

1 In the Code Replacement Tool, select **File > Generate registration file**.
2 In the **Generate registration file** dialog box, edit the dialog box fields to match the following figure, and then click **OK**.

![Generate Registration File](image)
3 In the **Select location to save the registration file** dialog box, specify a location for the registration file. The location must be on the MATLAB path or in the current working folder. Save the file. The tool saves the file as `rtwTargetInfo.m`.

**Register the Code Replacement Table**

At the command prompt, enter:

```matlab
RTW.TargetRegistry.getInstance('reset');
```

**Review and Test Code Replacements**

Apply your code replacement library. Verify that the code generator makes code replacements that you expect.

1 Check for errors. At the command line, invoke the table definition file. For example:

```matlab
tbl = crl_table_sinfcn
```

```
tbl =

    TflTable with properties:

    Version: '1.0'
    ReservedSymbols: []
    StringResolutionMap: []
    AllEntries: [2x1 RTW.TflCFunctionEntry]
    EnableTrace: 1
```

If an error exists in the definition file, the invocation triggers a message to appear. Fix the error and try again.

2 Use the Code Replacement Viewer to check your code replacement entries. For example:

```matlab
crviewer('Sin Function Example')
```

In the viewer, select entries in your table and verify that the content is what you expect. The viewer can help you detect issues such as:

- Incorrect argument order.
- Conceptual argument names that do not match what is expected by the code generator.
• Incorrect priority settings.

3 Identify existing or create new MATLAB code that calls the \texttt{sin} function. For example:

```matlab
function \texttt{y = my\_sin\_fnc(x)}
    \texttt{y = sin(x)};
end
```

4 Open the MATLAB Coder app.

5 Add the function that includes a call to the \texttt{sin} function as an entry-point file. For example, add \texttt{my\_sin\_func.m}. The app creates a project named \texttt{my\_sin\_func.prj}.

6 Click \textbf{Next} to go to the \textbf{Define Input Type} step. Define the types for the entry-point function inputs.

7 Click \textbf{Next} to go to the \textbf{Check for Run-Time Issues} step. This step is optional. However, it is a best practice to perform this step. Provide a test file that calls your entry-point function. The app generates a MEX function from your entry-point function. Then, the app runs the test file, replacing calls to the MATLAB function with calls to the generated MEX function.

8 Click \textbf{Next} to go to the \textbf{Generate Code} step. To open the \textbf{Generate} dialog box, click the \textbf{Generate} arrow.

9 Set \textbf{Build type} to generate a library or executable.

10 Click \textbf{More Settings}.

11 Configure the code generator to use your code replacement library. On the \textbf{Custom Code} tab, set the \textbf{Code replacement library} parameter to the name of your library. For example, \texttt{Sin Function Example}.

12 Configure the code generation report. On the \textbf{Debug} tab, set the \textbf{Always create a code generation report}, \textbf{Code replacements}, and \textbf{Automatically launch a report if one is generated} parameters.

13 Configure the code generator to generate code only. For \textbf{Build type}, select \textbf{Source code}. You want to review your code replacements in the generated code before building an executable.

14 Click \textbf{Generate} to generate C code and a report.

15 Review code replacement results in the Code Replacements Report section of the code generation report.

The report indicates that the code generator found a match and applied the replacement code for the function \texttt{sin\_dbl}.
Review the code replacements. In the report, click the MATLAB function that triggered the replacement, `my_sin_func.m`. The MATLAB Editor opens and highlights the function call that triggers the code replacement.

Identify Code Replacement Requirements

The first step to developing a code replacement library is to consider the following types of requirements for your code replacement library.

Mapping Information Requirements

• Are you defining a code replacement mapping for the first time?
• Are you updating code replacement entries in an existing library? Or, are you creating a new library?
• Are you rapid prototyping code replacements?
• Can you base your mappings on existing mappings?
• What type of code do you want to replace? Options include:
  • Math operation
  • Function
  • BLAS operation
  • CBLAS operation
  • Net slope fixed-point operation
  • Semaphore or mutex functions
• Do you want to change the inline or nonfinite behavior for functions?
• What specific functions and operations do you want to replace?
• What input and output arguments does the function or operator that you are replacing take? For each argument, what is the data type, complexity, and dimensionality?
• What does the prototype for your replacement code look like?
  • What is the replacement function name?
  • What are the input and output arguments?
  • Are there return values?
  • What is the data type, complexity, and dimensionality of each argument and return value?
**Build Information Requirements**

- Does your replacement function implementation require a header file? If yes, specify the header file.
- If the replacement function implementation requires a header file, what is the path for that file?
- Is the source file for the replacement function in your working folder? If not, you can explicitly specify the source file name and extension. For example, if the file is required in the generated makefile or specified in a build information object, specify the source file.
- Does the replacement function use additional include files? If yes, what are they and what are the paths for those files?
- Does the replacement function use additional source files? If yes, what are they and what are the paths for those files?
- What compiler flags are required for compiling code that includes the replacement code?
- What linker flags are required for building an executable that includes the replacement code?
- Are the required header, source, and object files for building an executable that includes your replacement code in the working folder for your project? If not, before starting the build process, do you want the code generator to copy required files to the build folder?

**Registration Information Requirements**

- What do you want to name your code replacement library?
- What code replacement tables do you want to include in the library? What are the file names and paths for the tables?
- What is the purpose of the library? You can document the purpose as the library description.
- Does the library apply to specific hardware devices? If yes, what devices?
- Are you developing a hierarchy of code replacement libraries? Is the library that you are developing based (dependent) on another library? For example, you can specify a general TI device library as the base library for a more specific TI C28x device library.
• Do you need to specify data alignment for the library? What data alignments are required? For each specification, what type of alignment is required and for what programming language?

Next, prepare for developing a library by reviewing a code replacement library development checklist.

Prepare for Code Replacement Library Development

After you identify your code replacement requirements, prepare for library development by reviewing this checklist:

- Get familiar with the library development process.
- Decide whether to define code replacement mappings and produce a registration file interactively with the Code Replacement Tool or programmatically.
- Identify or develop MATLAB code and Simulink models to test your code replacement library.
- Consider the hierarchy and organization of your library. A library can consist of multiple tables and each table can include multiple entries. How do you want to organize the library to optimize reuse of tables and entries? For example, a registration file can define code replacement tables organized in a hierarchy of code replacement libraries based on entries that increase in specificity:
  - Common entries
  - Entries for TI devices
  - Entries for TI C6xx devices
  - Entries specific to the TI C67x device
- If support files, such as header files, additional source files, and dynamically linked libraries are not in your current working folder, note their location. You need to specify the paths for such files.

Next, based on your requirements and preparation, define code replacement mappings.

- “Develop a Code Replacement Library” on page 55-15
Define Code Replacement Mappings

After you prepare for library development, use your requirements to define code replacement mappings. A code replacement mapping associates a conceptual representation of a function or operator that is familiar to the code generator with a custom implementation representation that specifies a C or C++ replacement function prototype. You capture a mapping as an entry in a code replacement table:

- Interactively, by using the Code Replacement Tool.
- Programmatically, by using a MATLAB programming interface.

Choose an Approach for Defining Code Replacement Mappings

The following table lists situations to help you decide when to use the interactive or programmatic approach.

<table>
<thead>
<tr>
<th>Situation</th>
<th>Approach</th>
</tr>
</thead>
<tbody>
<tr>
<td>Defining mappings for the first time.</td>
<td>Code Replacement Tool.</td>
</tr>
<tr>
<td>Rapid prototyping mappings.</td>
<td>Code Replacement Tool to quickly generate, register, and test mappings.</td>
</tr>
<tr>
<td>Developing a mapping as a template or starting point for defining similar mappings.</td>
<td>Code Replacement Tool to generate definition code that you can copy and modify.</td>
</tr>
<tr>
<td>Modifying a registration file, including copying and pasting content.</td>
<td>MATLAB Editor to update the programming interface directly.</td>
</tr>
<tr>
<td>Defining mappings that specify attributes not available from the Code Replacement Tool (for example, sets of algorithm parameters).</td>
<td>Programming interface.</td>
</tr>
<tr>
<td>Reusing existing code for new mappings by copying, pasting, and editing existing mappings.</td>
<td>Programming interface.</td>
</tr>
</tbody>
</table>
Define Mappings Interactively with the Code Replacement Tool

This example shows how to use the Code Replacement Tool to develop code replacement mappings. The tool is ideal for getting started with developing mappings, rapid prototyping, and developing a mapping to use as a starting point for defining similar mappings.

Open the Code Replacement Tool

Do one of the following:

- In the Command Window, enter the command `crtool`.
- In the Configuration Parameters dialog box, navigate to Code Generation pane. In the Advanced parameters section, scroll down and click Custom CRL... button.

An Embedded Coder license is not required to create a custom code replacement library. However, you must have an Embedded Coder license to use a such a library.

By default, the tool displays, left to right, a root pane, a list pane, and a dialog pane. You can manipulate the display:

- Drag boundaries to widen, narrow, shorten, or lengthen panes, and to resize table columns.
- Select View > Show dialog pane to hide or display the right-most pane.
- Click a table column heading to sort the table based on contents of the selected column.
- Right-click a table column heading and select Hide to remove the column from the display. (You cannot hide the Name column.)

Create a Code Replacement Table

1 In the Code Replacement Tool window, select File > New table.
2 In the right pane, name the table and click Apply. Later, when you save the table, the tool uses the table name that you specify to name the file. For example, if you enter the name `my_sinfcn`, the tool names the file `my_sinfcn.m`. 
Create Table Entries

Create one or more table entries. Each entry maps the conceptual representation of a function or operator to your implementation representation. The information that you enter depends on the type of entry you create. Enter the following information:

1. In the left pane, select the table to which you want to add the entry.
2. Select File > New entry > entry-type, where entry-type is one of:
   - Math Operation
   - Function
   - BLAS Operation
   - CBLAS Operation
   - Net Slope Fixed-Point Operation
   - Semaphore entry
   - Customization entry

   The new entry appears in the middle pane, initially without a name.

3. In the middle pane, select the new entry.
4. In the right pane, on the Mapping Information tab, from the Function or Operation menu, select the function or operation that you want the code generator to replace. Regardless of the entry type, make a selection from this menu. Your selection determines what other information you specify.

   Except for customization entries, you also specify information for your replacement function prototype. You can also specify implementation attributes, such as the rounding modes to apply.

5. If prompted, specify additional entry information that you want the code generator to use when searching for a match. For example, when you select an addition or subtraction operation, the tool prompts you to specify an algorithm (Cast before operation or Cast after operation).

6. Review the conceptual argument information that the tool populates for the function or operation. Conceptual input and output arguments represent arguments for the function or operator being replaced. Conceptual arguments observe naming conventions (‘y1’, ‘u1’, ‘u2’, ...) and data types familiar to the code generator.
When validating the entry, the code generator validates that each conceptual argument has an I/O type that is compatible with the argument name. For example, an input must have I0Type of RTW_IO_INPUT.

If you do not want the data types for your implementation to be the same as the conceptual argument types, clear the Make the conceptual and implementation argument types the same check box. For example, most ANSI-C functions operate on and return double data. Clear the check box if want to map a conceptual representation of the function to an implementation representation that specifies an argument and return value. For example, clear the check box to map the conceptual representation of the function sin to an implementation representation that specifies an argument and return value of type single (single sin(single)), of type double (double sin(double)). In this case, the code generator produces the following code:

\[ y = (\text{single}) \sin(u1); \]

If you select Custom for a function entry, specify only conceptual argument information.

7 Specify the name and argument information for your replacement function. As you enter the information and click Apply, the tool updates the Function signature preview.

When validating the entry, the code generator validates that each implementation argument has an I/O type that is compatible with the conceptual argument to which it is mapped. For example, an conceptual argument of type RTW_IO_OUTPUT requires a compatible implementation argument of type RTW_IO_OUTPUT or RTW_IO_INPUT_OUTPUT. The default I/O type is RTW_IO_INPUT.

8 Specify additional implementation attributes that apply. For example, depending on the type and name of the entry that you specify, the tool prompts you to specify:

- Integer saturation mode
- Rounding modes
- Whether to allow inputs that include expressions
- Whether a function modifies internal or global state

9 Click Apply.

Validate Tables and Entries

The Code Replacement Tool provides a way to validate the syntax of code replacement tables and table entries as you define them. If the tool finds validation errors, you can
address them and retry the validation. Repeat the process until the tool does not report errors.

<table>
<thead>
<tr>
<th>To</th>
<th>Do</th>
</tr>
</thead>
<tbody>
<tr>
<td>Validate table entries</td>
<td>Select an entry, scroll to the bottom of the Mapping Information tab, and click Validate entry. Alternatively, select one or more entries, right-click, and select Validate entries.</td>
</tr>
<tr>
<td>Validate a table</td>
<td>Select the table. Then, select Actions &gt; Validate table.</td>
</tr>
</tbody>
</table>

**Save a Table**

When you save a table, the tool validates unvalidated content.

1. Select **File > Save table**.
2. In the Browse For Folder dialog box, specify a location and name for the file. Typically, you select a location on the MATLAB path. By default, the tool names the file using the name that you specify for the table with the extension .m.
3. Click **Save**.

**Open and Modify Tables**

After saving a code replacement table, to make changes in the table:

1. Select **File > Open table**.
2. In the Import file dialog box, browse to the MATLAB file that contains the table.

Repeat the sequence to open and work on multiple tables.

If you open multiple tables, you can manage the tables together. For example, use the tool to:

- Create new table entries.
- Delete entries.
- Copy and paste or cut and paste information between tables.

**Define Mappings Programmatically**

This example shows how to define a code replacement mapping programmatically. The programming interface for defining code replacement table mappings is ideal for
• Modifying tables that you create with the Code Replacement Tool.
• Defining mappings for specialized entries that you cannot create with the Code Replacement Tool.
• Replicating and modifying similar entries and tables.

Steps for defining a mapping programmatically are:

• “Create Code Replacement Table” on page 55-34
• “Create Table Entry” on page 55-34
• “Set Entry Parameters” on page 55-36
• “Create Conceptual Arguments” on page 55-38
• “Create Implementation Arguments” on page 55-40
• “Add Entry to Table” on page 55-44
• “Validate Entry” on page 55-44
• “Save Table” on page 55-45

Create Code Replacement Table

1 Create a table definition file that contains a function definition. For example:

```matlab
function hTable = crl_table_sinfcn()
```

2 Within the function body, create the table by calling the function `RTW.TflTable`

```matlab
hTable = RTW.TflTable;
```

Create Table Entry

For each function or operator that you want the code generator to replace, map a conceptual representation of the function or operator to an implementation representation as a table entry.

1 Within the body of a table definition file, create a code replacement entry object. Call one of the following functions.

<table>
<thead>
<tr>
<th>Entry Type</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>Math operation</td>
<td><code>RTW.TflCOperationEntry</code></td>
</tr>
<tr>
<td>Function</td>
<td><code>RTW.TflCFunctionEntry</code></td>
</tr>
<tr>
<td>BLAS operation</td>
<td><code>RTW.TflBlasEntryGenerator</code></td>
</tr>
<tr>
<td>Entry Type</td>
<td>Function</td>
</tr>
<tr>
<td>------------------------------------------------</td>
<td>-----------------------------------------------</td>
</tr>
<tr>
<td>CBLAS operation</td>
<td>RTW.TflCBlasEntryGenerator</td>
</tr>
<tr>
<td>Fixed-point addition and subtraction operations</td>
<td>RTW.TflCOperationEntryGenerator</td>
</tr>
<tr>
<td>(support for SlopesMustBeTheSame and MustHaveZeroNetBias parameters)</td>
<td></td>
</tr>
<tr>
<td>Net slope fixed-point operation</td>
<td>RTW.TflCOperationEntryGenerator_NetSlope</td>
</tr>
<tr>
<td>Semaphore or mutex entry</td>
<td>RTW.TflCSemaphoreEntry</td>
</tr>
<tr>
<td>Custom function entry</td>
<td>MyCustomFunctionEntry (where MyCustomFunctionEntry is a class derived from RTW.TflCFunctionEntryML)</td>
</tr>
<tr>
<td>Custom operation entry</td>
<td>MyCustomOperationEntry (where MyCustomOperationEntry is a class derived from RTW.TflCOperationEntryML)</td>
</tr>
</tbody>
</table>

For example:

```c
hEnt = RTW.TflCFunctionEntry;
```

You can combine steps of creating the entry, setting entry parameters, creating conceptual and implementation arguments, and adding the entry to a table with a single function call to `registerCFunctionEntry`, `registerCPPFunctionEntry`, or `registerCPromotableMacroEntry` if you are creating an entry for a function and the function implementation meets the following criteria:

- Implementation argument names and order match the names and order of corresponding conceptual arguments.
- Input arguments are of the same type.
- The return and input argument names follow the code generator’s default naming conventions:
  - Return argument is `y1`.
  - Input arguments are `u1`, `u2`, ..., `un`.

For example:
As another alternative, you can significantly reduce the amount of code that you write by combining the steps of creating the entry and conceptual and implementation arguments with a call to the `createCRLEntry` function. In this case, specify the conceptual and implementation information as character vector specifications.

For example:

```matlab
hEnt = createCRLEntry(hTable, ...
    'double y1 = sin(double u1)', ...
    'mySin');
```

This approach does not support:

- C++ implementations
- Data alignment
- Operator replacement with net slope arguments
- Entry parameter specifications (for example, priority, algorithm, building information)
- Semaphore and mutex function replacements

### Set Entry Parameters

Set entry parameters, such as the priority, algorithm information, and implementation (replacement) function name. Call the function listed in the following table for the entry type that you created.

<table>
<thead>
<tr>
<th>Entry Type</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>Math operation</td>
<td><code>setTflCOperationEntryParameters</code></td>
</tr>
<tr>
<td>Function</td>
<td><code>setTflCFun....</code></td>
</tr>
<tr>
<td>BLAS operation</td>
<td><code>setTflCOperationEntryParameters</code></td>
</tr>
<tr>
<td>CBLAS operation</td>
<td><code>setTflCOperationEntryParameters</code></td>
</tr>
</tbody>
</table>
### Entry Type

<table>
<thead>
<tr>
<th>Fixed-point addition and subtraction operations where there is a many-to-one mapping, such as a mapping for a range of fixed-point types to the same replacement function (support for SlopesMustBeTheSame and MustHaveZeroNetBias parameters)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Net slope fixed-point operation</td>
</tr>
<tr>
<td>Semaphore or mutex entry</td>
</tr>
<tr>
<td>Custom function entry</td>
</tr>
<tr>
<td>Custom operation entry</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>setTflCOperationEntryParameters</td>
</tr>
<tr>
<td>setTflCOperationEntryParameters</td>
</tr>
<tr>
<td>setTflCSemaphoreEntryParameters</td>
</tr>
<tr>
<td>setTflCFunctionEntryParameters</td>
</tr>
<tr>
<td>setTflCOperationEntryParameters</td>
</tr>
</tbody>
</table>

To see a list of the parameters that you can set, at the command line, create a new entry and omit the semicolon at the end of the command. For example:

```matlab
hEnt = RTW.TflCFunctionEntry
```

```matlab
hEnt =

TflCFunctionEntry with properties:

  Implementation: [1x1 RTW.CImplementation]
  SlopesMustBeTheSame: 0
  BiasMustBeTheSame: 0
  AlgorithmParams: []
  ImplType: 'FCN IMPL FUNCT'
  AdditionalHeaderFiles: {0x1 cell}
  AdditionalSourceFiles: {0x1 cell}
  AdditionalIncludePaths: {0x1 cell}
  AdditionalSourcePaths: {0x1 cell}
  AdditionalLinkObjs: {0x1 cell}
  AdditionalLinkObjsPaths: {0x1 cell}
  AdditionalLinkFlags: {0x1 cell}
  AdditionalCompileFlags: {0x1 cell}
  SearchPaths: {0x1 cell}
  Key: ''
  Priority: 100
  ArrayLayout: 'COLUMN_MAJOR'
  ConceptualArgs: [0x1 handle]
  EntryInfo: []
```
To see the implementation parameters, enter:

```matlab
hEnt.Implementation
```

```matlab
ans =

CImplementation with properties:

  HeaderFile: ''
  SourceFile: ''
  HeaderPath: ''
  SourcePath: ''
  Return: []
  StructFieldMap: []
  Name: ''
  Arguments: [0x1 RTW.Argument]
  ArgumentDescriptor: []
```

For example, to set entry parameters for the `sin` function and name your replacement function `sin_dbl`, use the following function call:

```matlab
setTflCFunctionEntryParameters(hEnt, ...
  'Key', 'sin', ...
  'ImplementationName', 'sin_dbl');
```

**Create Conceptual Arguments**

Create conceptual arguments and add them to the entry's array of conceptual arguments.

- Specify output arguments before input arguments.
- Specify argument names that comply with code generator argument naming conventions:
• \( y_1 \) for a return argument
• \( u_1, \ldots, u_n \) for input arguments

Specify data types that are familiar to the code generator.

The function signature, including argument naming, order, and attributes, must fulfill the signature match sought by function or operator callers.

The code generator determines the size of the value for an argument with an unsized type, such as integer, based on hardware implementation configuration settings.

For each argument:

1 Identify whether the argument is for input or output, the name, and data type. If you do not know what arguments to specify for a supported function or operation, use the Code Replacement Tool to find them. For example, to find the conceptual arguments for the \( \sin \) function, open the tool, create a table, create a function entry, and in the **Function** menu select \( \sin \).

When validating the entry, the code generator validates that each conceptual argument has an I/O type that is compatible with the argument name. For example, an input must have IOType of RTW_IO_INPUT.

2 Create and add the conceptual argument to an entry. You can choose a method from the methods listed in this table.

<table>
<thead>
<tr>
<th>If</th>
<th>Then</th>
</tr>
</thead>
</table>
| You want simpler code or want to explicitly specify whether the argument is scalar or nonscalar (vector or matrix). | Call the function `createAndAddConceptualArg`. For example:  
`createAndAddConceptualArg(hEnt, ... 
'RTW.TflArgNumeric', ..., 
'Name', 'y1', ..., 
'IOType', RTW_IO_OUTPUT, ..., 
'DataTypeMode', 'double');`  
The second argument specifies whether the argument is scalar (RTW.TflArgNumeric or RTW.TflArgMatrix). |
### Table: Core Code Replacement Customization

<table>
<thead>
<tr>
<th><strong>If</strong></th>
<th><strong>Then</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>You want to create an argument based on a built-in argument definition (for example, scalar or nonscalar).</td>
<td>Call <code>getTflArgFromString</code> to create the argument. Then, call <code>addConceptualArg</code> to add the argument to the entry. arg = <code>getTflArgFromString(hEnt, 'y1','double')</code>; arg.IOType = 'RTW_IO_OUTPUT'; addConceptualArg(hEnt, arg);</td>
</tr>
<tr>
<td>You need to define several similar mappings, you want to minimize the code to write, and the entries do not require data alignment, use net slope arguments, or involve semaphore or mutex replacements.</td>
<td>Call <code>createCRLEntry</code> to create the entry and specify conceptual and implementation arguments in a single function call. hEnt = <code>createCRLEntry(hTable, ... 'double y1 = sin(double u1)', ... 'mySin');</code></td>
</tr>
</tbody>
</table>

The following code shows the second approach listed in the table for specifying the conceptual output and input argument definitions for the `sin` function.

```matlab
% Conceptual Args
arg = getTflArgFromString(hEnt, 'y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEnt, arg);
arg = getTflArgFromString(hEnt, 'u1','double');
addConceptualArg(hEnt, arg);

Create Implementation Arguments

Create implementation arguments for the C or C++ replacement function and add them to the entry.

- When replacing code, the code generator uses the argument names to determine how it passes data to the implementation function.
- For function replacements, the order of implementation argument names must match the order of the conceptual argument names.
• For operator replacements, the order of implementation argument names do not have to match the order of the conceptual argument names. For example, for an operator replacement for addition, \( y_1 = u_1 + u_2 \), the conceptual arguments are \( y_1, u_1, \) and \( u_2 \), in that order. If the signature of your implementation function is \( t \text{myAdd}(t \ u_2, \ t \ u_1) \), where \( t \) is a valid C type, based on the argument name matches, the code generator passes the value of the first conceptual argument, \( u_1 \), to the second implementation argument of \text{myAdd}. The code generator passes the value of the second conceptual argument, \( u_2 \), to the first implementation argument of \text{myAdd}.

• For operator replacements, you can remap operator output arguments to implementation function input arguments.

For each argument:

1. Identify whether the argument is for input or output, the name, and the data type.

   When validating the entry, the code generator validates that each implementation argument has an I/O type that is compatible with the conceptual argument to which it is mapped. For example, an conceptual argument of type \( \text{RTW\_IO\_OUTPUT} \) requires a compatible implementation argument of type \( \text{RTW\_IO\_OUTPUT} \) or \( \text{RTW\_IO\_INPUT\_OUTPUT} \). The default I/O type is \( \text{RTW\_IO\_INPUT} \).

2. Create and add the implementation argument to an entry. You can choose a method from the methods listed in this table.

<table>
<thead>
<tr>
<th>If</th>
<th>Then</th>
</tr>
</thead>
<tbody>
<tr>
<td>You want to populate implementation arguments as copies of previously created matching conceptual arguments</td>
<td>Call the function \text{copyConceptualArgsToImplementation}. For example: \text{copyConceptualArgsToImplementation}(hEnt);</td>
</tr>
<tr>
<td>If</td>
<td>Then</td>
</tr>
<tr>
<td>--------------------------------------------------</td>
<td>----------------------------------------------------------------------</td>
</tr>
<tr>
<td>You want to create and add implementation arguments individually, or vary argument attributes, while maintaining conceptual argument order</td>
<td>Call functions createAndSetCImplementationReturn and createAndAddImplementationArg. For example:</td>
</tr>
<tr>
<td></td>
<td>createAndSetCImplementationReturn(hEnt,</td>
</tr>
<tr>
<td></td>
<td>'RTW.TflArgNumeric', ...</td>
</tr>
<tr>
<td></td>
<td>'Name',       'y1', ...</td>
</tr>
<tr>
<td></td>
<td>'IOType',     'RTW_IO_OUTPUT', ...</td>
</tr>
<tr>
<td></td>
<td>'IsSigned',   true, ...</td>
</tr>
<tr>
<td></td>
<td>'WordLength', 32, ...</td>
</tr>
<tr>
<td></td>
<td>'FractionLength', 0);</td>
</tr>
<tr>
<td></td>
<td>createAndAddImplementationArg(op_entry,</td>
</tr>
<tr>
<td></td>
<td>'RTW.TflArgNumeric',...</td>
</tr>
<tr>
<td></td>
<td>'Name',       'u1', ...</td>
</tr>
<tr>
<td></td>
<td>'IOType',     'RTW_IO_INPUT',...</td>
</tr>
<tr>
<td></td>
<td>'IsSigned',   true,...</td>
</tr>
<tr>
<td></td>
<td>'WordLength', 32, ...</td>
</tr>
<tr>
<td></td>
<td>'FractionLength', 0 );</td>
</tr>
<tr>
<td><strong>If</strong></td>
<td><strong>Then</strong></td>
</tr>
<tr>
<td>---</td>
<td>---</td>
</tr>
<tr>
<td>You want to minimize the amount of code, or specify constant arguments to pass to the implementation function</td>
<td>Create the argument with a call to the function <code>getTflArgFromString</code>. Then, use the convenience method <code>setReturn</code> or <code>addArgument</code> to specify whether an argument is a return value or argument and to add the argument to the entry’s array of implementation arguments. For example:</td>
</tr>
</tbody>
</table>

```matlab
arg = getTflArgFromString(hEnt,...
   'y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);

arg = getTflArgFromString(hEnt,...
   'u1','double');
hEnt.Implementation.addArgument(arg);
```

The following call to `getTflArgFromString` passes the constant 0 to argument `u2`:

```matlab
arg = getTflArgFromString(hEnt,...
   'u2', 'int16', 0)
hEnt.Implementation.addArgument(arg);
```

For semaphore and mutex entries, use the functions `getTflDWorkFromString` and `addDWorkArg` to create and add a DWork argument to the entry. Then create implementation arguments as shown above with `getTflArgFromString` and the convenience methods `setReturn` and `addArgument`. For example:

```matlab
arg = getTflDWorkFromString(...
   'd1', 'void*')
hEnt.addDWorkArg(arg);

arg = hEnt.getTflArgFromString(...
   'y1', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);

arg = hEnt.getTflArgFromString(...
   'u1', 'integer');
hEnt.Implementation.addArgument(arg);
```
If | Then
--- | ---

arg = hEnt.getTflArgFromString(
    'd1', 'void**');
hEnt.Implementation.addArgument(arg);

You need to define several similar mappings, you want to minimize the code to write, and the entries do not require data alignment, use net slope arguments, or involve semaphore or mutex replacements.

Call `createCRLEntry` to create the entry and specify conceptual and implementation arguments in a single function call.

hEnt = createCRLEntry(hTable, ...
    'double y1 = sin(double u1)', ...
    'mySin');

The following code shows the third approach listed in the table for specifying the implementation output and input argument definitions for the `sin` function:

```matlab
% Implementation Args
arg = hEnt.getTflArgFromS etr ing('y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);

arg = hEnt.getTflArgFromS etr ing('u1','double');
hEnt.Implementation.addArgument(arg);
```

**Add Entry to Table**

Add an entry to a code replacement table by calling the function `addEntry`.

```matlab
addEntry(hTable, hEnt);
```

**Validate Entry**

After you create or modify a code replacement table entry, validate it by invoking it at the MATLAB command line. For example:

```matlab
hTbl = crl_table_sinf cn
hTbl =
```
If the table includes errors, MATLAB reports them. The following examples shows how MATLAB reports a typo in a data type name:

```matlab
hTbl = crl_table_sinfcn
??? RTW_CORE:tfl:TflTable: Unsupported data type, 'dooble'.
Error in ==> crl_table_sinfcn at 7
hTable.registerCFunctionEntry(100, 1, 'sin', 'dooble', 'sin_dbl', ...
```

**Save Table**

Save the table definition file. Use the name of the table definition function to name the file, for example, `crl_table_sinfcn.m`.

Next, from your requirements, determine whether you need to specify build information for your replacement code.

Specify Build Information for Replacement Code

After you define code replacement mappings, determine whether you need to specify build information for your replacement code. A code replacement table entry can specify build information for the code generator to use when replacing code for a match. For example, specify files for implementation replacement code if you are using a generated makefile and the code generation software compiles the code.

Add build information to an entry:

• Interactively, by using the Build Information tab in the Code Replacement Tool.
• Programmatically, by using a MATLAB programming interface.

Build Information

The build information can include:

• Paths and file names for header files
• Paths and file names for source files
• Paths and file names for object files
• Compile flags
• Link flags

Choose an Approach for Specifying Build Information

The following table lists situations to help you decide when to use an interactive or programmatic approach to specifying build information:

<table>
<thead>
<tr>
<th>Situation</th>
<th>Approach</th>
</tr>
</thead>
<tbody>
<tr>
<td>Creating code replacement entries for the first time.</td>
<td>Code Replacement Tool.</td>
</tr>
<tr>
<td>You used the Code Replacement Tool to create the entries for which the build information applies.</td>
<td>Code Replacement Tool to specify the build information quickly.</td>
</tr>
<tr>
<td>Situation</td>
<td>Approach</td>
</tr>
<tr>
<td>-----------------------------------------------</td>
<td>---------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Rapid prototyping entries.</td>
<td>Code Replacement Tool to generate, register, and test entries quickly.</td>
</tr>
<tr>
<td>Developing an entry to use as a template or</td>
<td>Code Replacement Tool to generate entry code that you can copy and modify.</td>
</tr>
<tr>
<td>starting point for defining similar entries.</td>
<td></td>
</tr>
<tr>
<td>Modifying existing mappings.</td>
<td>MATLAB Editor to update the programming interface directly.</td>
</tr>
</tbody>
</table>

- If an entry uses header, source, or object files, consider whether to make the files accessible to the code generator. You can copy files to the build folder or you can specify individual file names and paths explicitly.

- If you specify additional header files/include paths or source files/paths and you copy files, the compiler and utilities such as packNGo might find duplicate instances of files (an instance in the build folder and an instance in the original folder).

- If you choose to copy files to the build folder and you are using the packNGo function to relocate static and generated code files to another development environment:
  - In the call to packNGo, specify the property-value pair 'minimalHeaders' true (the default). That setting instructs the function to include the minimal header files required to build the code in the zip file.
  - Do not collocate files that you copy with files that you do not copy. If the packNGo function finds multiple instances of the same file, the function returns an error.
  - If you use the programming interface, paths that you specify can include tokens. A token is a variable defined as a character vector or cell array of character vectors in the MATLAB workspace that you enclose with dollar signs ($variable$). The code generator evaluates and replaces a token with the defined value. For example, consider the path $myfolder\folder1$, where myfolder is a character vector variable defined in the MATLAB workspace as 'd:\work\source\module1'. The code generator generates the custom path as d:\work\source\module1\folder1.

**Specify Build Information Interactively with the Code Replacement Tool**

The Code Replacement Tool provides a quick, easy way for you to specify build information for code replacement table entries. It is ideal for getting started with defining a table entry, rapid prototyping, and developing table entries to use as a starting point for defining similar mappings.
1 Determine the information that you must specify.
2 Open the Code Replacement Tool.
3 Select the code replacement table entry for which you want to specify the build information. In the left pane, select the table that contains the entry. In the middle pane, select the entry that you want to modify.
4 In the right pane, select the **Build Information** tab.
5 On the **Build Information** tab, specify your build information.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Specify</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Implementation header file</strong></td>
<td>File name and extension for the header file the code generator needs to generate the replacement code. For example, <code>sin_db1.h</code>.</td>
</tr>
<tr>
<td><strong>Implementation source file</strong></td>
<td>File name and extension for the C or C++ source file the code generator needs to generate the replacement code. For example, <code>sin_db1.c</code>.</td>
</tr>
<tr>
<td><strong>Additional header files/ include paths</strong></td>
<td>Paths and file names for additional header files the code generator needs to generate the replacement code. For example, <code>C:\libs\headerFiles\common.h</code>. This parameter adds <code>-I</code> to the compile line in the generated makefile.</td>
</tr>
<tr>
<td><strong>Additional source files/ paths</strong></td>
<td>Paths and file names for additional source files the code generator needs to generate the replacement code. For example, <code>C:\libs\srcFiles\common.c</code>. This parameter adds <code>-I</code> to the compile line in the generated makefile.</td>
</tr>
<tr>
<td><strong>Additional object files/ paths</strong></td>
<td>Paths and file names for additional object files the linker needs to build the replacement code. For example, <code>C:\libs\objFiles\common.obj</code>.</td>
</tr>
<tr>
<td><strong>Additional link flags</strong></td>
<td>Flags the linker needs to generate an executable file for the replacement code.</td>
</tr>
<tr>
<td><strong>Additional compile flags</strong></td>
<td>Flags the compiler needs to generate object code for the replacement code.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Specify</td>
</tr>
<tr>
<td>---------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Copy files to build directory</td>
<td>Whether to copy header, source, or object files, which are required to generate replacement code, to the build folder before code generation. If you specify files with Additional header files/include paths or Additional source files/paths and you copy files, the compiler and utilities such as packNGo might find duplicate instances of files.</td>
</tr>
</tbody>
</table>

6 Click **Apply**.

7 Select the **Mapping Information** tab. Scroll to the bottom of that table and click **Validate entry**. The tool validates the changes that you made to the entry.

8 Save the table that includes the entry that you just modified.

**Specify Build Information Programmatically**

The programming interface for specifying build information for a code replacement entry is ideal for:

- Modifying entries created with the Code Replacement Tool.
- Replicating and then modifying similar entries and tables.

The basic workflow for specifying build information programmatically is:

1 Identify or create the code replacement entry that you want to specify the build information.

2 Determine what information to specify.

3 Specify your build information.
<table>
<thead>
<tr>

</tr>
<tr>
<td></td>
<td>If a match occurs for a table entry, a call to the function RTW.copyFileToBuildDir copies required files to the build folder.</td>
</tr>
<tr>
<td></td>
<td>If you specify additional header files/include paths or additional source files/paths and you copy files, the compiler and utilities such as packNGo might find duplicate instances of files.</td>
</tr>
<tr>
<td>4 Save the table that includes the entry that you added or modified.</td>
<td></td>
</tr>
</tbody>
</table>

The following example defines a table entry for an optimized multiplication function that takes signed 32-bit integers and returns a signed 32-bit integer, taking saturation into account. Multiplications in the generated code are replaced with calls to the optimized function. The optimized function does not reside in the build folder. For the code generator to access the files, copy them into the build folder to be compiled and linked into the application.

The table entry specifies the source and header file names and paths. To request the copy operation, the table entry sets the genCallback property to 'RTW.copyFileToBuildDir' in the call to the setTflCOperationEntryParameters function. In this example, the header file s32_mul.h contains an inlined function that invokes assembly functions contained in s32_mul.s. If a match occurs for the table entry,
the function `RTW.copyFileToBuildDir` copies the specified source and header files to the build folder for use during the remainder of the build process.

```matlab
function hTable = make_my_crl_table
    hTable = RTW.TflTable;
    op_entry = RTW.TflCOperationEntry;
    setTflCOperationEntryParameters(op_entry, ...
        'Key',                      'RTW_OP_MUL', ...
        'Priority',                 100, ...
        'SaturationMode',           'RTW_SATURATE_ON_OVERFLOW', ...
        'RoundingModes',            {'RTW_ROUND_UNSPECIFIED'}, ...
        'ImplementationName',       's32_mul_s32_s32_sat', ...
        'ImplementationHeaderFile', 's32_mul.h', ...
        'ImplementationSourceFile', 's32_mul.s', ...
        'ImplementationHeaderPath', {fullfile('$(MATLAB_ROOT)','crl')}, ...
        'ImplementationSourcePath', {fullfile('$(MATLAB_ROOT)','crl')}, ...
        'GenCallback',              'RTW.copyFileToBuildDir');

    addEntry(hTable, op_entry);

The following example uses the functions `addAdditionalHeaderFile`, `addAdditionalIncludePath`, `addAdditionalSourceFile`, `addAdditionalSourcePath`, `addAdditionalLinkObj`, and `addAdditionalLinkObjPath` in addition to the code generation callback function `RTW.copyFileToBuildDir`.

```matlab
hTable = RTW.TflTable;

% Path to external source, header, and object files
libdir = fullfile('$(MATLAB_ROOT)','..', '..', 'lib');

op_entry = RTW.TflCOperationEntry;
setTflCOperationEntryParameters(op_entry, ...
    'Key',                      'RTW_OP_ADD', ...
    'Priority',                 90, ...
    'SaturationMode',           'RTW_SATURATE_UNSPECIFIED', ...
    'RoundingModes',            {'RTW_ROUND_UNSPECIFIED'}, ...
    'ImplementationName',       's32_add_s32_s32', ...
    'ImplementationHeaderFile', 's32_add_s32_s32.h', ...
    'ImplementationSourceFile', 's32_add_s32_s32.c'...
    'GenCallback',              'RTW.copyFileToBuildDir');

addAdditionalHeaderFile(op_entry, 'all_additions.h');
addAdditionalIncludePath(op_entry, fullfile(libdir, 'include'));
addAdditionalSourceFile(op_entry, 'all_additions.c');
addAdditionalSourcePath(op_entry, fullfile(libdir, 'src'));
addAdditionalLinkObj(op_entry, 'addition.o');
addAdditionalLinkObjPath(op_entry, fullfile(libdir, 'bin'));
addEntry(hTable, op_entry);

Next, include your code replacement table in a code replacement library and register the library with the code generator.

**More About**

- “Define Code Replacement Mappings” on page 55-29
- “Register Code Replacement Mappings” on page 55-56
- “Develop a Code Replacement Library” on page 55-15
- “Code You Can Replace from MATLAB Code” on page 55-5
Register Code Replacement Mappings

After you define code replacement entries in a code replacement table, you can include the table in a code replacement library that you register with the code generator. When registered, a library appears in the list of available code replacement libraries that you can choose from when configuring the code generator.

Register a code replacement table as a code replacement library:

- Interactively, by using the Code Replacement Tool
- Programmatically, by using a MATLAB programming interface

Choose an Approach for Creating the Registration File

The following table lists situations to help you decide when to use an interactive or programmatic approach to creating a registration file:

<table>
<thead>
<tr>
<th>If...</th>
<th>Then...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Registering a code replacement table for the first time</td>
<td>Use the Code Replacement Tool.</td>
</tr>
<tr>
<td>You used the Code Replacement Tool to create the table</td>
<td>Use the Code Replacement Tool to quickly register the table.</td>
</tr>
<tr>
<td>Rapid prototyping code replacement</td>
<td>Use the Code Replacement Tool to quickly generate, register, and test entries.</td>
</tr>
<tr>
<td>Creating registration file to use as a template or starting point for defining similar registration files</td>
<td>Use the Code Replacement Tool to generate code that you can copy and modify.</td>
</tr>
<tr>
<td>Modifying existing registration files</td>
<td>Use the MATLAB Editor to update the registration file.</td>
</tr>
<tr>
<td>Defining multiple code replacement libraries in one registration file</td>
<td>Use the MATLAB Editor to create a new or extend an existing registration file.</td>
</tr>
<tr>
<td>Defining code replacement library hierarchy in a registration file</td>
<td>Use the MATLAB Editor to create a new or extend an existing registration file.</td>
</tr>
</tbody>
</table>
Create Registration File Interactively with the Code Replacement Tool

The Code Replacement tool provides a quick, easy way for you to create a registration file for a code replacement table. It is ideal for getting started, rapid prototyping, and generating a registration file that you want to use as a starting point for similar registrations.

1. After you validate and save a code replacement table, select File > Generate registration file to open the Generate registration file dialog box.

2. Enter the registration information. Minimally, specify:

<table>
<thead>
<tr>
<th>For...</th>
<th>Specify...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Registry name</td>
<td>Text naming the code replacement library. For example, Sin Function Example.</td>
</tr>
</tbody>
</table>
For... | Specify...
---|---
Table list | Text naming one or more code replacement tables to include in the library. Specify each table as one of the following:

- Name of a table file on the MATLAB search path
- Absolute path to a table file
- Path to a table file relative to $(MATLAB_ROOT)$

You can specify multiple tables. If you do, separate the table specifications with a comma. For example:

crl_table_sinfcn, c:/work_crl/
crl_table_muldiv

See “Registration Files That Define Multiple Code Replacement Libraries” on page 55-62 for examples of each type of table specification.

Optionally, you can specify:

<table>
<thead>
<tr>
<th>For...</th>
<th>Specify...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Description</td>
<td>Text that describes the purpose and content of the library.</td>
</tr>
<tr>
<td>Target HW device</td>
<td>Text naming one or more hardware devices the code replacement library supports. Separate names with a comma. To support all device types, enter an asterisk (*). For example, TI C28x, TI C62x.</td>
</tr>
<tr>
<td>Base CRL</td>
<td>Text naming a code replacement library that you want to serve as a base library for the library you are registering. Use this field to specify library hierarchies. For example, you can specify a general TI device library as the base library for a more specific TI C28x device library.</td>
</tr>
<tr>
<td>Generate data alignment specification</td>
<td>Flag that enables data alignment specification.</td>
</tr>
</tbody>
</table>
Create Registration File Programmatically

The programming interface for creating a registration file for a code replacement table is ideal for:

- Modifying registration files created with the Code Replacement Tool
- Replicating and modifying similar registration files
- Defining multiple code replacement libraries in one registration file

The basic workflow for creating a registration file programmatically consists of the following steps:

1. Define an `rtwTargetInfo` function. The code generator recognizes this function as a customization file. The function definition must include at least the following content:

   ```matlab
   function rtwTargetInfo(cm)
   cm.registerTargetInfo(@loc_register_crl);
   function this = loc_register_crl
   this(1) = RTW.TflRegistry;
   this(1).Name = 'crl-name';
   this(1).TableList = {'table',...};
   ``

<table>
<thead>
<tr>
<th>For...</th>
<th>Replace...</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>this(1).Name</code></td>
<td><code>crl-name</code> with text naming the code replacement library. For example, Sin</td>
</tr>
<tr>
<td><code>function</code></td>
<td>Function Example.</td>
</tr>
</tbody>
</table>
For... | Replace...
---|---
\texttt{this(1).TableList = \{\textquote{table}',...\};} | \textit{table} with text that identifies the code replacement table that contains your code replacement entries. Specify a table as one of the following:

- Name of a table file on the MATLAB search path
- Absolute path to a table file
- Path to a table file relative to $\texttt{MATLAB\_ROOT}$

You can specify multiple tables. If you do, separate the table specifications with commas.

Optionally, you can specify:

<table>
<thead>
<tr>
<th>For...</th>
<th>Replace...</th>
</tr>
</thead>
</table>
\texttt{this(1).Description = \textquote{text}} | \textit{text} with text that describes the purpose and content of the library. |
\texttt{this(1).TargetHWDeviceType = \{\textquote{device-type}',...\}} | \textit{device-type} with text that names a hardware device the code replacement library supports. You can specify multiple device types. Separate device types with a comma. For example, \textit{TI C28x, TI C62x}. To support all device types, enter an asterisk (*). |
For...

<table>
<thead>
<tr>
<th>For...</th>
<th>Replace...</th>
</tr>
</thead>
<tbody>
<tr>
<td>this(1).BaseTfl = 'base-lib'</td>
<td>base-lib with text that names a code replacement library that you want to serve as a base library for the library you are registering. Use this field to specify library hierarchies. For example, you can specify a general TI device library as the base library for a TI C28x device library. See “Registration Files That Define Code Replacement Library Hierarchies” on page 55-62 for an example.</td>
</tr>
</tbody>
</table>

For example:

```matlab
function rtwTargetInfo(cm)
    cm.registerTargetInfo(@loc_register_crl);
    function this = loc_register_crl
        this(1) = RTW.TflRegistry;
        this(1).Name = 'Sin Function Example';
        this(1).TableList = {'crl_table_sinfcn'};
        this(1).TargetHWDeviceType = {'*'};
        this(1).Description = 'Example - sin function replacement';
    end
end
```

2. Save the file with the name rtwTargetInfo.m.
3. Place the file on the MATLAB path. When the file is on the MATLAB path, the code generator reads the file after starting and applies the customizations during the current MATLAB session.

**Register a Code Replacement Library**

Before you can use the code replacement tables defined in a registration file, you must refresh Simulink customizations within the current MATLAB session. To initiate a refresh, enter the following command:

```matlab
RTW.TargetRegistry.getInstance('reset');
```
Registration Files That Define Multiple Code Replacement Libraries

Use the programming interface to create a registration file that defines a code replacement library that includes multiple code replacement tables. The following example defines a library that includes multiple tables. The TableList fields specify tables that reside at different locations. The tables reside on the MATLAB search path or at locations specified with a path.

```matlab
function rtwTargetInfo(cm)
    cm.registerTargetInfo(@locCrlRegFcn);

    function thisCrl = locCrlRegFcn
        % Register a code replacement library for use with model: rtwdemo_crladdsub
        thisCrl(1) = RTW.TflRegistry;
        thisCrl(1).Name = 'Addition & Subtraction Examples';
        thisCrl(1).Description = 'Example of addition/subtraction op replacement';
        thisCrl(1).TableList = {'crl_table_addsub'};
        thisCrl(1).TargetHWDeviceType = {'*'};

        % Register a code replacement library for use with model: rtwdemo_crlmuldiv
        thisCrl(2) = RTW.TflRegistry;
        thisCrl(2).Name = 'Multiplication & Division Examples';
        thisCrl(2).Description = 'Example of mult/div op repl for built-in integers';
        thisCrl(2).TableList = {'c:/work_crl/crl_tablemuldiv'};
        thisCrl(2).TargetHWDeviceType = {'*'};

        % Register a code replacement library for use with model: rtwdemo_crlfixpt
        thisCrl(3) = RTW.TflRegistry;
        thisCrl(3).Name = 'Fixed-Point Examples';
        thisCrl(3).Description = 'Example of fixed-point operator replacement';
        % thisCrl(3).TableList = {fullfile('$MATLAB_ROOT', ...
        %     'toolbox','rtw','rtwdemos','crl_demo','crl_table_fixpt')};
        thisCrl(3).TargetHWDeviceType = {'*'};

Registration Files That Define Code Replacement Library Hierarchies

Using the programming interface, you can organize multiple code replacement libraries in a hierarchy. The following example shows a registration file that defines four code replacement tables organized in a hierarchy of four code replacement libraries. The tables include entries that increase in specificity: common entries, entries for TI devices, entries for TI C6xx devices, and entries specific to the TI C67x device.

```matlab
function rtwTargetInfo(cm)
```
cm.registerTargetInfo(@locCrlRegFcn);

function thisCrl = locCrlRegFcn

% Register a code replacement library that includes common entries
thisCrl(1) = RTW.TflRegistry;
thisCrl(1).Name = 'Common Replacements';
thisCrl(1).Description = 'Common code replacement entries shared by other libraries';
thisCrl(1).TableList = {'crl_table_general'};
thisCrl(1).TargetHWDeviceType = {'*'};

% Register a code replacement library for TI devices
thisCrl(2) = RTW.TflRegistry;
thisCrl(2).Name = 'TI Device Replacements';
thisCrl(2).Description = 'Code replacement entries shared across TI devices';
thisCrl(2).TableList = {'crl_table_TI_devices'};
thisCrl(2).TargetHWDeviceType = {'TI C28x', 'TI C55x', 'TI C62x', 'TI C64x', 'TI 67x'};
thisCrl(1).BaseTfl = 'Common Replacements'

% Register a code replacement library for TI c6xx devices
thisCrl(3) = RTW.TflRegistry;
thisCrl(3).Name = 'TI c6xx Device Replacements';
thisCrl(3).Description = 'Code replacement entries shared across TI C6xx devices';
thisCrl(3).TableList = {'crl_table_TIC6xx_devices'};
thisCrl(3).TargetHWDeviceType = {'TI C62x', 'TI C64x', 'TI 67x'};

% Register a code replacement library for the TI c67x device
thisCrl(3) = RTW.TflRegistry;
thisCrl(3).Name = 'TI c67x Device Replacements';
thisCrl(3).Description = 'Code replacement entries for the TI C67x device';
thisCrl(3).TableList = {'crl_table_TIC67x_device'};
thisCrl(3).TargetHWDeviceType = {'TI 67x'};

After registering your code replacement mappings, verify that code replacements occur.

- “Code You Can Replace from MATLAB Code” on page 55-5
Troubleshoot Code Replacement Library Registration

If a code replacement library is not listed as a configuration option or does not appear in the Code Replacement Viewer:

- Refresh the library registration information within the current MATLAB session (RTW.TargetRegistry.getInstance('reset'); or for the Simulink environment, sl_refresh_customizations).
- See whether the registration file, rtwTargetInfo.m, contains an error.

See Also

More About
- “Register Code Replacement Mappings” on page 55-56
Verify Code Replacements

After you create or modify a code replacement table, use the following techniques to examine and validate the table and its entries.

• Invoke the table definition file at the command prompt.
• Use the Code Replacement Viewer to examine libraries, tables, and entries.
• Trace code replacements from the source where you applied the code replacement library.
• Examine code replacement hits and misses logged during code generation.

Code Replacement Hits and Misses

The code generator logs code replacement table entries for which it finds and does not find matches in the hit cache and miss cache, respectively. When a code replacement entry match fails and code is not replaced, the code generator logs the call site object (CSO) for the miss in the miss cache. When an entry match succeeds, the code generator logs the matched entry in the hit cache.

The code generator overwrites the hit and miss cache data each time it produces code. The cache data reflects hits and misses for only the last application component (MATLAB code or Simulink model) for which you generate code.

You can use the Code Replacement Viewer to review trace information based on logged hit and miss trace data. The hit cache provides trace information that helps to verify code replacements.

The miss cache and related miss data collected and stored in code replacement tables provide trace information for misses. Use this information for misses to troubleshoot expected code replacements that do not occur. Trace information for a miss:

• Identifies the call site object.
• Provides a link to the relevant source location for the miss.
• Includes information about the reason for the miss.
Validate a Table Definition File

After you create or modify a code replacement table definition file, validate it. At the command prompt, specify the name of the table in a call to the `isvalid` function. For example:

```matlab
isvalid(crl_table_sinfcn)
```

```matlab
ans =
   1
```

MATLAB displays errors that occur. In the following example, MATLAB detects a typo in a data type name.

```matlab
isvalid(crl_table_sinfcn)
```

```matlab
??? RTW_CORE:tfl:TflTable: Unsupported data type, 'dooble'.
```

```matlab
Error in ==> crl_table_sinfcn at 7
hTable.registerCFunctionEntry(100, 1, 'sin', 'dooble', 'sin_dbl', ...
```

Review Library Content

After you create or modify a code replacement library, use the Code Replacement Viewer to review and verify the list of tables in the library and the entries in each table.

1. Open the viewer to display the contents of your library. At the command prompt, enter the following command:

```matlab
crviewer('library')
```

For example:

```matlab
crviewer('Addition & Subtraction Examples')
```
2 Review the list of tables in the left pane. Are tables missing? Are the tables listed in the correct relative order? By default, the viewer displays tables in search order.

3 In the left pane, click each table and review the list of entries in the center pane. Are entries missing? Does the list include extraneous or unexpected entries?
Review Table Content

After you create or modify a code replacement table, use the Code Replacement Viewer to review and verify table entries.

1. Open the viewer to display the contents of your table. At the command prompt, enter the following command. *table* is a MATLAB file that defines code replacement tables. The file must be in the current folder or on the MATLAB path.

   ```matlab
crviewer(table)
```

   For example:

   ```matlab
crviewer(crl_table_addsub)
```
2 Review the list of entries in the center pane. Are entries missing? Does the list include extraneous or unexpected entries? By default, the viewer displays entries in search order.

3 In the center pane, click each entry and verify the entry information in the right pane.
- Argument order is correct.
- Conceptual argument names match code generator naming conventions.
• Implementation argument names are correct.
• Algorithm properties (for example, saturation and rounding mode) are set correctly.
• Header or source file specification is not missing.
• I/O types are correct.
• Relative priority of entries is correct.

Review Code Replacements

After you review the content of your code replacement library and tables, generate code and a code generation report. Verify that the code generator replaces code as you expect.

The Code Replacements Report details the code replacement library functions that the code generator uses for code replacements. The report provides a mapping between each replacement instance and the line of MATLAB code that triggered the replacement. The Code Replacements report is not available for generated MEX functions.

The following example illustrates two complementary approaches for reviewing code replacements:

• Check the Code Replacements Report section of the code generation report for expected replacements.
• Trace code replacements.

1 Identify the MATLAB function where you anticipate that a function or operator replacement occurs. This example uses the function `matlabroot/toolbox/rtw/rtwdemos/crl_demo/addsub_two_int16.m`.

```matlab
function [y1, y2] = addsub_two_int16(u1, u2)
    y1 = int16(u1 + u2);
    y2 = int16(u1 - u2);
```

2 Identify or create code or a script to exercise the function. For example, consider test file `addsub_to_int16_test.m`, which includes the following code:

```matlab
disp('Input')
u1 = int16(10)
u2 = int16(10)
[y1, y2] = addsub_two_int16(u1, u2);
```
disp('Output')
disp('y1 =')
disp(y1);
disp('y2 =')
disp(y2);

3 Open the MATLAB Coder app.

4 On the Select Source Files page, add your function to the project. For this example, add function addsub_two_int16. Click Next.

5 On the Define Input Types page, use the test file addsub_to_int16_test to automatically define the input types. Click Next.

6 On the Check for Run-Time Issues page, specify the test file addsub_to_int16_test. The app runs the test file, replacing calls to addsub_to_int16_test with calls to a MEX version of addsub_to_int16_test. Click Next.

7 To open the Generate dialog box, on the Generate Code page, click the Generate arrow ▼.

8 Set Build type to generate source code. Before you build an executable, you want to review your code replacements in the generated code.

9 In the Generate dialog box, click More Settings.

10 Configure the code generator to use your code replacement library. On the Custom Code tab, set the Code replacement library parameter to the name of your library. For this example, set the library to Addition & Subtraction Examples.

11 Configure the code generation report to include the Code Replacements Report. On the Debugging tab, select:

- Always create a code generation report
- Code replacements
- Automatically launch a report if one is generated

12 To generate code and a report, set Build type to Source Code. Then, click Generate.

13 Open the Code Replacements Report section of the code generation report.

That report lists the replacement functions that the code generator used. The report provides a mapping between each replacement instance and the MATLAB code that triggered the replacement.
Review the report:

- Check whether expected function and operator code replacements occurred.
- In the replacements sections, click each code link to see the source that triggered the reported code replacement.

If a function or operator is not replaced as expected, the code generator used a higher-priority (lower-priority value) match or did not find a match.

To analyze and troubleshoot code replacement misses, use the trace information that the Code Replacement Viewer provides. See “Troubleshoot Code Replacement Misses” on page 55-74.

Troubleshoot Code Replacement Misses

Use miss reason messages that appear in the Code Replacement Viewer to analyze and correct code replacement misses.

Miss Reason Messages

The Code Replacement Viewer displays miss reason messages in trace information for code replacement misses. A legend listing each message that appears in the miss report precedes the report details. A message consists of:

- Numeric identifier, which identifies the message in the report details.
- Message text, which in some cases includes placeholders for names of arguments, call site object values, table entry values, and property names.

For example:

1. Mismatched data types (argument name, CSO value, table entry value)

The parenthetical information represents placeholders for actual values that appear in the report details.

In the Miss Source Locations table that lists the miss details, the Reason column includes:

- The message identifier, as listed in the legend.
- The placeholder values for that instance of the miss reason message.

The following Reason details indicate a data type mismatch because the call site object specifies data type int8 for arguments y1, u1, and u2, while the code replacement table entry specifies uint32.

1. y1, int8, uint32
   u1, int8, uint32
   u2, int8, uint32

Depending on your situation and the reported miss reason, troubleshoot reported misses by looking for instances of the following:

- A typo in the code replacement table entry definition or a source parameter setting.
• Information missing from the code replacement table entry or a source parameter setting.
• Invalid or incorrect information in the code replacement table entry definition or a source parameter setting.
• Arguments incorrectly ordered in the code replacement table entry definition or the source being replaced with replacement code.
• Failed algorithm classification for an addition or subtraction operation due to:
  • An ideal accumulator not being calculated because the type of an input argument is not fixed-point or the slope adjustment factors of the input arguments are not equal.
  • Input or output casts with a floating-point cast type.
  • Input or output casts with cast types that have different slope adjustment factors or biases.
  • Output casts not being convertible to a single output cast.
  • Input casts resulting in loss of bits.

### Analyze and Correct Code Replacement Misses

The following example shows how to use Code Replacement Viewer trace information to troubleshoot code replacement misses. You must have already reviewed and tested code replacements for your MATLAB code.

1. Review the code generated for a specific code element, looking for expected code replacement. Regenerate or reopen the code generation report for your MATLAB code. If you already generated the code generation report that includes the Code Replacements Report for `matlabroot/toolbox/rtw/rtwdemos/crl_demo/addsub_two_int16.m`, open the file `codegen/lib/addsub_two_int16/html/mldatx.html`. For information on how to regenerate the report, see “Verify Code Replacements” on page 55-65.

To examine the code generated for the function, from the code generation report, open the generated file `addsub_two_int16.h`.

```c
extern void addsub_two_int16(double u1, double u2, short *b_y1, short *y2);
```

The code generator replaced code, but the replacement is for the signed version of the 16-bit addition and subtraction operations. You expected code replacements for operations on unsigned data.
Open the Code Replacements Report for the MATLAB code.

Click the link to open the Code Replacement Viewer.

In the viewer left pane, select your code replacement table. For this example, select code replacement table `crl_table_addsub`.

In the middle pane, select table entry `RTW_OP_ADD` with implementation function `u16_add_u16_u16`.

In the right pane, select the Trace Information tab.

The Trace Information is a table that lists the following information for each miss:

- Call site object preview. The call site object is the conceptual representation of the addition operator. The code generator uses this object to query the code replacement library for a match.
- A link to the source location in the MATLAB function where the code generator considered replacing code.
- The reasons that the miss occurred. See “Miss Reason Messages” on page 55-74.

For this example, the report shows misses for function `addsub_two_int16.m`.

Find the source in the trace information. Depending on your situation and the reported miss reason, consider looking for a condition such as a typo in the code replacement table entry definition or a source parameter setting. For a list of conditions to consider, see “Miss Reason Messages” on page 55-74.

For this example, determine why code for function `addsub_two_int16` is not replaced with code for an unsigned 16-bit addition operation. The miss reasons for the function indicate data type and algorithm mismatches:

- The data type in the call site object is a signed 16-bit integer. The code replacement entry specifies an unsigned 16-bit integer.
- The algorithm property in the call site object is `RTW_CAST_AFTER_OP` while the code replacement entry specifies `RTW_CAST_BEFORE_OP`.

Fix the specified MATLAB code and relevant specifications or code replacement table entry. If the issue concerns the MATLAB code, use the source location in the trace information to find the code to fix. For this example, you expected an unsigned addition operation to occur for the `addsub_two_int16` function.

To fix the mismatches, in the test file `addsub_to_int16_test`, change the data types definitions for `u1` and `u2` as follows:
u1 = uint16(10)
u2 = uint16(10)

In the MATLAB Coder app:

- Open the project that contains the addsub_to_int16 function.
- Use the updated test file addsub_to_int16_test to automatically redefine the input types.
- Change the addition and subtraction algorithm setting. Open the code replacement library crl_table_addsub. Change the entry Algorithm parameter setting from Cast before operation (RTW_CAST_BEFORE_OP) to Cast after operation (RTW_CAST_AFTER_OP).
- Regenerate code and a report.

From the Code Replacements Report, open the Code Replacement Viewer. Use the Code Replacement Viewer trace information to verify that your MATLAB code or code replacement table entry corrects the code replacement issue. The trace information shows a hit for function addsub_two_int16.

Deploy Code Replacement Library

After you verify code replacements and are ready to package and deploy a code replacement library for others to use:

1. Move your code replacement table files to an area that is on the MATLAB search path and that is accessible to and shared by other users.

2. Move the rtwTargetInfo.m registration file, to an area that is on the MATLAB search path and that is accessible to and shared by other users. If you are deploying a library to a folder in a development environment that already contains a rtwTargetInfo.m file, copy the registration code from your code replacement library version of rtwTargetInfo.m and paste it into the shared version of that file.

3. Register the library customizations or restart MATLAB.

4. Verify that the libraries are available for configuring the code generator and that code replacements occur as expected.

5. Inform users that the libraries are available and provide direction on when and how to apply them.

Math Function Code Replacement

This example shows how to define a code replacement mapping for a math function. The example defines a mapping for the \texttt{sin} function programmatically. Alternatively, you can use the \textbf{Code Replacement Tool} to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```matlab
   function hTable = crl_table_sinfcn2()
   %CRL_TABLE_SINFCN2 - Define function entry for code replacement table.
   hTable = RTW.TflTable;
   ```

2. Within the function body, create the table by calling the function \texttt{RTW.TflTable}.

3. Create an entry for the function mapping with a call to the \texttt{RTW.TflCFunctionEntry} function.

   ```matlab
   % Create entry for sin function replacement
   fcn_entry = RTW.TflCFunctionEntry;
   ```

4. Set function entry parameters with a call to the \texttt{setTflCFunctionEntryParameters} function.

   ```matlab
   setTflCFunctionEntryParameters(fcn_entry, ... 'Key', 'sin', ... 'Priority', 30, ... 'ImplementationName', 'mySin', ... 'ImplementationHeaderFile', 'basicMath.h', ... 'ImplementationSourceFile', 'basicMath.c');
   ```

5. Create conceptual arguments \texttt{y1} and \texttt{u1}. There are multiple ways to set up the conceptual arguments. This example uses calls to the \texttt{createAndAddConceptualArg} function to create and add an argument with one function call.

   ```matlab
   createAndAddConceptualArg(fcn_entry, 'RTW.TflArgNumeric', ... 'Name', 'y1', ... 'IOType', 'RTW_IO_OUTPUT', ... 'DataTypeMode', 'double');
   ```

   ```matlab
   createAndAddConceptualArg(fcn_entry, 'RTW.TflArgNumeric', ... 'Name', 'u1', ... 'IOType', 'RTW_IO_INPUT', ... 'DataTypeMode', 'double');
   ```

6. Copy the conceptual arguments to the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses a call to the \texttt{copyConceptualArgsToImplementation} function to create and add implementation arguments to the entry by copying matching conceptual arguments.
copyConceptualArgsToImplementation(fcn_entry);

7 Add the entry to a code replacement table with a call to the `addEntry` function.

    addEntry(hTable, fcn_entry);

8 Save the table definition file. Use the name of the table definition function to name the file.

**See Also**

- “Develop a Code Replacement Library” on page 55-15
Memory Function Code Replacement

This example shows how to define a code replacement mapping for a memory function. The example defines a mapping for the `memcpy` function programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

```matlab
function hTable = crl_table_memcpy()
```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

```matlab
hTable = RTW.TflTable;
```

3. Create an entry for the function mapping with a call to the `RTW.TflCFunctionEntry` function.

```matlab
% Create entry for void* memcpy(void*, void*, size_t)
fcn_entry = RTW.TflCFunctionEntry;
```

4. Set function entry parameters with a call to the `setTflCFunctionEntryParameters` function.

```matlab
% Set SideEffects to 'true' for function returning void to prevent it from % being optimized away.
sdTflCFunEntryParameters(fcn_entry, ... ...
  'Key', 'memcpy', ...
  'Priority', 90, ...
  'ImplementationName', 'memcpy_int', ...
  'ImplementationHeaderFile', 'memcpy_int.h',...
  'SideEffects', true);
```

5. Create conceptual arguments `y1`, `u1`, `u2`, and `u3`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create and add the arguments.

```matlab
arg = getTflArgFromString(hTable, 'y1', 'void*');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(fcn_entry, arg);

arg = getTflArgFromString(hTable, 'u1', 'void*');
addConceptualArg(fcn_entry, arg);

arg = getTflArgFromString(hTable, 'u2', 'void*');
addConceptualArg(fcn_entry, arg);

arg = getTflArgFromString(hTable, 'u3', 'size_t');
addConceptualArg(fcn_entry, arg);
```

6. Copy the conceptual arguments to the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses a call to the
copyConceptualArgsToImplementation function to create and add implementation arguments to the entry by copying matching conceptual arguments.

copyConceptualArgsToImplementation(fcn_entry);

7 Add the entry to a code replacement table with a call to the addEntry function.

addEntry(hTable, fcn_entry);

8 Save the table definition file. Use the name of the table definition function to name the file.

Specify In-Place Code Replacement

In-place code replacement is an optimization technique that uses a single buffer, that is, the same memory, to store function input and output data, as in \( x = \text{foo}(x) \).

When you generate C or C++ code from MATLAB code, the code generator supports in-place function argument code replacement. When you interactively create a code replacement table entry with the Code Replacement Tool, you can specify in-place function argument replacement. You can also specify in-place function argument replacement programmatically with the Code Replacement Library API.

**Argument Specification Requirements**

- The argument must be a pointer.
- An argument can be in-place with only one other argument.
- Specify an input argument as in-place (shares memory) with an output argument or an output argument as in-place with an input argument.

**Interactive Argument Replacement Specification with Code Replacement Tool**

This example shows how to specify in-place function argument replacement when replacing code for a MATLAB function with the Code Replacement Tool. The tool enforces in-place argument specification requirements as you add arguments and modify argument properties.

1. Create the following MATLAB function, `customFunction.m`.
   ```matlab
   function x = customFunction(x)
   % Function that updates the input and returns it as an output
   coder.replace('-errorifnoreplacement');
   x = sin(x);
   ```

2. In the Code Replacement Tool, add a new table, select that table, and add a new function entry. For more information, see “Define Code Replacement Mappings” on page 55-29.

3. On the **Mapping Information** tab, select Custom for the **Function** parameter.

4. In the **function-name** text box, name the custom function. For this example, type the name `customFunction`. 

55-83
5 Under the **Conceptual arguments** list box, click + to add two arguments. By default, the tool creates an output argument \( y1 \) and an input argument \( u1 \), both of type double.

6 In the **Replacement function** > **Function prototype** section, type the name `custom_function_inplace_impl` in the **Name** text box.

7 Under the **Function arguments** list box, click + to add two function implementation arguments. By default, the tool creates an output argument \( y1 \) and an input argument \( u1 \), both of type double.

8 For each input argument that you want to specify as in-place with a corresponding output argument, in the **Argument properties** box, select the **Pointer** check box. The **Argument properties** section of the dialog box expands to include an **In-place argument** drop-down list. For this example, in the **Function arguments** list, select input argument \( u1 \), and then select the **Pointer** check box.

9 From the **In-place argument** list, select \( y1 \), the output argument for the code replacement mapping. The **Function arguments** list box is updated to show possible in-place argument mappings.
Select and delete one of the two possible argument mappings. For this example, delete the mapping \( y_1 \leftrightarrow u_1 \).

In the **Function signature preview** box, if the function signature appears as expected, click **Apply**. Otherwise, make adjustments, and then click **Apply**. The function signature for this example, appears as

\[
\text{void custom\_function\_inplace\_impl}(\text{double}\*, u_1);\]

Click **Validate entry**.

Save the code replacement table in the same folder as `customFunction.m`. Name the file `htfl_inplace_table.m`.

To test the example:

1. Register the table that contains the entry in a code replacement library.
2. Configure the code generator to use a code replacement library and to include the Code Replacements Report in the code generation report.
3. Generate the replacement code and a code generation report.
4. Review the code replacements.
Programmatic Argument Replacement Specification

This example shows how to specify in-place function argument replacement when replacing code for a MATLAB function programmatically. For the input implementation argument that shares the memory buffer, the example:

- Sets the name of the implementation argument to the same name as the corresponding conceptual argument.
- Associates the corresponding implementation argument with the argument property ArgumentForInPlaceUse.

1. Create the following MATLAB function, `customFunction.m`.

   ```matlab
   function y = customFunction(x)
   % Function that updates the input and returns it as an output
   coder.replace('-errorifnoreplacement');
   x = sin(x);
   ```

2. Create a table definition file that contains a function definition. For example:

   ```matlab
   function hTable = crl_table_inplace()
   ```

3. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```matlab
   hTable = RTW.TflTable;
   ```

4. Create an entry for the function mapping with a call to the `RTW.TflCFunctionEntry` function.

   ```matlab
   hEnt = RTW.TflCFunctionEntry;
   ```

5. Set function entry parameters with a call to the `setTflCFunctionEntryParameters` function.

   ```matlab
   setTflCFunctionEntryParameters(hEnt, ...
   'Key', 'customFunction', ...
   'Priority', 100, ...
   'ImplementationName', 'custom_function_inplace_impl', ...
   'SideEffects', true);
   ```

6. Create conceptual arguments `y1` and `u1`. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create and add the arguments.

   ```matlab
   arg = getTflArgFromString(hEnt, 'y1','double');
   arg.IOType = 'RTW_IO_OUTPUT';
   addConceptualArg(hEnt, arg);
   ```
Create the implementation arguments and add them to the entry. This example uses calls to the `getTflArgFromString` function to create implementation arguments that map to arguments in the replacement function prototype: output argument `y1` and input argument `u1`. For each argument, the example uses the convenience method `setReturn` or `addArgument` to specify whether an argument is a return value or argument. For each argument, this example adds the argument to the entry array of implementation arguments.

```matlab
arg = getTflArgFromString(hEnt, 'u1','double');
addConceptualArg(hEnt, arg);
arg = getTflArgFromString(hEnt, 'y2','void');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);
arg = getTflArgFromString(hEnt, 'u1','double*');
arg.ArgumentForInPlaceUse = 'y1';
hEnt.Implementation.addArgument(arg);
```

Add the entry to a code replacement table with a call to the `addEntry` function.

```matlab
addEntry(hLib, hEnt);
```

Save the table definition file. Use the name of the table definition function to name the file.

To test the example:

1. Register the table that contains the entry in a code replacement library.
2. Configure the code generator to use a code replacement library and to include the Code Replacements Report in the code generation report.
3. Generate the replacement code and a code generation report.
4. Review the code replacements.

Data Alignment for Code Replacement

Code replacement libraries can align data objects passed into a replacement function to a specified boundary.

Code Replacement Data Alignment

You can take advantage of function implementations that require aligned data to optimize application performance when using MATLAB Coder. To configure data alignment for a function implementation:

1. Specify the data alignment requirements in a code replacement entry. Specify alignment separately for each implementation function argument or collectively for all function arguments. See “Specify Data Alignment Requirements for Function Arguments” on page 54-136.

2. Specify the data alignment capabilities and syntax for one or more compilers. Include the alignment specifications in a library registration entry in the rtwTargetInfo.m file. See “Provide Data Alignment Specifications for Compilers” on page 54-138.

3. Register the library containing the table entry and alignment specification object.

4. Configure the code generator to use the code replacement library and generate code. Observe the results.

For examples, see “Basic Example of Code Replacement Data Alignment” on page 54-143 and the “Data Alignment for Function Implementations” section of the “Optimize Generated Code By Developing and Using Code Replacement Libraries - Simulink®” example page.

**Note** If replacement that requires alignment uses imported data (for example, I/O of an entry-point function or exported function), specify the data alignment with coder.dataAlignment statements in the MATLAB code. Specify alignment separately for each instance of imported data. See “Specify Data Alignment in MATLAB Code for Imported Data” on page 55-95.

Specify Data Alignment Requirements for Function Arguments

To specify the data alignment requirement for an argument in a code replacement entry:
• If you are defining a replacement function in a code replacement table registration file, create an argument descriptor object (RTW.ArgumentDescriptor). Use its AlignmentBoundary property to specify the required alignment boundary and assign the object to the argument Descriptor property.

• If you are defining a replacement function using the Code Replacement Tool, on the Mapping Information tab, in the Argument properties section for the replacement function, enter a value for the Alignment value parameter.

The AlignmentBoundary property (or Alignment value parameter) specifies the alignment boundary for data passed to a function argument, in number of bytes. The AlignmentBoundary property is valid only for addressable objects, including matrix and pointer arguments. It is not applicable for value arguments. Valid values are:

• -1 (default) — If the data is a Simulink.Bus, Simulink.Signal, or Simulink.Parameter object, specifies that the code generator determines an optimal alignment based on usage. Otherwise, specifies that there is not an alignment requirement for this argument.

• Positive integer that is a power of 2, not exceeding 128 — Specifies number of bytes in the boundary. The starting memory address for the data allocated for the function argument is a multiple of the specified value. If you specify an alignment boundary that is less than the natural alignment of the argument data type, the alignment directive is emitted in the generated code. However, the target compiler ignores the directive.

The following code specifies the AlignmentBoundary for an argument as 16 bytes.
hLib = RTW.TflTable;
entry = RTW.TflCOperationEntry;
arg = getTflArgFromString(hLib, 'u1','single*');
desc = RTW.ArgumentDescriptor;
desc.AlignmentBoundary = 16;
arg.Descriptor = desc;
entry.Implementation.addArgument(arg);

The equivalent alignment boundary specification in the Code Replacement Tool dialog box is in this figure.

![Argument properties](image)

**Note** If your model imports Simulink.Bus, Simulink.Parameter, or Simulink.Signal objects, specify an alignment boundary in the object properties, using the **Alignment** property. For more information, see Simulink.Bus, Simulink.Parameter, and Simulink.Signal.

## Provide Data Alignment Specifications for Compilers

To support data alignment in generated code, describe the data alignment capabilities and syntax for your compilers in the code replacement library registration. Provide one or more alignment specifications for each compiler in a library registry entry.

To describe the data alignment capabilities and syntax for a compiler:

- If you are defining a code replacement library registration entry in a `rtwTargetInfo.m` customization file, add one or more `AlignmentSpecification` objects to an `RTW.DataAlignment` object. Attach the `RTW.DataAlignment` object to the `TargetCharacteristics` object of the registry entry.

The `RTW.DataAlignment` object also has the property `DefaultMallocAlignment`, which specifies the default alignment boundary, in bytes, that the compiler uses for dynamically allocated memory. If the code generator uses dynamic memory allocation...
for a data object involved in a code replacement, this value determines if the memory satisfies the alignment requirement of the replacement. If not, the code generator does not use the replacement. The default value for `DefaultMallocAlignment` is -1, indicating that the default alignment boundary used for dynamically allocated memory is unknown. In this case, the code generator uses the natural alignment of the data type to determine whether to allow a replacement.

Additionally, you can specify the alignment boundary for complex types by using the `addComplexTypeAlignment` function.

- If you are generating a customization file function using the Code Replacement Tool, fill out the following fields for each compiler:

  ![Alignment Specification 1](image)

  - Click the plus (+) symbol to add additional compiler specifications.
  - For each data alignment specification, provide the following information.
<table>
<thead>
<tr>
<th>Alignment-Specification Property</th>
<th>Dialog Box Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AlignmentType</td>
<td>Alignment type</td>
<td>Cell array of predefined enumerated strings, specifying which types of alignment this specification supports.</td>
</tr>
</tbody>
</table>

- DATA_ALIGNMENT_LOCAL_VAR — Local variables.
- DATA_ALIGNMENT_GLOBAL_VAR — Global variables.
- DATA_ALIGNMENT_STRUCT_FIELD — Individual structure fields.
- DATA_ALIGNMENT_WHOLE_STRUCT — Whole structure, with padding (individual structure field alignment, if specified, is favored and takes precedence over whole structure alignment).

Each alignment specification must specify at least DATA_ALIGNMENT_GLOBAL_VAR and DATA_ALIGNMENT_STRUCT_FIELD.
<table>
<thead>
<tr>
<th>Alignment-Specification Property</th>
<th>Dialog Box Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| AlignmentPosition                | Alignment position   | Predefined enumerated string specifying the position in which you must place the compiler alignment directive for alignment type `DATA_ALIGNMENT_WHOLE_STRUCT`:

- **DATA_ALIGNMENT_PREDIRECTIVE** — The alignment directive is emitted before `struct st_tag{...}`, as part of the type definition statement (for example, MSVC).
- **DATA_ALIGNMENT_POSTDIRECTIVE** — The alignment directive is emitted after `struct st_tag{...}`, as part of the type definition statement (for example, gcc).
- **DATA_ALIGNMENT_PRECEDING_STATEMENT** — The alignment directive is emitted as a standalone statement immediately preceding the definition of the structure type. A semicolon (;) must terminate the registered alignment syntax.
- **DATA_ALIGNMENT_FOLLOWING_STATEMENT** — The alignment directive is emitted as a standalone statement immediately following the definition of the structure type. A semicolon (;) must terminate the registered alignment syntax.

For alignment types other than `DATA_ALIGNMENT_WHOLE_STRUCT`, code generation uses alignment position `DATA_ALIGNMENT_PREDIRECTIVE`. |
<table>
<thead>
<tr>
<th><strong>Alignment-Specification Property</strong></th>
<th><strong>Dialog Box Parameter</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>AlignmentSyntax-Template</td>
<td><strong>Alignment syntax</strong></td>
<td>Specifies the alignment directive string that the compiler supports. The string is registered as a syntax template that has placeholders in it. These placeholders are supported:</td>
</tr>
<tr>

</tr>
</tbody>
</table>

Here is a data alignment specification for the GCC compiler:

```matlab
da = RTW.DataAlignment;
as = RTW.AlignmentSpecification;
as.AlignmentType = {'DATA_ALIGNMENT_LOCAL_VAR', ...
    'DATA_ALIGNMENT_STRUCT_FIELD', ...
    'DATA_ALIGNMENT_GLOBAL_VAR'};
as.AlignmentSyntaxTemplate = '__attribute__((aligned(%n)))';
as.AlignmentPosition = 'DATA_ALIGNMENT_PREDIRECTIVE';
asUPPORTEDLANGUAGES = {'c', 'c++'};
da.addAlignmentSpecification(as);

tc = RTW.TargetCharacteristics;
tc.DataAlignment = da;
```

Here is the corresponding specification in the **Generate customization** dialog box of the Code Replacement Tool.
Specify Data Alignment in MATLAB Code for Imported Data

If MATLAB Coder code replacements that require data alignment use imported data, such as an entry-point or exported function I/O, specify data alignment to external code with `coder.dataAlignment` statements in the MATLAB code.

If MATLAB Coder code replacements occur that require data alignment (uses imported data), such as an entry-point or exported function with I/O, specify code replacement data alignment with `coder.DataAlignment` statements in the MATLAB code.

To specify the data alignment requirements for imported data in a MATLAB code:

- For each instance of imported data that requires data alignment, specify the alignment in the function with a `coder.dataAlignment` statement of the form:

  ```matlab
coder.dataAlignment('varName', align_value)
```

- The `varName` is a character array of the variable name that requires alignment information specification. The `align_value` is an integer number which should be a power of 2, from 2 through 128. This number specifies the power-of-2 byte alignment boundary.

- An example function that specifies data alignment is:

  ```matlab
  function y = testFunction(x1,x2)
  coder.dataAlignment('x1',16); % Specifies information
  ```
coder.dataAlignment('x2',16); % Specifies information
coder.dataAlignment('y',16); % Specifies information

y = x1 + x2;
end

If `testFunction` is an entry-point or exported function, imported data `x1`, `x2`, and `y` are not aligned automatically by the code generator. The `coder.DataAlignment` statements for these variables are only meant as information for the code generator. The call sites allocating memory for the data need to ensure that the data is aligned as specified.

You also can specify code replacement data alignment for exported data, such as a `global` variable or an `ExportedGlobal` custom storage class. For more information, see “Built-In Storage Classes You Can Choose” on page 22-85 and “Choose a Storage Class for Controlling Data Representation in the Generated Code” on page 22-69.

**Replacing Math Functions and Operators with Implementations that require Data Alignment - MATLAB®**

This example shows how to develop and use code replacement library entries for target-specific function implementations that require data to be aligned to optimize application performance. To configure data alignment for a function implementation:

- Specify the data alignment requirements in a table entry. You can specify alignment for implementation function arguments individually or collectively.
- Specify the data alignment capabilities and syntax for your compiler. Attach an `AlignmentSpecification` object to the `TargetCharacteristics` object of the registry entry specified in your `rtwTargetInfo.m` file.

If externally allocated data (e.g. entry-point function arguments) are used in an operation that can be replaced with an implementation that requires alignment, use the `coder.dataAlignment` directive to specify alignment so that replacement occurs.

This example is configured to use either the GCC, Clang, or MSVC compilers.

**Create a New Folder and Copy Relevant Files**

The following code creates a folder in your current working folder (pwd). The new folder will contain the files that are relevant for this example. If you do not want to affect the
current folder (or if you cannot generate files in this folder), you should change your working folder.

**Run Command: Create a New Folder and Copy Relevant Files**

coderdemo_setup('coderdemo_crlalign');
cleanupObj = {};
mlpath = addpath(fullfile( ...
    matlabroot,'toolbox','coder','codegen','coderdemo_crlalign'));
cleanupObj{end+1} = onCleanup(@()path(mlpath));

**Check selected compiler**

This example is configured to use either GCC, Clang, or MSVC to compile the generated code.

c = rtwprivate('getMexCompilerInfo');
isDaDemoSupported = strcmpi(c.comp.Manufacturer,'GNU') || ...
    strcmpi(c.comp.Manufacturer,'Apple') || ...
    strcmpi(c.comp.Manufacturer,'Microsoft');
if ~isDaDemoSupported
    recMsg = ['Use "mex -setup" to select either GCC, Clang,'...
        'or MSVC and restart this example'];
    warning(['Example %s is configured to use either GCC, Clang,'...
        'or MSVC to compile the generated code. %s.'], mfilename,recMsg);
end

**Set MATLAB Coder options**

Set up the configuration object and define the function input types.

cfg = coder.config('lib','ecoder',true);
cfg.GenerateReport = false;
cfg.LaunchReport = false;
cfg.VerificationMode = 'SIL';
cfg.CodeExecutionProfiling = true;

len = 400000;
args = {coder.typeof(single(0),[len,1]), ...
    coder.typeof(single(0))};
global g1;
g1 = single(zeros([len,1]));

**Generate code using the SIMD Examples Code Replacement Library**

To see the code replacement table definition file, look here.
RTW.TargetRegistry.getInstance('reset');

mcode_da16 = 'biased_sum_of_square_differences_da16';
cfg.CodeReplacementLibrary = 'SIMD Examples';
codegen('-config',cfg, mcode_da16,'-args',args,'-global',{'g1',g1});

**Inspect the MATLAB Coder Generated Code**

After compiling, explore the generated source code.

**Performance Gain from Data Alignment**

Compare performance of normal ANSI code against the earlier generated code that used SIMD intrinsics.

```matlab
% Generate ansi code
mcode_noda = 'biased_sum_of_square_differences';
cfg.CodeReplacementLibrary = 'None';
codegen('-config',cfg, mcode_noda,'-args',args,'-global',{'g1',g1});

% Run SIMD executable and collect execution profile information
coder.runTest('run_biased_ssd_da16',[mcode_da16,'_sil.',mexext])
 pause(120);
clear([mcode_da16,'_sil']); % stop simulation
executionProfile_simd = getCoderExecutionProfile(mcode_da16);
idx_section = find(strcmp(mcode_da16,{executionProfile_simd.Sections.Name}),1);
avg_selftime_simd = executionProfile_simd.Sections(idx_section)....
 .TotalSelfTimeInTicks/executionProfile_simd.Sections(idx_section).NumCalls;

% Run ANSI executable and collect execution profile information
coder.runTest('run_biased_ssd',[mcode_noda,'_sil.',mexext])
 pause(120);
clear([mcode_noda,'_sil']); % stop simulation
executionProfile_ansi = getCoderExecutionProfile(mcode_noda);
idx_section = find(strcmp(mcode_noda,{executionProfile_ansi.Sections.Name}),1);
avg_selftime_ansi = executionProfile_ansi.Sections(idx_section)....
 .TotalSelfTimeInTicks/executionProfile_ansi.Sections(idx_section).NumCalls;

% Compare execution profile results
barObj = bar([avg_selftime_ansi; ...
     avg_selftime_simd]);
axesObj = barObj.Parent;
figObj = axesObj.Parent;
axesObj.XTickLabel = {'ANSI SSD', 'SIMD SSD'};
axesObj.YLabel.String = 'Average Execution Time (Timer Ticks)';
```
axesObj.YLim = [min([0, avg_selftime_ansi, avg_selftime_simd]), ...
    max(avg_selftime_ansi, avg_selftime_simd)*1.3];

percent_perf_gain = ...
    100 * (avg_selftime_ansi-avg_selftime_simd)/avg_selftime_ansi;
annotation(figObj, 'textbox', axesObj.Position, ... 
    'String', sprintf(...
    'Execution speed increased by %d%% on average', percent_perf_gain), ... 
    'FontWeight', 'bold', 'FontSize', 12, 'HorizontalAlignment', 'center', ... 
    'FitBoxToText','On'); 

### Starting SIL execution for 'biased_sum_of_square_differences_da16'
To terminate execution: clear biased_sum_of_square_differences_da16_sil
Execution profiling data is available for viewing. Go to <a href="matlab:Simulink.sdi.view;">Simulation Data Inspector.</a>
Execution profiling report available after termination.

### Stopping SIL execution for 'biased_sum_of_square_differences_da16'
Execution profiling report: report(getCoderExecutionProfile('biased_sum_of_square_differences_da16'))

### Starting SIL execution for 'biased_sum_of_square_differences'
To terminate execution: clear biased_sum_of_square_differences_sil
Execution profiling data is available for viewing. Go to <a href="matlab:Simulink.sdi.view;">Simulation Data Inspector.</a>
Execution profiling report available after termination.

### Stopping SIL execution for 'biased_sum_of_square_differences'
Execution profiling report: report(getCoderExecutionProfile('biased_sum_of_square_differences'))
**Cleanup**

Remove files and return to original folder
Run Command: Cleanup

```java
RTW.TargetRegistry.getInstance('reset');
cleanup
```

- “Develop a Code Replacement Library” on page 54-27
Array Layout and Code Replacement

To improve the performance of algorithms or simplify integration with external code or data, you can define code replacement mappings that apply a specific layout for storing array elements in memory. By default, the code generator stores array elements in a column-major layout. To change the layout to row-major, change the value of the entry parameter `ArrayLayout` to `ROW_MAJOR`.

The following table definition file for a sum operation uses the row-major array layout.

1. Create a table definition file that contains a function definition. For example:
   ```
   function hTable = crl_table_rowmajor_matrix
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.
   ```
   hTable = RTW.TflTable;
   ```

3. Create an entry for the operator mapping with a call to the `RTW.TflCOperationEntry` function.
   ```
   % Create operation entry
   hent = RTW.TflCOperationEntry;
   ```

4. Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. In the function call, set the parameter `ArrayLayout` to `ROW_MAJOR`
   ```
   setTflCOperationEntryParameters(hEnt, ... 
     'Key',                      'RTW_OP_MUL', ... 
     'Priority',                 100, ... 
     'ArrayLayout',              'ROW_MAJOR' 
     'ImplementationName'        'MyMul_ROW', ... 
     'ImplementationHeaderFile', 'MyMul_ROW.h', ... 
     'ImplementationSourceFile', 'MyMul_ROW.c');
   ```

5. Create conceptual arguments y1, u1, and u2. There are multiple ways to set up the conceptual arguments. This example uses calls to the `RTW.TflArgMatrix` and `addConceptualArg` functions to create and add the arguments.
   ```
   arg = RTW.TflArgMatrix('y1', 'RTW_IO_OUTPUT', 'double');
   arg.DimRange = [2 2; 50 50];
   hEnt.addConceptualArg(arg);
   ```

   ```
   arg = RTW.TflArgMatrix('u1', 'RTW_IO_INPUT', 'double');
   arg.DimRange = [2 3; 2 3];
   ```
Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `getTflArgFromString` function to create the arguments. When defining the implementation function return argument, create a `void` output argument. When defining the implementation function argument for the conceptual output argument (y1), set the operator output argument as an additional input argument. Mark its `IOType` as output. Make its type a pointer type. The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument and adds the argument to the entry’s array of implementation arguments.

% Implementation Args
arg = hEnt.getTflArgFromString('unused','void');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);

arg = hEnt.getTflArgFromString('u1','double*');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u2','double*');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('y1','double*');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u3','uint32',2);
arg.Type.ReadOnly = true;
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u4','uint32',3);
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u5','uint32',3);
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u6','uint32',4);
hEnt.Implementation.addArgument(arg);

Add the entry to a code replacement table with a call to the `addEntry` function.
addEntry(hTable, hEnt);

8  Save the table definition file. To name the file, use the name of the table definition function. Then, generate code and a code generation report and review the code replacements.

• “Row-Major and Column-Major Array Layouts” (MATLAB Coder)
• “Define Code Replacement Mappings” on page 54-43
Replace MATLAB Functions with Custom Code Using coder.replace

The `coder.replace` function provides the ability to replace a specified MATLAB function with a code replacement function in generated code. Use `coder.replace` in MATLAB code from which you want to generate C code using:

- MATLAB Coder
- MATLAB code in a Simulink MATLAB Function block

You can replace MATLAB functions that have:

- Single or multiple inputs
- Single or multiple outputs
- Scalar and matrix inputs and outputs

Supported types include:

- `single`, `double` (complex and noncomplex)
- `int8`, `uint8` (complex and noncomplex)
- `int16`, `uint16` (complex and noncomplex)
- `int32`, `uint32` (complex and noncomplex)
- Fixed-point integers
- Mixed types (different type on each input)

Replace coder.ceval Calls to External Functions

The coder.ceval function calls external C/C++ functions from code generated from MATLAB code. The code replacement software supports replacement of the function that you specify in a call to coder.ceval. An application of this code replacement scenario is to write generic MATLAB code that you can customize for different platforms with code replacements. A code replacement library can define hardware-specific code replacements for the function call. Use coder.ceval in MATLAB code from which you want to generate C code using:

- MATLAB Coder
- MATLAB code in a Simulink MATLAB Function block

Example Files

For the examples in “Interactive External Function Call Replacement Specification with Code Replacement Tool” on page 55-107 and “Programmatic External Function Call Replacement Specification” on page 55-109 you must have set up the following:

- Custom C function my_add.c.
  
  /* my_add.c */

  #include "my_add.h"

  double my_add(double in1, double in2)
  {
    return in1 + in2;
  }
- Custom C header file my_add.h.
  
  /* my_add.h */

  double my_add(double in1, double in2);
- MATLAB function call_my_add.m, which uses coder.ceval to invoke my_add.c.
  
  function y = call_my_add(in1, in2)  %#codegen

  y=0.0;

  if ~coder.target('Rtw')
% Executing in MATLAB, call MATLAB equivalent of C function my_add
  y = in1+in2;
else
  % Executing in generated code, call C function my_add
  y = coder.ceval('my_add', in1, in2);
end

• MATLAB test function call_my_add_test.m, which calls call_my_add.m.

  in1=10;
in2=20;
  
y = call_my_add(in1, in2);
  
disp('Output')
disp('y =')
disp(y);

• Replacement C function my_add_replacement.c.

  /* my_add_replacement.c */
  
  #include "my_add_replacement.h"
  
  double my_add_replacement(double in1, double in2)
  {
    return in1 + in2;
  }

• Replacement C header file my_add_replacement.h.

  /* my_add_replacement.h */
  
  double my_add_replacement(double in1, double in2);

**Interactive External Function Call Replacement Specification with Code Replacement Tool**

This example shows how to define a code replacement table entry for a MATLAB function that calls coder.ceval to invoke an external C function. The example shows how to define the entry interactively with the Code Replacement Tool.

1 Identify or create the C/C++ code and relevant header files, the MATLAB function that calls coder.ceval, a MATLAB test function, and the source and header files for
your replacement code. To follow along with this example, set up the files identified in “Example Files” on page 55-106.

2 In the Code Replacement Tool, add a table, select that table, and add a function entry. For more information, see “Define Code Replacement Mappings” on page 55-29.

3 On the Mapping Information tab, select Custom for the Function parameter.

4 In the function-name text box, type the custom function name. For this example, type the name my_add.

5 Under the Conceptual arguments list box, click + to add three arguments. By default, the tool creates an output argument y1 and input arguments u1 and u2 of type double.

6 In the Replacement function > Function prototype section, type the name my_add_replacement in the Name text box.

7 Under the Function arguments list box, click + to add three function implementation arguments. By default, the tool creates an output argument y1 and input arguments u1 and u2 of type double. Use the default settings.

8 In the Function signature preview box, if you see the expected function signature, click Apply. The function signature for this example, appears as:

   double my_add_replacement(double u1, double u2);

9 On the Build Information tab, specify my_add_replacement.h for the Implementation header file parameter and my_add_replacement.c for the Implementation source file.

10 Click Validate entry.

11 Save the code replacement table in the same folder as my_add_replacement.c. Name the file crl_table_my_add.m.

To test the example:

1 Register the table that contains the entry in a code replacement library.

2 Configure the code generator to use the code replacement library and to include the Code Replacements Report in the code generation report.

3 Generate code and the report.

4 Review the code replacements.
Programmatic External Function Call Replacement Specification

This example shows how to define a code replacement table entry for a MATLAB function that calls `coder.ceval` to invoke an external C function. The example shows how to define the entry programatically.

1. Identify or create the C/C++ code and relevant header files, the MATLAB function that calls `coder.ceval` to invoke the C/C++ function, a MATLAB test function, and the source and header files for your replacement code. To follow along with this example, set up the files identified in “Example Files” on page 55-106.

2. Create a table definition file that contains a function definition. For example:

   ```
   function hLib = crl_table_my_add
   ```

3. Within the function body, create the table by calling the function `RTW.TflTable`.

4. Create an entry for the function mapping with a call to the `RTW.TflCFunctionEntry` function.

   ```
   hEnt = RTW.TflCFunctionEntry;
   ```

5. Set function entry parameters with a call to the `setTflCFunctionEntryParameters` function.

   ```
   hEnt.setTflCFunctionEntryParameters( ...
     'Key', 'my_add', ...
     'Priority', 100, ...
     'ImplementationName', 'my_add_replacement', ...
     'ImplementationHeaderFile', 'my_add_replacement.h', ...
     'ImplementationSourceFile', 'my_add_replacement.c');
   ```

6. Create conceptual arguments `y1`, `u1`, and `u2`. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create and add the arguments.

   ```
   arg = hEnt.getTflArgFromString('y1','double');
   arg.IOType = 'RTW_IO_OUTPUT';
   hEnt.addConceptualArg(arg);
   ```

   ```
   arg = hEnt.getTflArgFromString('u1','double');
   hEnt.addConceptualArg(arg);
   ```

   ```
   arg = hEnt.getTflArgFromString('u2','double');
   hEnt.addConceptualArg(arg);
   ```
Create the implementation arguments and add them to the entry. This example uses calls to the `getTflArgFromString` function to create implementation arguments. These functions map to arguments in the replacement function prototype: output argument `y1` and input arguments `u1` and `u2`. For each argument, the example uses the convenience method `setReturn` or `addArgument` to specify whether an argument is a return value or argument. For each argument, this example adds the argument to the entry array of implementation arguments.

```matlab
arg = hEnt.getTflArgFromString('y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);

arg = hEnt.getTflArgFromString('u1','double');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u2','double');
hEnt.Implementation.addArgument(arg);
```

Add the entry to a code replacement table with a call to the `addEntry` function.

```matlab
hLib.addEntry(hEnt);
```

Save the table definition file. Use the name of the table definition function to name the file.

To test the example:

1. Register the table that contains the entry in a code replacement library.
2. Configure the code generator to use the code replacement library and to include the Code Replacements Report in the code generation report.
3. Generate code and the report.
4. Review the code replacements.

Reserved Identifiers and Code Replacement

The code generator and C programming language use, internally, reserved keywords for code generation. Do not use reserved keywords as identifiers or function names. Reserved keywords for code generation include many code replacement library identifiers, the majority of which are function names, such as `acos`.

To view a list of reserved identifiers for the code replacement library that you use to generate code, specify the name of the library in a call to the function `RTW.TargetRegistry.getInstance.getTflReservedIdentifiers`. For example:

```python
crl_ids = RTW.TargetRegistry.getInstance.getTflReservedIdentifiers('GNU99 (GNU)')
```

In a code replacement table, the code generator registers each function implementation name defined by a table entry as a reserved identifier. You can register additional reserved identifiers for the table on a per-header-file basis. Providing additional reserved identifiers can help prevent duplicate symbols and other identifier-related compile and link issues.

To register additional code replacement reserved identifiers, use the `setReservedIdentifiers` function. This function registers specified reserved identifiers to be associated with a code replacement table.

You can register up to four reserved identifier structures in a code replacement table. You can associate one set of reserved identifiers with a code replacement library, while the other three (if present) must be associated with ANSI C. The following example shows a reserved identifier structure that specifies two identifiers and the associated header file.

```python
d{1}.LibraryName = 'ANSI C';
d{1}.HeaderInfos{1}.HeaderName = 'math.h';
d{1}.HeaderInfos{1}.ReservedIds = {'y0', 'y1'};
```

The code generator adds the identifiers to the list of reserved identifiers and honors them during the build procedure.

**More About**

- "Code You Can Replace from MATLAB Code" on page 55-5
• “Customize Match and Replacement Process” on page 55-113
• “Define Code Replacement Mappings” on page 55-29
• “Develop a Code Replacement Library” on page 55-15
Customize Match and Replacement Process

During the build process, the code generator uses:

- Preset match criteria to identify functions and operators for which application-specific implementations replace default implementations.
- Preset replacement function signatures.

It is possible that preset match criteria and preset replacement function signatures do not completely meet your function and operator replacement needs. For example:

- You want to replace an operator with a particular fixed-point implementation function only when fraction lengths are within a particular range.
- When a match occurs, you want to modify your replacement function signature based on compile-time information, such as passing fraction-length values into the function.

To add extra logic into the code replacement match and replacement process, create custom code replacement table entries. With custom entries, you can specify additional match criteria and modify the replacement function signature to meet application needs.

To create a custom code replacement entry:

1. Create a custom code replacement entry class, derived from `RTW.TflCFunctionEntryML` (for function replacement) or `RTW.TflCOperationEntryML` (for operator replacement).

2. In your derived class, implement a `do_match` method with a fixed preset signature as a MATLAB function. In your `do_match` method, provide either or both of the following customizations that instantiate the class:

   - Add match criteria that the base class does not provide. The base class provides a match based on:
     - Argument number
     - Argument name
     - Signedness
     - Word size
     - Slope (if not specified with wildcards)
     - Bias (if not specified with wildcards)
• Math modes, such as saturation and rounding
• Operator or function key
• Modify the implementation signature by adding additional arguments or setting constant input argument values. You can inject a constant value, such as an input scaling value, as an additional argument to the replacement function.

3 Create code replacement entries that instantiate the custom entry class.
4 Register a library containing the code replacement table that includes your entries.

During code generation, the code replacement match process tries to match function or operator call sites with the base class of your derived entry class. If the process finds a match, the software calls your do_match method to execute your additional match logic (if any) and your replacement function customizations (if any).

**Customize Match and Replacement Process for Operators**

This example shows how to create custom code replacement entries that add logic to the code match and replacement process for a scalar operation. Custom entries specify additional match criteria or modify the replacement function signature to meet application needs.

For example:

• When fraction lengths are within a specific range, replace an operator with a fixed-point implementation function.
• When a match occurs, modify the replacement function signature based on compile-time information, such as passing fraction-length values into the function.

This example modifies a fixed-point addition replacement such that the implementation function passes in the fraction lengths of the input and output data types as arguments.

To create custom code replacement entries that add logic to the code replacement match and replacement process:

1 Create a class, for example TflCustomOperationEntry, that is derived from the base class RTW.TflCOperationEntryML. The derived class defines a do_match method with the following signature:

```matlab
function ent = do_match(hThis, ...
    hCSO, ...
    targetBitPerChar, ...
```
In the `do_match` signature:

- `ent` is the return handle, which is returned as empty (indicating that the match failed) or as a `TflCOperationEntry` handle.
- `hThis` is the handle to the class instance.
- `hCSO` is a handle to an object that the code generator creates for querying the library for a replacement.
- Remaining arguments are the number of bits for various data types of the current target.

The `do_match` method adds match criteria that the base class does not provide. The method makes modifications to the implementation signature. In this case, the `do_match` method relies on the base class for checking word size and signedness. `do_match` must match only the number of conceptual arguments to the value 3 (two inputs and one output) and the bias for each argument to value 0. If the code generator finds a match, `do_match`:

- Sets the return handle.
- Removes slope and bias wild cards from the conceptual arguments (the match is for specific slope and bias values).
- Writes fraction-length values for the inputs and output into replacement function arguments 3, 4, and 5.

You can create and add three additional implementation function arguments for passing fraction lengths in the class definition or in each code replacement entry definition that instantiates this class. This example creates the arguments, adds them to a code replacement table definition file, and sets them to specific values in the class definition code.

```matlab
classdef TflCustomOperationEntry < RTW.TflCOperationEntryML
    methods
        function ent = do_match(hThis, ...
            hCSO, ... %#ok
            targetBitPerChar, ... %#ok
            targetBitPerShort, ... %#ok
            targetBitPerInt, ... %#ok
            targetBitPerLong, ... %#ok
            targetBitPerLongLong) %#ok
```
% DO_MATCH - Create a custom match function. The base class checks the types of the arguments prior to calling this method. This class will check additional data and can modify the implementation function.

% The base class checks word size and signedness. Slopes and biases have been wildcarded, so the only additional checking to do is to check that the biases are zero and that there are only three conceptual arguments (one output, two inputs)

ent = []; % default the return to empty, indicating the match failed

if length(hCSO.ConceptualArgs) == 3 && ...
  hCSO.ConceptualArgs(1).Type.Bias == 0 && ...
  hCSO.ConceptualArgs(2).Type.Bias == 0 && ...
  hCSO.ConceptualArgs(3).Type.Bias == 0
% Modify the default implementation. Since this is a generator entry, a concrete entry is created using this entry as a template. The type of entry being created is a standard TflCOperationEntry. Using the standard operation entry provides required information, and you do not need a custom match function.
ent = RTW.TflCOperationEntry(hThis);

% Since this entry is modifying the implementation for specific fraction-length values (arguments 3, 4, and 5), the conceptual argument wild cards must be removed (the wildcards were inherited from the generator when it was used as a template for the concrete entry). This concrete entry is now for a specific slope and bias. hCSO holds the slope and bias values (created by the code generator).
for idx=1:3
  ent.ConceptualArgs(idx).CheckSlope = true;
  ent.ConceptualArgs(idx).CheckBias = true;

  % Set the specific Slope and Biases
  ent.ConceptualArgs(idx).Type.Slope = hCSO.ConceptualArgs(idx).Type.Slope;
  ent.ConceptualArgs(idx).Type.Bias = 0;
end

% Set the fraction-length values in the implementation function.
ent.Implementation.Arguments(3).Value = ...
  -1.0*hCSO.ConceptualArgs(2).Type.FixedExponent;
ent.Implementation.Arguments(4).Value = ...
  -1.0*hCSO.ConceptualArgs(3).Type.FixedExponent;
ent.Implementation.Arguments(5).Value = ...
  -1.0*hCSO.ConceptualArgs(1).Type.FixedExponent;
end
end
end

Exit the class folder and return to the previous working folder.
Create and save the following code replacement table definition file, `crl_table_custom_sinfcn_double.m`. This file defines a code replacement table that contains a single operator entry, an entry generator for unsigned 32-bit fixed-point addition operations, with arbitrary fraction-length values on the inputs and the output. The table entry:

- Instantiates the derived class `TflCustomOperationEntry` from the previous step. If you want to replace word sizes and signedness attributes, you can use the same derived class, but not the same entry, because you cannot use a wild card with the `WordLength` and `IsSigned` arguments. For example, to support `uint8`, `int8`, `uint16`, `int16`, and `int32`, add five other distinct entries. To use different implementation functions for saturation and rounding modes other than overflow and round to floor, add entries for those match permutations.
- Sets operator entry parameters with the call to the `setTflCOperationEntryParameters` function.
- Calls the `createAndAddConceptualArg` function to create conceptual arguments `y1`, `u1`, and `u2`.
- Calls `createAndSetCImplementationReturn` and `createAndAddImplementationArg` to define the signature for the replacement function. Three of the calls to `createAndAddImplementationArg` create implementation arguments to hold the fraction-length values for the inputs and output. Alternatively, the entry can omit those argument definitions. Instead, the `do_match` method of the derived class `TflCustomOperationEntry` can create and add the three implementation arguments. When the number of additional implementation arguments required can vary based on compile-time information, use the alternative approach.
- Calls `addEntry` to add the entry to a code replacement table.

```matlab
function hTable = crl_table_custom_sinfcn_double

hTable = RTW.TflTable;

% Add TflCustomOperationEntry
op_entry = TflCustomOperationEntry;

setTflCOperationEntryParameters(op_entry, ...
    'Key', 'RTW_OP_ADD', ...
    'Priority', 30, ...
    'SaturationMode', 'RTW_SATURATE_ON_OVERFLOW', ...
    'RoundingModes', {'RTW_ROUND_FLOOR'}, ...
    'ImplementationName', 'myFixptAdd', ...

```
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
'Name', 'y1', ...
'IOType', 'RTW.IO_OUTPUT', ...
'CheckSlope', false, ...
'CheckBias', false, ...
'DataType', 'Fixed', ...
'Scaling', 'BinaryPoint', ...
'IsSigned', false, ...
'WordLength', 32);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
'Name', 'u1', ...
'IOType', 'RTW.IO_INPUT', ...
'CheckSlope', false, ...
'CheckBias', false, ...
'DataType', 'Fixed', ...
'Scaling', 'BinaryPoint', ...
'IsSigned', false, ...
'WordLength', 32);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
'Name', 'u2', ...
'IOType', 'RTW.IO_INPUT', ...
'CheckSlope', false, ...
'CheckBias', false, ...
'DataType', 'Fixed', ...
'Scaling', 'BinaryPoint', ...
'IsSigned', false, ...
'WordLength', 32);

% Specify replacement function signature
createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...
'Name', 'y1', ...
'IOType', 'RTW.IO_OUTPUT', ...
'IsSigned', false, ...
'WordLength', 32, ...
'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric', ...
'Name', 'u1', ...
'IOType', 'RTW.IO_INPUT', ...)
3 Check the validity of the operator entry.
   • At the command prompt, invoke the table definition file.

```
> tbl = crl_table_custom_sinfcn_double
```
   • In the Code Replacement Viewer, view the table definition file.
crviewer(crl_table_custom_sinfcn_double)

Scalar Operator Code Replacement

This example shows how to define a code replacement mapping for a scalar operator. The example defines a mapping for the + (addition) operator programatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```matlab
   function hTable = crl_table_add_uint8
   ```

2. Within the function body, create the table by calling the function RTW.TflTable.

   ```matlab
   hTable = RTW.TflTable;
   ```

3. Create an entry for the operator mapping with a call to the RTW.TflCOperationEntry function.

   ```matlab
   % Create operation entry
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set function entry parameters with a call to the setTflCOperationEntryParameters function.

   ```matlab
   % Define addition operation of built-in uint8 data type
   % Saturation on, Rounding unspecified
   setTflCOperationEntryParameters(op_entry, ...
   'Key',                      'RTW_OP_ADD', ...,
   'Priority',                 90, ...,
   'SaturationMode',           'RTW_SATURATE_ON_OVERFLOW', ...,
   'RoundingModes',            {'RTW_ROUND_UNSPECIFIED'}, ...,
   'ImplementationName',       'u8_add_u8_u8', ...,
   'ImplementationHeaderFile', 'u8_add_u8_u8.h', ...,
   'ImplementationSourceFile', 'u8_add_u8_u8.c' );
   ```

5. Create conceptual arguments y1, u1, and u2. There are multiple ways to set up the conceptual arguments. This example uses calls to the getTflArgFromString and addConceptualArg functions to create and add the arguments.

   ```matlab
   arg = getTflArgFromString(hTable, 'y1', 'uint8');
   arg.IOType = 'RTW_IO_OUTPUT';
   addConceptualArg(op_entry, arg);
   arg = getTflArgFromString(hTable, 'u1', 'uint8');
   addConceptualArg(op_entry, arg);
   arg = getTflArgFromString(hTable, 'u2', 'uint8');
   addConceptualArg(op_entry, arg);
   ```

6. Copy the conceptual arguments to the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses a call to the
copyConceptualArgsToImplementation function to create and add implementation arguments to the entry by copying matching conceptual arguments.

copyConceptualArgsToImplementation(op_entry);

7 Add the entry to a code replacement table with a call to the addEntry function.

addEntry(hTable, op_entry);

8 Save the table definition file. Use the name of the table definition function to name the file.

Addition and Subtraction Operator Code Replacement

Consider the following when defining mappings for addition and subtraction operator code replacements.

Algorithm Options

When creating a code replacement table entry for an addition or subtraction operator, first determine the type of algorithm that your library function implements.

- Cast-before-operation (CBO), default — Prior to performing the addition or subtraction operation, the algorithm type casts input values to the output type. If the output data type cannot exactly represent the input values, losses can occur as a result of the cast to the output type. Additional loss can occur when the result of the operation is cast to the final output type.

- Cast-after-operation (CAO) — The algorithm computes the ideal result of the addition or subtraction operation of the two inputs. The algorithm then type casts the result to the output data type. Loss occurs during the type cast. This algorithm behaves similarly to the C language except when the signedness of the operands does not match. For example, when you add a signed long operand to an unsigned long operand, standard C language rules convert the signed long operand to an unsigned long operand. The result is a value that is not ideal.

Interactive Specification with Code Replacement Tool

When you use the Code Replacement Tool to create a code replacement table entry for an addition or subtraction operation, the tool displays an Algorithm menu. Use that menu to specify the Cast before operation or Cast after operation algorithm for that entry.
Programmatic Specification

Create a code replacement table file, as a MATLAB function, that describes the addition or subtraction code replacement table entry. In the call to `setTflCOperationEntryParameters`, set at least these parameters:

- **Key** to `RTW_OP_ADD` or `RTW_OP_MINUS`
- **ImplementationName** to the name of your replacement function
- **EntryInfoAlgorithm** to `RTW_CAST_BFORE_OP` (cast-before-operation) or `RTW_CAST_AFTER_OP` (cast-after-operation)

This example sets parameters for a code replacement operator entry for a cast-after-operation implementation of a `uint8` addition.

```matlab
op_entry = RTW.TflCOperationEntry;
setTflCOperationEntryParameters(op_entry, ...
    'Key',                      'RTW_OP_ADD', ...
    'EntryInfoAlgorithm',       'RTW_CAST_AFTER_OP', ...
    'ImplementationName',       'u8_add_u8_u8');
```

For more information, see `setTflCOperationEntryParameters`.

Algorithm Classification

During code generation, the code generator examines addition and subtraction operations, including adjacent type cast operations, to determine the type of algorithm to compute the expression result. Based on the data types in the expression and the type of the accumulator (type used to hold the result of the addition or subtraction operation), the code generator uses these rules.

- Floating-point and fixed-point types on the immediate addition or subtraction operation

<table>
<thead>
<tr>
<th>Algorithm</th>
<th>Conditions</th>
</tr>
</thead>
</table>
| CBO | One of the following is true:  
  - Operation type is double.  
  - Operation type is single and input types are single or fixed-point. |
| CAO | Operation type is a superset of input types—that is, output type can represent values of input types without loss of data. |

- Fixed-point types only

<table>
<thead>
<tr>
<th>Algorithm</th>
<th>Conditions</th>
</tr>
</thead>
</table>
| CBO | At least one of the following is true:  
  - Accumulator type equals output type ($T_{acc} == T_{out}$).  
  - Output type is a superset of input types ($T_{acc} >= \{T_{in1}, T_{in2}\}$) and accumulator type is a superset of output type ($T_{acc} >= T_{out}$).  
  - Operation does not incur range or precision loss. |
In many cases, the numerical result of a CBO operation is equal to that of a CAO operation. For example, if the input and output types are such that the operation produces the ideal result, as in the case of `int8 + int8 -> int16`. To maximize the probability of code replacement occurring in such cases, set the algorithm to cast-after-operation.

**Limitations**

- The code generator does not replace operations with nonzero net bias.
- When classifying an operation as a CAO operation, the code generator includes the adjacent casts in the expression when the expression involves only fixed-point types. Otherwise, the code generator classifies and replaces only the immediate addition or subtraction operation. Casts that the code generator excludes from the classification appear in the generated code.
- To enable the code generator to include multiple cast operations, which follow an addition or subtraction of fixed-point data, in the classification of an expression, the rounding mode must be `simplest` or `floor`. Consider the expression `y=(cast A) (cast B)(u1+u2)` If the rounding mode of `(cast A)`, `(cast B)`, and the addition operator (+) are set to `simplest` or `floor`, the code generator takes into account `(cast A)` and `(cast B)` when classifying the expression and performing the replacement only.

Small Matrix Operation to Processor Code Replacement

This example shows how to define code replacement mappings that replace nonscalar small matrix operations with processor-specific intrinsic functions. The example defines a table containing two matrix operator replacement entries for the + (addition) operator and the double data type. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

```matlab
function hTable = crl_table_matrix_add_double
```

2. Within the function body, create the table by calling the function RTW.TflTable.

```matlab
hTable = RTW.TflTable;
```

3. Create the entry for the first operator mapping with a call to the RTW.TflCOperationEntry function.

```matlab
% Create table entry for matrix_sum_2x2_double
op_entry = RTW.TflCOperationEntry;
```

4. Set operator entry parameters with a call to the setTflCOperationEntryParameters function. The code generator ignores saturation and rounding modes for floating-point nonscalar addition and subtraction. For code replacement entries for nonscalar addition and subtraction operations that do not involve fixed-point data, in the call to setTflCOperationEntryParameters, specify 'RTW_SATURATE_UNSPECIFIED' for the SaturationMode property and {'RTW_ROUND_UNSPECIFIED'} for RoundingModes.

```matlab
setTflCOperationEntryParameters(op_entry,...
    'Key',                      'RTW_OP_ADD', ...
    'Priority',                 30, ...;
    'SaturationMode',           'RTW_WRAP_ON_OVERFLOW', ...;
    'ImplementationName',       'matrix_sum_2x2_double', ...;
    'ImplementationHeaderFile', 'MatrixMath.h', ...;
    'ImplementationSourceFile', 'MatrixMath.c', ...;
    'ImplementationHeaderPath', LibPath, ...;
    'ImplementationSourcePath', LibPath, ...;
    'AdditionalIncludePaths',   {LibPath}, ...;
    'GenCallback',              'RTW.copyFileToBuildDir', ...
    'SideEffects',              true);
```

5. Create conceptual arguments y1, u1, and u2. There are multiple ways to set up the conceptual arguments. This example uses calls to the createAndAddConceptualArg function to create and add an argument with one function call. To specify a matrix argument in the function call, use the argument class RTW.TflArgMatrix. Specify the base type and the dimensions for which the
argument is valid. The first table entry specifies [2 2] and the second table entry specifies [3 3].

% Specify operands and result
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
    'Name',         'y1', ...
    'IOType',       'RTW_IO_OUTPUT', ...
    'BaseType',     'double', ...
    'DimRange',     [2 2]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
    'Name',         'u1', ...
    'BaseType',     'double', ...
    'DimRange',     [2 2]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
    'Name',         'u2', ...
    'BaseType',     'double', ...
    'DimRange',     [2 2]);

Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the getTflArgFromString to create the arguments. The convenience methods setReturn and addArgument specify whether an argument is a return value or argument and adds the argument to the entry's array of implementation arguments.

arg = getTflArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);
arg = getTflArgFromString(hTable, 'u1', ['double' '*']);
op_entry.Implementation.addArgument(arg);
arg = getTflArgFromString(hTable, 'u2', ['double' '*']);
op_entry.Implementation.addArgument(arg);
arg = getTflArgFromString(hTable, 'y1', ['double' '*']);
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.addArgument(arg);

Add the entry to a code replacement table with a call to the addEntry function.

addEntry(hTable, op_entry);

Create the entry for the second operator mapping.

% Create table entry for matrix_sum_3x3_double
op_entry = RTW.TflCOperationEntry;
setTflCOperationEntryParameters(op_entry, ...
    'Key',                      'RTW_OP_ADD', ...
    'Priority',                 30, ...
    'SaturationMode',           'RTW_WRAP_ON_OVERFLOW', ...
    'ImplementationName',       'matrix_sum_3x3_double', ...
    'ImplementationHeaderFile', 'MatrixMath.h', ...
'ImplementationSourceFile', 'MatrixMath.c', ...  
'ImplementationHeaderPath', LibPath, ... 
'ImplementationSourcePath', LibPath, ... 
'AdditionalIncludePaths', {LibPath}, ...  
'GenCallback', 'RTW.copyFileToBuildDir', ... 
'SideEffects', true);

% Specify operands and result
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ... 
  'Name', 'y1', ...  
  'IOType', 'RTW_IO_OUTPUT', ... 
  'BaseType', 'double', ...  
  'DimRange', [3 3]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ... 
  'Name', 'u1', ...  
  'BaseType', 'double', ...  
  'DimRange', [3 3]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ... 
  'Name', 'u2', ...  
  'BaseType', 'double', ...  
  'DimRange', [3 3]);

% Specify replacement function signature
arg = getTflArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);
arg = getTflArgFromString(hTable, 'u1', ['double' '*']);
op_entry.Implementation.addArgument(arg);
arg = getTflArgFromString(hTable, 'u2', ['double' '*']);
op_entry.Implementation.addArgument(arg);
arg = getTflArgFromString(hTable, 'y1', ['double' '*']);
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.IOType = 'RTW_IO_OUTPUT';
addEntry(hTable, op_entry);

9  Save the table definition file. Use the name of the table definition function to name the file.

Matrix Multiplication Operation to MathWorks BLAS Code Replacement

This example shows how to define code replacement mappings that replace nonscalar multiplication operations with Basic Linear Algebra Subroutine (BLAS) multiplication functions \(xgemm\) and \(xgemv\). The example defines code replacement entries that map floating-point matrix/matrix and matrix/vector multiplication operations to MathWorks BLAS library multiplication functions \(dgemm\) and \(dgemv\). The example defines the function mappings programmatically. Alternatively, you can use the Code Replacement Tool to define the same mappings.

BLAS libraries support matrix/matrix multiplication in the form of

\[
C = a(\text{op}(A) \ast \text{op}(B)) + bC \quad \text{where} \quad \text{op}(X) \quad \text{means} \; X, \; \text{transposition of} \; X, \; \text{or Hermitian transposition of} \; X. \; \text{However, code replacement libraries support only the limited case of}
\]

\[
C = \text{op}(A) \ast \text{op}(B) \quad (a = 1.0, \; b = 0.0). \quad \text{Correspondingly, although BLAS libraries support}
\]

matrix/vector multiplication in the form of \(y = a(\text{op}(A) \ast x) + by\), code replacement libraries support only the limited case of \(y = \text{op}(A) \ast x \quad (a = 1.0, \; b = 0.0)\).

1. Create a table definition file that contains a function definition. For example:

```matlab
function hTable = crl_table_tmwblas_mmult_double
```

2. Within the function body, create the table by calling the function \(\text{RTW.TflTable}\).

```matlab
hTable = RTW.TflTable;
```

3. Define the path for the BLAS function library. If your replacement functions are on the MATLAB search path or are in your working folder, you can skip this step.

```matlab
% Define library path for Windows or UNIX
arch = computer('arch');
if ~ispc
    LibPath = fullfile('$(MATLAB_ROOT)', 'bin', arch);
else
    % Use Stateflow to get the compiler info
    compilerInfo = sf('Private','compilerman','get_compiler_info');
    compilerName = compilerInfo.compilerName;
    if strcmp(compilerName, 'msvc90') || ...
        strcmp(compilerName, 'msvc80') || ...
        strcmp(compilerName, 'msvc71') || ...
        strcmp(compilerName, 'msvc60'), ...
        compilerName = 'microsoft';
    end
    LibPath = fullfile('$(MATLAB_ROOT)', 'bin', compilerName);
else
    LibPath = fullfile('$(MATLAB_ROOT)', 'bin', arch);
end
```
LibPath = fullfile('$(MATLAB_ROOT)', 'extern', 'lib', arch, compilerName);

4 Create an entry for the first mapping with a call to the RTW.TflBlasEntryGenerator function.

% Create table entry for dgemm32
op_entry = RTW.TflBlasEntryGenerator;

5 Set operator entry parameters with a call to the setTflCFunctionEntryParameters function. The function call sets matrix multiplication operator entry properties. The code generator ignores saturation and rounding modes for floating-point nonscalar addition and subtraction. For code replacement entries for nonscalar addition and subtraction operations that do not involve fixed-point data, in the call to setTflCFunctionEntryParameters, specify 'RTW_SATURATE_UNSPECIFIED' for the SaturationMode property and {'RTW_ROUND_UNSPECIFIED'} for RoundingModes.

if ispc
    libExt = 'lib';
else if ismac
    libExt = 'dylib';
else
    libExt = 'so';
end
setTflCOperationEntryParameters(op_entry, ...
    'Key',                      'RTW_OP_MUL', ...,
    'Priority',                 100, ...,
    'ImplementationName',       'dgemm32', ...,
    'ImplementationHeaderFile', 'blascompat32_crl.h', ...,
    'ImplementationHeaderPath', fullfile('$(MATLAB_ROOT)','extern','include'), ...
    'AdditionalLinkObjs',       {["libmwblascompat32." libExt]}, ...
    'AdditionalLinkObjsPaths',  {LibPath}, ...
    'SideEffects',              true);

6 Create conceptual arguments y1, u1, and u2. There are multiple ways to set up the conceptual arguments. This example uses calls to the createAndAddConceptualArg function to create and add an argument with one function call. To specify a matrix argument in the function call, use the argument class RTW.TflArgMatrix and specify the base type and the dimensions for which the argument is valid. This type of table entry supports a range of dimensions specified in the format [Dim1Min Dim2Min ... DimNMin; Dim1Max Dim2Max ... DimNMax]. For example, [2 2; inf inf] means a two-dimensional matrix of size 2x2 or larger. The conceptual output argument for the dgemm32 entry for matrix/matrix multiplication replacement specifies dimensions [2 2; inf inf], while the conceptual output argument for the dgemv32 entry for matrix/vector multiplication replacement specifies dimensions [2 1; inf 1].
Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `getTflArgFromString` and `RTW.TflArgCharConstant` functions to create the arguments. The example code configures special implementation arguments that are required for `dgemm` and `dgemv` function replacements. The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument and adds the argument to the entry’s array of implementation arguments.

% Using RTW.TflBlasEntryGenerator for xgemm requires the following
% implementation signature:
% void f(char* TRANSA, char* TRANSB, int* M, int* N, int* K,
% type* ALPHA, type* u1, int* LDA, type* u2, int* LDB,
% type* BETA, type* y, int* LDC)
% When a match occurs, the code generator computes the
% values for M, N, K, LDA, LDB, and LDC and inserts them into the
% generated code. TRANSA and TRANSB are set to 'N'.

% Specify replacement function signature
arg = getTflArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);

arg = RTW.TflArgCharConstant('TRANSA');
% Possible values for PassByType property are
% RTW_PASSBY_AUTO, RTW_PASSBY_POINTER,
% RTW_PASSBY_VOID_POINTER, RTW_PASSBY_BASE_POINTER
arg.PassByType = 'RTW_PASSBY_POINTER';
op_entry.Implementation.addArgument(arg);

arg = RTW.TflArgCharConstant('TRANSB');
arg.PassByType = 'RTW_PASSBY_POINTER';
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'M', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'N', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'K', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'ALPHA', 'double', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u1', ['double' '*']);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDA', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u2', ['double' '*']);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDB', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'BETA', 'double', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'y1', ['double' '*']);
arg.IOType = 'RTW_IO_OUTPUT';
arg.PassByType = 'RTW_PASSBY_POINTER';
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDC', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

8 Add the entry to a code replacement table with a call to the addEntry function.

addEntry(hTable, op_entry);

Matrix Multiplication Operation to ANSI/ISO C BLAS Code Replacement

This example shows how to define code replacement mappings that replace nonscalar multiplication operations with ANSI/ISO C BLAS multiplication functions \texttt{xgemm} and \texttt{xgemv}. The example defines code replacement entries that map floating-point matrix/matrix and matrix/vector multiplication operations to ANSI/ISO C BLAS library multiplication functions \texttt{dgemm} and \texttt{dgemv}. The example defines the function mappings programmatically. Alternatively, you can use the \textbf{Code Replacement Tool} to define the same mappings.

BLAS libraries support matrix/matrix multiplication in the form of

\[ \mathbf{C} = a(\text{op}(\mathbf{A}) \times \text{op}(\mathbf{B})) + b\mathbf{C} \]

\text{op}(\mathbf{X}) \text{ means } \mathbf{X}, \text{ transposition of } \mathbf{X}, \text{ or Hermitian transposition of } \mathbf{X}. \text{ However, code replacement libraries support only the limited case of}

\[ \mathbf{C} = \text{op}(\mathbf{A}) \times \text{op}(\mathbf{B}) \text{ (} a = 1.0, b = 0.0 \text{)} \]

Correspondingly, although BLAS libraries support matrix/vector multiplication in the form of \[ y = a(\text{op}(\mathbf{A}) \times \mathbf{x}) + b\mathbf{y} \], code replacement libraries support only the limited case of \[ y = \text{op}(\mathbf{A}) \times \mathbf{x} \text{ (} a = 1.0, b = 0.0 \text{)}. \]

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_cblas_mmult_double
   ```

2. Within the function body, create the table by calling the function \texttt{RTW.TflTable}.

   ```
   hTable = RTW.TflTable;
   ```

3. Define the path for the CBLAS function library. For example:

   ```
   LibPath = fullfile(matlabroot, 'toolbox', 'rtw', 'rtwdemos', 'crl_demo');
   ```

4. Create an entry for the first mapping with a call to the \texttt{RTW.TflBlasEntryGenerator} function.

   ```
   % Create table entry for cblas_dgemm
   op_entry = RTW.TflCBlasEntryGenerator;
   ```

5. Set operator entry parameters with a call to the \texttt{setTflCOperationEntryParameters} function. The function call sets matrix multiplication operator entry properties. The code generator ignores saturation and rounding modes for floating-point nonscalar addition and subtraction.

   ```
   setTflCOperationEntryParameters(op_entry, ...
   'Key', 'RTW_OP_MUL', ...
   ```
Create conceptual arguments \( y_1, u_1, \) and \( u_2 \). There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. To specify a matrix argument in the function call, use the argument class `RTW.TflArgMatrix` and specify the base type and the dimensions for which the argument is valid. This type of table entry supports a range of dimensions specified in the format \([\text{Dim1Min} \ \text{Dim2Min} \ldots \ \text{DimNMin}; \ \text{Dim1Max} \ \text{Dim2Max} \ldots \ \text{DimNMax}]\). For example, \([2 \ 2; \ \text{inf} \ \text{inf}]\) means a two-dimensional matrix of size 2x2 or larger. The conceptual output argument for the `dgemm32` entry for matrix/matrix multiplication replacement specifies dimensions \([2 \ 2; \ \text{inf} \ \text{inf}]\). The conceptual output argument for the `dgemv32` entry for matrix/vector multiplication replacement specifies dimensions \([2 \ 1; \ \text{inf} \ 1]\).

```matlab
% Specify operands and result
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
    'Name',         'y1', ...
    'IOType',       'RTW.IO_OUTPUT', ...
    'BaseType',     'double', ...
    'DimRange',     [2 2; inf inf]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
    'Name',         'u1', ...
    'BaseType',     'double', ...
    'DimRange',     [2 2; inf inf]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
    'Name',         'u2', ...
    'BaseType',     'double', ...
    'DimRange',     [1 1; inf inf]);
```

Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `getTflArgFromString` function to create the arguments. The example code configures special implementation arguments that are required for `dgemm` and `dgemv` function replacements. The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument and adds the argument to the entry’s array of implementation arguments.

```matlab
% Using RTW.TflCBlasEntryGenerator for xgemm requires the following
% implementation signature:
% % void f(enum ORDER, enum TRANSNA, enum TRANSNB, int M, int N, int K,
% %     type ALPHA, type* u1, int LDA, type* u2, int LDB,
% %     type BETA, type* y, int LDC)
```
Since CRLs do not have the ability to specify enums, you must use integer. (This will cause problems with C++ code generation, so for C++, use a wrapper function to cast each int to the corresponding enumeration type.)

When a match occurs, the code generator computes the values for M, N, K, LDA, LDB, and LDC and insert them into the generated code.

Specify replacement function signature

arg = getTflArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);

arg = getTflArgFromString(hTable, 'ORDER', 'integer', 102);
% arg.Type.ReadOnly=true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'TRANSA', 'integer', 111);
% arg.Type.ReadOnly=true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'TRANSB', 'integer', 111);
% arg.Type.ReadOnly=true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'M', 'integer', 0);
op_entry.Implementation.addArgument(arg);
arg = getTflArgFromString(hTable, 'N', 'integer', 0);
op_entry.Implementation.addArgument(arg);
arg = getTflArgFromString(hTable, 'K', 'integer', 0);
op_entry.Implementation.addArgument(arg);
arg = getTflArgFromString(hTable, 'ALPHA', 'double', 1);
op_entry.Implementation.addArgument(arg);
arg = getTflArgFromString(hTable, 'u1', ['double' '*']);
op_entry.Implementation.addArgument(arg);
arg = getTflArgFromString(hTable, 'LDA', 'integer', 0);
op_entry.Implementation.addArgument(arg);
arg = getTflArgFromString(hTable, 'u2', ['double' '*']);
op_entry.Implementation.addArgument(arg);
arg = getTflArgFromString(hTable, 'LDB', 'integer', 0);
op_entry.Implementation.addArgument(arg);
arg = getTflArgFromString(hTable, 'BETA', 'double', 0);
op_entry.Implementation.addArgument(arg);
arg = getTflArgFromString(hTable, 'y1', ['double' '*']);
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDC', 'integer', 0);
op_entry.Implementation.addArgument(arg);

8 Add the entry to a code replacement table with a call to the addEntry function.
addEntry(hTable, op_entry);

9 Create the entry for the second mapping.

% Create table entry for cblas_dgemv
op_entry = RTW.TflCBlasEntryGenerator;
setTflCOperationEntryParameters(op_entry, ...
    'Key',                      'RTW_OP_MUL', ...

    'Name',         'u2',      
    'BaseType',     'double',  
    'DimRange',     [1 1; inf 1]);

% Using RTW.TflCBlasEntryGenerator for xgemv requires the following
% implementation signature:
% void f(enum ORDER, enum TRANSA, int M, int N,  
% type ALPHA, type* u1, int LDA, type* u2, int INCX,  
% type BETA, type* y, int INCY)  
% Since CRLs do not have the ability to specify enums, you must
% use integer. (This will cause problems with C++ code generation,
% so for C++, use a wrapper function to cast each int to the
% corresponding enumeration type.)
% Upon a match, the CRL entry will compute the
% values for M, N, LDA, INCX, and INCY and insert them into the
% generated code.
% Specify replacement function signature

arg = getTflArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);

arg = getTflArgFromString(hTable, 'ORDER', 'integer', 102);
% arg.Type.ReadOnly=true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'TRANSA', 'integer', 111);
% arg.Type.ReadOnly=true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'M', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'N', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'ALPHA', 'double', 1);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u1', ['double' '*']);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDA', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u2', ['double' '*']);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'INCX', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'BETA', 'double', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'y1', ['double' '*']);
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'INCY', 'integer', 0);
op_entry.Implementation.addArgument(arg);

addEntry(hTable, op_entry);

10  Save the table definition file. Use the name of the table definition function to name the file.

To test this example, create a model that uses two Product blocks. For example:

1  Create a model that includes two Product blocks, such as the following:
2 Configure the model with the following settings:

- On the **Solver** pane, select a fixed-step, discrete solver with a fixed-step size such as 0.1.
- On the **Code Generation** pane, select an ERT-based system target file.
- On the **Code Generation > Interface** pane, select the code replacement library that contains your addition operation entry.

3 For each Product block, set the block parameter **Multiplication** to the value **Matrix(*)**.

4 In the Model Explorer, configure the **Signal Attributes** for the In1, In2, and In3 source blocks. For In1 and In2, set **Port dimensions** to [3 3] and set the **Data type** to double. For In3, set **Port dimensions** to [3 1] and set the **Data type** to double.

5 Generate code and a code generation report.

6 Review the code replacements.

Remap Operator Output to Function Input

If your generated code must meet a specific coding pattern or you want more flexibility, for example, to further improve performance, you can remap operator outputs to input positions in an implementation function argument list.

**Note** Remapping outputs to implementation function inputs is supported only for operator replacement.

For example, for a sum operation, the code generator produces code similar to:

```plaintext
add8_Y.Out1 = u8_add_u8_u8(add8_U.In1, add8_U.In2);
```

If you remap the output to the first input, the code generator produces code similar to:

```plaintext
u8_add_u8_u8(&add8_Y.Out1;, add8_U.In1, add8_U.In2);
```

The following table definition file for a sum operation remaps operator output `y1` as the first function input argument.

1. Create a table definition file that contains a function definition. For example:
   ```plaintext
   function hTable = crl_table_add_uint8
   ``

2. Within the function body, create the table by calling the function `RTW.TflTable`.
   ```plaintext
   hTable = RTW.TflTable;
   ``

3. Create an entry for the operator mapping with a call to the `RTW.TflCOperationEntry` function.
   ```plaintext
   % Create operation entry
   op_entry = RTW.TflCOperationEntry;
   ``

4. Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. In the function call, set the property `SideEffects` to `true`.
   ```plaintext
   setTflCOperationEntryParameters(op_entry, ...
   'Key',                      'RTW_OP_ADD', ...
   'Priority',                 90, ...
   'ImplementationName',       'u8_add_u8_u8', ...
   'ImplementationHeaderFile', 'u8_add_u8_u8.h', ...
   'ImplementationSourceFile', 'u8_add_u8_u8.c', ...
   'SideEffects',              true );
   ```
Create conceptual arguments \( y_1, u_1, \) and \( u_2 \). There are multiple ways to set up the conceptual arguments. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create and add the arguments.

```matlab
arg = getTflArgFromString(hTable, 'y1', 'uint8');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(op_entry, arg);

arg = getTflArgFromString(hTable, 'u1', 'uint8');
addConceptualArg(op_entry, arg);

arg = getTflArgFromString(hTable, 'u2', 'uint8');
addConceptualArg(op_entry, arg);
```

Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `getTflArgFromString` function to create the arguments. When defining the implementation function return argument, create a new `void` output argument, for example, \( y_2 \). When defining the implementation function argument for the conceptual output argument \( (y_1) \), set the operator output argument as an additional input argument. Mark its `IOType` as output. Make its type a pointer type. The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument and adds the argument to the entry’s array of implementation arguments.

```matlab
% Create new void output \( y_2 \)
arg = getTflArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);

% Set \( y_1 \) as first input arg, mark IOType as output, and use pointer type
arg = getTflArgFromString(hTable, 'y1', 'uint8*');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u1', 'uint8');
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u2', 'uint8');
op_entry.Implementation.addArgument(arg);
```

Add the entry to a code replacement table with a call to the `addEntry` function.

```matlab
addEntry(hTable, op_entry);
```

Save the table definition file. Use the name of the table definition function to name the file.

To test this example, create a model that uses an Add block. For example:

Create a model that includes an Add block, such as the following:
2 Configure the model with the following settings:
   - On the Solver pane, select a fixed-step solver.
   - On the Code Generation pane, select an ERT-based system target file.
   - On the Code Generation > Interface pane, select the code replacement library that contains your addition operation entry.
   - Set the Optimize global data access parameter to Use global to hold temporary results. This reduces data copies in the generated code.

3 Generate code and a code generation report.

4 Review the code replacements.

Fixed-Point Operator Code Replacement

If you have a Fixed-Point Designer license, you can define fixed-point operator code replacement entries to match:

- A binary-point-only scaling combination on the operator inputs and output.
- A slope bias scaling combination on the operator inputs and output.
- Relative scaling or net slope between multiplication or division operator inputs and output. Use one of these methods to map a range of slope and bias values to a replacement function for multiplication or division.
- Equal slope and zero net bias across addition or subtraction operator inputs and output. Use this method to disregard specific slope and bias values and map relative slope and bias values to a replacement function for addition or subtraction.

Common Ways to Match Fixed-Point Operator Entries

The following table maps common ways to match fixed-point operator code replacement entries with the associated fixed-point parameters that you specify in a code replacement table definition file.

<table>

</table>
Fixed-Point Numbers and Arithmetic

Fixed-point numbers use integers and integer arithmetic to represent real numbers and arithmetic with the following encoding scheme:

\[ V = \bar{V} = SQ + B \]

- \( V \) is an arbitrarily precise real-world value.
- \( \bar{V} \) is the approximate real-world value that results from fixed-point representation.
- \( Q \) is an integer that encodes \( \bar{V} \), referred to as the quantized integer.
- \( S \) is a coefficient of \( Q \), referred to as the slope.
- \( B \) is an additive correction, referred to as the bias.

The general equation for an operation between fixed-point operands is:

\[ (S_O Q_O + B_O) = (S_1 Q_1 + B_1) < op > (S_2 Q_2 + B_2) \]

The objective of fixed-point operator replacement is to replace an operator that accepts and returns fixed-point or integer inputs and output with a function that accepts and returns built-in C numeric data types. The following sections provide additional programming information for each supported operator.

**Addition**

The operation \( V_0 = V_1 + V_2 \) implies that

\[ Q_0 = \left( \frac{S_1}{S_0} \right) Q_1 + \left( \frac{S_2}{S_0} \right) Q_2 + \left( \frac{B_1 + B_2 - B_0}{S_0} \right) \]

If an addition replacement function is defined such that the scaling on the operands and sum are equal and the net bias
is zero (for example, a function `s8_add_s8_s8` that adds two signed 8-bit values and produces a signed 8-bit result), then the operator entry must set the operator entry parameters `SlopesMustBeTheSame` and `MustHaveZeroNetBias` to true. To match for replacement, the slopes must be the same for all addition conceptual arguments. (For parameter descriptions, see the reference page for the function `setTflCOperationEntryParameters`.)

**Subtraction**

The operation $V_0 = V_1 - V_2$ implies that

$$Q_0 = \left( \frac{S_1}{S_0} \right) Q_1 - \left( \frac{S_2}{S_0} \right) Q_2 + \left( \frac{B_1 - B_2 - B_0}{S_0} \right)$$

If a subtraction replacement function is defined such that the scaling on the operands and difference are equal and the net bias

$$\left( \frac{B_1 - B_2 - B_0}{S_0} \right)$$

is zero (for example, a function `s8_sub_s8_s8` that subtracts two signed 8-bit values and produces a signed 8-bit result), then the operator entry must set the operator entry parameters `SlopesMustBeTheSame` and `MustHaveZeroNetBias` to true. To match for replacement, the slopes must be the same for all subtraction conceptual arguments. (For parameter descriptions, see the reference page for the function `setTflCOperationEntryParameters`.)

**Multiplication**

There are different ways to specify multiplication replacements. The most direct way is to specify an exact match of the input and output types. This is feasible if a model contains only a few (known) slope and bias combinations. Use the `TflCOperationEntry` class and specify the exact values of slope and bias on each argument. For scenarios where
there are numerous slope/bias combinations, it is not feasible to specify each value with a different entry. Use a net slope entry or create a custom entry.

The operation $V_0 = V_1 \times V_2$ implies, for binary-point-only scaling, that

$$S_0Q_0 = (S_1Q_1)(S_2Q_2)$$
$$Q_0 = \left(\frac{S_1S_2}{S_0}\right)Q_1Q_2$$
$$Q_0 = S_nQ_1Q_2$$

where $S_n$ is the net slope.

It is common to replace all multiplication operations that have a net slope of 1.0 with a function that performs C-style multiplication. For example, to replace all signed 8-bit multiplications that have a net scaling of 1.0 with the s8_mul_s8_u8_replacement function, the operator entry must define a net slope factor, $F2^E$. You specify the values for $F$ and $E$ using operator entry parameters NetSlopeAdjustmentFactor and NetFixedExponent. For the s8_mul_s8_u8 function, set NetSlopeAdjustmentFactor to 1 and NetFixedExponent to 0.0. Also, set the operator entry parameters SlopesMustBeTheSame and MustHaveZeroNetBias to true. To match for replacement, the biases must be zero for all multiplication conceptual arguments. (For parameter descriptions, see the reference page for the function setTflCOperationEntryParameters.)

**Note** When an operator entry specifies NetSlopeAdjustmentFactor and NetFixedExponent, matching entries must have arguments with zero bias.

### Division

There are different ways to specify division replacements. The most direct way is to specify an exact match of the input and output types. This is feasible if a model contains only a few (known) slope and bias combinations. For this, use the TflCOperationEntry class and specify the exact values of slope and bias on each argument. For scenarios where there are numerous slope/bias combinations, it is not feasible to specify each value with a different entry. For this, use a net slope entry or create a custom entry (see “Customize Match and Replacement Process” on page 54-159).
The operation \( V_0 = (V_1 / V_2) \) implies, for binary-point-only scaling, that

\[
S_0 Q_0 = \left( \frac{S_1 Q_1}{S_2 Q_2} \right)
\]

\[
Q_0 = S_n \left( \frac{Q_1}{Q_2} \right)
\]

where \( S_n \) is the net slope.

It is common to replace all division operations that have a net slope of 1.0 with a function that performs C-style division. For example, to replace all signed 8-bit divisions that have a net scaling of 1.0 with the s8_mul_s8_u8 replacement function, the operator entry must define a net slope factor, \( F^{2E} \). You specify the values for \( F \) and \( E \) using operator entry parameters NetSlopeAdjustmentFactor and NetFixedExponent. For the s16_netslopeOp5_div_s16_s16 function, you would set NetSlopeAdjustmentFactor to 1 and NetFixedExponent to 0.0. Also, set the operator entry parameters SlopesMustBeTheSame and MustHaveZeroNetBias to true. To match for replacement, the biases must be zero for all division conceptual arguments. (For parameter descriptions, see the reference page for the function setTflCOperationEntryParameters.)

**Note** When an operator entry specifies NetSlopeAdjustmentFactor and NetFixedExponent, matching entries must have arguments with zero bias.

### Data Type Conversion (Cast)

The data type conversion operation \( V_0 = V_1 \) implies, for binary-point-only scaling, that

\[
Q_0 = \left( \frac{S_1}{S_0} \right) Q_1
\]

\[
Q_0 = S_n Q_1
\]

where \( S_n \) is the net slope. Set the operator entry parameters SlopesMustBeTheSame and MustHaveZeroNetBias to true. To match for replacement, the biases must be zero for
all cast conceptual arguments. (For parameter descriptions, see the reference page for the function setTflCOperationEntryParameters.)

**Shift**

The shift left or shift right operation \( V_0 = (V_1 / 2^n) \) implies, for binary-point-only scaling, that

\[
S_0 Q_0 = \left( \frac{S_1 Q_1}{2^n} \right)
\]

\[
Q_0 = \left( \frac{S_1}{S_0} \right) + \left( \frac{Q_1}{2^n} \right)
\]

\[
Q_0 = S_n \left( \frac{Q_1}{2^n} \right)
\]

where \( S_n \) is the net slope. Set the operator entry parameters SlopesMustBeTheSame and MustHaveZeroNetBias to true. To match for replacement, the biases must be zero for all shift conceptual arguments. (For parameter descriptions, see the reference page for the function setTflCOperationEntryParameters.)

Binary-Point-Only Scaling Code Replacement

You can define code replacement entries for operations on fixed-point data types such that they match a binary-point-only scaling combination on operator inputs and output. These binary-point-only scaling entries can map the specified binary-point-scaling combination to a replacement function for addition, subtraction, multiplication, or division.

This example creates a code replacement entry for multiplication of fixed-point data types. You specify arguments using binary-point-only scaling. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_fixed_binptscale
   ```

2. Within the function body, create the table by calling the function RTW.TflTable.

   ```
   hTable = RTW.TflTable;
   ```

3. Create the entry for the operator mapping with a call to the RTW.TflCOperationEntry function.

   ```
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set operator entry parameters with a call to the setTflCOperationEntryParameters function. The parameters specify the type of operation as multiplication, the saturation mode as saturate on integer overflow, rounding modes as unspecified, and the name of the replacement function as `s32_mul_s16_s16_binarypoint`.

   ```
   setTflCOperationEntryParameters(op_entry, ...
   'Key',                      'RTW_OP_MUL', ...
   'Priority',                 90, ...
   'SaturationMode',           'RTW_SATURATE_ON_OVERFLOW', ...
   'RoundingModes',            {'RTW_ROUND_UNSPECIFIED'}, ...
   'ImplementationName',       's32_mul_s16_s16_binarypoint', ...
   'ImplementationHeaderFile', 's32_mul_s16_s16_binarypoint.h', ...
   'ImplementationSourceFile', 's32_mul_s16_s16_binarypoint.c');
   ```

5. Create conceptual arguments y1, u1, and u2. There are multiple ways to set up the conceptual arguments. This example uses calls to the createAndAddConceptualArg function to create and add an argument with one function call. Each argument specifies that the data type is fixed-point, the mode is binary-point-only scaling, and its derived slope and bias values must exactly match the call-site slope and bias values. The output argument is 32 bits, signed, with a
fraction length of 28. The input arguments are 16 bits, signed, with fraction lengths of 15 and 13.

```matlab
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric',
    'Name',           'y1', ...
    'IOType',         'RTW_IO_OUTPUT', ...
    'CheckSlope',     true, ...
    'CheckBias',      true, ...
    'DataTypeMode',   'Fixed-point: binary point scaling', ...
    'IsSigned',       true, ...
    'WordLength',     32, ...
    'FractionLength', 28);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'u1', ...
    'IOType',         'RTW_IO_INPUT', ...
    'CheckSlope',     true, ...
    'CheckBias',      true, ...
    'DataTypeMode',   'Fixed-point: binary point scaling', ...
    'IsSigned',       true, ...
    'WordLength',     16, ...
    'FractionLength', 15);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'u2', ...
    'IOType',         'RTW_IO_INPUT', ...
    'CheckSlope',     true, ...
    'CheckBias',      true, ...
    'DataTypeMode',   'Fixed-point: binary point scaling', ...
    'IsSigned',       true, ...
    'WordLength',     16, ...
    'FractionLength', 13);

6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `createAndSetCImplementationReturn` and `createAndAddImplementationArg` functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). In this case, the output argument is 32 bits and signed (int32). The input arguments are 16 bits and signed (int16).

```matlab
createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'y1', ...
    'IOType',         'RTW_IO_OUTPUT', ...
    'IsSigned',       true, ...
    'WordLength',     32, ...
    'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'u1', ...
    'IOType',         'RTW_IO_INPUT', ...
    'IsSigned',       true, ...
    'WordLength',     16, ...
```

7 Add the entry to a code replacement table with a call to the addEntry function.

addEntry(hTable, op_entry);

8 Save the table definition file. Use the name of the table definition function to name the file.

Slope Bias Scaling Code Replacement

You can define code replacement for operations on fixed-point data types as matching a slope bias scaling combination on the operator inputs and output. The slope bias scaling entries can map the specified slope bias combination to a replacement function for addition, subtraction, multiplication, or division.

This example creates a code replacement entry for division of fixed-point data types. You specify arguments using slope bias scaling. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```matlab
   function hTable = crl_table_fixed_s16divslopebias
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```matlab
   hTable = RTW.TflTable;
   ```

3. Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntry` function.

   ```matlab
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as division, the saturation mode as saturate on integer overflow, rounding modes as round to ceiling, and the name of the replacement function as `s16_div_s16_s16_slopebias`.

   ```matlab
   setTflCOperationEntryParameters(op_entry, ...
   'Key',                      'RTW_OP_DIV', ...
   'Priority',                 90, ...
   'SaturationMode',           'RTW_SATURATE_ON_OVERFLOW', ...
   'RoundingModes',            {'RTW_ROUND_CEILING'}, ...
   'ImplementationName',       's16_div_s16_s16_slopebias', ...
   'ImplementationHeaderFile', 's16_div_s16_s16_slopebias.h', ...
   'ImplementationSourceFile', 's16_div_s16_s16_slopebias.c');
   ```

5. Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Each argument specifies that the data type is fixed-point, the mode is slope bias scaling, and its specified slope and bias values must exactly match the call-site slope and bias values. The output argument and input arguments are 16 bits, signed, each with specific slope bias specifications.
Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the createAndSetCImplementationReturn and createAndAddImplementationArg functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). In this case, the output and input arguments are 16 bits and signed (int16).

createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ... 'Name', 'y1', ... 'IOType', 'RTW_IO_OUTPUT', ... 'IsSigned', true, ... 'WordLength', 16, ... 'FractionLength', 0);
createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric', ... 'Name', 'u1', ... 'IOType', 'RTW_IO_INPUT', ... 'IsSigned', true, ... 'WordLength', 16, ... 'FractionLength', 0);
createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric', 'Name', 'u2', 'IOType', 'RTW_IO_INPUT', 'IsSigned', true, 'WordLength', 16, 'FractionLength', 0);

7 Add the entry to a code replacement table with a call to the `addEntry` function.

    addEntry(hTable, op_entry);

8 Save the table definition file. Use the name of the table definition function to name the file.

Net Slope Scaling Code Replacement

Multiplication and Division with Saturation

You can define code replacement entries for operations on fixed-point data types as matching net slope between operator inputs and output. The net slope entries can map a range of slope and bias values to a replacement function for multiplication or division.

This example creates a code replacement entry for division of fixed-point data types, using wrap on overflow saturation mode and a net slope. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

```matlab
function hTable = crl_table_fixed_netslopesaturate
```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

```matlab
hTable = RTW.TflTable;
```

3. Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntryGenerator_Netslope` function, which provides access to the fixed-point parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`.

```matlab
wv = [16,32];
for iy = 1:2
    for inum = 1:2
        for iden = 1:2
            hTable = getDivOpEntry(hTable, ...
                fixdt(1,wv(iy)),fixdt(1,wv(inum)),fixdt(1,wv(iden)));
            end
        end
    end
end
```

```matlab
function hTable = getDivOpEntry(hTable,dty,dtnum,dtden)
```

```matlab
% Create an entry for division of fixed-point data types where
% arguments are specified using Slope and Bias scaling
% Saturation on, Rounding unspecified

funcStr = sprintf('user_div_%s_%s_%s','... typeStrFunc(dty),...
    typeStrFunc(dtnum),...
    typeStrFunc(dtden));
```
Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as division, the saturation mode as wrap on overflow, rounding modes as unspecified, and the name of the replacement function as `user_div_*`.

The `NetSlopeAdjustmentFactor` and `NetFixedExponent` specify the $F$ and $E$ parts of the net slope $F2^E$.

Create conceptual arguments $y_1$, $u_1$, and $u_2$. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Specify each argument as fixed-point and signed. Also, for each argument, specify that code replacement request processing does not check for an exact match to the call-site slope and bias values.
Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `getTflArgFromString` function to create the arguments. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument. These methods add the argument to the entry array of implementation arguments.

```matlab
arg = getTflArgFromString(hTable, 'y1', typeStrBase(dty));
op_entry.Implementation.setReturn(arg);
arg = getTflArgFromString(hTable, 'u1', typeStrBase(dtnum));
op_entry.Implementation.addArgument(arg);
arg = getTflArgFromString(hTable, 'u2', typeStrBase(dtden));
op_entry.Implementation.addArgument(arg);
```

Add the entry to a code replacement table with a call to the `addEntry` function.

```matlab
addEntry(hTable, op_entry);
```

Define functions that determine the data type word length.

```matlab
%-------------------------------------------------------------
function str = typeStrFunc(dt)
%-------------------------------------------------------------
if dt.Signed
    sstr = 's';
else
    sstr = 'u';
end
str = sprintf('%s%d', sstr, dt.WordLength);
%-------------------------------------------------------------
function str = typeStrBase(dt)
%-------------------------------------------------------------
if dt.Signed
    sstr = ;
else
    sstr = 'u';
end
str = sprintf('%sint%d', sstr, dt.WordLength);
```
Save the table definition file. Use the name of the table definition function to name the file.

**Multiplication and Division with Rounding Mode and Additional Implementation Arguments**

You can define code replacement entries for multiplication and division operations on fixed-point data types such that they match the net slope between operator inputs and output. The net slope entries can map a range of slope and bias values to a replacement function for multiplication or division.

This example creates a code replacement entry for division of fixed-point data types, using the ceiling rounding mode and a net slope scaling factor. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   
   ```matlab
   function hTable = crl_table_fixed_netsloperound
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```matlab
   hTable = RTW.TflTable;
   ```

3. Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntryGenerator_Netslope` function, which provides access to the fixed-point parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`.

   ```matlab
   op_entry = RTW.TflCOperationEntryGenerator_NetSlope;
   ```

4. Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as division, the saturation mode as saturation off, rounding modes as round to ceiling, and the name of the replacement function as `s16_div_s16_s16`. `NetSlopeAdjustmentFactor` and `NetFixedExponent` specify the $F$ and $E$ parts of the relative scaling factor $F2^E$.

   ```matlab
   setTflCOperationEntryParameters(op_entry, ...'
   'Key',                      'RTW_OP_DIV', ...
   'Priority',                 90, ...
   'SaturationMode',           'RTW_WRAP_ON_OVERFLOW', ...
   'RoundingModes',            {'RTW_ROUND_CEILING'}, ...
   'NetSlopeAdjustmentFactor',   1.0, ...
   'NetFixedExponent',           0.0, ...
   ```
Create conceptual arguments $y_1$, $u_1$, and $u_2$. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Specify each argument as fixed-point, 16 bits, and signed. Also, for each argument, specify that code replacement request processing does not check for an exact match to the call-site slope and bias values.

```matlab
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ... 
    'Name',           'y1', ... 
    'IOType',         'RTW_IO_OUTPUT', ... 
    'CheckSlope',     false, ... 
    'CheckBias',      false, ... 
    'DataType',       'Fixed', ... 
    'IsSigned',       true, ... 
    'WordLength',     16);
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ... 
    'Name',           'u1', ... 
    'IOType',         'RTW_IO_INPUT', ... 
    'CheckSlope',     false, ... 
    'CheckBias',      false, ... 
    'DataType',       'Fixed', ... 
    'IsSigned',       true, ... 
    'WordLength',     16);
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ... 
    'Name',           'u2', ... 
    'IOType',         'RTW_IO_INPUT', ... 
    'CheckSlope',     false, ... 
    'CheckBias',      false, ... 
    'DataType',       'Fixed', ... 
    'IsSigned',       true, ... 
    'WordLength',     16);
```

Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `createAndSetCImplementationReturn` and `createAndAddImplementationArg` functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). In this case, the output and input arguments are 16 bits and signed (`int16`).

```matlab
createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ... 
    'Name',           'y1', ... 
    'IOType',         'RTW_IO_OUTPUT', ... 
    'IsSigned',       true, ... 
    'WordLength',     16, ... 
    'FractionLength', 0);
```
createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric', ... 
    'Name', 'u1', ... 
    'IOType', 'RTW_IO_INPUT', ... 
    'IsSigned', true, ... 
    'WordLength', 16, ... 
    'FractionLength', 0);
createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric', ... 
    'Name', 'u2', ... 
    'IOType', 'RTW_IO_INPUT', ... 
    'IsSigned', true, ... 
    'WordLength', 16, ... 
    'FractionLength', 0);

7 Add the entry to a code replacement table with a call to the `addEntry` function.

    addEntry(hTable, op_entry);

8 Save the table definition file. Use the name of the table definition function to name the file.

Equal Slope and Zero Net Bias Code Replacement

You can define code replacement entries for addition or subtraction of fixed-point data types such that they match relative slope and bias values (equal slope and zero net bias) across operator inputs and output. These entries allow you to disregard slope and bias values. Map relative slope and bias values to a replacement function for addition or subtraction.

This example creates a code replacement entry for addition of fixed-point data types. Slopes must be equal and net bias must be zero across the operator inputs and output. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```matlab
   function hTable = crl_table_fixed_slopeseq_netbiaszero
   ```

2. Within the function body, create the table by calling the function RTW.TflTable.

   ```matlab
   hTable = RTW.TflTable;
   ```

3. Create the entry for the operator mapping with a call to the RTW.TflCOperationEntryGenerator function, which provides access to the fixed-point parameters SlopesMustBeTheSame and MustHaveZeroNetBias.

   ```matlab
   op_entry = RTW.TflCOperationEntryGenerator;
   ```

4. Set operator entry parameters with a call to the setTflCOperationEntryParameters function. The parameters specify the type of operation as addition, the saturation mode as saturation off, rounding modes as unspecified, and the name of the replacement function as u16_add_SameSlopeZeroBias. SlopesMustBeTheSame and MustHaveZeroNetBias are set to true, indicating that slopes must be equal and net bias must be zero across the addition inputs and output.

   ```matlab
   setTflCOperationEntryParameters(op_entry, ...
   'Key',                   'RTW_OP_ADD', ...
   'Priority',              90, ...
   'SaturationMode',        'RTW_WRAP_ON_OVERFLOW', ...
   'RoundingModes',         {'RTW_ROUND_UNSPECIFIED'}, ...
   'SlopesMustBeTheSame',   true, ...
   'MustHaveZeroNetBias',   true, ...
   'ImplementationName',    'u16_add_SameSlopeZeroBias', ...
   'ImplementationHeaderFile', 'u16_add_SameSlopeZeroBias.h', ...
   'ImplementationSourceFile', 'u16_add_SameSlopeZeroBias.c');
   ```

5. Create conceptual arguments y1, u1, and u2. There are multiple ways to set up the conceptual arguments. This example uses calls to the
createAndAddConceptualArg function to create and add an argument with one function call. Each argument is specified as 16 bits and unsigned. Each argument specifies that code replacement request processing does not check for an exact match to the call-site slope and bias values.

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
'Name',           'y1', ...
'IOType',         'RTW_IO_OUTPUT', ...
'CheckSlope',     false, ...
'CheckBias',      false, ...
'IsSigned',       false, ...
'WordLength',     16);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
'Name',           'u1', ...
'IOType',         'RTW_IO_INPUT', ...
'CheckSlope',     false, ...
'CheckBias',      false, ...
'IsSigned',       false, ...
'WordLength',     16);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
'Name',           'u2', ...
'IOType',         'RTW_IO_INPUT', ...
'CheckSlope',     false, ...
'CheckBias',      false, ...
'IsSigned',       false, ...
'WordLength',     16);

Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the createAndSetCImplementationReturn and createAndAddImplementationArg functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). In this case, the output and input arguments are 16 bits and unsigned (uint16).

createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...
'Name',           'y1', ...
'IOType',         'RTW_IO_OUTPUT', ...
'IsSigned',       false, ...
'WordLength',     16, ...
'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',...
'Name',           'u1', ...
'IOType',         'RTW_IO_INPUT', ...
'IsSigned',       false, ...
'WordLength',     16, ...
'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',...
Add the entry to a code replacement table with a call to the `addEntry` function.

```matlab
addEntry(hTable, op_entry);
```

Save the table definition file. Use the name of the table definition function to name the file.

Data Type Conversions (Casts) and Operator Code Replacement

You can use code replacement entries to replace code that the code generator produces for data type conversion (cast) operations.

This example creates a code replacement entry that replaces `int32` to `int16` data type conversion (cast) operations. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```matlab
   function hTable = crl_table_cast_int32_to_int16
   ...
   end
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```matlab
   hTable = RTW.TflTable;
   ```

3. Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntry` function.

   ```matlab
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as cast, the saturation mode as saturate on integer overflow, rounding modes as toward negative infinity, and the name of the replacement function as `my_sat_cast`.

   ```matlab
   setTflCOperationEntryParameters(op_entry, ...
   'Key',                      'RTW_OP_CAST', ...  
   'Priority',                 50, ...          
   'ImplementationName',      'my_sat_cast', ...
   'SaturationMode',           'RTW_SATURATE_ON_OVERFLOW', ...
   'RoundingModes',            {'RTW_ROUND_FLOOR'}, ...
   'ImplementationHeaderFile', 'some_hdr.h', ...
   'ImplementationSourceFile', 'some_hdr.c');
   ```

5. Create the `int16` argument as conceptual argument `y1` and the implementation return value. There are multiple ways to set up the conceptual and implementation arguments. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create the conceptual argument and add it to the entry. Convenience method `setReturn` specifies the argument as the implementation return value.

   ```matlab
   ```

55-173
arg = getTflArgFromString(hTable, 'y1', 'int16');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(op_entry, arg);
op_entry.Implementation.setReturn(arg);

6  Create the int32 argument as conceptual and implementation argument u1. This example uses calls to the getTflArgFromString and addConceptualArg functions to create the conceptual argument and add it to the entry. Convenience method addArgument specifies the argument as implementation input argument.

arg = getTflArgFromString(hTable, 'u1', 'int32');
addConceptualArg(op_entry, arg);
op_entry.Implementation.addArgument(arg);

7  Add the entry to a code replacement table with a call to the addEntry function.

addEntry(hLib, hEnt);

8  Save the table definition file. Use the name of the table definition function to name the file.

You can use code replacement entries to replace code that the code generator produces for data type conversion (cast) operations.

This example creates a code replacement entry to replace data type conversions (casts) of fixed-point data types by using a net slope. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1  Create a table definition file that contains a function definition. For example:

    function hTable = crl_table_cast_fixpt_net_slope

2  Within the function body, create the table by calling the function RTW.TflTable.

    hTable = RTW.TflTable;

3  Create the entry for the operator mapping with a call to the
   RTW.TflCOperationEntryGenerator_Netslope function, which provides access to the fixed-point parameters NetSlopeAdjustmentFactor and NetFixedExponent

    op_entry = RTW.TflCOperationEntryGenerator_NetSlope;

4  Set operator entry parameters with a call to the
   setTflCOperationEntryParameters function. The parameters specify the type of
   operation as cast, the saturation mode as saturate on integer overflow, rounding
   modes as toward negative infinity, and the name of the replacement function as
my_fxp_cast.NetSlopeAdjustmentFactor and NetFixedExponent specify the F and E parts of the net slope $F2^E$.

InFL = 2;
InWL = 16;
InSgn = true;
OutFL = 4;
OutWL = 32;
OutSgn = true;
setTflCOperationEntryParameters(op_entry, ...
'Key', 'RTW_OP_CAST', ...
'Priority', 50, ...
'SaturationMode', 'RTW_SATURATE_ON_OVERFLOW', ...
'RoundingModes', {'RTW_ROUND_FLOOR'}, ...
'NetSlopeAdjustmentFactor', 1.0, ...
'NetFixedExponent', (OutFL - InFL), ...
'ImplementationName', 'my_fxp_cast', ...
'ImplementationHeaderFile', 'some_hdr.h', ...
'ImplementationSourceFile', 'some_hdr.c');

Create conceptual arguments $y1$ and $u1$. There are multiple ways to set up the conceptual arguments. This example uses calls to the createAndAddConceptualArg function to create and add an argument with one function call. Each argument is specified as fixed-point and signed. Each argument specifies that code replacement request processing does not check for an exact match to the call-site slope and bias values.

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
'Name', 'y1', ...
'IOType', 'RTW_IO_OUTPUT', ...
'CheckSlope', false, ...
'CheckBias', false, ...
'DataTypeMode', 'Fixed-point: binary point scaling', ...
'IsSigned', OutSgn, ...
'WordLength', OutWL, ...
'FractionLength', OutFL);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
'Name', 'u1', ...
'IOType', 'RTW_IO_INPUT', ...
'CheckSlope', false, ...
'CheckBias', false, ...
'DataTypeMode', 'Fixed-point: binary point scaling', ...
'IsSigned', InSgn, ...
'WordLength', InWL, ...
'FractionLength', InFL);

Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the createAndSetCImplementationReturn and createAndAddImplementationArg functions to create and add implementation...
arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types).

```matlab
createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ... 'Name',           'y1', ... 'IOType',         'RTW_IO_OUTPUT', ... 'IsSigned',       OutSgn, ... 'WordLength',     OutWL, ... 'FractionLength', 0);
createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',... 'Name',           'u1', ... 'IOType',         'RTW_IO_INPUT', ... 'IsSigned',       InSgn, ... 'WordLength',     InWL, ... 'FractionLength', 0);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

```matlab
addEntry(hTable, op_entry);
```

8 Save the table definition file. Use the name of the table definition function to name the file.

Shift Left Operations and Code Replacement

You can use code replacement entries to replace code that the code generator produces for shift (<<) operations.

This example creates a code replacement entry to replace shift left operations for int16 data. The example defines the function mapping programatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1. Create a table definition file that contains a function definition. For example:
   ```matlab
   function hTable = crl_table_shift_left_int16
   end
   ```

2. Within the function body, create the table by calling the function RTW.TflTable.
   ```matlab
   hTable = RTW.TflTable;
   ```

3. Create the entry for the operator mapping with a call to the RTW.TflCOperationEntry function.
   ```matlab
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set operator entry parameters with a call to the setTflCOperationEntryParameters function. The parameters specify the type of operation as shift left and the name of the replacement function as my_shift_left.
   ```matlab
   setTflCOperationEntryParameters(op_entry, ...
   'Key',                      'RTW_OP_SL', ...
   'Priority',                 50, ...
   'ImplementationName',       'my_shift_left', ...
   'ImplementationHeaderFile', 'some_hdr.h', ...
   'ImplementationSourceFile', 'some_hdr.c');
   ```

5. Create the int16 argument as conceptual argument y1 and the implementation return value. There are multiple ways to set up the conceptual and implementation arguments. This example uses calls to the getTflArgFromString and addConceptualArg functions to create the conceptual argument and add it to the entry. Convenience method setReturn specifies the argument as the implementation return value.
   ```matlab
   arg = getTflArgFromString(hTable, 'y1', 'int16');
   arg.IOType = 'RTW_IO_OUTPUT';
   addConceptualArg(op_entry, arg);
   op_entry.Implementation.setReturn(arg);
   ```

6. Create the int16 argument as conceptual and implementation argument u1. This example uses calls to the getTflArgFromString and addConceptualArg functions to create the conceptual argument and add it to the entry. Convenience method addArgument specifies the argument as an implementation input argument.
arg = getTflArgFromString(hTable, 'u1', 'int16');
addConceptualArg(op_entry, arg);
op_entry.Implementation.addArgument(arg);

7 Create the int8 argument as conceptual and implementation argument u2. This example uses calls to the getTflArgFromString and addConceptualArg functions to create the conceptual argument and add it to the entry. This argument specifies the number of bits to shift the previous input argument. Because the argument type is not relevant, the example disables type checking by setting the CheckType property to false. Convenience method addArgument specifies the argument as implementation input argument.

arg = getTflArgFromString(hTable, 'u2', 'int8');
arg.CheckType = false;
addConceptualArg(op_entry, arg);
op_entry.Implementation.addArgument(arg);

• The function getTflArgFromString is called to create an int8 input argument. This argument is added to the operator entry both as the third conceptual argument and the second implementation input argument.
• Add the entry to a code replacement table with a call to the addEntry function.

addEntry(hTable, op_entry);
• Save the table definition file. Use the name of the table definition function to name the file.

You can use code replacement entries to replace code that the code generator produces for shift (<<) operations.

This example creates a code replacement entry to replace shift left operations for fixed-point data using a net slope. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

1 Create a table definition file that contains a function definition. For example:

function hTable = crl_table_shift_left_fixpt_net_slope

2 Within the function body, create the table by calling the function RTW.TflTable.

hTable = RTW.TflTable;

3 Create the entry for the operator mapping with a call to the RTW.TflCOperationEntryGenerator_Netslope function. This function provides access to the fixed-point parameters NetSlopeAdjustmentFactor and NetFixedExponent.
Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as shift left, the saturation mode as saturate on integer overflow, rounding modes as toward negative infinity, and the name of the replacement function as `my_fxp_shift_left`. `NetSlopeAdjustmentFactor` and `NetFixedExponent` specify the $F$ and $E$ parts of the net slope $F2^E$.

```
InFL = 2;
InWL = 16;
InSgn = true;
OutFL = 4;
OutWL = 32;
OutSgn = true;
setTflCOperationEntryParameters(op_entry, ...
   'Key',                       'RTW_OP_SL', ...  
   'Priority',                  50, ...          
   'SaturationMode',            'RTW_SATURATE_ON_OVERFLOW', ... 
   'RoundingModes',             {'RTW_ROUND_FLOOR'}, ... 
   'NetSlopeAdjustmentFactor',  1.0, ...        
   'NetFixedExponent',          (OutFL - InFL), ... 
   'ImplementationName',        'my_fxp_shift_left', ... 
   'ImplementationHeaderFile',  'some_hdr.h', ...  
   'ImplementationSourceFile',  'some_hdr.c');
```

Create conceptual arguments $y_1$ and $u_1$. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Each argument is specified as fixed-point and signed. Each argument specifies that code replacement request processing does not check for an exact match to the call-site slope and bias values.

```
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
   'Name',         'y1', ... 
   'IOType',       'RTW_IO_OUTPUT', ...  
   'CheckSlope',   false, ... 
   'CheckBias',    false, ... 
   'DataTypeMode', 'Fixed-point: binary point scaling', ... 
   'IsSigned',     OutSgn, ... 
   'WordLength',   OutWL, ... 
   'FractionLength',OutFL);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
   'Name',         'u1', ... 
   'IOType',       'RTW_IO_INPUT', ...   
   'CheckSlope',   false, ... 
   'CheckBias',    false, ... 
   'DataTypeMode', 'Fixed-point: binary point scaling', ... 
   'IsSigned',     InSgn, ... 
   'WordLength',   InWL, ... 
   'FractionLength',InFL);
```
Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `createAndSetCImplementationReturn` and `createAndAddImplementationArg` functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types).

```matlab
createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...
    'Name', 'y1', ...
    'IOType', 'RTW_IO_OUTPUT', ...
    'IsSigned', OutSgn, ...
    'WordLength', OutWL, ...
    'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name', 'u1', ...
    'IOType', 'RTW_IO_INPUT', ...
    'IsSigned', InSgn, ...
    'WordLength', InWL, ...
    'FractionLength', 0);
```

Create the `int8` argument as conceptual and implementation argument `u2`. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create the conceptual argument and add it to the entry. This argument specifies the number of bits to shift the previous input argument. Because the argument type is not relevant, type checking is disabled by setting the `CheckType` property to `false`. Convenience method `addArgument` specifies the argument as implementation input argument.

```matlab
arg = getTflArgFromString(hTable, 'u2', 'uint8');
arg.CheckType = false;
addConceptualArg(op_entry, arg);
op_entry.Implementation.addArgument(arg);
```

Add the entry to a code replacement table with a call to the `addEntry` function.

```matlab
addEntry(hTable, op_entry);
```

Save the table definition file. Use the name of the table definition function to name the file.

“Build Large Model Reference Hierarchies in Parallel” on page 56-3
“Minimize Memory Requirements During Code Generation” on page 56-4
“Generate Only Code” on page 56-5
“No Creation of a Code Generation Report” on page 56-5

The amount of time it takes to generate code for a model depends on the size and configuration settings of the model. For instance, if you are working with a large model, it can take awhile to generate code. To decrease the amount of time for code generation of a model, try one or more of the following methods:

- Build a model in increments
- Build large model reference hierarchies in parallel
- Minimize memory requirements during code generation
- Generate only code
- Disable the creation of a code generation report

Build a Model in Increments

You can use the `rtwbuild` command to build a model and generate code. By default, when rebuilding a model, `rtwbuild` provides an incremental model build, which only rebuilds a model or submodels that have changed since the most recent model build. Incremental model build saves code generation time. Use the `Rebuild` parameter on the Model Referencing pane to change the method that Simulink uses to determine when to rebuild code for referenced models. For more information on the `Rebuild` parameter, see “Rebuild” (Simulink).

Build Large Model Reference Hierarchies in Parallel

In a parallel computing environment, whenever conditions allow, you can increase the speed of code generation and compilation by building models containing large model reference hierarchies in parallel. For example, if you have Parallel Computing Toolbox software, you can distribute code generation and compilation for each referenced model.
across the cores of a multicore host computer. If you have MATLAB Distributed Computing Server software, you can distribute code generation and compilation for each referenced model across remote workers in your MATLAB Distributed Computing Server configuration.

The performance gain realized by using parallel builds for referenced models depends on several factors, including:

- How many models can be built in parallel for a given model referencing hierarchy
- The size of the referenced models
- Parallel computing resources such as the number of local and remote workers available
- The hardware attributes of the local and remote machines (amount of RAM, number of cores, and so on)

For more information, see “Reduce Build Time for Referenced Models” (Simulink Coder).

**Minimize Memory Requirements During Code Generation**

Models that have large amounts of parameter and constant data (such as lookup tables) can tax memory resources and slow code generation. The code generator copies this data to the `model.rtw` file. The `model.rtw` file is a partial representation of the model that the Target Language Compiler parses to transform block computations, parameters, signals, and constant data into a high-level language (for example, C). The Target Language Compiler (TLC) is an integral part of the code generator. The code generator copies parameters and data into `model.rtw`, whether they originate in the model or come from variables or objects in a workspace.

You can improve code generation speed by specifying the maximum number of elements that data vectors can have for the code generator to copy this data to `model.rtw`. When a data vector exceeds the specified size, the code generator places a reference key in `model.rtw`. The TLC uses this key to access the data from Simulink and format it into the generated code. Reference keys result in maintaining only one copy of large data vectors in memory.

The default value above which the code generator uses reference keys in place of actual data values is 10 elements. You can verify this value. In the Command Window, type the following command:

```matlab
get_param(0, 'RTWDataReferencesMinSize')
```
To set the threshold to a different value, in the Command Window, type the following `set_param` function:

```
set_param(0, 'RTWDataReferencesMinSize', <size>)
```

Provide an integer value for `size` that specifies the number of data elements above which the code generator uses reference keys in place of actual data values.

**Generate Only Code**

You can increase code generation speed by specifying that the build process generate code and a makefile, but not invoke the make command. When the code generator invokes the make command, the build process takes longer because the code generator generates code, compiles code, and creates an executable file.

On the **Code Generation** pane in the Model Configuration Parameters dialog box, you can specify that the build process generate only code by selecting the **Generate code only** parameter. You can specify that the code generation process build a makefile by selecting the **Configuration Parameters > Code Generation > Build process > Makefile configuration > Generate makefile** parameter.

**No Creation of a Code Generation Report**

You can speed up code generation by not generating a code generation report as a part of the build process. To disable the creation of a code generation report, on the **Code Generation > Report** pane, clear the **Create code generation report** parameter. After the build process, you can generate a code generation report by doing this procedure, “Generate Code Generation Report After Build Process” (Simulink Coder).

Control Compiler Optimizations

To control compiler optimizations for a makefile build at the GUI level, use the **Compiler optimization level** parameter. The **Compiler optimization level** parameter provides

- Target-independent values **Optimizations on (faster runs)** and **Optimizations off (faster builds)**, which allow you to easily toggle compiler optimizations on and off during code development
- The value **Custom** for entering custom compiler optimization flags at the Simulink GUI level, rather than editing compiler flags into template makefiles (TMFs) or supplying compiler flags to build process make commands

The default setting is **Optimizations off (faster builds)**. Selecting the value **Custom** enables the **Custom compiler optimization flags** field, in which you can enter custom compiler optimization flags (for example, `-O2`).

**Note** If you specify compiler options for your makefile build using **OPT_OPTS**, **MEX_OPTS** (except **MEX_OPTS=\"-v\"**), or **MEX_OPT_FILE**, the value of **Compiler optimization level** is ignored and a warning is issued about the ignored parameter.

For more information about the **Compiler optimization level** parameter and its values, see “Compiler optimization level” (Simulink Coder) and “Custom compiler optimization flags” (Simulink Coder).

Optimization Tools and Techniques

Use the Model Advisor to Optimize a Model for Code Generation

You can use the Model Advisor to analyze a model for code generation and identify aspects of your model that impede production deployment or limit code efficiency. You can select from a set of checks to run on a model's current configuration. The Model Advisor analyzes the model and generates check results providing suggestions for improvements in each area. Most Model Advisor diagnostics do not require the model to be in a compiled state; those that do are noted.

Before running the Model Advisor, select the target you plan to use for code generation. The Model Advisor works most effectively with ERT and ERT-based system target files.

Use the following examples to investigate optimizing models for code generation using the Model Advisor:

- rtwdemo_advisor1
- rtwdemo_advisor2
- rtwdemo_advisor3

**Note** Example models rtwdemo_advisor2 and rtwdemo_advisor3 require Stateflow and Fixed-Point Designer software.

For more information on using the Model Advisor, see “Run Model Checks” (Simulink). For more information about the checks, see “Simulink Coder Checks” (Simulink Coder).

Design Tips for Optimizing Generated Code for Stateflow Objects

Do Not Access Machine-Parented Data In a Graphical Function

This restriction prevents long parameter lists from appearing in the code generated for a graphical function. You can access local data that resides in the same chart as the graphical function. For more information, see “Reuse Logic Patterns Using Graphical Functions” (Stateflow).
Be Explicit About the Inline Option of a Graphical Function

When you use a graphical function in a Stateflow chart, select Inline or Function for the property **Function Inline Option**. Otherwise, the code generated for a graphical function may not appear as you want. For more information, see “Specify Graphical Function Properties” (Stateflow).

Avoid Using Multiple Edge-Triggered Events in Stateflow Charts

When you use a bus object, you reduce the number of parameters in the parameter list of a generated function. This guideline also applies to output signals of a chart. For more information, see “Define Stateflow Structures” (Stateflow).

Combine Input Signals of a Chart Into a Single Bus Object

When you use a bus object, you reduce the number of parameters in the parameter list of a generated function. This guideline also applies to output signals of a chart. For more information, see “Define Stateflow Structures” (Stateflow).

Use Charts with Discrete Sample Times

The code generated for discrete charts that are not inside a triggered or enabled subsystem uses integer counters to track time instead of Simulink provided time. This allows for more efficient code generation in terms of overhead and memory, as well as enabling this code for use in Software-in-the-Loop(SIL) and Processor-in-the-Loop(PIL) simulation modes.

Additional Optimization Techniques

You can apply the following techniques to optimize a model for code generation:

- For Embedded Coder users, if your application uses only integer arithmetic, clear the **Support floating-point numbers** parameter in the **Software environment** section of the **Interface** pane so that the generated code contains no floating-point data or operations. When this parameter is cleared, an error is raised if noninteger data or expressions are encountered during code generation. The error message reports the offending blocks and parameters.
- Disable the **Configuration Parameters > Code Generation > Interface > Advanced parameters > MAT-file logging** parameter. Deselecting this parameter eliminates extra code and memory usage for initializing, updating, and cleaning-up
logging variables. In addition, the code generated to support MAT-file logging invokes `malloc`, which can be undesirable for your application.

- Use the Upgrade Advisor to upgrade older models (saved by prior versions or the current version) to use current features. For details, see “Model Upgrades” (Simulink).
- Before building, set optimization flags for the compiler (for example, `-O2` for `gcc`, `-Ot` for the Microsoft Visual C++ compiler).
- Directly inline C/C++ S-functions into the generated code by writing a TLC file for the S-function. For more information, see “Accelerate Simulation, Reuse Code, or Protect Intellectual Property by Using S-Function Target” (Simulink Coder) and see “Inline C MEX S-Functions” (Simulink Coder).
- Use a Simulink data type other than `double` when possible. The available data types are Boolean, signed and unsigned 8-, 16-, and 32-bit integers, and 32- and 64-bit floats (a double is a 64-bit float). For more information, see “About Data Types in Simulink” (Simulink). For a block-by-block summary, click `showblockdatatypetable` or type the command in the Command Window.
- For tunable block parameters that you configure to store in memory in the generated code, you can match parameter data types with signal data types to eliminate unnecessary typecasts and C shifts. Where possible, store parameter values in small integer data types. See “Parameter Data Types in the Generated Code” on page 22-156.
- Remove repeated values in lookup table data.
- Use the Merge block to merge the output of signals wherever possible. This block is particularly helpful when you need to control the execution of function-call subsystems with a Stateflow chart. The following model shows an example of how to use the Merge block.
When more than one signal connected to a Merge block has a non-Auto storage class, all non-Auto signals connected to that block must be identically labeled and have the same storage class. When Merge blocks connect directly to one another, these rules apply to the signals connected to any of the Merge blocks in the group.

Control Memory Allocation for Time Counters

The Application lifespan (days) parameter lets you control the allocation of memory for absolute and elapsed time counters. Such counters exist in the code for blocks that use absolute or elapsed time. For a list of such blocks, see “Absolute Time Limitations” (Simulink Coder).

The size of the time counters in generated code is 8, 16, 32, or 64 bits. The size is set automatically to the minimum that can accommodate the duration value specified by Application lifespan (days) given the step size specified in the Configuration Parameters Solver pane. To minimize the amount of RAM used by time counters, specify the smallest lifespan possible and the largest step size possible.

An application runs to its specified lifespan. It may be able to run longer. For example, running a model with a step size of one millisecond (0.001 seconds) for one day requires a 32-bit timer, which could continue running without overflow for 49 days more.

To maximize application lifespan, specify Application lifespan (days) as inf. This value allocates 64 bits (two uint32 words) for each timer. Using 64 bits to store timing data would allow a model with a step size of 0.001 microsecond (10E-09 seconds) to run for more than 500 years, which would rarely be required. 64-bit counters do not violate the usual code generator length limitation of 32 bits because the value of a time counter does not provide the value of a signal, state, or parameter.

Execution Profiling for Generated Code

Use code execution profiling to:

- Determine whether the generated code meets execution time requirements for real-time deployment on your target hardware.
- Identify code sections that require performance improvements.

The following tasks represent a general workflow that uses code execution profiling:

1. With the Simulink model, design and optimize your algorithm.
2. Configure the model for code execution profiling, and generate code.
3. Execute generated code on target. For example, you can:
   - Run a software-in-the-loop (SIL) simulation on your development computer.
   - Run a processor-in-the-loop (PIL) simulation using a target support package or custom PIL target.
   - Perform real-time execution with Simulink Real-Time or a target support package.
4. Analyze performance through code execution profiling plots and reports. For example, check that the algorithm code satisfies execution time requirements for real-time deployment:
   - If the algorithm code easily meets the requirements, consider enhancing your algorithm to exploit available processing power.
   - If the code cannot be executed in real time, look for ways to reduce execution time.

Identify the tasks that require the most time. For these tasks, investigate whether trade-offs between functionality and speed are possible.

If your target is a multicore processor, distribute the execution of algorithm code across available cores.

5. If required, refine the model and return to step 2.

Optimize Generated Code by Combining Multiple for Constructs

This example shows how the code generator combines for loops. The generated code uses for constructs to represent a variety of modeling patterns, such as a matrix signal or Iterator blocks. Using data dependency analysis, the code generator combines for constructs to reduce static code size and runtime branching.

The benefits of optimizing for loops are:

- Reducing ROM and RAM consumption.
- Increasing execution speed.

for Loop Modeling Patterns

In the model, rtwdemo_forloop, the Switch block and MATLAB Function block represent for constructs. In the In1 Block Parameters dialog box, the Port dimensions parameter is set to 10.
Generate Code

In the model, there are no data dependencies across the for loop iterations. Therefore, the code generator combines all for loops into one loop. Build the model and view the generated code.

```c
/* Model step function */
void rtwdemo_forloop_step(void)
{
    int32_T k;

    /* MATLAB Function: '<Root>/Accum' */
```
rtwdemo_forloop_Y.Out1 = 0.0;

for (k = 0; k < 10; k++) {
    if (3.0 * rtwdemo_forloop_U.In1[k] >= 0.0) {
        rtwdemo_forloop_DW.Delay_DSTATE[k] = rtwdemo_forloop_U.In1[k] - rtwdemo_forloop_DW.Delay_DSTATE[k];
    } else {
        rtwdemo_forloop_DW.Delay_DSTATE[k] = (rtwdemo_forloop_DW.Delay_DSTATE[k] - rtwdemo_forloop_U.In1[k]) * 5.0;
    }
}

rtwdemo_forloop_Y.Out1 += (1.0 + (real_T)k) + rtwdemo_forloop_DW.Delay_DSTATE[k];

Close the model.

Subnormal Number Performance

Subnormal numbers, formerly known as denormal numbers in floating-point literature, fill the underflow gap around zero in floating-point arithmetic. Subnormal values are a special category of floating-point values that are too close to \( 0.0 \) to be represented as a normalized value. The leading significand (mantissa) of a subnormal number is zero. When adding and subtracting floating-point numbers, subnormal numbers prevent underflow.

Using subnormal numbers provides precision beyond the normal representation by using leading zeros in the significand to represent smaller values after the representation reaches the minimum exponent. As the value approaches \( 0.0 \), you trade off precision for extended range. Subnormal numbers are useful if your application requires extra range.

However, in a real-time system, using subnormal numbers can dramatically increase execution latency, resulting in excessive design margins and real-time overruns. If the simulation or generated code performs calculations that produce or consume subnormal numbers, the execution of these calculations can be up to 50 times slower than similar calculations on normal numbers. The actual simulation or code execution time for subnormal number calculations depends on your computer operating environment. Typically, for desktop processors, the execution time for subnormal number calculations is five times slower than similar calculations on normal numbers.

To minimize the possibility of execution slowdowns or overruns due to subnormal number calculation latency, do one of the following:

- In your model, manually flush to zero any incoming or computed subnormal values at inputs and key operations, such as washouts and filters. For an example, see “Flush Subnormal Numbers to Zero” on page 56-21.

To detect a subnormal value for a single precision, 32-bit floating-point number:

1. Find the smallest normalized number on a MATLAB host. In the Command Window, type:

   ```matlab
   >> SmallestNormalSingle = realmin('single')
   ```

   In the C language, FLT_MIN, defined in float.h, is equivalent to
   ```c
   realmin('single')
   ```

2. Look for values in range:

   \[ 0 < \text{fabsf}(x) < \text{SmallestNormalSingle} \]
To detect a subnormal value for a double precision, 64-bit floating-point number:

1. Find the smallest normalized number on a MATLAB host. In the Command Window, type:

   \[
   \text{>> SmallestNormalDouble = \text{realmin('double')}}
   \]

   In the C language, DBL_MIN, defined in float.h, is equivalent to \text{realmin('double')}.  

2. To detect a subnormal value, look for values in this range:

   \[0 < \text{fabs}(x) < \text{SmallestNormalDouble}\]

   - On your processor, set flush-to-zero mode or, with your compiler, specify an option to disable subnormal numbers. Flush-to-zero modes treat a subnormal number as 0 when it is an input to a floating-point operation. Underflow exceptions do not occur in flush-to-zero mode.

   For example, in Intel® processors, the flush-to-zero (FTZ) and denormals-are-zero (DAZ) flags in the MXCSR register control floating-point calculations. For the gcc compiler on Linux, -ffast-math sets abrupt underflow (FTZ), flush-to-zero, while -O3 -ffast-math reverts to gradual underflow, using subnormal numbers.

   For more information, see the IEEE Standard 754, *IEEE Standard for Floating-Point Arithmetic*.

**Simulation Time With and Without Subnormal Numbers**

This model shows how using subnormal numbers increases simulation time by \(\sim 5\) times.

Open the model ex_subnormal. The Gain is set to subnormal value \text{realmin('double')}/2.
To run a simulation, in the Command Window, type for k=1:5, tic; sim('ex_subnormal'); toc,end. Observe the elapsed times for simulation using subnormals, similar to the following:

>> for k=1:5, tic; sim('ex_subnormal'); toc,end
Elapsed time is 9.909326 seconds.
Elapsed time is 9.617966 seconds.
Elapsed time is 9.797183 seconds.
Elapsed time is 9.702397 seconds.
Elapsed time is 9.893946 seconds.

Set the Gain to a number, 2, that is not a subnormal value:

>> set_param('ex_subnormal/Gain', 'Gain', '2');

To run a simulation, in the Command Window, type for k=1:5, tic; sim('ex_subnormal'); toc,end. Observe elapsed times for simulations that do not use subnormal values, similar to the following:

>> for k=1:5, tic; sim('ex_subnormal'); toc,end
Elapsed time is 2.045123 seconds.
Elapsed time is 1.796598 seconds.
Elapsed time is 1.758458 seconds.
Elapsed time is 1.721721 seconds.
Elapsed time is 1.780569 seconds.

Flush Subnormal Numbers to Zero

This example shows how to flush single precision subnormal numbers to zero.

1 Open the model ex_flush_to_zero:
• **Repeating Sequence Stair** generates a sequence of numbers from two raised to the power of 0 through two raised to the power of -165. The sequence approaches zero.

• **ConditionRealScalar** flushes subnormal single precision values that are less than `realmin('single')` to zero.

• MATLAB function block `log2` generates the base 2 logarithm of the Repeating Sequence Stair output. Specifically, `log2` generates the numbers 0 through -165.

2 On the **Simulation > Stepping Options** pane:

• Select **Enable stepping back**.
• Select **Pause simulation when time reaches** and enter 121.

3 In the model window, run the simulation. The simulation pauses at T=121. The displayed values:

• ConditionRealScalar output approaches zero.
• Repeating Sequence Stair output approaches zero.

4 Step the simulation forward to T=127. ConditionRealScalar flushes the subnormal value output from Repeating Sequence Stair to zero.

5 Continue stepping the simulation forward. ConditionRealScalar flushes the subnormal single precision values output from Repeating Sequence Stair to zero. When T=150, the output of Repeating Sequence Stair is itself zero.

Remove Code From Floating-Point to Integer Conversions That Wraps Out-of-Range Values

In this section...

<tr>
<td>“Generate Code Without Optimization” on page 56-25</td>
</tr>
<tr>
<td>“Generate Code with Optimization” on page 56-26</td>
</tr>
</tbody>
</table>

This example shows how to remove code for out-of-range floating-point to integer conversions. Without this code, there might be a mismatch between simulation and code generation results. Standard C does not define the behavior of out-of-range floating-point to integer conversions, while these conversions are well-defined during simulation. In Standard C and during simulation, floating-point to integer conversions are well-defined for input values in the range of the output type.

If the input values in your application are in the range of the output type, remove code for out-of-range floating-point to integer conversions. Removing this code reduces the size and increases the speed of the generated code.

Example Model

In this model, a Data Type Conversion block converts an input signal from a double to a uint8. A uint8 can support values from 0 to 255. If the input signal has a value outside of this range, an out-of-range conversion occurs. In this example, the model is named conversion_ex.

1. Use Inport, Outport, and Data Type Conversion blocks to create the example model.
2. Open the Inport Block Parameters dialog box and select the Signal Attributes tab. For the Data Type parameter, select double.
3 Open the Data Type Conversion dialog box. For the **Output data type** parameter, select `uint8`.

4 For the signal feeding into the Data Type Conversion block, open the Signal Properties dialog box. Enter the name `U`. On the **Code Generation** tab, for the **Storage Class** parameter, select `ImportedExtern`.

5 For the signal leaving the Data Type Conversion block, open the Signal Properties dialog box. Enter the name `Y`. On the **Code Generation** tab, for the **Storage Class** parameter, select `ImportedExtern`.

**Generate Code Without Optimization**

1 Open the Model Configuration Parameters dialog box. On the **Solver** pane, for the **Type** parameter, select `Fixed-step`.

2 On the **Code Generation > Report** pane, select `Create code generation report`.

3 On the **Code Generation** pane, select `Generate code only`, and then, in the model window, press `Ctrl+B`. When code generation is complete, an HTML code generation report opens.

4 In the Code Generation report, select the `conversion_ex.c` file and view the model step function. The code generator applies the `fmod` function to handle out-of-range results.

```c
/* Model step function */
void conversion_ex_step(void)
{
  real_T tmp;

  /* DataTypeConversion:
     '<Root>/Data Type Conversion' incorporates:
      Inport: '<>/In1'
  */
  tmp = floor(U);
  if (rtIsNaN(tmp) || rtIsInf(tmp)) {
    tmp = 0.0;
  } else {
    tmp = fmod(tmp, 256.0);
  }

  Y = (uint8_T)
    (tmp < 0.0 ?
    (int32_T)
(uint8_T)-(int8_T)
(uint8_T)-tmp :
(int32_T)
(uint8_T) tmp);

Generate Code with Optimization

1  Open the Configuration Parameters dialog box. On the Optimization pane, select Remove code from floating-point to integer conversions that wraps out-of-range values. Generate code.

2  In the code generation report, select the conversion_ex.c file and view the model step function. The generated code does not contain code that protects against out-of-range values.
   
   /* Model step function */
   void conversion_ex_step(void)
   {
       /* DataTypeConversion: '<Root>/Data Type Conversion' incorporates:
        *  Inport: '<Root>/In1'
        */
       Y = (uint8_T)U;
   }

   The generated code is more efficient without this protective code, but it is possible that the execution of generated code does not produce the same results as simulation for values not in the range of 0 to 255.

Remove Code That Maps NaN to Integer Zero

This example shows how to remove code that maps NaN to integer zero. For floating-point to integer conversions involving saturation, Simulink converts NaN to integer zero during simulation. If your model contains an input value of NaN, you can specify that the code generator produce code that maps NaN to zero. Without this code, there is a mismatch between simulation and code generation results because in Standard C, every condition involving NaN evaluates to false.

If there are no input values of NaN in your application, you can remove code that maps NaN to integer zero. Removing this code reduces the size and increases the speed of the generated code.

Example Model

In this model, a Data Type Conversion block converts an input signal from a double to a uint8. In this example, the model is named conversion_ex.

1 Use Inport, Outport, and Data Type Conversion blocks to create the example model.
2 Open the Inport Block Parameters dialog box and click the Signal Attributes tab. For the Data Type parameter, select double.
3 Open the Data Type Conversion dialog box. For the Output data type parameter, select uint8.
4  Select **Saturate on integer overflow**. Selecting this parameter specifies that an out-of-range signal value equals either the minimum or maximum value that the data type can represent.

5  For the signal feeding into the Data Type Conversion block, open the Signal Properties dialog box. Enter a name of U. On the **Code Generation** tab, for the **Storage Class** parameter, select **ImportedExtern**.

6  For the signal leaving the Data Type Conversion block, open the Signal Properties dialog box. Enter a name of Y. On the **Code Generation** tab, for the **Storage Class** parameter, select **ImportedExtern**.

**Generate Code**

1  Set the **Configuration Parameters > Solver > Solver options > Type** parameter to **Fixed-step**.

2  Disable the **Configuration Parameters > Optimization > Advanced parameters > Remove code from floating-point to integer conversions with saturation that maps NaN to zero** parameter.

3  Enable the **Configuration Parameters > Code Generation > Report > Create code generation report** parameter.

4  Enable the **Configuration Parameters > Code Generation > Build process > Generate code only** parameter. Then, in the model window, press Ctrl+B. When code generation is complete, an HTML code generation report opens.

5  In the Code Generation report, select the `nan_int_ex.c` file and view the model step function. For an input value of NaN, there is agreement between the generated code and simulation because NaN maps to integer zero.

```c
/* Model step function */
void nan_int_ex_step(void)
{
    /* DataTypeConversion: '<Root>/Data Type Conversion' incorporates:
     *  Inport: '<Root>/In1'
    */
    if (U < 256.0) {
        if (U >= 0.0) {
            Y = (uint8_T)U;
        } else {
            Y = 0U;
        }
    } else if (U >= 256.0) {
```

\[ \text{Y} = \text{MAX\_uint8\_T}; \]

\} else {
    \text{Y} = \text{0U};
\}

**Generate Code with Optimization**

1. Enable the Configuration Parameters > Optimization > Code generation > Integer and fixed-point > Remove code from floating-point to integer conversions that wraps out-of-range values parameter. Generate code.

2. In the Code Generation report, select the `nan_int_ex.c` section and view the model step function. The generated code maps NaN to 255 and not integer zero. The generated code is more efficient without the extra code that maps NaN to integer zero, but the execution of the generated code does not produce the same results as simulation for NaN values.

```c
/* Model step function */
void nan_int_ex_step(void)
{
    /* DataTypeConversion: '<Root>/Data Type Conversion' incorporates:
     * Inport: '<Root>/In1'
    */
    if (U < 256.0) {
        if (U >= 0.0) {
            Y = (uint8_T)U;
        } else {
            Y = 0U;
        }
    } else {
        Y = MAX\_uint8\_T;
    }

    /* End of DataTypeConversion: '<Root>/Data Type Conversion' */
}
```

Disable Nonfinite Checks or Inlining for Math Functions

When the code generator produces code for math functions:

- If the model option **Support non-finite numbers** is selected, nonfinite number checking is generated uniformly for math functions, without the ability to specify that nonfinite number checking should be generated for some functions, but not for others.
- By default, inlining is applied uniformly for math functions, without the ability to specify that inlining should be generated for some functions, while invocations should be generated for others.

You can use code replacement library (CRL) customization entries to:

- Selectively disable nonfinite checks for math functions. This can improve the execution speed of the generated code.
- Selectively disable inlining of math functions. This can increase code readability and decrease code size.

The functions for which these customizations are supported include the following:

- Floating-point only: atan2, copysign, fix, hypot, log, log10, round, sincos, and sqrt
- Floating-point and integer: abs, max, min, mod, rem, saturate, and sign

The general workflow for disabling nonfinite number checking and/or inlining is as follows:

1. If you can disable nonfinite number checking for a particular math function, or if you want to disable inlining for a particular math function and instead generate a function invocation, you can copy the following MATLAB function code into a MATLAB file with an .m file name extension, for example, `crl_table_customization.m`.

   ```matlab
   function hTable = crl_table_customization
   
   % Create an instance of the Code Replacement Library table for controlling
   % function intrinsic inlining and nonfinite support
   hTable = RTW.TflTable;
   
   % Inline - true (if function needs to be inline)
   % false (if function should not be inlined)
   % SNF (support nonfinite) - ENABLE (if non-finite checking should be performed)
   % DISABLE (if non-finite checking should NOT be performed)
   ```
% registerCustomizationEntry(hTable, ...  
%       Priority, numInputs, key, inType, outType, Inline, SNF);

100, 1, 'fix', 'single', 'single', false, 'UNSPECIFIED');
registerCustomizationEntry(hTable, ...  
100, 1, 'copysign', 'double', 'double', true, 'UNSPECIFIED');
registerCustomizationEntry(hTable, ...  
100, 1, 'copysign', 'single', 'single', true, 'UNSPECIFIED');

2 To reduce the size of the file, you can delete the registerCustomizationEntry lines for functions for which the default nonfinite number checking and inlining behavior is acceptable.

3 For each remaining entry,
   • Set the Inline argument to true if the function should be inlined or false if it should not be inlined.
   • Set the SNF argument to ENABLE if nonfinite checking should be generated, DISABLE if nonfinite checking should not be generated, or UNSPECIFIED to accept the default behavior based on the model option settings.

Save the file.

4 Optionally, perform a quick check of the syntactic validity of the customization table entries by invoking the table definition file at the MATLAB command line (>> tbl = crl_table_customization). Fix syntax errors that are flagged.

5 Optionally, view the customization table entries in the Code Replacement Viewer (>> crviewer(crl_table_customization)). For more information about viewing code replacement tables, see “Choose a Code Replacement Library” (Simulink Coder).

6 To register these changes and make them appear in the Code replacement library drop-down list located on the Code Generation > Interface pane of the Configuration Parameters dialog box, first copy the following MATLAB function code into an instance of the file rtwTargetInfo.m.

Note For the example below, specify the argument 'RTW' if a GRT target is selected for your model, otherwise omit the argument.
function rtwTargetInfo(cm)
% rtwTargetInfo function to register a code replacement library (CRL)
    % Register the CRL defined in local function locCrlRegFcn
    cm.registerTargetInfo(@locCrlRegFcn);
end % End of RTWTARGETINFO

% Local function to define a CRL containing crl_table_customization
function thisCrl = locCrlRegFcn
    % Instantiate a CRL registry entry - specify 'RTW' for GRT
    thisCrl = RTW.TflRegistry('RTW');

    % Define the CRL properties
    thisCrl.Name = 'CRL Customization Example';
    thisCrl.Description = 'Example of CRL Customization';
    thisCrl.TableList = {'crl_table_customization'};
    thisCrl.TargetHWDeviceType = {'*'};
end % End of LOCCRLREGFCN

You can edit the Name field to specify the library name that appears in the Code replacement library drop-down list. Also, the file name in the TableList field must match the name of the file you created in step 1.

To register your changes, with both of the MATLAB files you created present in the MATLAB path, enter the following command at the MATLAB command line:

sl_refresh_customizations

7 Create or open a model that generates function code corresponding to one of the math functions for which you specified a change in nonfinite number checking or inlining behavior.

8 Open the Configuration Parameters dialog box, go to the Code Generation > Interface pane, and use the Code replacement library drop-down list to select the code replacement entry you registered in step 6, for example, CRL Customization Example.

9 Generate code for the model and examine the generated code to verify that the math functions are generated as expected.
Expression Folding

Expression folding optimizes code to minimize the computation of intermediate results at block outputs and the storage of such results in temporary buffers or variables. When expression folding is on, the code generator collapses (folds) block computations into a single expression, instead of generating separate code statements and storage declarations for each block in the model. Most Simulink blocks support expression folding.

Expression folding improves the efficiency of generated code, frequently achieving results that compare favorably to hand-optimized code. In many cases, entire groups of model computations fold into a single, highly optimized line of code.

You can use expression folding in your own inlined S-function blocks. For more information, see “S-Functions That Support Expression Folding” (Simulink Coder).

Example Model
Generate Code

With expression folding off, in the explfld.c file, the code generator generates this code.

```c
/* Model step function */
void exprfld_step(void)
{
    /* Gain: '<Root>/Gain' incorporates:
     * Inport: '<Root>/In1'
     */
    exprfld_B.S1 = exprfld_P.Gain_Gain * exprfld_U.i1;

    /* Gain: '<Root>/Gain1' incorporates:
     * Inport: '<Root>/In2'
     */
    exprfld_B.S2 = exprfld_P.Gain1_Gain * exprfld_U.i2;

    /* Outport: '<Root>/Out1' incorporates:
     * Product: '<Root>/Product'
     */
    exprfld_Y.Out1 = exprfld_B.S1 * exprfld_B.S2;
}
```

There are separate code statements for both Gain blocks. Before final output, these code statements compute temporary results for the Gain blocks.

Enable Optimization

Expression folding is on by default. To see if expression folding is on for an existing model:

1. Expression folding is available only when the Configuration Parameters > Signal storage reuse parameter is selected because expression folding operates only on expressions involving local variables. Enable the Signal storage reuse parameter.

2. When you select Signal storage reuse, the Enable local block outputs, Reuse local block outputs, and Eliminate superfluous local variables (expression folding) parameters are all on by default.
Generate Code with Optimization

With expression folding, the code generator generates a single-line output computation, as shown in the `expfld.c` file. The generated comments document the block parameters that appear in the expression.

```c
/* Model step function */
void exprfld_step(void)
{
    /* Outport: '<Root>/Out1' incorporates:
        * Gain: '<Root>/Gain'
        * Gain: '<Root>/Gain1'
        * Inport: '<Root>/In1'
        * Inport: '<Root>/In2'
        * Product: '<Root>/Product'
    */
    exprfld_Y.Out1 =
        exprfld_P.Gain_Gain *
        exprfld_U.i1 *
        (exprfld_P.Gain1_Gain * exprfld_U.i2);
}
```

For an example of expression folding in the context of a more complex model, click `rtwdemo_slexprfold`, or at the command prompt, type:

```c
rtwdemo_slexprfold
```

For more information, see “Enable and Reuse Local Block Outputs in Generated Code” (Simulink Coder)

Inline Invariant Signals

You can optimize the generated code by selecting **Inline invariant signals** on the **Optimization** pane. The generated code uses the numerical values of the invariant signals instead of their symbolic names.

An invariant signal is a block output signal that does not change during Simulink simulation. For example, the signal S3 is an invariant signal. An invariant signal is not the same as an invariant constant. The two constants (1 and 2) and the gain value of 3 are invariant constants. To inline invariant constants, set **Default parameter behavior** to Inlined.

Optimize Generated Code Using Inline Invariant Signals

This example shows how to use inline invariant signals to optimize the generated code. This optimization transforms symbolic names of invariant signals into constant values.

The **InlineInvariantSignals** optimization:

- Reduces ROM and RAM consumption.
- Improves execution speed.

**Example Model**

Consider the model matlab:rtwdemo_inline_invariant_signals.

```matlab
model = 'rtwdemo_inline_invariant_signals';
open_system(model);
```
Generate Code

Create a temporary folder (in your system temporary folder) for the build and inspection process.

```matlab
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model using Simulink Coder.

```matlab
rtwbuild(model)
```

### Starting build procedure for model: rtwdemo_inline_invariant_signals
### Successful completion of build procedure for model: rtwdemo_inline_invariant_signals

View the generated code without the optimization. These lines of code are in `rtwdemo_inline_invariant_signals.c`.

```matlab
cfile = fullfile(cgDir,'rtwdemo_inline_invariant_signals_grt_rtw','rtwdemo_inline_invariant_signals.c');
rtwdemodbtype(cfile,'/* Output and update for atomic system', 1, 0);

/* Output and update for atomic system: '<Root>/InlinedConstFcn' */
void rtwdemo_inline__InlinedConstFcn(int32_T rtu_In1,
    B_InlinedConstFcn rtwdemo_inl_T *localB, const ConstB_InlinedConstFcn rtwdemo_T *
    *localC)
{
    /* Product: '<S1>/Product' */
    localB->Product = rtu_In1 * localC->Sum_p;
}
Enable Optimization

1. Open the Configuration Parameters dialog box.
2. On the Optimization pane, select Inline Invariant Signals.

Alternatively, you can use the command-line API to enable the optimization:

```matlab
set_param(model, 'InlineInvariantSignals', 'on');
```

Generate Code with Optimization

The generated code uses the numerical values of the folded constants instead of creating an additional structure (rtwdemo_inline_invariant(ConstB)).

Build the model using Simulink Coder.

```matlab
rtwbuild(model)
```

### Starting build procedure for model: rtwdemo_inline_invariant_signals
### Successful completion of build procedure for model: rtwdemo_inline_invariant_signals

View the generated code with the optimization. These lines of code are in rtwdemo_minmax.c.

```c
rtwdemodbtype(cfile,...
    /* Output and update for atomic system', '/* Model output', 1, 0);

/* Output and update for atomic system: '<Root>/InlinedConstFcn' */
void rtwdemo_inline_InlinedConstFcn(int32_T rtu_In1,
    B_InlinedConstFcn_rtwdemo_inl_T *localB)
{
    /* Product: '<S1>/Product' */
    localB->Product = rtu_In1 << 5;
}
```

Close the model and code generation report.
bdclose(model)
rtwdemoclean;
cd(currentDir)

Related Examples
•  “Optimization Tools and Techniques” on page 56-7
•  “Inline Numeric Values of Block Parameters” on page 56-44
Inline Numeric Values of Block Parameters

This example shows how to optimize the generated code by inlining the numeric values of block parameters. Block parameters include the Gain parameter of a Gain block and the table data and breakpoint sets of an n-D Lookup Table block.

This optimization determines whether numeric block parameters occupy global memory in the generated code. The optimization can:

- Improve execution speed.
- Reduce RAM and ROM consumption.

Explore Example Model

Open the example model rtwdemo_paraminline and configure it to show the generated names of blocks.

```matlab
load_system('rtwdemo_paraminline')
set_param('rtwdemo_paraminline','HideAutomaticNames','off')
open_system('rtwdemo_paraminline')
```
The model contains blocks that have these numeric parameters:

- The **Gain** parameters of the Gain blocks
- The **Constant value** parameters of the Constant blocks
- The table data and breakpoint sets of the n-D Lookup Table blocks

The output of the block G2, and the outputs of blocks upstream of G2, change only if you tune the values of the block parameters during simulation or during code execution. When you update the model diagram, these blocks and signal lines appear magenta in color.

Several blocks use `Simulink.Parameter` objects in the base workspace to set the values of their parameters. The parameter objects all use the storage class `Auto`, which means that you can configure the generated code to inline the parameter values.

### Generate Code Without Optimization

Create a temporary folder for the build and inspection process.

```matlab
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Disable the optimization by setting **Configuration Parameters > Default parameter behavior** to Tunable.

```matlab
set_param('rtwdemo_paraminline','DefaultParameterBehavior','Tunable')
```

Generate code from the model.

```matlab
rtwbuild('rtwdemo_paraminline')
```
/* Block parameters (default storage) */
P_rtwdemo_paraminline_T rtwdemo_paraminline_P = {
    /* Variable: MAX_LIFT */
    /* Referenced by: '<Root>/Constant' */
    /* */
    10.0,

    /* Variable: SLIDER_POS */
    /* Referenced by: '<Root>/Constant1' */
    /* */
    0.0,

    /* Variable: T1Break */
    /* Referenced by: '<Root>/1D Lookup' */
    /* */
    { -5.0, -4.0, -3.0, -2.0, -1.0, 0.0, 1.0, 2.0, 3.0, 4.0, 5.0 },

    /* Variable: T1Data */
    /* Referenced by: '<Root>/1D Lookup' */
    /* */
    { -1.0, -0.99, -0.98, -0.96, -0.76, 0.0, 0.76, 0.96, 0.98, 0.99, 1.0 },

    /* Variable: T2Break */
    /* Referenced by: '<Root>/2D Lookup' */
    /* */
    { 1.0, 2.0, 3.0 },

    /* Variable: T2Data */
    /* Referenced by: '<Root>/2D Lookup' */
    /* */
    { 4.0, 16.0, 10.0, 5.0, 19.0, 18.0, 6.0, 20.0, 23.0 },

    /* Expression: 2 */
    /* Referenced by: '<Root>/G1' */
    /* */
    2.0,

    /* Expression: -2 */
    /* Referenced by: '<Root>/G2' */
    /* */
    -2.0,

    /* Computed Parameter: uDLookup_maxIndex */
You can tune the structure fields during code execution because they occupy global memory. However, at each step of the generated algorithm, the code must calculate the output of each block, including the outputs of the block G2 and the upstream blocks. View the algorithm in the model step function in the file `rtwdemo_paraminline.c`.

```c
rtwdemo_paraminline_Y.Out1 = rtwdemo_paraminline_P.G1_Gain * rtwdemo_paraminline_U.In1 + rtwdemo_paraminline_P.G2_Gain * look2_binlx(rtwdemo_paraminline_P.MAX_LIFT, look1_binlx(rtwdemo_paraminline_P.SLIDER_POS, rtwdemo_paraminline_P.T1Break, rtwdemo_paraminline_P.T1Data, 10U), rtwdemo_paraminline_P.T2Break, rtwdemo_paraminline_P.T2Data, rtwdemo_paraminline_P.uDLookup_maxIndex, 3U);
```

**Generate Code with Optimization**

Set **Default parameter behavior** to **Inlined**.

```c
set_param('rtwdemo_paraminline','DefaultParameterBehavior','Inlined')
```

Generate code from the model.
### Starting build procedure for model: rtwdemo_paraminline
### Successful completion of build procedure for model: rtwdemo_paraminline

In the code generation report, view the algorithm in the file `rtwdemo_paraminline.c`.

```c
rtwdemodbtype(...
  cfile,'/* Model step function */','/* Model initialize function */',1,0);

/* Model step function */
void rtwdemo_paraminline_step(void)
{
  /* Outport: '<Root>/Out1' incorporates:
   *  Gain: '<Root>/G1'
   *  Inport: '<Root>/In1'
   *  Sum: '<Root>/Sum'
   */
  rtwdemo_paraminline_Y.Out1 = 2.0 * rtwdemo_paraminline_U.In1 + 150.0;
}
```

The code does not allocate memory for block parameters or for parameter objects that use the storage class `Auto`. Instead, the code generator uses the parameter values from the model, and from the parameter objects, to calculate and inline the constant output of the block G2, 150.0. The generator also inlines the value of the `Gain` parameter of the Gain block G1, 2.0.

With the optimization, the generated code leaves out computationally expensive algorithmic code for blocks such as the lookup tables. The optimized code calculates the output of a block only if the output can change during execution. For this model, only the outputs of the Inport block In1, the Gain block G1, and the Sum block can change.

Close the model and the code generation report.

```c
bdclose('rtwdemo_paraminline')
rtwdemoclean;
cd(currentDir)
```

**Preserve Block Parameter Tunability**

When you set **Default parameter behavior** to Inlined, you can preserve block parameter tunability by creating `Simulink.Parameter` objects for individual parameters. You can configure each object to appear in the code as a tunable field of the
global parameter structure or as an individual global variable. You can change parameter values during code execution and interface the generated code with your own handwritten code. For more information, see “Create Tunable Calibration Parameter in the Generated Code” (Simulink Coder).

**Inline Invariant Signals**

You can select the **Inline invariant signals** code generation option (which also places constant values in the generated code) only when you set **Default parameter behavior** to **Inlined**. See “Inline Invariant Signals” (Simulink Coder).

**See Also**

“Default parameter behavior” (Simulink Coder)

- “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 22-50
Configure Loop Unrolling Threshold

The **Loop unrolling threshold** parameter on the **Optimization** pane determines when a wide signal or parameter should be wrapped into a `for` loop and when it should be generated as a separate statement for each element of the signal. The default threshold value is 5.

For example, consider the model below:

![Model Diagram](image)

The gain parameter of the Gain block is the vector `myGainVec`.

Assume that the loop unrolling threshold value is set to the default, 5.

If `myGainVec` is declared as

```matlab
myGainVec = [1:10];
```

an array of 10 elements, `myGainVec_P.Gain_Gain[]`, is declared within the `Parameters_model` data structure. The size of the gain array exceeds the loop unrolling threshold. Therefore, the code generated for the Gain block iterates over the array in a `for` loop, as shown in the following code:
{ 
    int32_T i1;

    /* Gain: '<Root>/Gain' */
    for(i1=0; i1<10; i1++) {
        myGainVec_B.Gain_f[i1] = rtb_foo * myGainVec_P.Gain_Gain[i1];
    }
}

If myGainVec is declared as
myGainVec = [1:3];

an array of three elements, myGainVec_P.Gain_Gain[], is declared within the Parameters data structure. The size of the gain array is below the loop unrolling threshold. The generated code consists of inline references to each element of the array, as in the code below.

    /* Gain: '<Root>/Gain' */
    myGainVec_B.Gain_f[0] = rtb_foo * myGainVec_P.Gain_Gain[0];
    myGainVec_B.Gain_f[1] = rtb_foo * myGainVec_P.Gain_Gain[1];

See “Explore Variable Names and Loop Rolling” (Simulink Coder) for more information on loop rolling.

**Note** When a model includes Stateflow charts or MATLAB Function blocks, you can apply a set of Stateflow optimizations on the Optimization pane. The settings you select for the Stateflow options also apply to MATLAB Function blocks in the model. This is because the MATLAB Function blocks and Stateflow charts are built on top of the same technology and share a code base. You do not need a Stateflow license to use MATLAB Function blocks.

Use memcpy Function to Optimize Generated Code for Vector Assignments

In this section...

“Example Model” on page 56-54
“Generate Code” on page 56-55
“Generate Code with Optimization” on page 56-55

You can use the **Use memcpy for vector assignment** parameter to optimize generated code for vector assignments by replacing for loops with memcpy function calls. The memcpy function is more efficient than for-loop controlled element assignment for large data sets. This optimization improves execution speed.

Selecting the **Use memcpy for vector assignment** parameter enables the associated parameter **Memcpy threshold (bytes)**, which allows you to specify the minimum array size in bytes for which memcpy function calls should replace for loops in the generated code. For more information, see “Use memcpy for vector assignment” (Simulink Coder) and “Memcpy threshold (bytes)” (Simulink Coder). In considering whether to use this optimization,

- Verify that your target supports the memcpy function.
- Determine whether your model uses signal vector assignments (such as Y=expression) to move large amounts of data, for example, using the Selector block.

To apply this optimization,

1. Consider first generating code without this optimization and measuring its execution speed, to establish a baseline for evaluating the optimized assignment.
2. Select **Use memcpy for vector assignment** and examine the setting of **Memcpy threshold (bytes)**, which by default specifies 64 bytes as the minimum array size for which memcpy function calls replace for loops. Based on the array sizes used in your application's signal vector assignments, and target environment considerations that might bear on the threshold selection, accept the default or specify another array size.
3. Generate code, and measure its execution speed against your baseline or previous iterations. Iterate on steps 2 and 3 until you achieve an optimal result.
Note The \texttt{memcpy} optimization may not occur under certain conditions, including when other optimizations have a higher precedence than the \texttt{memcpy} optimization, or when the generated code is originating from Target Language Compiler (TLC) code, such as a TLC file associated with an S-function block.

Note If you are licensed for Embedded Coder software, you can use a code replacement library (CRL) to provide your own custom implementation of the \texttt{memcpy} function to be used in generated model code. For more information, see “Memory Function Code Replacement” on page 54-99.

Example Model

To examine the result of using the \textbf{Use memcpy for vector assignment} parameter on the generated vector assignment code, create a model that generates signal vector assignments. For example,

1. Use In, Out, and Selector blocks to create the following model.

![Model Diagram]

2. Open Model Explorer and configure the \textbf{Signal Attributes} for the In1 and In2 source blocks. For each, set \textbf{Port dimensions} to \([1,100]\), and set \textbf{Data type} to \texttt{int32}. Apply the changes and save the model. In this example, the model has the name \texttt{vectorassign}.
3 For each Selector block, set the **Index** parameter to **1:50**. Set the **Input port size** parameter to **100**.

### Generate Code

1. The **Use memcpy for vector assignment** parameter is on by default. To turn off the parameter, go to the **Optimization** pane and clear the **Use memcpy for vector assignment** parameter.

2. Go to the **Code Generation > Report** pane of the Configuration Parameters dialog box and select the **Create code generation report**. Then go to the **Code Generation** pane, select the **Generate code only** option, and generate code for the model. When code generation completes, the HTML code generation report is displayed.

3. In the HTML code generation report, click the **vectorassign.c** section and inspect the model step function. Notice that the vector assignments are implemented using for loops.

```c
/* Model step function */
void vectorassign_step(void)
{
    int32_T i;
    for (i = 0; i < 50; i++) {
        /* Outport: '<Root>/Out1' incorporates:
         *  Inport: '<Root>/In1'
         */
        vectorassign_Y.Out1[i] = vectorassign_U.In1[i];

        /* Outport: '<Root>/Out2' incorporates:
         *  Inport: '<Root>/In2'
         */
        vectorassign_Y.Out2[i] = vectorassign_U.In2[i];
    }
}
```

### Generate Code with Optimization

1. Go to the **Optimization** pane of the Configuration Parameters dialog box and select the **Use memcpy for vector assignment** option. Leave the **Memcpy threshold (bytes)** option at its default setting of **64**. Apply the changes and regenerate code for the model. When code generation completes, the HTML code generation report again is displayed.

2. In the HTML code generation report, click the **vectorassign.c** section and inspect the model output function. Notice that the vector assignments now are implemented using **memcpy** function calls.
/* Model step function */
void vectorassign_step(void)
{
    /* Outport: '<Root>/Out1' incorporates:
    * Inport: '<Root>/In1'
    */
    memcpy(&vectorassign_Y.Out1[0], &vectorassign_U.In1[0], 50U * sizeof(real_T));

    /* Outport: '<Root>/Out2' incorporates:
    * Inport: '<Root>/In2'
    */
    memcpy(&vectorassign_Y.Out2[0], &vectorassign_U.In2[0], 50U * sizeof(real_T));
}

Generate Target Optimizations Within Algorithm Code

Some application components are hardware-specific and cannot simulate on a host system. For example, consider a component that includes pragmas and assembly code for enabling hardware instructions for saturate on add operations or a Fast Fourier Transform (FFT) function.

The following table lists integration options to customize generated algorithm code with target-specific optimizations.

**Note** Solutions marked with *EC only* require an Embedded Coder license.

<table>
<thead>
<tr>
<th>If...</th>
<th>Then...</th>
<th>For More Information, See</th>
</tr>
</thead>
<tbody>
<tr>
<td>You want to optimize the execution speed and memory of the model code by replacing default math functions and operators with target-specific code</td>
<td><em>EC only</em>—Implement function and operator replacements by using the <strong>Code Replacement Tool</strong>, code replacement library (CRL) API, and <strong>Code Replacement Viewer</strong> to create, examine, validate, and register hardware-specific replacement tables</td>
<td>“Optimize Generated Code By Developing and Using Code Replacement Libraries - Simulink®”</td>
</tr>
</tbody>
</table>

• rtwdemo_advsc  
• “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 26-19 |
**Note** To simulate an algorithm that includes target-specific elements in a host environment, you must create code that is equivalent to the target code and can run in the host environment.
Remove Code for Blocks That Have No Effect on Computational Results

This example shows how the code generator optimizes generated code by removing code that has no effect on computational results. This optimization:

- Increases execution speed.
- Reduces ROM consumption.

Example

In the model `rtwdemo_blockreduction`, a Gain block of value `1.0` is in between Inport and Outport blocks.

```matlab
model = 'rtwdemo_blockreduction';
open_system(model);
```

Generate Code

Create a temporary folder for the build and inspection process.

```matlab
currentDir=pwd;
[~,cgDir]=rtwdemodir();

Build the model.

set_param(model,'BlockReduction','off');
rtwbuild(model)
```

```matlab
### Starting build procedure for model: rtwdemo_blockreduction
### Successful completion of build procedure for model: rtwdemo_blockreduction
```
Here is the code from `rtwdemo_blockreduction.c`.

```c
#include <stdio.h>

// rtwdemo_blockreduction.c

void rtwdemo_blockreduction_step(void)
{
    rtwdemo_blockreduction_Y.Out1 = 1.0 * rtwdemo_blockreduction_U.In1;
}
```

**Enable Optimization**

1. Open the Configuration Parameters dialog box.
2. Select **Block reduction**. This optimization is on by default.

Alternately, use the command-line API to enable the optimization.

```bash
set_param(model,'BlockReduction','on');
```

**Generate Code with Optimization**

```bash
rtwbuild(model)
```

### Starting build procedure for model: rtwdemo_blockreduction
### Successful completion of build procedure for model: rtwdemo_blockreduction

Here is the optimized code from `rtwdemo_blockreduction.c`.

```c
#include <stdio.h>

// rtwdemo_blockreduction.c

void rtwdemo_blockreduction_step(void)
{
    rtwdemo_blockreduction_Y.Out1 = 1.0 * rtwdemo_blockreduction_U.In1;
}
```
rtwdemo_blockreduction_Y.Out1 = rtwdemo_blockreduction_U.In1;
}

Because multiplying the input signal by a value of 1.0 does not impact computational results, the code generator excludes the Gain block from the generated code. Close the model and clean up.

bdclose(model)
rtwdemoclean;
cd(currentDir)

Eliminate Dead Code Paths in Generated Code

This example shows how the code generator eliminates dead (that is, unused) code paths from generated code. This optimization increases execution speed and conserves ROM and RAM consumption.

Example

In the model `rtwdemo_deadpathElim`, the signal leaving the Sum block divides into two separate code paths. The top path is not a dead code path. If the user disables the Assertion block, the bottom path becomes a dead code path.

```matlab
model = 'rtwdemo_deadpathElim';
open_system(model);
```

Generate Code with an Enabled Assertion Block

1. For the Assertion block, open the block parameters dialog box.
2. Select the **Enable assertion** box. Alternatively, use the command-line API to enable the Assertion block.

```matlab
set_param(fullfile(model, '/Assert1'), 'Enabled', 'on');
```

Create a temporary folder for the build and inspection process.

```matlab
currentDir = pwd;
 [~,cgDir] = rtwdemodir();
```

Build the model.

```matlab
rtwbuild(model)
### Starting build procedure for model: rtwdemo_deadpathElim
### Successful completion of build procedure for model: rtwdemo_deadpathElim
```
Because the Assertion block is enabled, these lines of `rtwdemo_deadpathElim.c` include code for the Gain and Assertion blocks.

```matlab
cfile = fullfile(cgDir,'rtwdemo_deadpathElim_grt_rtw','rtwdemo_deadpathElim.c');
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize function */', 0, 1);

void rtwdemo_deadpathElim_step(void)
{
    /* Sum: '<Root>/Sum1' incorporates:
    *  Constant: '<Root>/Constant1'
    *  Inport: '<Root>/In1'
    */
    rtwdemo_deadpathElim_Y.Out1 = rtwdemo_deadpathElim_U.In1 + 1.0;

    /* Assertion: '<Root>/Assert1' incorporates:
    *  Gain: '<Root>/G1'
    */
    utAssert(2.0 * rtwdemo_deadpathElim_Y.Out1 != 0.0);
}
```

**Generate Code with a Disabled Assertion Block**

Disable the Assertion block to generate a dead code path. The code generator detects the dead code path and eliminates it from the generated code.

1. For the Assertion block, open the Block Parameters dialog box.
2. Deselect the **Enable assertion** box.

Alternatively, use the command-line API to disable the Assertion block.

```matlab
set_param([model '/Assert1'], 'Enabled', 'off');
```

Build the model.

```matlab
rtwbuild(model)
```

### Starting build procedure for model: rtwdemo_deadpathElim
### Successful completion of build procedure for model: rtwdemo_deadpathElim

Because the Assertion block is disabled, these lines of `rtwdemo_deadpathElim.c` do not include code for the Gain and Assertion blocks.

```matlab
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize function */', 0, 1);
```
void rtwdemo_deadpathElim_step(void)
{
    /* Outport: '<Root>/Out1' incorporates:
       * Constant: '<Root>/Constant1'
       * Inport: '<Root>/In1'
       * Sum: '<Root>/Sum1'
       */
    rtwdemo_deadpathElim_Y.Out1 = rtwdemo_deadpathElim_U.In1 + 1.0;
}

Close the model and clean-up.

bdclose(model);
rtwdemoclean;
cd(currentDir)

For another example of how the code generator eliminates dead code paths in the
generated code, see rtwdemo_deadpath.

Floating-Point Multiplication to Handle a Net Slope Correction

This example shows how to use floating-point multiplication to handle a net slope correction. When converting floating-point data types to fixed-point data types in the generated code, a net slope correction is one method of scaling fixed-point data types. Scaling the fixed-point data types avoids overflow conditions and minimizes quantization errors.

For processors that support efficient multiplication, using floating-point multiplication to handle a net slope correction improves code efficiency. If the net slope correction has a value that is not a power of two, using division improves precision.

**Note:** This example requires a Fixed-Point Designer™ license.

**Example**

In the model `rtwdemo_float_mul_for_net_slope_correction`, a Convert block converts an input signal from a floating-point data type to a fixed-point data type. The net slope correction has a value of 3.

```matlab
model = 'rtwdemo_float_mul_for_net_slope_correction';
open_system(model);
```

**Generate Code**

Create a temporary folder for the build and inspection process.

```matlab
currentDir = pwd;
[~,cgDir] = rtwdemodir();

Build the model.
rtwbuild(model)

### Starting build procedure for model: rtwdemo_float_mul_for_net_slope_correction
### Successful completion of build procedure for model: rtwdemo_float_mul_for_net_slope_correction

In these lines of `rtwdemo_float_mul_for_net_slope_correction.c` code, the code generator divides the input signal by 3.0F.

cfile = fullfile(cgDir,'rtwdemo_float_mul_for_net_slope_correction_ert_rtw',...
   'rtwdemo_float_mul_for_net_slope_correction.c');
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);

    rtY.Output = (int16_T)(real32_T)floor((real_T)(rtU.Input / 3.0F));

/* Model step function */
void rtwdemo_float_mul_for_net_slope_correction_step(void)
{
   /* Outport: '<Root>/Output' incorporates:
      *  DataTypeConversion: '<Root>/Data Type Conversion'
      *  Inport: '<Root>/Input'
   */
   rtY.Output = (int16_T)(real32_T)floor((real_T)(rtU.Input / 3.0F));
}

Enable Optimization
1  Open the Configuration Parameters dialog box.
2  On the Math and Data Types pane, select **Use floating-point multiplication to handle net slope corrections**. This optimization is on by default.

Alternatively, you can use the command-line API to enable the optimization.

    set_param(model, 'UseFloatMulNetSlope', 'on');

Generate Code with Optimization

rtwbuild(model)

### Starting build procedure for model: rtwdemo_float_mul_for_net_slope_correction
### Successful completion of build procedure for model: rtwdemo_float_mul_for_net_slope_correction

In the optimized code, the code generator multiplies the input signal by the reciprocal of 3.0F, that is 0.333333343F.

cfile = fullfile(cgDir,'rtwdemo_float_mul_for_net_slope_correction_ert_rtw',...
   'rtwdemo_float_mul_for_net_slope_correction.c');
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);
/* Model step function */
void rtwdemo_float_mul_for_net_slope_correction_step(void)
{
    /* Outport: '<Root>/Output' incorporates:
        * DataTypeConversion: '<Root>/Data Type Conversion'
        * Inport: '<Root>/Input'
    */
    rtY.Output = (int16_T)(real32_T)floor((real_T)(rtU.Input * 0.333333343F));
}

Close the model and the code generation report.

bdclose(model)
rtwdemoclean;
cd(currentDir)

Use Conditional Input Branch Execution

This example shows how to optimize the generated code for a model that contains Switch and Multiport Switch blocks. When you select the model configuration parameter **Conditional input branch execution**, Simulink executes only blocks that compute the control input and data input that the control input selects. This optimization improves execution speed.

**Example Model**

In this example, switch paths are conditionally executed. If Switch1 control input is true, Switch1 executes blocks grouped in the Switch1:Path1 branch. If Switch1 control input is false, Switch1 executes blocks grouped in the Switch1:Path2 branch. If Switch1 executes blocks in the Switch1:Path2 branch and Switch2 control input is true, Switch2 executes blocks in the Switch2:Path1 branch. If Switch2 control input is false, Switch2 executes blocks in the Switch2:Path2 branch. The pseudo code shows this logic.

```matlab
model='rtwdemo_condinput';
open_system(model);
```
This model shows conditional input branch execution performed by Simulink and Simulink Coder. Conditional input branch execution improves simulation and code generation execution performance. In this example, switch paths are conditionally executed. That is, if Switch1’s control input is true, Switch1 executes blocks grouped in the "Switch1:Path1" branch. Otherwise, it executes blocks grouped in the "Switch1:Path2" branch. If blocks in "Switch1:Path2" are executed, Switch2 executes the "Switch2:Path1" branch if its control input is true. Otherwise, it executes the "Switch2:Path2" branch. This logic is illustrated by the pseudo code above.

Generate Code Using Simulink Coder (double-click)

Generate Code Using Embedded Coder (double-click)
Generate Code

The **Conditional input branch execution** parameter is on by default. Enter the following command-line API to turn off the parameter.

```matlab
set_param(model, 'ConditionallyExecuteInputs', 'off');
```

Create a temporary folder for the build and inspection process.

```matlab
currentDir = pwd;
[~, cgDir] = rtwdemodir();
```

Build the model.

```matlab
rtwbuild(model)
```

### Starting build procedure for model: rtwdemo_condinput
### Successful completion of build procedure for model: rtwdemo_condinput

View the generated code without the optimization. These lines of code are in the `rtwdemo_condinput.c` file.

```matlab
cfile = fullfile(cgDir,'rtwdemo_condinput_grt_rtw','rtwdemo_condinput.c');
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);
```

```c
/* Model step function */
void rtwdemo_condinput_step(void)
{
    /* Switch: '<Root>/ Switch2' incorporates:
    * Constant: '<Root>/ C_10'
    * Constant: '<Root>/C_5'
    * Gain: '<Root>/ G3'
    * Inport: '<Root>/input'
    * RelationalOperator: '<Root>/Relational Operator'
    * Sum: '<Root>/ Sum'
    */
    if (rtwdemo_condinput_U.input >= -5.0) {
        rtwdemo_condinput_Y.output = 3.0 * rtwdemo_condinput_U.input;
    } else {
        rtwdemo_condinput_Y.output = rtwdemo_condinput_U.input + -10.0;
    }

    /* End of Switch: '<Root>/ Switch2' */
```
The generated code contains an if-else statement for the Switch1 block and an if statement for the Switch2 block. Therefore, the generated code for Switch1:Path2 executes even if the if statement for Switch1:Path1 evaluates to true.

Enable Optimization

1. Open the Configuration Parameters dialog box.
2. Select the Conditional input branch execution parameter. Alternatively, you can use the command-line API to enable the optimization.

    set_param(model, 'ConditionallyExecuteInputs','on');

Generate Code with Optimization

    rtwbuild(model)
    cfile = fullfile(cgDir,'rtwdemo_condinput_grt_rtw','rtwdemo_condinput.c');
    rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);

    /* Model step function */
    void rtwdemo_condinput_step( void )
    {
        /* Switch: '<Root>/Switch1' incorporates:
         * Constant: '<Root>/C5'
         * Inport: '<Root>/input'
         * RelationalOperator: '<Root>/Relational Operator1'
         */
        if (rtwdemo_condinput_U.input >= 5.0) {
            /* Outport: '<Root>/output' incorporates:
             * Constant: '<Root>/  C10'
             * Sum: '<Root>/ Sum1'
             */
            rtwdemo_condinput_Y.output = rtwdemo_condinput_U.input + 10.0;
        }
    }

    /* End of Switch: '<Root>/Switch1' */
The generated code contains one if statement. The generated code for Switch1:Path2 only executes if the if statement evaluates to false.

**Close Model and Code Generation Report**

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

Optimize Generated Code for Complex Signals

This example shows how Simulink Coder handles complex signals efficiently. To view the data types of the signals, update the model using Simulation > Update Diagram. Complex signals are represented as structures in generated code. Simulink Coder performs various optimizations on these structures. For example:

- Expression Folding: Gain and Sum operations on the complex signal are folded into a single expression.
- For-loop fusion: Two separate for-loops, one for the complex signal and one for noncomplex signal, are combined into a single for-loop.
- Inlined block parameters: The value of Gain block "pi" is inlined in the expression of the complex Gain-Sum.

Because of optimizations such as these, the code generated for complex and noncomplex signals is equally efficient.

Example Model

```matlab
model='rtwdemo_complex';
open_system(model);
```
This model shows how Simulink Coder handles complex signals efficiently. To view the data types of the signals, update the model using Simulation > Update Diagram. Complex signals are represented as structures in generated code. Simulink Coder performs various optimizations on these structures. For example,

- Expression folding: Gain and Sum operations on the complex signal are folded into a single expression.
- For-loop fusion: Two separate for-loops, one for the complex signal and one for the noncomplex signal, are combined into a single for-loop.
- Inlined block parameters: The value of Gain block "pi" is inlined in the expression of the complex Gain-Sum.

Because of optimizations such as these, the code generated for complex and noncomplex signals is equally efficient.

Speed Up Linear Algebra in Code Generated from a MATLAB Function Block

To improve the execution speed of code generated for certain linear algebra functions in a MATLAB Function block, specify that the code generator produce LAPACK calls. LAPACK is a software library for numerical linear algebra. The code generator uses the LAPACKE C interface to LAPACK. If you specify that you want to generate LAPACK calls, and the input arrays for the linear algebra functions meet certain criteria, the code generator produces the LAPACK calls. Otherwise, the code generator produces code for the linear algebra functions.

The code generator uses the LAPACK library that you specify. Specify a LAPACK library that is optimized for your execution environment. See www.netlib.org/lapack/faq.html#_what_and_where_are_the_lapack_vendors_implementations.

Specify LAPACK Library

To generate LAPACK calls, you must have access to a LAPACK callback class. A LAPACK callback class specifies the LAPACK library and LAPACKE header file for the LAPACK calls. To indicate that you want to generate LAPACK calls and that you want to use a specific LAPACK library, specify the name of the LAPACK callback class. In the Configuration Parameters dialog box, set Custom LAPACK library callback to the name of the callback class, for example, useMyLAPACK.

Write LAPACK Callback Class

To specify the locations of a particular LAPACK library and LAPACKE header file, write a LAPACK callback class. Share the callback class with others who want to use this LAPACK library for LAPACK calls in generated code.

The callback class must derive from the abstract class coder.LAPACKCallback. Use this example callback class as a template.

```matlab
classdef useMyLAPACK < coder.LAPACKCallback
    methods (Static)
        function hn = getHeaderFilename()
            hn = 'mylapacke_custom.h';
        end
        function updateBuildInfo(buildInfo, buildctx)
    end
end
```
buildInfo.addIncludePaths(fullfile(pwd,'include'));
libName = 'mylapack';
libPath = fullfile(pwd,'lib');
 [~,linkLibExt] = buildctx.getStdLibInfo();
buildInfo.addLinkObjects([libName linkLibExt], libPath, ...
'\', true, true);
buildInfo.addDefines('HAVE_LAPACK_CONFIG_H');
buildInfo.addDefines('LAPACK_COMPLEX_STRUCTURE');
end
data
end

You must provide the getHeaderFilename and updateBuildInfo methods. The getHeaderFilename method returns the LAPACKE header file name. In the example callback class, replace mylapacke_custom.h with the name of your LAPACKE header file. The updateBuildInfo method provides the information required for the build process to link to the LAPACK library. Use code like the code in the template to specify the location of header files and the full path name of the LAPACK library. In the example callback class, replace mylapack with the name of your LAPACK library.

If your compiler supports only complex data types that are represented as structures, include these lines in the updateBuildInfo method.

buildInfo.addDefines('HAVE_LAPACK_CONFIG_H');
buildInfo.addDefines('LAPACK_COMPLEX_STRUCTURE');

**Generate LAPACK Calls by Specifying a LAPACK Callback Class**

This example shows how to generate code that calls LAPACK functions in a specific LAPACK library. For this example, assume that the LAPACK callback class useMyLAPACK specifies the LAPACK library that you want.

1. Create a Simulink model.
2. Add a MATLAB Function block to the model.
3. In the MATLAB Function block, add code that calls a linear algebra function. For example, add the function mysvd that calls the MATLAB function svd.

    ```matlab
    function s = mysvd(A)
        %#codegen
        s = svd(A);
    end
    ```
4. Add a Constant block to the left of the MATLAB Function block. Set the value to zeros(500).
5 Add an Outport block to the right of the MATLAB Function block.
6 Connect the blocks.

7 Set the **Configuration Parameters** > **Code Generation** > **Advanced parameters**
   > **Custom LAPACK library callback** parameter to `useMyLAPACK`.

   The callback class must be on the MATLAB path.

8 Build the model.

If the input to `mysvd` is large enough, the code generator produces a LAPACK call for `svd`. An example of a call to the LAPACK library function for `svd` is:

```c
info_t = LAPACKE_dgesvd( ...  
  _LAPACK_COL_MAJOR, 'N', 'N', (lapack_int)500, ...  
  (lapack_int)500, &A[0], (lapack_int)500, &S[0], ...  
  NULL, (lapack_int)1, NULL,(lapack_int)1, &superb[0]);
```

**Locate LAPACK Library in Execution Environment**

The LAPACK library must be available in your execution environment. If your LAPACK library is shared, use environment variables or linker options to specify the location of the LAPACK library.

- On a Windows platform, modify the PATH environment variable.
- On a Linux platform, modify the LD_LIBRARY_PATH environment variable or use the rpath linker option.
- On a macOS platform, modify the DYLD_LIBRARY_PATH environment variable or use the rpath linker option.

To specify the rpath linker option, you can use the build information `addLinkFlags` method in the `updateBuildInfo` method of your `coder.LAPACKCallback` class. For example, for a GCC compiler:

```c
buildInfo.addLinkFlags(sprintf('-Wl,-rpath,"%s",libPath));
```

Speed Up Fast Fourier Transforms in Code Generated from a MATLAB Function Block

This example shows how to generate calls to a specific installed FFTW library. For more information about FFTW, see www.fftw.org.

When you simulate a model that includes a MATLAB Function block that calls MATLAB fast Fourier transform (FFT) functions, the simulation software uses the library that MATLAB uses for FFT algorithms. If you generate C/C++ code for this model, by default, the code generator produces code for the FFT algorithms instead of producing FFT library calls. To increase the speed of fast Fourier transforms in generated code, specify that the code generator produce calls to a specific installed FFTW library.

The code generator produces FFTW library calls when all of these conditions are true:

- A MATLAB Function block calls one of these MATLAB functions: `fft`, `fft2`, `fftn`, `ifft`, `ifft2`, or `ifftn`.
- You generate C/C++ code from a model that includes the MATLAB Function block.
- You have access to an FFTW library installation, version 3.2 or later.
- You specify the FFTW library installation in an FFT library callback class that derives from `coder.fftw.StandaloneFFTW3Interface`.
- You set the **Custom FFT library callback** configuration parameter to the name of the callback class.

### Install an FFTW Library

If you do not have access to an installed FFTW library, version 3.2 or later, then you must install one.

For a Linux platform or a Mac platform, consider using a package manager to install the FFTW library.

For a Windows platform, in addition to `.dll` files, you must have `.lib` import libraries, as described in the Windows installation notes on the FFTW website.

See the installation instructions for your platform on the FFTW website.
Write FFT Callback Class

To specify your installation of the FFTW library, write an FFT callback class. Share the callback class with others who want to use this FFTW library for FFTW calls.

The callback class must derive from the abstract class `coder.fftw.StandaloneFFTW3Interface`. Use this example callback class as a template.

```matlab
% copyright 2017 The MathWorks, Inc.

classdef useMyFFTW < coder.fftw.StandaloneFFTW3Interface

    methods (Static)
    function th = getNumThreads
        coder.inline('always');
        th = int32(coder.const(1));
    end

    function updateBuildInfo(buildInfo, ctx)
        fftwLocation = '/usr/lib/fftw';
        includePath = fullfile(fftwLocation, 'include');
        buildInfo.addIncludePaths(includePath);
        libPath = fullfile(fftwLocation, 'lib');

        %Double
        libName1 = 'libfftw3-3';
        [~, libExt] = ctx.getStdLibInfo();
        libName1 = [libName1 libExt];
        addLinkObjects(buildInfo, libName1, libPath, 1000, true, true);

        %Single
        libName2 = 'libfftw3f-3';
        [~, libExt] = ctx.getStdLibInfo();
        libName2 = [libName2 libExt];
        addLinkObjects(buildInfo, libName2, libPath, 1000, true, true);
    end
end
end
```

Implement the `updateBuildInfo` and `getNumThreads` methods. In the `updateBuildInfo` method, set `fftwLocation` to the full path for your installation of the library. Set `includePath` to the full path of the folder that contains `fftw3.h`. Set `libPath` to the full path of the folder that contains the library files. If your FFTW installation uses multiple threads, modify the `getNumThreads` method to return the number of threads that you want to use.

Optionally, you can implement these methods:
• `getPlanMethod` to specify the FFTW planning method. See `coder.fftw.StandaloneFFTW3Interface`.

• `lock` and `unlock` to synchronize multithreaded access to the FFTW planning process. See “Synchronize Multithreaded FFTW Planning in Code Generated from a MATLAB Function Block” (Simulink Coder).

## Generate FFTW Calls by Specifying an FFT Callback Class

1. Create a Simulink model.
2. Add a MATLAB Function block to the model.
3. In the MATLAB Function block, add code that calls a MATLAB FFT function. For example, add the function `myfft` that calls the MATLAB function `fft`.

   ```matlab
   function y = myfft()
   t = 0:1/50:10-1/50;
   x = sin(2*pi*15*t) + sin(2*pi*20*t);
   y = fft(x);
   end
   ``

4. Connect the blocks.

5. Indicate that the code generator produce calls to the FFTW library specified in the FFT library callback class `useMyFFTW`. In the Configuration Parameters dialog box, set **Custom FFT library callback** to `useMyFFTW`.

   The callback class must be on the MATLAB path.

6. Build the model.

## Locate FFTW Library in Execution Environment

The FFTW library must be available in your execution environment. If the FFTW library is shared, use environment variables or linker options to specify the location of the library.

• On a Windows platform, modify the PATH environment variable.
• On a Linux platform, modify the `LD_LIBRARY_PATH` environment variable or use the `rpath` linker option.
• On a macOS platform, modify the DYLD_LIBRARY_PATH environment variable or use the rpath linker option.

To specify the rpath linker option, you can use the build information addLinkFlags method in the updateBuildInfo method of your coder.fftw.StandaloneFFTW3Interface class. For example, for a GCC compiler:

```cpp
buildInfo.addLinkFlags(sprintf('-Wl,-rpath,"%s"',libPath));
```

Synchronize Multithreaded FFTW Planning in Code Generated from a MATLAB Function Block

This example shows how to generate code that synchronizes multithreaded access to the FFTW planning process for FFTW library calls in code generated from a MATLAB Function block.

The code generator produces FFTW library calls when all of these conditions are true:

- A MATLAB Function block calls one of these functions: `fft`, `fft2`, `fftn`, `ifft`, `ifft2`, or `ifftn`.
- You generate C/C++ code for a model that includes the MATLAB Function block.
- You have access to an FFTW library installation, version 3.2 or later.
- You specify the FFTW library installation in an FFT library callback class that derives from `coder.fftw.StandaloneFFTW3Interface`.
- You set the **Custom FFT library callback** configuration parameter to the name of the callback class.

If you integrate the code that contains the FFTW calls with external code that runs on multiple threads, then you must prevent concurrent access to the FFTW planning process. In your FFT library callback class, implement the `lock` and `unlock` methods. You must also provide C code that manages a lock or mutex. Many libraries, such as OpenMP, pthreads, and the C++ standard library (C++ 11 and later), provide locks. This example shows how to implement the `lock` and `unlock` methods and provide supporting C code. To manage a lock, this example uses the OpenMP library.

**Prerequisites**

Before you start, for the basic workflow for generating FFTW library calls for fast Fourier transforms in a MATLAB Function block, see “Speed Up Fast Fourier Transforms in Code Generated from a MATLAB Function Block” (Simulink Coder).

You must have:

- Access to an installed FFTW library.
- A compiler that supports the OpenMP library. To use a different library, such as pthreads, modify the supporting C code accordingly.
Create a Model with a MATLAB Function Block That Calls an FFT Function

1. Create a Simulink model and add a MATLAB Function block to it.

2. Add this code to the MATLAB Function block.

   ```matlab
   function y = mycustomfft()
   
   t = 0:1/50:10-1/50;
   x = sin(2*pi*15*t) + sin(2*pi*20*t);
   y = fft(x);
   for k = 1:100
       y = y + ifft(x+k);
   end
   
   y
   ```

3. Add an `outport` block and connect it to the MATLAB Function block.

Write Supporting C Code

Write C functions that initialize, set, and unset a lock. This example uses the OpenMP library to manage the lock. For a different library, modify the code accordingly.

- Create a file `mylock.c` that contains this C code:

   ```c
   #include "mylock.h"
   #include "omp.h"

   static omp_nest_lock_t lockVar;

   void mylock_initialize(void)
   {
       omp_init_nest_lock(&lockVar);
   }
   
   void mylock(void)
   ```
```c
{  
    omp_set_nest_lock(&lockVar);
}

void myunlock(void)
{
    omp_unset_nest_lock(&lockVar);
}
```

- Create a header file `mylock.h` that contains:

```c
#ifndef MYLOCK_H
#define MYLOCK_H

void mylock_init(void);
void mylock(void);
void myunlock(void);

#endif
```

### Create an FFT Library Callback Class

Write an FFT callback class `myfftcb` that:

- Specifies the FFTW library.
- Implements `lock` and `unlock` methods that call the supporting C code to control access to the FFTW planning.

Use this class as a template. Replace `fftwLocation` with the location of your FFTW library installation.

```matlab
classdef myfftcb < coder.fftw.StandaloneFFTW3Interface

    methods (Static)
        function th = getNumThreads
            coder.inline('always');
            th = int32(coder.const(1));
        end

        function lock()
            coder.cinclude('mylock.h', 'InAllSourceFiles', true);
            coder.inline('always');
            coder.ceval('mylock');
        end
```
function unlock()
coder.cinclude('mylock.h', 'InAllSourceFiles', true);
coder.inline('always');
coder.ceval('myunlock');
end

function updateBuildInfo(buildInfo, ctx)
fftwLocation = '\usr\lib\fftw';
includePath = fullfile(fftwLocation, 'include');
buildInfo.addIncludePaths(includePath);
libPath = fullfile(fftwLocation, 'lib');

%Double
libName1 = 'libfftw3-3';
[~, libExt] = ctx.getStdLibInfo();
libName1 = [libName1 libExt];
addLinkObjects(buildInfo, libName1, libPath, 1000, true, true);

%Single
libName2 = 'libfftw3f-3';
[~, libExt] = ctx.getStdLibInfo();
libName2 = [libName2 libExt];
addLinkObjects(buildInfo, libName2, libPath, 1000, true, true);

end
end
end

Configure Code Generation Parameters and Build the Model

1 Configure code generation to use the FFTW callback class and the C code called by the lock and unlock methods. Configure code generation to generate a call to mylock_initialize in the initialization code.

In the Configuration Parameters dialog box:

• Set Custom FFT library callback to myfftcb.
• In Code Generation > Custom Code, under Additional build information, set Source files to mylock.c.
• In Code Generation > Custom Code, under Insert custom C code in generated, set Initialize function to mylock_initialize();.
2  Build the model.

Control Memory Allocation for Variable-Size Arrays in a MATLAB Function Block

Dynamic memory allocation allocates memory on the heap as needed at run time, instead of allocating memory statically on the stack. You can use dynamic memory allocation for arrays inside a MATLAB Function block.

You cannot use dynamic memory allocation for:

- Input and output signals. Variable-size input and output signals must have an upper bound.
- Parameters or global variables. Parameters and global variables must be fixed-size.
- Fields of bus arrays. Bus arrays cannot have variable-size fields.
- Discrete state properties of System objects associated with a MATLAB System block.

Dynamic memory allocation is beneficial when:

- You do not know the upper bound of an array.
- You do not want to allocate memory on the stack for large arrays.

Dynamic memory allocation and the freeing of this memory can result in slower execution of the generated code. To control the use of dynamic memory allocation for variable-size arrays in a MATLAB Function block, you can:

- Provide upper bounds for variable-size arrays on page 56-90.
- Disable dynamic memory allocation for MATLAB Function blocks on page 56-91.
- Modify the dynamic memory allocation threshold on page 56-91.

Provide Upper Bounds for Variable-Size Arrays

For an unbounded variable-size array, the code generator allocates memory dynamically on the heap. For a bounded variable-size array, if the size, in bytes, is less than the dynamic memory allocation threshold, the code generator allocates memory statically on the stack. To avoid dynamic memory allocation, provide upper bounds for the array dimensions so that the size of the array, in bytes, is less than the dynamic memory allocation threshold. See “Specify Upper Bounds for Variable-Size Arrays” (Simulink).
Disable Dynamic Memory Allocation for MATLAB Function Blocks

By default, dynamic memory allocation for MATLAB Function blocks is enabled for GRT-based targets and disabled for ERT-based targets. To change the setting, in the Configuration Parameters dialog box, clear or select **Dynamic memory allocation in MATLAB Function blocks**.

If you disable dynamic memory allocation, you must provide upper bounds for variable-size arrays.

Modify the Dynamic Memory Allocation Threshold

Instead of disabling dynamic memory allocation for all variable-size arrays, you can use the dynamic memory allocation threshold to specify when the code generator uses dynamic memory allocation.

Use the dynamic memory allocation threshold to:

- Disable dynamic memory allocation for smaller arrays. For smaller arrays, static memory allocation can speed up generated code. However, static memory allocation can lead to unused storage space. You can decide that the unused storage space is not a significant consideration for smaller arrays.
- Enable dynamic memory allocation for larger arrays. For larger arrays, when you use dynamic memory allocation, you can significantly reduce storage requirements.

The default value of the dynamic memory allocation threshold is 64 kilobytes. To change the threshold, in the Configuration Parameters dialog box, set the **Dynamic memory allocation threshold in MATLAB Function blocks** parameter.

To use dynamic memory allocation for all variable-size arrays, set the threshold to 0.

Optimize Memory Usage for Time Counters

This example shows how to optimize the amount of memory that the code generator allocates for time counters. The example optimizes the memory that stores elapsed time, the interval of time between two events.

The code generator represents time counters as unsigned integers. The word size of time counters is based on the setting of the model configuration parameter Application lifespan (days), which specifies the expected maximum duration of time the application runs. You can use this parameter to prevent time counter overflows. The default size is 64 bits.

The number of bits that a time counter uses depends on the setting of the Application lifespan (days) parameter. For example, if a time counter increments at a rate of 1 kHz, to avoid an overflow, the counter has the following number of bits:

- Lifespan < 0.25 sec: 8 bits
- Lifespan < 1 min: 16 bits
- Lifespan < 49 days: 32 bits
- Lifespan > 50 days: 64 bits

A 64-bit time counter does not overflow for 590 million years.

Open Example Model

Open the example model rtwdemo_abstime.
The model consists of three subsystems SS1, SS2, and SS3. On the **Math and Data Types** pane, the **Application lifespan (days)** parameter is set to the default, which is inf.
The three subsystems contain a discrete-time integrator that requires elapsed time as input to compute its output value. The subsystems vary as follows:

- **SS1** - Clocked at 1 kHz. Does not require a time counter. **Sample time type** parameter for trigger port is set to periodic. Elapsed time is inlined as 0.001.
- **SS2** - Clocked at 100 Hz. Requires a time counter. Based on a lifespan of 1 day, a 32-bit counter stores the elapsed time.
- **SS3** - Clocked at 0.5 Hz. Requires a time counter. Based on a lifespan of 1 day, a 16-bit counter stores the elapsed time.

**Simulate the Model**

Simulate the model. By default, the model is configured to show sample times in different colors. Discrete sample times for the three subsystems appear red, green, and blue. Triggered subsystems are blue-green.

**Generate Code and Report**

1. Create a temporary folder for the build and inspection process.
2. Configure the model for the code generator to use the GRT system target file and a lifespan of \( \text{inf} \) days.
3. Build the model.

```bash
### Starting build procedure for model: rtwdemo_abstime
### Successful completion of build procedure for model: rtwdemo_abstime
```

**Review Generated Code**

Open the generated source file `rtwdemo_abstime.c`.

```c
struct tag_RTM_rtwdemo_abstime_T {
    const char_T *errorStatus;

    /*
     * Timing:
     * The following substructure contains information regarding
     * the timing information for the model.
     */
    struct {
        uint32_T clockTick1;
```
uint32_T clockTickH1;
uint32_T clockTick2;
uint32_T clockTickH2;
struct {
    uint16_T TID[3];
    uint16_T cLimit[3];
} TaskCounters;
} Timing;
};

/* Block states (default storage) */
extern DW_rtwdemo_abstime_T rtwdemo_abstime_DW;

/* External inputs (root inport signals with default storage) */
extern ExtU_rtwdemo_abstime_T rtwdemo_abstime_U;

/* External outputs (root outports fed by signals with default storage) */
extern ExtY_rtwdemo_abstime_T rtwdemo_abstime_Y;

/* Model entry point functions */
extern void rtwdemo_abstime_initialize(void);
extern void rtwdemo_abstime_step(int_T tid);
extern void rtwdemo_abstime_terminate(void);

/* Real-time Model object */
extern RT_MODEL_rtwdemo_abstime_T *const rtwdemo_abstime_M;

/* The generated code includes comments that allow you to trace directly
back to the appropriate location in the model. The basic format
is <system>/block_name, where system is the system number (uniquely
assigned by Simulink) and block_name is the name of the block.

Use the MATLAB hilite_system command to trace the generated code back
to the model. For example,

hilite_system('<S3>') - opens system 3
hilite_system('<S3>/Kp') - opens and selects block Kp which resides in S3

Here is the system hierarchy for this model

'<Root>' : 'rtwdemo_abstime'
'<S1>' : 'rtwdemo_abstime/SS1'
'<S2>' : 'rtwdemo_abstime/SS2'
Four 32-bit unsigned integers, `clockTick1`, `clockTickH1`, `clockTick2`, and `clockTickH2` are counters for storing the elapsed time of subsystems SS2 and SS3.

**Enable Optimization and Regenerate Code**

1. Reconfigure the model to set the lifespan to 1 day.

2. Build the model.

```plaintext
### Starting build procedure for model: rtwdemo_abstime
### Successful completion of build procedure for model: rtwdemo_abstime
```

**Review the Regenerated Code**

```c
struct tag_RTM_rtwdemo_abstime_T {
    const char_T *errorStatus;

    /*
     * Timing:
     * The following substructure contains information regarding
     * the timing information for the model.
     */
    struct {
        uint32_T clockTick1;
        uint16_T clockTick2;
        struct {
            uint16_T TID[3];
            uint16_T cLimit[3];
        } TaskCounters;
    } Timing;

    /* Block states (default storage) */
    extern DW_rtwdemo_abstime_T rtwdemo_abstime_DW;

    /* External inputs (root inport signals with default storage) */
    extern ExtU_rtwdemo_abstime_T rtwdemo_abstime_U;

    /* External outputs (root outports fed by signals with default storage) */
    extern ExtY_rtwdemo_abstime_T rtwdemo_abstime_Y;
```
The new setting for the **Application lifespan (days)** parameter instructs the code generator to set aside less memory for the time counters. The regenerated code includes:

- 32-bit unsigned integer, `clockTick1`, for storing the elapsed time of the task for SS2
- 16-bit unsigned integer, `clockTick2`, for storing the elapsed time of the task for SS3

Optimize generated code by storing logical signals as Boolean data. When you select the model configuration parameter **Implement logic signals as Boolean data (vs. double)**, blocks that generate logic signals output Boolean signals.

The optimization:

- Reduces the ROM and RAM consumption.
- Improves execution speed.

**Example Model**

Consider the model `rtwdemo_logicalAsBoolean`. The outputs of the Relational Operator, Logical Operator and HitCrossing blocks are double, even though they represent logical data.

```matlab
model = 'rtwdemo.logicalAsBoolean';
open_system(model);
```

![Diagram of a Simulink model](image)
**Generate Code**

Create a temporary folder (in your system temporary folder) for the build and inspection process.

```matlab
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```matlab
rtwbuild(model)
```

### Starting build procedure for model: rtwdemo_logicalAsBoolean
### Successful completion of build procedure for model: rtwdemo_logicalAsBoolean

View the generated code without the optimization. These lines of code are in `rtwdemo_logicalAsBoolean.h`.

```matlab
hfile = fullfile(cgDir,'rtwdemo_logicalAsBoolean_ert_rtw','rtwdemo_logicalAsBoolean.h');
rtwdemodbtype(hfile,'/* External outputs','/* Parameters (default storage) */',1,0);
```

```c
/* External outputs (root outports fed by signals with default storage) */
typedef struct {
    real_T Out1;          /* '<Root>/Out1' */
    real_T Out2;          /* '<Root>/Out2' */
    real_T Out3;          /* '<Root>/Out3' */
} ExtY_rtwdemo_logicalAsBoolean_T;
```

**Enable Optimization**

1. Open the Configuration Parameters dialog box.
2. Select the **Implement logic signals as Boolean data (vs. double)** parameter.

Alternatively, you can use the command-line API to enable the optimization:

```matlab
set_param(model,'BooleanDataType','on');
```

**Generate Code with Optimization**

The generated code stores the logical signal output as Boolean data.

Build the model.
### Starting build procedure for model: rtwdemo_logicalAsBoolean
### Successful completion of build procedure for model: rtwdemo_logicalAsBoolean

View the generated code with the optimization. These lines of code are in rtwdemo_logicalAsBoolean.h.

```c
rtwdemodbtype(hfile,'/* External outputs','/* Parameters (default storage) */',1,0);

/* External outputs (root outports fed by signals with default storage) */
typedef struct {
    boolean_T Out1;   /* '<Root>/Out1' */
    boolean_T Out2;   /* '<Root>/Out2' */
    boolean_T Out3;   /* '<Root>/Out3' */
} ExtY_rtwdemo_logicalAsBoolean_T;
```

Close the model and code generation report.

```c
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

Reduce Memory Usage for Boolean and State Configuration Variables

1 Open the Model Configuration Parameters dialog box.
2 In the Model Configuration Parameters dialog box, select the Optimization pane.
3 Choose from these options:

• **Use bitsets for storing state configuration** — Reduces the amount of memory that stores state configuration variables. However, it can increase the amount of memory that stores target code if the target processor does not include instructions for manipulating bitsets.

• **Use bitsets for storing Boolean data** — Reduces the amount of memory that stores Boolean variables. However, it can increase the amount of memory that stores target code if the target processor does not include instructions for manipulating bitsets.

**Note** You cannot use bitsets when you generate code for these cases:

• An external mode simulation
• A target that specifies an explicit structure alignment

Customize Stack Space Allocation

Your application might be constrained by limited memory. Controlling the maximum allowable size for the stack is one way to modify whether data is defined as local or global in the generated code. You can limit the use of stack space by specifying a positive integer value for the “Maximum stack size (bytes)” (Simulink Coder) parameter, on the Optimization pane of the Configuration parameter dialog box. Specifying the maximum allowable stack size provides control over the number of local and global variables in the generated code. Specifically, lowering the maximum stack size might generate more variables into global structures. The number of local and global variables help determine the required amount of stack space for execution of the generated code.

The default setting for “Maximum stack size (bytes)” (Simulink Coder) is Inherit from target. In this case, the value of the maximum stack size is the smaller value of the following: the default value set by the code generator (200,000 bytes) or the value of the TLC variable MaxStackSize found in the system target file (ert.tlc).

To specify a smaller stack size for your application, select the Specify a value option of the Maximum stack size (bytes) parameter and enter a positive integer value. To specify a smaller stack size at the command line, use:

```
set_param(model_name, 'MaxStackSize', 65000);
```

**Note** For overall executable stack usage metrics, you might want to do a target-specific measurement, such as using runtime (empirical) analysis or static (code path) analysis with object code.

It is recommended that you use the Maximum stack size (bytes) parameter to control stack space allocation instead of modifying the TLC variable, MaxStackSize, in the system target file. However, a target author might want to set the TLC variable, MaxStackSize, for a target. To set MaxStackSize, use assign statements in the system target file (ert.tlc), as in the following example.

```
%assign MaxStackSize = 4096
```

Write your %assign statements in the Configure RTW code generation settings section of the system target file. The %assign statement is described in “Target Language Compiler” (Simulink Coder).

Optimize Generated Code Using memset Function

This example shows how to optimize the generated code by using the memset function to clear the internal storage. When you select the model configuration parameter **Use memset to initialize floats and doubles to 0.0**, the memset function clears internal storage, regardless of type, to the integer bit pattern 0 (that is, all bits are off).

If your compiler and target CPU both represent floating-point zero with the integer bit pattern 0, consider setting this parameter to gain execution and ROM efficiency.

**NOTE:** The command-line values are the reverse of the settings values. 'on' in the command line corresponds to clearing the setting. 'off' in the command line corresponds to selecting the setting.

This optimization:

- Reduces ROM consumption.
- Improves execution speed.

**Example Model**

Consider the model matlab:rtwdemo_memset.

```matlab
model = 'rtwdemo_memset';
open_system(model);
```

**Generate Code**

The code generator uses a loop to initialize the Constant block values.

Create a temporary folder (in your system temporary folder) for the build and inspection process.
currentDir = pwd;
[~,cgDir] = rtwdemodir();

Build the model.
rtwbuild(model)

### Starting build procedure for model: rtwdemo_memset
### Successful completion of build procedure for model: rtwdemo_memset

View the generated code without the optimization. These lines of code are in rtwdemo_memset.c.

cfile = fullfile(cgDir,'rtwdemo_memset_grt_rtw','rtwdemo_memset.c');
rtwdemodbtype(cfile,'/* Model initialize function */',
              '/* Model terminate function */',1,0);

/* Model initialize function */
void rtwdemo_memset_initialize(void)
{
  /* Registration code */

  /* initialize error status */
  rtmSetErrorStatus(rtwdemo_memset_M, (NULL));

  /* external outputs */
  {
    int32_T i;
    for (i = 0; i < 50; i++) {
      rtwdemo_memset_Y.Out1[i] = 0.0;
    }
  }

  {
    int32_T i;
    /* ConstCode for Outport: '<Root>/Out1' */
    for (i = 0; i < 50; i++) {
      rtwdemo_memset_Y.Out1[i] = 56.0;
    }
    /* End of ConstCode for Outport: '<Root>/Out1' */
  }
}
Enable Optimization

1. Open the Configuration Parameters dialog box.
2. Clear the **Use memset to initialize floats and doubles to 0.0** parameter. Alternatively, you can use the command-line API to enable the optimization:

   ```matlab
   set_param(model,'InitFltsAndDblsToZero','off');
   ```

Generate Code with Optimization

The code generator uses the `memset` function to initialize the Constant block values.

Build the model.

```matlab
rtwbuild(model)
```

### Starting build procedure for model: rtwdemo_memset
### Successful completion of build procedure for model: rtwdemo_memset

View the generated code with the optimization. These lines of code are in `rtwdemo_memset.c`.

```c
rtwdemodbtype(cfile,'/* Model initialize function */','
             '/* Model terminate function */',1,0);

/* Model initialize function */
void rtwdemo_memset_initialize(void)
{
    /* Registration code */

    /* initialize error status */
    rtmSetErrorStatus(rtwdemo_memset_M, (NULL));

    /* external outputs */
    (void) memset(&rtwdemo_memset_Y.Out1[0], 0,
                  50U*sizeof(real_T));

    {
        int32_T i;

        /* ConstCode for Outport: '<Root>/Out1' */
        for (i = 0; i < 50; i++) {
            rtwdemo_memset_Y.Out1[i] = 56.0;
        }
    }
```
/* End of ConstCode for Outport: '<Root>/Out1' */

} 

Close the model and the code generation report.

bdclose(model)
rtwdemoclean;
cd(currentDir)

Vector Operation Optimization

This example shows how Simulink® Coder™ optimizes generated code by setting block output that generates vectors to scalars, for blocks such as the Mux, Sum, Gain, and Bus. This optimization reduces stack memory by replacing temporary local arrays with local variables.

Example Model

In the model, rtwdemo_VectorOptimization, the output of Gain blocks G1 and G2 are the vector signals `tmp1` and `tmp2`. These vectors have a width of 10.

```matlab
model = 'rtwdemo_VectorOptimization';
open_system(model);
set_param(model, 'SimulationCommand', 'update')
```

Generate Code

Create a temporary folder (in your system temporary folder) for the build and inspection process.

```matlab
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```matlab
rtwbuild(model)
```
### Starting build procedure for model: rtwdemo_VectorOptimization
### Successful completion of build procedure for model: rtwdemo_VectorOptimization

The optimized code is in `rtwdemo_VectorOptimization.c`. The signals tmp1 and tmp2 are the local variables `rtb_tmp1` and `rtb_tmp2`.

```c

The optimized code is in `rtwdemo_VectorOptimization.c`. The signals tmp1 and tmp2 are the local variables `rtb_tmp1` and `rtb_tmp2`.

cfile = fullfile(cgDir,'rtwdemo_VectorOptimization_grt_rtw',...  
    'rtwdemo_VectorOptimization.c');
rtwodemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);

/* Model step function */
void rtwdemo_VectorOptimization_step(void)
{
    int32_T i;
    real_T rtb_tmp2;
    real_T rtb_tmp1;
    real_T rtb_Sum3;
    for (i = 0; i < 10; i++) {
        /* Gain: '<Root>/G2' incorporates:
         *  UnitDelay: '<Root>/X2'
         */
        rtb_tmp2 = 0.3 * rtwdemo_VectorOptimization_DW.X2_DSTATE[i];

        /* Gain: '<Root>/G1' incorporates:
         *  UnitDelay: '<Root>/X1'
         */
        rtb_tmp1 = 0.2 * rtwdemo_VectorOptimization_DW.X1_DSTATE[i];

        /* Sum: '<Root>/Sum3' incorporates:
         *  Gain: '<Root>/G3'
         *  Inport: '<Root>/In2'
         *  Sum: '<Root>/Sum1'
         *  Sum: '<Root>/Sum2'
         *  UnitDelay: '<Root>/X3'
         */
        rtb_Sum3 = ((rtwdemo_VectorOptimization_U.In2[i] - 0.4 * 
                     rtwdemo_VectorOptimization_DW.X3_DSTATE[i]) - rtb_tmp2) - 
                   rtb_tmp1;

        /* Outport: '<Root>/Out2' */
        rtwdemo_VectorOptimization_Y.Out2[i] = rtb_Sum3;

        /* Update for UnitDelay: '<Root>/X3' */
        rtwdemo_VectorOptimization_DW.X3_DSTATE[i] = rtb_tmp2;
    }
}
```

56-111
/* Update for UnitDelay: '<Root>/X2' */
rtwdemo_VectorOptimization ДW.X2_DSTATE[i] = rtb_tmp1;

/* Update for UnitDelay: '<Root>/X1' */

Enable and Reuse Local Block Outputs in Generated Code

In this section...

“Example Model” on page 56-113
“Generate Code Without Optimization” on page 56-114
“Enable Local Block Outputs and Generate Code” on page 56-114
“Reuse Local Block Outputs and Generate Code” on page 56-115

This example shows how to specify block output as local variables. The code generator can potentially reuse these local variables in the generated code. Declaring block output as local variables conserves ROM consumption. Reusing local variables conserves RAM consumption, reduces data copies, and increases execution speed.

Example Model

1 Use Inport, Outport, Gain, and Switch blocks to create the following model. In this example, the model is named local_variable_ex.

2 For G2, open the Gain Block Parameters dialog box. Enter a value of 2.

3 For G1, enter a value of 3.

4 For the Switch block, open the Block Parameters dialog box. For the Criteria for passing first input parameter, select u2>=Threshold.
Generate Code Without Optimization

1. Open the Model Configuration Parameters dialog box. Select the Solver pane. For the Type parameter, select Fixed-step.

2. Clear the Configuration Parameters > Signal storage reuse parameter.

4. Select the Code Generation pane. Select Generate code only, and then, in the model window, press Ctrl+B. When code generation is complete, an HTML code generation report appears.

5. In the code generation report, select the local_variable_ex.c section and view the model step function. The Gain block outputs are the global variables local_variable_ex_B.G2 and local_variable_ex_B.G1.

```c
/* Model step function */
void local_variable_ex_step(void)
{
    /* Switch: '<Root>/Switch' incorporates:
     * Inport: '<Root>/In1'
     */
    if (local_variable_ex_U.In1 >= 0.0) {
        /* Gain: '<Root>/G2' */
        local_variable_ex_B.G2 = 2.0 * local_variable_ex_U.In1;
        /* Outport: '<Root>/Out1' */
        local_variable_ex_Y.Out1 = local_variable_ex_B.G2;
    } else {
        /* Gain: '<Root>/G1' */
        local_variable_ex_B.G1 = 3.0 * local_variable_ex_U.In1;
        /* Outport: '<Root>/Out1' */
        local_variable_ex_Y.Out1 = local_variable_ex_B.G1;
    }
    /* End of Switch: '<Root>/Switch' */
}
```

Enable Local Block Outputs and Generate Code

1. Select the Configuration Parameters > Signal Storage Reuse parameter. The Signal Storage Reuse enables the following optimization parameters:
Enable local block outputs

• Reuse local block outputs
• Eliminate superfluous local variables (expression folding)

2 Clear **Reuse local block outputs** and **Eliminate superfluous local variables (expression folding)**.

3 Generate code and view the model step function. There are three local variables in the model step function because you selected the optimization parameter **Enable Local Block Outputs**. The local variables `rtb_G2` and `rtb_G1` hold the outputs of the Gain blocks. The local variable `rtb_Switch` holds the output of the Switch block.

```c
/* Model step function */
void local_variable_ex_step(void)
{
    real_T rtb_Switch;
    real_T rtb_G2;
    real_T rtb_G1;

    /* Switch: '<Root>/Switch' incorporates:
     *  Inport: '<Root>/In1'
     */
    if (local_variable_ex_U.In1 >= 0.0) {
        /* Gain: '<Root>/G2' */
        rtb_G2 = 2.0 * local_variable_ex_U.In1;
        rtb_Switch = rtb_G2;
    } else {
        /* Gain: '<Root>/G1' */
        rtb_G1 = 3.0 * local_variable_ex_U.In1;
        rtb_Switch = rtb_G1;
    }

    /* End of Switch: '<Root>/Switch' */

    /* Outport: '<Root>/Out1' */
    local_variable_ex_Y.Out1 = rtb_Switch;
}
```

**Reuse Local Block Outputs and Generate Code**

1 Select the **Configuration Parameters > Reuse local block outputs** parameter.

2 Generate code. In the `local_variable_ex.c` section, view the model step function. There is one local variable, `rtb_G2`, that the code generator uses three times.
void local_variable_ex_step(void)
{
    real_T rtb_G2;

    /* Switch: '<Root>/Switch' incorporates:
    *  Inport: '<Root>/In1'
    */
    if (local_variable_ex_U.In1 >= 0.0) {
        /* Gain: '<Root>/G2' */
        rtb_G2 = 2.0 * local_variable_ex_U.In1;
    } else {
        /* Gain: '<Root>/G1' */
        rtb_G2 = 3.0 * local_variable_ex_U.In1;
    }

    /* End of Switch: '<Root>/Switch' */

    /* Outport: '<Root>/Out1' */
    local_variable_ex_Y.Out1 = rtb_G2;
}

The extra temporary variable rtb_Switch and the associated data copy is not in the generated code.

Configuration in Embedded Coder
Set Hardware Implementation Parameters

Specification of target hardware device characteristics (such as word sizes for `char`, `short`, `int`, and `long` data types, or desired rounding behaviors in integer operations) for generated code can be critical in embedded systems development. The **Hardware Implementation** category of parameters in a configuration set provides a way to control such characteristics in simulation and code generation.

By configuring the **Hardware Implementation** parameters of the active configuration set for a model to match the behaviors of your compiler and hardware, you can generate more efficient code. For example, if you specify the **Byte ordering** parameter, you can avoid generation of extra code that tests the byte ordering of the target CPU.

Before generating and deploying code, get familiar with the **Hardware Implementation** pane of the Configuration Parameters dialog box. By default, target hardware microprocessor device details are hidden. To view the details, click the **Device details** arrow. See “Hardware Implementation Pane” (Simulink) and “Configure Run-Time Environment Options” (Simulink Coder) for more information.

You can use the example “Configure Target Hardware Characteristics” (Simulink Coder) to determine characteristics of your C or C++ compiler and target hardware. By using the example model with your target development system and debugger, you can observe the behavior of the code as it executes on the target hardware. You can then use the information to refine hardware target device parameters for your model.

Optimize Global Variable Usage

<table>
<thead>
<tr>
<th>In this section...</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Use Global to Hold Temporary Results” on page 58-2</td>
</tr>
<tr>
<td>“Minimize Global Data Access” on page 58-7</td>
</tr>
</tbody>
</table>

To tune your application and choose tradeoffs for execution speed and memory usage, you can choose a global variable reference optimization for the generated code.

On the Configuration Parameters dialog box, in the **Optimize global data access** dropdown list, three parameter options control global variable usage optimizations.

- **None.** Use default optimizations. This choice works well for most models. The code generator balances the use of local and global variables. It generates code which balances RAM and ROM consumption and execution speed.

- **Use global to hold temporary results.** Reusing global variables improves code efficiency and readability. This optimization reuses global variables, which results in the code generator defining fewer variables. It reduces RAM and ROM consumption and data copies.

- **Minimize global data access.** Using local variables to cache global data reduces ROM consumption by reducing code size in certain cases, such as when the global variables are scalars. This optimization improves execution speed because the code uses fewer instructions for local variable references than for global variable references.

Minimizing the use of global variables by using local variables interacts with stack usage control. For example, stack size can determine the number of local and global variables that the code generator can allocate in the generated code. For more information, see “Customize Stack Space Allocation” (Simulink Coder).

**Use Global to Hold Temporary Results**

The code generator uses global and local variables when you select **None** versus when you select **Use global to hold temporary results**.
Example Model

In the model matlab:rtwdemo_optimize_global_ebf, an Assignment block assigns values coming from the Inport and Constant blocks to an output signal. The output signal feeds into a Gain block.

```matlab
model = 'rtwdemo_optimize_global_ebf';
load_system('rtwdemo_optimize_global_ebf')
```

Generate Code without Optimization

1. In the Configuration Parameters dialog box, verify that the **Signal storage reuse** parameter is selected.

2. In the Configuration Parameters dialog box, for the **Optimize global access parameter**, select None or enter the following command in the MATLAB Command Window:

   ```matlab
   set_param('rtwdemo_optimize_global_ebf','GlobalVariableUsage','None');
   ```

   In your system's temporary folder, create a folder for the build and inspection process:

   ```matlab
   currentDir = pwd;
   [~,cgDir] = rtwdemodir();
   ```

   Build the model.

   ```matlab
   rtwbuild(model);
   ```

   ### Starting build procedure for model: rtwdemo_optimize_global_ebf
   ### Successful completion of build procedure for model: rtwdemo_optimize_global_ebf

   View the generated code without the optimization. Here is a portion of `rtwdemo_optimize_global_ebf.c`. 
The code assigns values to the local vector `rtb_Assignment`. The last statement copies the values in the local vector `rtb_Assignment` to the global vector `rtY.Out1`. Fewer global variable references result in improved execution speed. The code uses more instructions for global variable references than for local variable references.

In the Static Code Metrics Report, examine the Global Variables section.

1. In the Code Generation Report window, select **Static Code Metrics Report**.
2. Scroll down to the **Global Variables** section.
3. Select the `[+]` sign before each variable to expand it.
The total number of reads and writes for global variables is 2.

**Generate Code with Optimization**

In the Configuration Parameters dialog box, for the **Optimize global access parameter**, select **Use global to hold temporary results**, or enter the following command in the MATLAB Command Window:

```matlab
set_param('rtwdemo_optimize_global_ebf','GlobalVariableUsage','Use global to hold temporary results');
```

Build the model.

```matlab
rtwbuild(model);
```

### Starting build procedure for model: rtwdemo_optimize_global_ebf
### Successful completion of build procedure for model: rtwdemo_optimize_global_ebf

View the generated code with the optimization. Here is a portion of `rtwdemo_optimize_global_ebf.c`.

```c
int32_T i;
```
/* Assignment: '<Root>/Assignment' incorporates:
 *  Constant: '<Root>/Constant'
 *  Inport: '<Root>/In1'
 */
for (i = 0; i < 5; i++) {
    rtY.Out1[i] = rtCP_Constant_Value[i];
}

rtY.Out1[1] = rtU.In1;
/* End of Assignment: '<Root>/Assignment' */

/* Outport: '<Root>/Out1' incorporates:
 *  Gain: '<Root>/Gain'
 */
for (i = 0; i < 5; i++) {
    rtY.Out1[i] *= 2.0;
}
/* End of Outport: '<Root>/Out1' */
}

The code assigns values to the global vector rtY.Out1 without using a local variable. This assignment improves ROM and RAM consumption and reduces data copies. The code places the value in the destination variable for each assignment instead of copying the value at the end. In the Static Code Metrics Report, examine the Global Variables section.

Total               52            5

* The global variable is not directly used in any function.
As a result of using global variables to hold local results, the total number of reads and writes for global variables has increased from 2 to 5. This optimization reduces data copies by reusing global variables.

Close the code generation report.

rtwdemoclean;
cd(currentDir)

**Minimize Global Data Access**

Generate optimized code that reads from and writes to global variables less frequently.

**Example Model**

In the model matlab:rtwdemo_optimize_global, five signals feed into a Multiport Switch block.

```model = 'rtwdemo_optimize_global';
load_system('rtwdemo_optimize_global')```
Generate Code without Optimization

1. In the Configuration Parameters dialog box, verify that the **Signal storage reuse** parameter is selected.

2. In the Configuration Parameters dialog box, for the **Optimize global access** parameter, select **None** or enter the following command in the MATLAB Command Window:

   ```matlab
   set_param('rtwdemo_optimize_global','GlobalVariableUsage','None');
   ```

   In your system's temporary folder, create a folder for the build and inspection process.

   ```matlab
   currentDir = pwd;
   [~,cgDir] = rtwdemodir();
   ```

   Build the model.
rtwbuild(model);

### Starting build procedure for model: rtwdemo_optimize_global
### Successful completion of build procedure for model: rtwdemo_optimize_global

View the generated code without the optimization. Here is a portion of
rtwdemo_optimize_global.c.

cfile = fullfile(cgDir,'rtwdemo_optimize_global_ert_rtw',...
    'rtwdemo_optimize_global.c');
rtwdemodbtype(cfile,'/* Model step','/* Model initialize',1, 0);

/* Model step function */
void rtwdemo_optimize_global_step(void)
{
    /* MultiPortSwitch: '<Root>/Multiport Switch' incorporates:
    * Inport: '<Root>/In1'
    */
    switch ((int32_T)rtU.In1) {
    case 1:
        /* Outport: '<Root>/Out1' incorporates:
        * Constant: '<Root>/Constant'
        */
        rtY.Out1 = 1.0;
        break;

    case 2:
        /* Outport: '<Root>/Out1' incorporates:
        * Constant: '<Root>/Constant1'
        */
        rtY.Out1 = 2.0;
        break;

    case 3:
        /* Outport: '<Root>/Out1' incorporates:
        * Constant: '<Root>/Constant2'
        */
        rtY.Out1 = 3.0;
        break;

    default:
        /* Outport: '<Root>/Out1' incorporates:
        * Constant: '<Root>/Constant3'
        */
        rtY.Out1 = 4.0;
In the Static Code Metrics Report, examine the Global Variables section.

1. In the Code Generation Report window, select **Static Code Metrics Report**.
2. Scroll down to the Global Variables section.
3. Select the [+] sign before each variable to expand it.

The total number of reads and writes for global variables is 5.

**Enable Optimization and Generate Code**

In the Configuration Parameters dialog box, for the **Optimize global data access** parameter, select **Minimize global data access** or enter the following command in the MATLAB Command Window:

```matlab
set_param('rtwdemo_optimize_global',...  
'GlobalVariableUsage','Minimize global data access');
```

Build the model.

```matlab
rtwbuild(model);
```
View the generated code with the optimization. Here is a portion of
`rtwdemo_optimize_global.c`.

cfile = fullfile(cgDir, 'rtwdemo_optimize_global_ert_rtw', ...
   'rtwdemo_optimize_global.c');
rtwmodbtype(cfile, /* Model step', /* Model initialize',1, 0);

/* Model step function */
void rtwdemo_optimize_global_step(void)
{
    real_T tmp_Out1;

    /* MultiPortSwitch: '<Root>/Multiport Switch' incorporates:
     * Inport: '<Root>/In1'
     */
    switch ((int32_T)rtU.In1) {
    case 1:
      /* Outport: '<Root>/Out1' incorporates:
       * Constant: '<Root>/Constant'
       */
      tmp_Out1 = 1.0;
      break;

    case 2:
      /* Outport: '<Root>/Out1' incorporates:
       * Constant: '<Root>/Constant1'
       */
      tmp_Out1 = 2.0;
      break;

    case 3:
      /* Outport: '<Root>/Out1' incorporates:
       * Constant: '<Root>/Constant2'
       */
      tmp_Out1 = 3.0;
      break;

    default:
      /* Outport: '<Root>/Out1' incorporates:
       * Constant: '<Root>/Constant3'
       */
      tmp_Out1 = 4.0;
    }
break;
}
/* End of MultiPortSwitch: '<Root>/Multiport Switch' */
/* Outport: '<Root>/Out1' */
rtY.Out1 = tmp_Out1;
}

In `rtwdemo_optimize_global.c`, the code assigns a constant value to the local variable `tmp_Out1` in each case statement. The last statement in the code copies the value of `tmp_Out1` to the global variable `rtY.Out1`. Fewer global variable references result in fewer instructions and improved execution speed.

In the **Static Code Metrics Report**, examine the **Global Variables** section. As a result of minimizing global data accesses, the total number of reads and writes for global variables has decreased from 5 to 2.

Reuse Global Block Outputs in the Generated Code

Reduce ROM and RAM consumption and data copies and increase execution speed of generated code. Configure the code generator to reuse global variables by selecting the model configuration parameter **Reuse global block outputs**.

**Example**

In the Command Window, type `rtwdemo_reuse_global`.

---

**Generate Code without Optimization**

1. On the Configuration Parameters dialog box, verify that **Signal storage reuse** is selected.
2. Clear **Reuse global block outputs** and click **Apply**.
3. On the **Code Generation > Report** pane, select **Static code metrics**.
4. In your system's temporary folder, create a folder for the build and inspection process.

Press **Ctrl+B** to generate code.

```plaintext
### Starting build procedure for model: rtwdemo_reuse_global
### Successful completion of build procedure for model: rtwdemo_reuse_global
```
View the generated code without the optimization. Here is a portion of rtwdemo_reuse_global.c.

```c
/* Model step function */
void rtwdemo_reuse_global_step(void)
{
    /* Sum: '<Root>/Sum' incorporates:
        * Delay: '<Root>/Delay'
        * Inport: '<Root>/In1'
    */
    rtY.Out1 += rtU.In1;

    /* Outport: '<Root>/Out1' incorporates:
        * Delay: '<Root>/Delay'
    */
    rtY.Out1 = rtDW.Delay_DSTATE;
}
```

The generated code contains a data copy to the global variable rtDW.Delay_DSTATE. Open the Static Code Metrics Report. The total number of reads and writes for global variables is 8. The total size is 32 bytes.

**Enable Optimization and Generate Code**

1. On the Configuration Parameters dialog box, select **Reuse global block outputs** and click **Apply**.
2. Generate code.
3. View the generated code with the optimization. Here is a portion of rtwdemo_reuse_global.c.

```c
### Starting build procedure for model: rtwdemo_reuse_global
### Successful completion of build procedure for model: rtwdemo_reuse_global

/* Model step function */
void rtwdemo_reuse_global_step(void)
{
    /* Sum: '<Root>/Sum' incorporates:
        * Delay: '<Root>/Delay'
        * Inport: '<Root>/In1'
    */
    rtY.Out1 += rtU.In1;
}
```
The code generator eliminates a data copy, reduces two statements to one statement and three global variables to two global variables.

Open the Static Code Metrics Report. For global variables, this optimization reduces the total number of reads and writes for global variables from 8 to 5 and the total size from 32 bytes to 24 bytes.

- “Minimize Computations and Storage for Intermediate Results at Block Outputs” on page 56-37
- “Optimize Global Variable Usage” on page 58-2
Virtualized Output Ports Optimization

The virtualized output ports optimization lets you store the signal entering the root output port as a global variable. Clearing the MAT-file logging option and setting the TLC variable FullRootOutputVector to 0, both defaults for Embedded Coder, eliminate code and data storage associated with root output ports.

Consider the model in the following block diagram. The signal exportedSig has exportedGlobal storage class.

In the default case, the output of the Gain block is written to the signal storage location, exportedSig. The code generator does not generate code or data for the Out1 block, which has become a virtual block.

/* Gain Block: <Root>/Gain */
exportedSig = rtb_PulseGen * VirtOutPortLogOFF_P.Gain_Gain;

In cases where you enable MAT-file logging or set FullRootOutputVector = 1, the generated code represents root output ports as members of an external outputs vector.

The following code fragment was generated with MAT-file logging enabled. The output port is represented as a member of the external outputs vector VirtOutPortLogON_Y. The Gain block output value is copied to exportedSig and to the external outputs vector.

/* Gain Block: <Root>/Gain */
exportedSig = rtb_PulseGen * VirtOutPortLogON_P.Gain_Gain;

/* Outport Block: <Root>/Out1 */
VirtOutPortLogON_Y.Out1 = exportedSig;

Data maintenance in the external outputs vector can be significant for smaller models that perform benchmarks.

You can force root output ports to be stored in the external outputs vector (regardless of the setting of MAT-file logging) by setting the TLC variable FullRootOutputVector to 1. Add the statement
to the Embedded Coder system target file. Alternatively, you can enter the assignment from the MATLAB command line using the `set_param` command, the model parameter `TLCOptions`, and the TLC option `-a`. For more information, see “Specify TLC for Code Generation” (Simulink Coder) and “Configure TLC” (Simulink Coder).

For more information on how to control signal storage in generated code, see “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 22-50 and “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 22-81.

- “Optimize Global Variable Usage” on page 58-2
Specify Buffer Reuse by Using Simulink.Signal Objects

If your model has the optimal parameter settings for removing data copies, you might be able to remove additional data copies by using Simulink.Signal objects to specify buffer reuse. After studying the generated code and the Static Code Metrics Report and identifying areas where you think buffer reuse is possible, you specify signal objects on signal lines.

You can specify buffer reuse on signals that include a pair of root inport and outport signals. You can also specify buffer reuse on just a pair of root inport and outport signals. This optimization reduces ROM and RAM consumption because there are less global variables and data copies in the generated code. Code execution speed also increases.

Example Model

The model rtwdemo_reusable_csc contains the nonreusable subsystem DeltaSubsystem and the MATLAB Function block Downsample. DeltaSubsystem contains the MATLAB Function blocks DeltaX and DeltaY.

```matlab
code = 'rtwdemo_reusable_csc';
open_system(model);
```

Specify a Simulink Signal Object for Reuse

1. In the model, open the Model Data Editor (View > Model Data Editor).
2. In the Model Data Editor, on the Signals tab, from the Change view drop-down list, select Code.
3. Click the Show/refresh additional information button. Now, the Model Data Editor shows information about variables and objects in workspaces such as the base workspace.
4. Next to the Filter contents box, activate the Filter using selection button.
5 In the model, select the RCSC_REAL signal line. The Model Data Editor shows two rows: One that represents the signal line and one that represents a Simulink.Signal object in the base workspace.

6 For the row that represents the signal line, inspect the Resolve column. The check box is selected, which means the signal line resolves to the Simulink.Signal object, acquiring code generation settings from that object.

7 For the row that represents the signal object, inspect the Storage Class column. The signal object uses the storage class Reusable, which means the object appears in the generated code as a global variable named RCSC_REAL.

8 In the model, navigate into the DeltaSubsystem subsystem.

9 Select the RCSC_REAL signal line in this subsystem. This signal also resolves to the signal object in the base workspace.

With the Reusable storage class, the generated code can store the output of the Complex to Real-Imag block (at the root level of the model) and the output of the DeltaX block (in the subsystem) in the RCSC_REAL global variable.

**Generate Code**

Build the model.

```matlab
currentDir = pwd;
[~,cgDir] = rtwdemodir();
rtwbuild(model);

### Starting build procedure for model: rtwdemo_reusable_csc
### Successful completion of build procedure for model: rtwdemo_reusable_csc

For buffer reuse, the rtwdemo_reusable_csc.c file contains these global variables:

- static real_T RCSC_IMAG[1048576];
- static real_T RCSC_IMAG2[262144];
- static real_T RCSC_REAL[1048576];
- static real_T RCSC_REAL2[262144];

The rtwdemo_reusable_csc.c file contains this code:

```
/** Output and update for atomic system: '<Root>/Downsample' */
rtwdemodbtype(cfile,...
/** Model step function */','/* Model initialize function */',1,0);

/** Output and update for atomic system: '<Root>/DeltaSubsystem' */
static void DeltaSubsystem(void)
{
    /* MATLAB Function: '<S1>/DeltaX' */
    DeltaX((&(RCSC_REAL2[0])), (&(RCSC_IMAG2[0])), (&(RCSC_REAL[0])),
            (RCSC_IMAG[0])));

    /* MATLAB Function: '<S1>/DeltaY' */
    DeltaY((&(RCSC_REAL[0])), (&(RCSC_IMAG[0])), (&(RCSC_REAL2[0])),
            (RCSC_IMAG2[0])));
}

/** Model step function */
void rtwdemo_reusable_csc_step(void)
{
    int32_T i;

    /* ComplexToRealImag: '<Root>/Complex to Real-Imag' incorporates:
    *  Inport: '<Root>/ComplexData'
    */
    for (i = 0; i < 1048576; i++) {
        RCSC_REAL[i] = rtU.ComplexData[i].re;
        RCSC_IMAG[i] = rtU.ComplexData[i].im;
    }

    /* End of ComplexToRealImag: '<Root>/Complex to Real-Imag' */

    /* MATLAB Function: '<Root>/Downsample' */
    Downsample((RCSC_REAL[0])), (RCSC_IMAG[0]), (RCSC_REAL2[0]),
                (RCSC_IMAG2[0])));

    /* Outputs for Atomic SubSystem: '<Root>/DeltaSubsystem' */
    DeltaSubsystem();

    /* End of Outputs for SubSystem: '<Root>/DeltaSubsystem' */

    /* Outport: '<Root>/Out1' incorporates:
    *  RealImagToComplex: '<Root>/Real-Imag to Complex'
    */
    for (i = 0; i < 261121; i++) {

The variables RCSC_REAL and RCSC_IMAG hold the outputs of the Complex to Real-Image block and DeltaX. These variables hold the inputs to the DeltaY block. The variables RCSC_REAL2 and RCSC_IMAG2 hold the outputs of Downsample and DeltaY. These variables hold the inputs to the DeltaX block. By interleaving buffers in this way, you eliminate global variables in the generated code.

To remove the signal objects from the signal lines and regenerate code, in the MATLAB Command Window, enter these commands:

```matlab
portHandles = get_param(...
    'rtwdemo_reusable_csc/Complex to Real-Imag','portHandles');
set_param(portHandles.Outport(1),'MustResolveToSignalObject','off');
set_param(portHandles.Outport(2),'MustResolveToSignalObject','off');

portHandles = get_param(...
    'rtwdemo_reusable_csc/Downsample','portHandles');
set_param(portHandles.Outport(1),'MustResolveToSignalObject','off');
set_param(portHandles.Outport(2),'MustResolveToSignalObject','off');

portHandles = get_param(...
    'rtwdemo_reusable_csc/DeltaSubsystem/DeltaX','portHandles');
set_param(portHandles.Outport(1),'MustResolveToSignalObject','off');
set_param(portHandles.Outport(2),'MustResolveToSignalObject','off');

portHandles = get_param(...
    'rtwdemo_reusable_csc/DeltaSubsystem/DeltaY','portHandles');
set_param(portHandles.Outport(1),'MustResolveToSignalObject','off');
set_param(portHandles.Outport(2),'MustResolveToSignalObject','off');

rtwbuild(model);
```
rtwdemodbtype(cfile,...
    /* Output and update for atomic system: '<Root>/DeltaSubsystem' */
    /* Output and update for atomic system: '<Root>/Downsample' */
rtwdemodbtype(cfile,...
    /* Model step function */
    /* Model initialize function */
);}

/* Output and update for atomic system: '<Root>/DeltaSubsystem' */
static void DeltaSubsystem(void)
{
    /* MATLAB Function: '<S1>/DeltaX' */
    DeltaX(rtDWork.z2, rtDWork.z1, rtDWork.z1_m, rtDWork.z2_c);

    /* MATLAB Function: '<S1>/DeltaY' */
    DeltaY(rtDWork.z1_m, rtDWork.z2_c, &rtDWork.z1[0], &rtDWork.z2[0]);
}

/* Model step function */
void rtwdemo_reusable_csc_step(void)
{
    int32_T i;

    /* ComplexToRealImag: '<Root>/Complex to Real-Imag' incorporates:
    *  Inport: '<Root>/ComplexData'
    */
    for (i = 0; i < 1048576; i++) {
        rtDWork.RCSC_REAL[i] = rtU.ComplexData[i].re;
        rtDWork.RCSC_IMAG[i] = rtU.ComplexData[i].im;
    }

    /* End of ComplexToRealImag: '<Root>/Complex to Real-Imag' */

    /* MATLAB Function: '<Root>/Downsample' */
    Downsample(rtDWork.RCSC_REAL, rtDWork.RCSC_IMAG, rtDWork.z2, rtDWork.z1);

    /* Outputs for Atomic SubSystem: '<Root>/DeltaSubsystem' */
    DeltaSubsystem();

    /* End of Outputs for SubSystem: '<Root>/DeltaSubsystem' */

    /* Outport: '<Root>/Out1' incorporates:
    *  RealImagToComplex: '<Root>/Real-Imag to Complex'
    */
    for (i = 0; i < 261121; i++) {
        rtY.Out1[i].re = rtDWork.z1[i];
rtY.Out1[i].im = rtDWork.z2[i];
}

/* End of Outport: '<Root>/Out1' */
}

The generated code contains two additional global variables for holding block inputs and outputs.

Note: You can specify buffer reuse on signals that the code generator cannot implement. For those cases, use two new diagnostics to specify the message type that the model displays. In the Configuration Parameters dialog box, these diagnostics are Detect non-reused custom storage classes and Detect ambiguous custom storage class final values.

bdclose(model)
rtwdemoclean;
cd(currentDir)

**Buffer Reuse for Unit Delay and Delay Blocks**

To reuse the signal of a Unit Delay or Delay block:

1. Use the same reusable custom storage class specification for a pair of input and state arguments or a pair of output and state arguments of a Unit Delay block or a Delay block.

2. In the Model Data Editor, select the **States** tab and from the **Change view** dropdown list, select **Code**.

3. Use the **Name** column to set the name of the target Unit Delay or Delay block states. Specify the name of the signal object that you want to reuse.

4. For each state, check the box in the **Resolve** column.

For Delay blocks, you must set the **Delay length** parameter to 1 and **Initial condition > Source** to **Dialog**. To access these parameters, in the model, open the Property Inspector (**View > Property Inspector**) and click the block in the model.

**Limitations for Root Inport and Outport Signals**

These limitations apply to a model in which you specify buffer reuse for a pair of root inport and outport signals:

- The output ports cannot be conditional.
• If the code generator cannot reuse the same buffer in a top model, the generated code contains additional buffers. If the top model is a reference model, the code generator reports an error. To resolve the error, remove the Simulink.signal specification from the signal that connects to the outport port.

• When you run the executable that the code generator produces, and you reuse a pair of root inport and outport signals, when the root input value is zero, the root output value must also be zero. If the output value is nonzero and you reuse the signals, then the results from the simulation can differ from the results that the executable produces.

**Limitations for the Model**

These limitations apply to a model in which you specify buffer reuse for signals:

• Signals that you specify for reuse must have the same data types and sampling rates.

• For user-specified buffer reuse, blocks that modify a signal specified for reuse must execute before blocks that use the original signal value. Sometimes the code generator has to change the block operation order so that buffer reuse can occur. For models in which the code generator is unable to reorder block operations, buffer reuse does not occur.

• For models in which the code generator reorders block operations so that Simulink.Signal reuse can occur, you can observe the difference in the sorted order. In the model window, select **Display > Blocks > Sorted Execution Order**. To display the sorted execution order during simulation, select **Simulation > Update Diagram**. To display the execution order in the generated code, select **Code > C/C++ Code > Build Model**.

Specify Buffer Reuse for MATLAB Function Blocks in a Path

In this section...

“Example Model” on page 58-27
“Generate Code with Optimization” on page 58-27

You can specify buffer reuse across MATLAB Function blocks by using the same variable name for the input and output arguments. The code generator tries to reuse the output of one MATLAB Function block as the input to the next MATLAB Function block. This optimization conserves RAM and ROM consumption and reduces data copies.

Example Model

1 Use Inport, Outport, and MATLAB Function blocks to create the model mf_inplace.

2 Open each MATLAB Function block and copy the following code:

```matlab
function y = fcn(y)
    y = y + 4;
```

3 Open the Configuration Parameters dialog box. On the Code Generation tab, change the System target file to ert.tlc.

4 On the Solver tab, change the Type parameter to Fixed-step.

Generate Code with Optimization

Generate code for the model. The mf_inplace.c file contains this code:
void mf_inplace_MATLABFunction(real_T *rty_y)
{
    *rty_y += 4.0;
}

void mf_inplace_step(void)
{
    real_T rtb_y_p5;
    rtb_y_p5 = mf_inplace_U.In1;
    mf_inplace_MATLABFunction(&rtb_y_p5);
    mf_inplace_MATLABFunction(&rtb_y_p5);
    mf_inplace_MATLABFunction(&rtb_y_p5);
    mf_inplace_Y.Out1 = rtb_y_p5;
    mf_inplace_MATLABFunction(&mf_inplace_Y.Out1);
}

The code generator reuses the variable rtb_y_p5 for the input and output arguments of each MATLAB Function block.

**Note** On the **Code Generation** tab in the Subsystem Block Parameters dialog box, if the **Function packaging** parameter is set to **Nonreusable function** and the **Function interface** parameter is set to **Allow arguments**, the code generator cannot reuse the input and output arguments.

Remove Data Copies by Reordering Block Operations in the Generated Code

This example shows how to remove data copies by changing the **Optimize block order in the generated code** parameter from off to **Improved Execution Speed**. Changing this setting indicates to the code generator to reorder block operations where possible to remove data copies. This parameter is in the Configuration Parameters dialog box. This optimization conserves RAM and ROM consumption.

**Example Model**

In the model `ex_optimizeblockorder`, the signal that leaves the Sum block enters a Subtract block and a Concatenate block. The signal that leaves the Subtract block enters a Product block and a Sum of Elements block.
Generate Code without Optimization

The image shows the model `ex_optimizeblockorder` after a model build. The red numbers indicate the default block order in the generated code. The Subtract block executes before the Concatenate block. The Product block executes before the Sum of Elements block.

View the generated code without the optimization. Here is the `ex_optimizeblockorder_step` function.

```c
/* Model step function */
void ex_optimizeblockorder_step(void)
{
    real_T rtb_Sum2x3[6];
    int32_T i;
    real_T rtb_Sum2x3_d;
    real_T rtb_Subtract;

    /* Sum: '<Root>/SumOfElements' */
    rtY.Out2 = -0.0;
```
for (i = 0; i < 6; i++) {
   /* Sum: '<Root>/Sum2x3' incorporates:
   * Inport: '<Root>/In1'
   * Inport: '<Root>/In2'
   */
   rtb_Sum2x3_d = rtU.In1[i] + rtU.In2;

   /* Sum: '<Root>/Subtract' incorporates:
   * Inport: '<Root>/In3'
   */
   rtb_Subtract = rtb_Sum2x3_d - rtU.In3;

   /* Outport: '<Root>/Out1' incorporates:
   * Inport: '<Root>/In4'
   * Product: '<Root>/Product'
   */
   rtY.Out1[i] = rtU.In4[i] * rtb_Subtract;

   /* Sum: '<Root>/Sum2x3' */
   rtb_Sum2x3[i] = rtb_Sum2x3_d;

   /* Sum: '<Root>/SumOfElements' */
   rtY.Out2 += rtb_Subtract;
}

/* Concatenate: '<Root>/MatrixConcat ' */
for (i = 0; i < 3; i++) {
   /* Outport: '<Root>/Out3' incorporates:
   * Inport: '<Root>/In5'
   */
   rtY.Out3[i << 2] = rtb_Sum2x3[i << 1];
   rtY.Out3[2 + (i << 2)] = rtU.In5[i << 1];
   rtY.Out3[1 + (i << 2)] = rtb_Sum2x3[(i << 1) + 1];
   rtY.Out3[3 + (i << 2)] = rtU.In5[(i << 1) + 1];
}

/* End of Concatenate: '<Root>/MatrixConcat ' */

With the default order, the generated code contains three buffers, rtb_Sum2x3[6], rtb_Sum2x3_d, and rtb_Subtract. The generated code contains these temporary variables and associated data copies because the Matrix Concatenate block must use the output from the Sum block and the Sum of Elements block must use the output from the Subtract block.
Generate Code with Optimization

The image shows the ex_optimizeblockorder model after setting the **Optimize block order in the generated code** parameter to **Improved Execution Speed** and building the model. The Subtract block executes after the Concatenate block. The Product block executes after the Sum of Elements block.

In the optimized code, the three buffers `rtb_Sum2x3[6]`, `rtb_Sum2x3_d`, and `rtb_Subtract` and their associated data copies are gone. The generated code does not require these temporary variables to hold the outputs of the Sum and Subtract blocks because the Subtract block executes after the Concatenate block and the Product block executes after the Sum of Elements block.

```c
/* Model step function */
void ex_optimizeblockorder_step(void)
{
    int32_T i;

    /* Sum: '<Root>/Sum2x3' incorporates:
```
To implement buffer reuse, the code generator does not violate user-specified block priorities.

Data Copy Reduction for Data Store Read and Data Store Write Blocks

This example shows how the code generator removes temporary buffers for Data Store Read and Data Store Write blocks. This optimization improves execution speed and reduces RAM consumption.

Example Model

The model `rtwdemo_optimizeddatastorebuffers` contains the Function caller `UpdateFunc`, which calls the Simulink Function `DefineUpdateFunc`. The Data Store Read block `DSR` reads from `mem`. The Data Store Write block `DSW` writes to `mem`.

```matlab
model='rtwdemo_optimizeddatastorebuffers';
open_system(model);
```

Generate Code without Optimization

In the Configuration Parameters dialog box, deselect the **Reuse buffers for Data Store Read and Data Store Write blocks** parameter or at the MATLAB command prompt, enter this command:
set_param(model,'OptimizeDataStoreBuffers','off');

Build the model.

currentDir = pwd;
[~,cgDir] = rtwdemodir();
rtwbuild(model)

### Starting build procedure for model: rtwdemo_optimizedatastorebuffers
### Successful completion of build procedure for model: rtwdemo_optimizedatastorebuffers

View the generated code without the optimization. This code is in rtwdemo_optimizedatastorebuffers.c.

cfile = fullfile(cgDir,'rtwdemo_optimizedatastorebuffers_ert_rtw','rtwdemo_optimizedatastorebuffers.c');
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);

/* Model step function */
void rtwdemo_optimizedatastorebuffers_step(void)
{
    real_T rtb_DSR_last;
    real_T rtb_SimFuncCall_o1;
    real_T rtb_Sum_p;

    /* DataStoreRead: '<Root>/DSR' */
    rtb_DSR_last = mem.last;

    /* Switch: '<Root>/Switch' incorporates:
    * Constant: '<Root>/Constant'
    * DataStoreRead: '<Root>/DSR'
    * Inport: '<Root>/Clear'
    */
    if (rtU.Clear) {
        rtb_SimFuncCall_o1 = 0.0;
    } else {
        rtb_SimFuncCall_o1 = mem.max;
    }

    /* End of Switch: '<Root>/Switch' */

    /* FunctionCaller: '<Root>/SimFuncCall' incorporates:
    * Inport: '<Root>/DataNew'
    */
UpdateFunc(rtb_SimFuncCall_01, rtU.DataNew, &rtb_SimFuncCall_01, &rtb_Sum_p);
/* DataStoreWrite: '<Root>/DSW' */
mem.last = rtb_SimFuncCall_01;
mem.max = rtb_Sum_p;

/* Outport: '<Root>/Delta' incorporates:
 * Inport: '<Root>/DataNew'
 * Sum: '<Root>/Sum'
 */
rtY.Delta = rtU.DataNew - rtb_DSR_last;
}

The generated code contains data copies for the Data Store Read and Data Store Write blocks, respectively.

**Generate Code with Optimization**

In the Configuration Parameters dialog box, clear the **Reuse buffers for Data Store Read and Data Store Write blocks** parameter or at the MATLAB command prompt, enter this command:

```
set_param(model,'OptimizeDataStoreBuffers','on');
```

Build the model.

```
rtwbuild(model)
```

### Starting build procedure for model: rtwdemo_optimizedatastorebuffers
### Successful completion of build procedure for model: rtwdemo_optimizedatastorebuffers

View the generated code with the optimization. This code is in

```
rtwdemo_optimizedatastorebuffers.c.
```

cfile = fullfile(cgDir,'rtwdemo_optimizedatastorebuffers_ert_rtw', ...
   'rtwdemo_optimizedatastorebuffers.c');
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);

/* Model step function */
void rtwdemo_optimizedatastorebuffers_step(void)
{
    real_T rtb_DSR_last;
    real_T tmp;
/* DataStoreRead: '<Root>/DSR' */
rtb_DSR_last = mem.last;

/* Switch: '<Root>/Switch' incorporates:
*  Constant: '<Root>/Constant'
*  DataStoreRead: '<Root>/DSR'
*  Inport: '<Root>/Clear'
*/
if (rtU.Clear) {
    tmp = 0.0;
} else {
    tmp = mem.max;
}

/* End of Switch: '<Root>/Switch' */

/* FunctionCaller: '<Root>/SimFuncCall' incorporates:
*  DataStoreWrite: '<Root>/DSW'
*  Inport: '<Root>/DataNew'
*/
UpdateFunc(tmp, rtU.DataNew, &mem.last, &mem.max);

/* Outport: '<Root>/Delta' incorporates:
*  Inport: '<Root>/DataNew'
*  Sum: '<Root>/Sum'
*/
rtY.Delta = rtU.DataNew - rtb_DSR_last;
}

The data copy for the Data Store Write block is not in the generated code. The code contains the data copy for the Data Store Read block because the Sum block executes after the Data Store Write block. The generated code contains the variable `rtb_DSR_last` to hold the output of the Sum block. Therefore, the Sum block gets the values that SimFuncCall calculates at the start of the time step rather than those values at the next time step. If the priority of the Sum block is lower than SimFuncCall, the code generator can remove the data copy for the Data Store Read block. Some other cases in which the code generator might not eliminate data copies are:

- A Simulink Function internally writes to the Data Store Memory block.
- The Data Store Read or Data Store Write blocks select elements of an array from the Data Store Memory block.
- The Data Store Memory block has a custom storage class.
• The Data Store Read and Data Store Write blocks occur on the same block unless that block is a Bus Assignment block or an Assignment block.

Close the model and clean up.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

Reduce Data Copies for Bus Assignment Blocks

For models containing a Bus Assignment block, if possible, the code generator uses the same variable for the block input and output. Reusing these variables reduces data copies, conserves RAM consumption and increases code execution speed.

Example Model

For example, in bus_assignoptim, a bus signal containing six elements feeds into a Bus Assignment block and a Bus Selector block. The Bus Assignment block assigns new values to the bus element a1_real_array. This bus signal feeds into Out1.

Generate Code Without Optimization

Generate code without the optimization by setting the Perform inplace updates for Bus Assignment blocks parameter to on. Without the optimization the bus_assignoptim_step function contains this code:

```c
void bus_assignoptim_step(void)
{
    real_T rtb_Assignment[36];
    int32_T i;

    /* Assignment: '<Root>/Assignment' incorporates:
     * Inport: '<Root>/In1'
     * Inport: '<Root>/In2'
     * Product: '<Root>/Product'
     * Selector: '<Root>/Selector'
     * Sum: '<Root>/Sum1'
     */
    for (i = 0; i < 36; i++) {
        rtb_Assignment[i] = bus_assignoptim_U.In1.a1_real_array[i];
    }
}
```
for (i = 0; i < 2; i++) {
   rtb_Assignment[(int32_T)(i + 22)] = (bus_assignoptim_U.In1.a1_real_array[(int32_T)(i + 22)] + bus_assignoptim_U.In1.a1_num) * bus_assignoptim_U.In2;
}

/* End of Assignment: '<Root>/Assignment' */

/* Outport: '<Root>/Out' incorporates:
 *  BusAssignment: '<Root>/Bus Assignment'
 *  Inport: '<Root>/In1'
 */
bus_assignoptim_Y.Out = bus_assignoptim_U.In1;

/* BusAssignment: '<Root>/Bus Assignment' incorporates:
 *  Outport: '<Root>/Out'
 */
for (i = 0; i < 36; i++) {
   bus_assignoptim_Y.Out.a1_real_array[i] = rtb_Assignment[i];
}

The generated code contains the temporary array rtb_Assignment for holding data before this data is assigned to bus_assignoptim_Y.Out.a1_real_array.

**Generate Code with Optimization**

Generate code with the optimization by setting the **Perform inplace updates for Bus Assignment blocks** parameter to off. With the optimization, the bus_assignoptim_step function contains this code:

/* Model step function */
void bus_assignoptim_step(void)
{
   int32_T i;

   /* Outport: '<Root>/Out' incorporates:
   *  Inport: '<Root>/In1'
   *  SignalConversion: '<Root>/TmpBusAssignmentBufferAtBus AssignmentInport1'
   */
   bus_assignoptim_Y.Out = bus_assignoptim_U.In1;
for (i = 0; i < 36; i++) {
    bus_assignoptim_Y.Out.a1_real_array[i] =
        bus_assignoptim_U.In1.a1_real_array[i];
}

for (i = 0; i < 2; i++) {
    bus_assignoptim_Y.Out.a1_real_array[(int32_T)(i + 22)] =
        (bus_assignoptim_U.In1.a1_real_array[(int32_T)(i + 22)] +
             bus_assignoptim_U.In1.a1_num) * bus_assignoptim_U.In2;
}

The generated code does not contain the temporary array rtb_Assignment1 for holding data. The generated code directly assigns this data to bus_assignoptim_Y.Out.a1_real_array.

58-42
Optimize Generated Code by Using Signal Labels to Guide Buffer Reuse

If your model has the optimal parameter settings for removing data copies, you might be able to remove additional data copies by using signal labels. After studying the generated code and the Static Code Metrics Report and identifying areas where you think buffer reuse is possible, you can add labels to signal lines. If possible, the code generator reorders block operations to implement the reuse specification.

Specifying buffer reuse improves execution speed and may reduce RAM consumption.

Example Model

The model `rtwdemo_label_guided_reuse` demonstrates how you can use signal labels to request buffer reuse for block input and output signals. For this model, the code generator can use the same variable for the Atomic Subsystem and either the Gain or Saturation block outputs. The generated code uses the same variable for the Saturation and Atomic Subsystem block outputs because those signals contain the same label and the Use Signal Labels to Guide Buffer Reuse parameter is selected.

Generate Code Without Optimization

1. Open the model.

   ```mex
   model='rtwdemo_label_guided_reuse';
   open_system(model);
   ```
In the Configuration Parameters dialog box, clear the **Use Signal Labels to Guide Buffer Reuse** parameter.

Build the model. The `rtwdemo_label_guided_reuse_step` function contains this code:

```c
void rtwdemo_label_guided_reuse_step(void)
{
    real_T rtb_Saturation[4];
    real_T rtb_Bias[4];
    int32_T i;
    AtomicSubsystem(rtU.In1, rtb_Bias);
    for (i = 0; i < 4; i++) {
        if (rtb_Bias[i] > 10.0) {
            rtb_Saturation[i] = 10.0;
        } else if (rtb_Bias[i] < -10.0) {
            rtb_Saturation[i] = -10.0;
        } else {
            rtb_Saturation[i] = rtb_Bias[i];
        }
    }
    rtb_Bias[i] *= 3.0;
}

AtomicSubsystem1(rtb_Saturation, rtb_Bias, rtY.Out1);
```

By default, within the for loop, the Gain block executes after the Saturation block. The generated code uses the same variable for the output of the Atomic Subsystem and the Gain blocks. As a result, the generated code contains two local variables `rtb_Saturation` and `rtb_Bias` for holding intermediate results.

**Generate Code with Optimization**

In the Configuration Parameters dialog box, select the **Use Signal Labels to Guide Buffer Reuse** parameter and build the model. The `rtwdemo_label_guided_reuse_step` function contains this code:

```c
void rtwdemo_label_guided_reuse_step(void)
{
    real_T rtb_Gain1[4];
    int32_T i;
    AtomicSubsystem(rtU.In1, rtY.Out1);
    for (i = 0; i < 4; i++) {
```
\(\text{rtb\_Gain1}[i] = 3.0 \times \text{rtY\_Out1}[i];\) 
\(\text{if (rtY\_Out1}[i] > 10.0) \{\) 
\(\quad \text{rtY\_Out1}[i] = 10.0;\) 
\(\} \text{ else } \{\) 
\(\quad \text{if (rtY\_Out1}[i] < -10.0) \{\) 
\(\quad\quad \text{rtY\_Out1}[i] = -10.0;\) 
\(\} \}\) 
\(\) 
\(\text{AtomicSubsystem1(rtY\_Out1, rtb\_Gain1, rtY\_Out1);}\) 
\}

The code generator changed the block execution order so that within the for loop, the Saturation block executes after the Gain block. The generated code contains one local variable \(\text{rtb\_Gain1}\) for holding intermediate results.

In addition to requesting which buffers to reuse, another possible use case is to request buffer reuse for block input and output signals that are complex.

**Using Label-Based Reuse Versus Reusable Custom Storage Classes**

You can also use the same Reusable custom storage class specification on different signal lines to specify which buffers to reuse. As compared to using Reusable custom storage classes, using signal labels to specify reuse has these benefits:

- Signal labels are not observation points in the generated code, so using them does not block other optimizations such as dead code elimination and expression folding.
- The code generator does not force a signal with a label to be a global variable in the generated code. The signal can be a local or global variable.
- Signals with labels can reuse buffers with signals that do not have labels, so reuse among local and global variables is possible.

Using signal labels is a more conservative method of specifying reuse than using Reusable custom storage classes. The code generator does not implement label-based reuse when it can implement reuse by using Reusable custom storage classes in these cases:

- Reuse that can potentially prevent other optimizations from occurring in the generated code.
• Reuse on root inport and outport ports.
• Reuse across model reference or subsystem boundaries.
• Within a subsystem, buffer reuse on an intermediary signal and an input or output port.

Reduce Memory Usage for Signals

The configuration parameter **Signal storage reuse** reduces the memory requirements of your real-time program by enabling parameters that reuse the memory allocated for signals with an auto storage class. These parameters are the following:

- **Enable local block outputs**
- **Reuse local block outputs**
- **Reuse global block outputs**
- **Optimize global data access**

When the **Enable local block outputs** parameter is on, where possible the code generator declares block outputs as local variables instead of global variables. Replacing global variables with local variables improves execution speed and reduces RAM/ROM consumption. Creating more local variables can increase stack usage. Some of the global variables that the code generator can localize include:

- Global signals that cross subsystem boundaries
- Global signals across Simulink and Stateflow domains
- Unused global state variables
- Redundant local Data Store Memory block signals

When the **Reuse local block outputs** parameter is on, wherever possible the code generator reuses local (function) variables for block outputs. When you select **Reuse global block outputs**, the code generator reuses global (function) variables wherever possible.

The **Optimize global data access** parameter has these settings:

- None
- Use global to hold temporary results
- Minimize global data access

When you select None, the code generator uses the default optimizations. The setting **Use global to hold temporary results** maximizes the use of global variables. The setting **Minimize global data access** minimizes the use of global variables by using local variables to hold intermediate values.
Clearing **Signal storage reuse** makes all block outputs global and unique, which often significantly increases RAM and ROM usage.

The code generator does not localize global variables for MATLAB system objects or AUTOSAR.

Remove Initialization Code

The “Remove root level I/O zero initialization” (Simulink Coder) and “Remove internal data zero initialization” (Simulink Coder) parameters control whether the generated code contains initialization code for internal data (block states and block outputs) and external data (root inports and outports) whose value is zero. If your embedded application initializes RAM to zero at startup, you might not need initialization code. Eliminating this code accelerates model initialization, reduces ROM consumption and increases the execution speed of the generated code.

Remove Zero Initialization Code for Internal Data

This example shows how to eliminate code that initializes internal data to zero. If your embedded application does not require generating initialization code for internal data whose value is zero, you can enable this optimization.

Example Model

Open the model rtwdemo_internal_init. The model contains an enabled subsystem whose initial output is zero. The subsystem contains a Unit Delay block whose initial condition is 0.

Generate Code Without Optimization

Build the model using Embedded Coder.

```plaintext
### Starting build procedure for model: rtwdemo_internal_init
### Successful completion of build procedure for model: rtwdemo_internal_init
```
This code is in the `rtwdemo_internal_init.c` file.

/* Model initialize function */
void rtwdemo_internal_init_initialize(void)
{
    /* Registration code */

    /* initialize error status */
    rtmSetErrorStatus(rtM, (NULL));

    /* states (dwork) */
    (void) memset((void *)&rtDWork, 0, sizeof(D_Work));

    /* SystemInitialize for Enabled SubSystem: '<Root>/Enabled Subsystem' */
    /* InitializeConditions for UnitDelay: '<S1>/Unit Delay' */
    rtDWork.UnitDelay_DSTATE = 0.0;

    /* End of SystemInitialize for SubSystem: '<Root>/Enabled Subsystem' */
}

/* Enable Optimization */

Open the Configuration Parameters dialog box. On the Optimization pane, select Remove internal data zero initialization.

Alternatively, you can use the command prompt to enable the optimization. To enable the optimization, set the model parameter ZeroInternalMemoryAtStartup to 'off'.

```
set_param(model, 'ZeroInternalMemoryAtStartup', 'off');
```

**Generate Code with Optimization**

Build the model using Embedded Coder.

```
### Starting build procedure for model: rtwdemo_internal_init
### Successful completion of build procedure for model: rtwdemo_internal_init
```

This code is in the `rtwdemo_internal_init.c` file. The generated code does not initialize internal data by assignment to zero.

/* Model initialize function */
void rtwdemo_internal_init_initialize(void)
{
   /* (no initialization code required) */
}

/*

If you select the **Remove internal data zero initialization** parameter, be aware that memory might not be in a known state each time the generated code executes. This means that running a model (or a generated S-function) multiple times can result in different answers for each run. This behavior is sometimes desirable. For example, you can select the **Remove internal data zero initialization** parameter if you want to test the behavior of your design during a warm boot (that is, a restart without full system reinitialization). For models in which you select the **Remove internal data zero initialization** parameter but still want to get the same answer on every run from an S-function, you can use either of the following commands before each run:

```c
clear SFcnName
```
where `SFcnName` is the name of the S-function, or

```c
clear mex
```

**Remove Initialization Code for Root-Level Inports and Outports Set to Zero**

This example shows how to remove initialization code for root-level inports and outports set to zero. If your embedded application does not require generating initialization code for external data whose value is zero, you can enable this optimization.

**Note:** This example requires an Embedded Coder® license.

**Example Model**

In the model `rtwdemo_rootlevel_zero_initialization`, all of the input and output signals have a numeric value of zero. Because signals `sig1` and `sig2` have data types `int16` and `Boolean`, respectively, and all of the output signals have data type `double`, these signals also have initial values of bitwise zero. The signals have an integer bit pattern of 0, meaning that all bits are off. Signals `sig1_b` and `sig2_b` have a fixed-point data type with bias, so their initial value is not bitwise zero.

```c
model = 'rtwdemo_rootlevel_zero_initialization';
open_system(model);
```
Generate Code

In your system temporary folder, create a temporary folder for the build and inspection process.

currentDir = pwd;
[~,cgDir] = rtwdemodir();

Build the model.

set_param(model, 'ZeroExternalMemoryAtStartup','on');
rtwbuild(model)

### Starting build procedure for model: rtwdemo_rootlevel_zero_initialization
### Successful completion of build procedure for model: rtwdemo_rootlevel_zero_initialization

These lines of rtwdemo_rootlevel_zero_initialization.c code show the initialization of root-level inports and outports without the optimization. The four input signals are individually initialized as global variables. The four output signals are members of a global structure that the memset function initializes to bitwise zero.

cfile = fullfile(cgDir,'rtwdemo_rootlevel_zero_initialization_ert_rtw',...
              'rtwdemo_rootlevel_zero_initialization.c');
rtwdemodbtype(cfile, 'rtwdemo_rootlevel_zero_initialization_initialize',...
              'trailer for generated code', 1, 0);

void rtwdemo_rootlevel_zero_initialization_initialize(void)
{
    /* Registration code */

    /* external inputs */
sig1 = 0;
sig1_b = -3;
sig2 = false;
sig2_b = -3;

/* external outputs */
(void) memset((void *)&rtY, 0,
sizeof(ExternalOutputs));
}

@Enable Optimization

1. Open the Configuration Parameters dialog box.
2. On the Optimization pane, select Remove root level I/O zero initialization.

Alternatively, use the command-line API to enable the optimization:

```matlab
set_param(model, 'ZeroExternalMemoryAtStartup','off');
```

**Generate Code with Optimization**

The optimized code does not contain initialization code for the input signals `sig1`, `sig2`, and the four output signals, because their initial values are bitwise zero.

Build the model.

```bash
rtwbuild(model)
```

### Starting build procedure for model: rtwdemo_rootlevel_zero_initialization
### Successful completion of build procedure for model: rtwdemo_rootlevel_zero_initialization

Here is the `rtwdemo_rootlevel_zero_initialization.c` optimized code in the initialization function.

```c
void rtwdemo_rootlevel_zero_initialization_initialize(void)
{
/* Registration code */
```
/* external inputs */
sig1_b = -3;
sig2_b = -3;
}

Close the model and the code generation report.

bdclose(model)
rtwdemoclean;
cd(currentDir)

**Additional Information**

- You can use the **Use memset to initialize floats and doubles** parameter to control the representation of zero during initialization. See “Use memset to initialize floats and doubles to 0.0” (Simulink Coder).
- The code still initializes data structures whose value is not zero when you select **Remove internal data zero initialization** and **Remove root level I/O zero initialization**.
- The data of *ImportedExtern* or *ImportedExternPointer* storage classes are not initialized, regardless of the settings of the **Remove internal data zero initialization** and **Remove root level I/O zero initialization** parameters.

**See Also**

**Related Examples**

- “Optimization Tools and Techniques” on page 56-7

Simplify Multiply Operations in Array Indexing

The generated code might have multiply operations when indexing an element of an array. You can select the optimization parameter “Simplify array indexing” (Simulink Coder) to replace multiply operations in the array index with a temporary variable. This optimization can improve execution speed by reducing the number of times the multiply operation executes.

Example Model

If you have the following model:

The Constant blocks have the following Constant value:

- Const1: reshape(1:30, [1 5 3 2])
- Const2: reshape(1:20, [1 5 2 2])
- Const3: reshape(1:90, [1 5 9 2])

The Concatenate block parameter Mode is set to Multidimensional array. The Constant blocks Sample time parameter is set to –1.
Generate Code

Building the model with the **Simplify array indexing** parameter turned off generates the following code:

```c
int32_T i;
int32_T i_0;
int32_T i_1;

for (i = 0; i < 2; i++) {
    for (i_1 = 0; i_1 < 3; i_1++) {
        for (i_0 = 0; i_0 < 5; i_0++) {
            ex_arrayindex_Y.Out[(i_0 + 5 * i_1) + 70 * i] =
                ex_arrayindex_P.Constant1_Value[(5 * i_1 + i_0) + 15 * i];
        }
    }
}

for (i = 0; i < 2; i++) {
    for (i_1 = 0; i_1 < 2; i_1++) {
        for (i_0 = 0; i_0 < 5; i_0++) {
            ex_arrayindex_Y.Out[(i_0 + 5 * (i_1 + 3)) + 70 * i] =
                ex_arrayindex_P.Constant2_Value[(5 * i_1 + i_0) + 10 * i];
        }
    }
}

for (i = 0; i < 2; i++) {
    for (i_1 = 0; i_1 < 9; i_1++) {
        for (i_0 = 0; i_0 < 5; i_0++) {
            ex_arrayindex_Y.Out[(i_0 + 5 * (i_1 + 5)) + 70 * i] =
                ex_arrayindex_P.Constant3_Value[(5 * i_1 + i_0) + 45 * i];
        }
    }
}
```

Generate Code with Optimization

Open the Configuration Parameters dialog box and select the **Simplify array indexing** parameter. Build the model again. In the generated code, \([(i_0 + \text{tmp}_1) + \text{tmp}]\) replaces a multiply operation in the array index, \([(i_0 + 5 * i_1) + 70 * i]\). The generated code is now:
int32_T i;
int32_T i_0;
int32_T i_1;
int32_T tmp;
int32_T tmp_0;
int32_T tmp_1;

tmp = 0;
tmp_0 = 0;
for (i = 0; i < 2; i++) {
    tmp_1 = 0;
    for (i_1 = 0; i_1 < 3; i_1++) {
        for (i_0 = 0; i_0 < 5; i_0++) {
            ex_arrayindex_Y.Out[(i_0 + tmp_1) + tmp] =
                ex_arrayindex_P.Constant1_Value[(i_0 + tmp_1) + tmp_0];
        }
        tmp_1 += 5;
    }
    tmp += 70;
    tmp_0 += 15;
}

tmp = 0;
tmp_0 = 0;
for (i = 0; i < 2; i++) {
    tmp_1 = 0;
    for (i_1 = 0; i_1 < 2; i_1++) {
        for (i_0 = 0; i_0 < 5; i_0++) {
            ex_arrayindex_Y.Out[((i_0 + tmp_1) + tmp) + 15] =
                ex_arrayindex_P.Constant2_Value[((i_0 + tmp_1) + tmp) + tmp_0];
        }
        tmp_1 += 5;
    }
    tmp += 70;
    tmp_0 += 10;
}

tmp = 0;
tmp_0 = 0;
for (i = 0; i < 2; i++) {

59-12
tmp_1 = 0;
for (i_1 = 0; i_1 < 9; i_1++) {
    for (i_0 = 0; i_0 < 5; i_0++) {
        ex_arrayindex_Y.Out[((i_0 + tmp_1) + tmp) + 25] =
            ex_arrayindex_P.Constant3_Value[(i_0 + tmp_1) + tmp_0];
    }
    tmp_1 += 5;
}

tmp += 70;
tmp_0 += 45;

Replace boolean with Specific Integer Data Type

Depending on the architecture of the processor that your production hardware uses, you can improve the execution speed of the generated code. Select a specific integer data type for the built-in type boolean. Using data type replacement, in the generated code you can replace the boolean built-in data type with one of these integer types:

- int8
- uint8
- intn

To match the integer word size for the production hardware, replace n with 8, 16, or 32.

Example Model

The model ex_bool contains two blocks that output boolean values and two blocks that take boolean values as inputs. This example shows how to replace the data type boolean with the integer data type int32 in the code generated for a 32-bit hardware target.
Generate Code That Contains the Default boolean Data Type

View the generated file `rtwtypes.h`. The typedef statements contain the generic type definition of `boolean_T`, which is the code generation name for `boolean`.

```c
/*===========================================================================*
* Generic type definitions: boolean_T, char_T, byte_T, int_T, uint_T,       *
*                           real_T, time_T, ulong_T.                        *
*===========================================================================*/
typedef double real_T;
typedef double time_T;
typedef unsigned char boolean_T;
typedef int int_T;
typedef unsigned int uint_T;
typedef unsigned long ulong_T;
```
typedef char char_T;
typedef unsigned char uchar_T;
typedef char_T byte_T;

View the generated file ex_bool.c. The code declares boolean variables by using the type boolean_T.

/* External inputs (root inport signals with auto storage) */
typedef struct {
    real_T In1;                          /* '<Root>/In1' */
    real_T In2;                          /* '<Root>/In2' */
    boolean_T In3;                       /* '<Root>/In3' */
    boolean_T In4;                       /* '<Root>/In4' */
    real_T In5;                          /* '<Root>/In5' */
} ExtU_ex_bool_T;

/* External outputs (root outports fed by signals with auto storage) */
typedef struct {
    boolean_T Out1;                      /* '<Root>/Out1' */
    boolean_T Out2;                      /* '<Root>/Out2' */
    real_T Out3;                         /* '<Root>/Out3' */
} ExtY_ex_bool_T;

**Generate Code That Contains the Target boolean Data Type**

1. Define a Simulink.AliasType object with a base type of int32. Name the object using the replacement name that you want to appear in the generated code.

   ```
   mybool = Simulink.AliasType;
   mybool.BaseType = 'int32';
   ```

2. In the Configuration Parameters dialog box, specify the Replacement Name field for the data type boolean as mybool.
View the generated file `rtwtypes.h`. The code maps the identifier `mybool` to the native integer type of the target hardware by creating `typedef` statements.

```c
/* Generic type definitions ... */
...
typedef int boolean_T;
.../* Define Simulink Coder replacement data types. */
typedef boolean_T mybool; /* User defined replacement datatype for boolean_T */
```

View the generated file `ex_bool.c`. The code declares `boolean` variables that use the type `mybool`.

```c
/* External inputs (root inport signals with auto storage) */
typedef struct {
  real_T In1; /* '<Root>/In1' */
  real_T In2; /* '<Root>/In2' */
  mybool In3; /* '<Root>/In3' */
  mybool In4; /* '<Root>/In4' */
  real_T In5; /* '<Root>/In5' */
} ExtU_ex_bool_T;

/* External outputs (root outports fed by signals with auto storage) */
typedef struct {
  mybool Out1; /* '<Root>/Out1' */
  mybool Out2; /* '<Root>/Out2' */
  real_T Out3; /* '<Root>/Out3' */
} ExtY_ex_bool_T;
```

• “Model Configuration Parameters: Code Generation Data Type Replacement”
Remove Code That Guards Against Division Exceptions for Integers and Fixed-Point Data

Optimize generated code by removing code that protects against division by zero and overflows in division INT_MIN/-1 operations for integers and fixed-point data. If you are sure that these arithmetic exceptions do not occur during program execution, enable this optimization.

This optimization:

• Increases execution speed.
• Reduces ROM consumption.

NOTE: If you enable this optimization, it is possible that simulation results and results from generated code are not in bit-for-bit agreement. This example requires an Embedded Coder® license.

Example Model

In the model rtwdemo_nzcheck, two signals of type int8 feed into a divide block.

```matlab
model = 'rtwdemo_nzcheck';
open_system(model);
```

![Diagram of model rtwdemo_nzcheck](image)

Generate Code

In your system's temporary folder, create a temporary folder for the build and inspection process.
currentDir = pwd;
[~,cgDir] = rtwdemodir();

Build the model.

set_param(model, 'NoFixptDivByZeroProtection', 'off');
rtwbuild(model);

### Starting build procedure for model: rtwdemo_nzcheck
### Successful completion of code generation for model: rtwdemo_nzcheck

View the generated code without the optimization. Here is a portion of rtwdemo_nzcheck.c.

```c
int32_T div_s32(int32_T numerator, int32_T denominator)
{
    int32_T quotient;
    uint32_T tempAbsQuotient;
    if (denominator == 0) {
        quotient = numerator >= 0 ? MAX_int32_T : MIN_int32_T;
    } else {
        tempAbsQuotient = (numerator < 0 ? ~(uint32_T)numerator + 1U : (uint32_T)numerator) / (denominator < 0 ? ~(uint32_T)denominator + 1U : (uint32_T)denominator);
        quotient = (numerator < 0) != (denominator < 0) ? -(int32_T)tempAbsQuotient : (int32_T)tempAbsQuotient;
    }
    return quotient;
}
```

Enable Optimization

1. Open the Configuration Parameters dialog box.
2 On the **Optimization** pane, select **Remove code that protects against division arithmetic exceptions**.

Alternatively, you may use the command-line API to enable the optimization:

```matlab
set_param(model, 'NoFixptDivByZeroProtection', 'on');
```

**Generate Code with Optimization**

The optimized code does not contain code that checks for whether or not the divisor has a value of zero.

Build the model.

```matlab
rtwbuild(model);
```

```bash
### Starting build procedure for model: rtwdemo_nzcheck
### Successful completion of code generation for model: rtwdemo_nzcheck
```

The following is a portion of `rtwdemo_nzcheck.c`. The code that protects against division arithmetic exceptions is not in the generated code.

```c
rtwdemodbtype(cfile,'/* Real-time model','/* Model step function',1, 1);

/* Real-time model */
RT_MODEL_rtwdemo_nzcheck rtwdemo_nzcheck_M_
RT_MODEL_rtwdemo_nzcheck *const rtwdemo_nzcheck_M = &rtwdemo_nzcheck_M_
```

Close the model and code generation report.

```bash
bdclose(model)
rtwdemoclean;
```

```bash
cd(currentDir)
```

• “Division Arithmetic Exceptions in Generated Code” on page 59-23
Division Arithmetic Exceptions in Generated Code

The Remove code that protects against division arithmetic exceptions parameter in the Optimization pane of the Configuration Parameters dialog box controls the generation of code that protects against division arithmetic exceptions in integer and fixed-point operations. Division arithmetic exceptions include division by zero and INT_MIN/-1, which results in a quotient that cannot be represented.

When the parameter is selected, the generated code does not contain code that guards against these types of exceptions. This produces smaller, more efficient code, however it can affect numerical results. Select the parameter if you are sure that your model would not encounter these exceptions to optimize the efficiency of the generated code.

When the parameter is not selected, the generated code does not contain code that guards against division arithmetic exceptions. The added protection code checks that there is a numerical match between simulation and code generation for division operations at a cost of code size and performance.

Division by Zero

Division by zero is undefined and results in a runtime error in the generated code. When the Remove code that protects against division arithmetic exceptions parameter is selected, the code generator does not produce code that protects against division by zero. Select this option only when you are sure that your model will not produce such a division operation.

INT_MIN/-1

When you divide the minimum representable value of a signed integer by negative one, the ideal result is equal to the maximum representable value plus one (INT_MAX + 1), which is not representable. This exception may cause the application to unexpectedly halt or crash at run-time. When the Remove code that protects against division arithmetic exceptions parameter is selected, the code generator does not produce code that protects against this situation. Select this option only when you are sure that your model will not produce such a division operation.

The following illustrates an example of this type of exception:

\begin{verbatim}
    a = int32(-2147483648);
    b = a/-1
\end{verbatim}
The ideal quotient of this operation is 2147483648, but this is not representable in an int32 data type, resulting in an exception at runtime.

**Other Factors Affecting Generated Code of Division Operations**

In addition to the **Remove code that protects against division arithmetic exceptions** parameter, there are several other factors that can affect the appearance of code generated for division operations. The manner in which this parameter controls code generated from blocks containing MATLAB code with integer or fixed-point division operations differs from the built-in Divide block in Simulink. Blocks containing MATLAB code include MATLAB Function blocks and Stateflow charts using MATLAB action language. To balance the efficiency and semantics of fixed-point and integer divisions in these blocks, use fi objects and set the fimath properties to fit your needs. Usage of fi and fimath objects requires a Fixed-Point Designer license.

Rounding and overflow modes also affect the size and efficiency of the generated code. For more information, see “Optimize Generated Code with the Model Advisor” (Fixed-Point Designer).

Optimize Generated Code by Consolidating Redundant If-Else Statements

This example shows how to optimize generated code by combining `if-else` statements that share the same condition. This optimization:

- Improves control flow.
- Reduces code size.
- Reduces RAM consumption.
- Increases execution speed.

Example

The model `rtwdemo_controlflow_opt` contains three Switch blocks. The Constant block provides the control input to the Switch blocks. The variable named `Cond` determines the value of the Constant block.

```plaintext
model = 'rtwdemo_controlflow_opt';
open_system(model);
```
Generate Code

Create a temporary folder for the build and inspection process.

currentDir = pwd;
[~,cgDir] = rtwdemodir();

Build the model.

rtwbuild(model)

### Starting build procedure for model: rtwdemo_controlflow_opt
### Successful completion of build procedure for model: rtwdemo_controlflow_opt

These lines of rtwdemo_controlflow_opt.c code show that in the generated code, two if-else statements and one else-if statement represent the three Switch blocks.
cfile = fullfile(cgDir, 'rtwdemo_controlflow_opt_ert_rtw', ...
    'rtwdemo_controlflow_opt.c');
rtwodemodbtype(cfile, '/* Model step', '/* Model initialize', 1, 0);

/* Model step function */
void rtwdemo_controlflow_opt_step(void)
{
    /* Switch: '<Root>/Switch3' incorporates:
        * Constant: '<Root>/Const'
        * Switch: '<Root>/Switch2'
    */
    if (Cond) {
        /* Switch: '<Root>/Switch1' */
        if (Cond) {
            /* Outport: '<Root>/Out1' incorporates:
                * Inport: '<Root>/In1'
            */
            rtY.Out1 = rtU.In1;
        } else {
            /* Outport: '<Root>/Out1' incorporates:
                * Inport: '<Root>/In2'
            */
            rtY.Out1 = rtU.In2;
        }
    } else if (Cond) {
        /* Switch: '<Root>/Switch2' incorporates:
            * Inport: '<Root>/In1'
            * Outport: '<Root>/Out1'
        */
        rtY.Out1 = rtU.In1;
    } else {
        /* Outport: '<Root>/Out1' incorporates:
            * Inport: '<Root>/In2'
        */
        rtY.Out1 = rtU.In2;
    }

    /* End of Switch: '<Root>/Switch1' */
}

/* End of Switch: '<Root>/Switch3' */
}
Enable Optimization

1. Open the Configuration Parameters dialog box.
2. On the Code generation -> Code Style pane, clear Preserve condition expression in if statement. This parameter is on by default.

Alternatively, use the command-line API to turn off the parameter:

```matlab
set_param(model, 'PreserveIfCondition', 'off');
```

Generate Code with Optimization

In the optimized code, the code generator consolidates the two if-else statements and one else-if statement into one if-else statement. The code generator consolidates these statements because they all share the same condition. There is no intervening code that affects the outcomes of these statements.

Build the model.

```bash
rtwbuild(model)
```

### Starting build procedure for model: rtwdemo_controlflow_opt
### Successful completion of build procedure for model: rtwdemo_controlflow_opt

Here is the `rtwdemo_controlflow_opt.c` optimized code.

```c
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);

/* Model step function */
void rtwdemo_controlflow_opt_step(void)
{
    /* Switch: '<Root>/Switch1' incorporates:
       *  Constant: '<Root>/Const'
       *  Switch: '<Root>/Switch3'
    */
    if (Cond) {
        /* Outport: '<Root>/Out1' incorporates:
           *  Inport: '<Root>/In1'
        */
        rtY.Out1 = rtU.In1;
    } else {
        /* Outport: '<Root>/Out1' incorporates:
           *  Inport: '<Root>/In2'
        */
```
rtY.Out1 = rtU.In2;
}

/* End of Switch: '<Root>/Switch1' */
}

Close the model and clean up.

bdclose(model)
rtwdemoclean;
cd(currentDir)

Optimize Generated Code for Fixed-Point Data Operations

This example shows how the code generator optimizes fixed-point operations by replacing expensive division operations with highly efficient product operations. This optimization improves execution speed.

Example Model

In the model `rtwdemo_fixptdiv`, two fixed point signals connect to a Divide block. The `Number of inputs` parameter has the value `/*`.

```matlab
model='rtwdemo_fixptdiv';
load_system(model);
set_param(model,'HideAutomaticNames','off','SimulationCommand','Update')
open_system(model);
```
Generate Code

Create a temporary folder for the build and inspection process.

```matlab
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```matlab
set_param(model,'GenCodeOnly','on');
rtwbuild(model);
```
### Starting build procedure for model: rtwdemo_fixptdiv
### Successful completion of code generation for model: rtwdemo_fixptdiv

View the generated code. Here is a portion of `rtwdemo_fixptdiv.c`

```c
rtY.Out1 = (int16_T)(rtU.In1 >> 3);
```

The generated code contains a highly efficient right shift operation instead of an expensive division operation. The generated code also contains the precomputed value for the constant input to the Product block.

Note that the resulting operation also includes the adjustment in signal scaling from $2^{-3}$ to $2^{-5}$.

Close the model and code generation report.

```c
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

Optimize Generated Code By Developing and Using Code Replacement Libraries - Simulink®

Develop and use code replacement libraries to replace function and operators in generated code. Code replacement is a technique to change the code that the code generator produces for functions and operators to meet application code requirements. For example, you can replace generated code to meet requirements such as:

- Optimization for a specific run-time environment, including, but not limited to, specific target hardware
- Integration with existing application code
- Compliance with a standard, such as AUTOSAR
- Modification of code behavior, such as enabling or disabling nonfinite or inline support
- Application- or project-specific code requirements, such as use of BLAS or elimination of math.h, system header files, or calls to memcpy or memset.

You can configure a model such that the code generator uses a code replacement library that MathWorks® provides. If you have an Embedded Coder® license, you can develop your own code replacement library interactively with the Code Replacement Tool or programmatically.

This example uses models to show a variety of ways you can define code replacement mappings programmatically. Each model includes buttons that you can use to

- View the code replacement library table definitions from the Code Replacement Viewer
- Open the library table definition file in the editor
- Open the library registration file in the editor
- View the model configuration
- Generate code

For more information, see “Define Code Replacement Mappings” on page 54-43 and “Register Code Replacement Mappings” on page 54-70.

Steps for Developing a Code Replacement Library

1 Identify your code replacement requirements with respect to function or operating mappings, build information, and registration information.
2 Prepare for code replacement library development (for example, identify or develop models to test your library).
3 Define code replacement mappings.
4 Specify build information for replacement code.
5 Register code replacement mappings.
6 Verify code replacements.
7 Deploy the library.

For more information, see “Quick Start Code Replacement Library Development - Simulink®” on page 54-28.

**Math Function Replacement**

This example defines and registers code replacement mappings for math functions. You can define code replacement mappings for a variety of functions (see “Code You Can Replace From Simulink Models” on page 54-7).

Open the model `rtwdemo_crlmath` and use the buttons at the bottom of the model window to explore the files that define and register the code replacement library mappings.

For more information, see “Math Function Code Replacement” on page 54-97.

```matlab
open_system('rtwdemo_crlmath')
```
Set of supported math functions:
floating point versions of
sin, cos, tan, asin, acos, atan, sinh, cosh, tanh,
exp, log, log10, ceil, floor, abs, sqrt, pow/power

Replaced with:
cos_db1, pow_db1 and log10_sgl

Replaced with:
asin_db1 and tanh_db1

Replaced with:
pow_db1

Set of additional supported functions:
memcpy, getNaN, getInf, getMinusInf

Replaced memcpy with memcpy_int

Replaced non-finite support utility functions
getNaN, getInf, getMinusInf
(see rt_InitInfAndNaN)

Addition and Subtraction Operator Replacement

This example shows how to define and register code replacement mappings for addition (+) and subtraction (-) operations. When defining entries for addition and subtraction operations, you can specify which of the following algorithms (EntryInfoAlgorithm) your library functions implement:

- Cast-before-operation (CBO) (RTW_CAST_BEFORE_OP), the default
- Cast-after-operation (CAO) (RTW_CAST_AFTER_OP)

1. Open the model rtwdemo_crladdsub. The model shows how to define and register code replacement mappings for scalar addition subtraction (-) operations on two operands with the following pairings of built-in integer data types:

- int8, uint8
- int16, uint16
- int32, uint32

CBO, the default algorithm, is assumed.

open_system('rtwdemo_crladdsub')
Optimize Generated Code By Developing and Using Code Replacement Libraries - Simulink®

Built-in integer operator replacement for scalar addition and subtraction

Note:
The default 'EntryInfoAlgorithm' setting for addition/ subtraction code replacement library entries is 'RTW_CAST_BEFORE_OP'.
2. Use the buttons at the bottom of the model window to explore the files that define and register the code replacement library mappings.

3. Explore the differences between the CBO and CAO algorithms by opening the model `rtwdemo_crl.cbo.cao`. The model shows two SUM blocks, each demonstrating one of the algorithm settings to match a corresponding code replacement entry.

   - For the `Cast_before_operation_Sub` block, the code generator calculates the subtraction operation in the accumulator data type (`int8`), which is smaller than the input data type (`int16`). This is equivalent to a CBO because the code generator converts the input to the output data type before calculating the result.

   - For the `Cast_after_operation_Sub` block, the code generator calculates the subtraction operation in the accumulator data type (`int32`), which is larger than the input data type (`int16`). This is equivalent to a CAO because the code generator produces the same result by calculating the result without loss of range or precision before converting to the output data type.

```matlab
open_system('rtwdemo_crl.cbo.cao')
```
4. Use the buttons at the bottom of the model window to explore the files that define and register the code replacement library mappings.

For more information on addition and subtraction operator replacement, see “Addition and Subtraction Operator Code Replacement” on page 54-177. For more information on the addition and subtraction algorithm (EntryInfoAlgorithm) options, see setTflCOperationEntryParameters.
**Multiplication and Division Operator Replacement for Built-In Integers**

This example defines and registers code replacement mappings for scalar multiplication (*) and division (/) operations. The operations take two operands with the following pairings of built-in integer data types:

- int8, uint8
- int16, uint16
- int32, uint32

Open the model `rtwdemo_crlmuldiv` and use the buttons at the bottom of the model window to explore the files that define and register the code replacement library mappings.

```matlab
open_system('rtwdemo_crlmuldiv')
```
Scalar Operator Replacement

This example defines and registers code replacement mappings for scalar operations: addition, subtraction, multiplication, complex conjugate, cast, arithmetic shift right, and arithmetic shift left.

Supported types include:

- single, double
- int8, uint8
- int16, uint16
- int32, uint32
- csingle, cdouble
- cint8, cuint8
- cint16, cuint16
- cint32, cuint32
- fixed-point integers
- mixed types (different type on each input)

Open the model `rtwdemo_crlscalarops` and use the buttons at the bottom of the model window to explore the files that define and register the code replacement library mappings.

CBO, the default algorithm for addition and subtraction operations, is assumed.

`open_system('rtwdemo_crlscalarops')`
This example shows how to replace scalar operations with function calls using code replacement libraries.

The supported scalar operations are addition, subtraction, multiplication, complex conjugate, cast, arithmetic shift right and shift left.

NOTE: For replacement of shift right operation of target unsigned integer, an entry for logical shift right must be registered.
Matrix Operator Replacement

This example defines and registers code replacement mappings for matrix operations: addition, subtraction, multiplication, transposition, conjugate, and Hermitian.

Supported types include:

• single, double
• int8, uint8
• int16, uint16
• int32, uint32
• csingle, cdouble
• cint8, cuint8
• cint16, cuint16
• cint32, cuint32
• fixed-point integers
• mixed types (different type on each input)

Open the model `rtwdemo_crlmatops`, which shows some of these replacements. Use the buttons at the bottom of the model window to explore the files that define and register the code replacement library mappings.

For more information on matrix operator replacement, see “Small Matrix Operation to Processor Code Replacement” on page 54-182.

CBO, the default algorithm for addition and subtraction operations, is assumed.

```matlab
open_system('rtwdemo_crlmatops')
```
Optimize Generated Code By Developing and Using Code Replacement Libraries - Simulink®

This example shows how to replace matrix operations with function calls using code replacement libraries.

The supported matrix operations are addition, subtraction, multiplication, division, inverse, transposition, hermitian and complex conjugate.

Generate Code Using Embedded Coder (double-click)

View Interface Configuration (double-click)
**Matrix Multiplication Replacement for BLAS**

This example defines and registers code replacement mappings for Basic Linear Algebra Subroutines (BLAS) subroutines `xGEMM` and `xGEMV`. You can map the following operations to a BLAS subroutine:

- Matrix multiplication
- Matrix multiplication with transpose on single or both inputs
- Matrix multiplication with Hermitian operation on single or both inputs

Open the model `rtwdemo_crlblas` and use the buttons at the bottom of the model window to explore the files that define and register the code replacement library mappings.

For more information on matrix multiplication replacement for BLAS, see “Matrix Multiplication Operation to MathWorks BLAS Code Replacement” on page 54-186.

```
open_system('rtwdemo_crlblas')
```
This example replaces floating point matrix multiplication with either MathWorks BLAS library calls or with ANSI/ISO C BLAS library calls. Double-click the 'Current CRL' button to switch between the BLAS and ANSI/ISO C BLAS code replacement libraries.

Although BLAS supports matrix/matrix multiplication in the form of \( C = a \times \text{op}(A) \times \text{op}(B) + bC \), code replacement only supports the limited case of \( C = \text{op}(A) \times \text{op}(B) \) (\( a = 1.0 \), \( b = 0.0 \)). Likewise, although BLAS supports matrix/vector multiplication in the form of \( y = a \times \text{op}(A)x + by \), code replacement only supports the limited case of \( y = \text{op}(A)x \) (\( a = 1.0 \), \( b = 0.0 \)).

\[
\text{Here, op}(X) = X \text{ (no Transpose), XT} \text{ (Transpose), } XH \text{ (Conjugate Transpose)}
\]

The BLAS library used by this example is supported on Windows and UNIX platforms.

The C BLAS example does not include BLAS implementations and therefore does not create an executable.
**Fixed-Point Operator Replacement for Basic Operators**

This example defines and registers code replacement mappings for scalar addition (+), subtraction (-), multiplication (*), and division (/) operations. The operations take two operands with fixed-point data types.

You can define code replacements as matching:

- Slope/bias scaling combination on the inputs and output
- Binary-point scaling combination on the inputs and output
- Relative scaling between the inputs and output
- Same slope value and a zero net bias across the inputs and output.

Open the model `rtwdemo_crlfixpt` and use the buttons at the bottom of the model window to explore the files that define and register the code replacement library mappings.

- By default, for addition and subtraction operator code replacements, the code generator assumes that replacement code implements a cast-before-operation (CBO) algorithm.
- Using fixed-point data types in a model requires a Fixed-Point Designer™ license.

For more information about fixed-point operator code replacement, see “Fixed-Point Operator Code Replacement” on page 54-204.

```matlab
open_system('rtwdemo_crlfixpt')
```

**Match and Replacement Process Customization for Functions**

This example defines and registers code replacement mappings for custom entries. You can create your own entry by subclassing from `RTW.TflCFunctionEntryML` or `RTW.TflCOperationEntryML`. Your entry class must implement a `do_match` method that customizes your matching logic or modifies the matched entry. The `do_match` method must have a fixed preset signature.

Open the model `rtwdemo_crlcustomentry`. The model shows how to modify the matched entry by injecting constants as additional implementation function arguments. DTC1, Trigonometric Function, and Product show custom entry code replacement for:

- Cast operation that demonstrates how to extract the fraction lengths from types and pass them into the implementation function - `Out1 = custom_cast(In1, 2, 4)`.
- Sine that demonstrates how to pass a constant value to the implementation function - `Out2 = custom_sin(In2, 1)`.
- Multiplication operation that demonstrates how to compute the net slope of an operation and pass that into the implementation function - `Out3 = custom_multiply_shift_right(In3, In4, 3)`.

Use the buttons at the bottom of the model window to explore the files that define and register the code replacement mappings.

For more information on custom entries, see “Customize Match and Replacement Process” on page 54-159.

`open_system('rtwdemo_crlcustomentry')`
Custom entry replacement for cast operation demonstrates how to extract the fraction-lengths from types and pass them into the implementation function.

\[ \text{Out1} = \text{custom\_cast(In1, 2, 4)} \]

Custom entry replacement for sine demonstrates how to pass a constant value to the implementation function.

\[ \text{Out2} = \text{custom\_sin(In2, 1)} \]

Custom entry replacement for the multiplication operation demonstrates how to compute the net slope of an operation and pass that into the implementation function.

\[ \text{Out3} = \text{custom\_multiply\_shift\_right(In3, In4, 3)}; \]

MATLAB Function Replacement

This example defines and registers code replacement mappings for MATLAB® functions specified in the MATLAB Function block. The function can be opted for replacement by specifying `coder.replace` within it. This feature supports replacement of MATLAB® functions with the following:

- Single or multiple inputs
- Single or multiple outputs
- Scalar and matrix inputs and outputs

Open the model `rtwdemo_crlcoderreplace`. The model shows some of these requirements. Supported types include:

- `single`, `double`
- `int8`, `uint8`
- `int16`, `uint16`
- `int32`, `uint32`
- `csingle`, `cdouble`
- `cint8`, `cuint8`
- `cint16`, `cuint16`
- `cint32`, `cuint32`
- Fixed-point integers
- Mixed types (different type on each input)

Use the buttons at the bottom of the model window to explore the files that define and register the code replacement mappings.

For more information on MATLAB® function replacement, see `coder.replace`.

`open_system('rtwdemo_crlcoderreplace')`
Data Alignment for Function Implementations

This example shows how to specify the alignment of matrix operands passed into a replacement function. Some target-specific function implementations require data to be aligned to optimize application performance. To configure data alignment for a function implementation:

- Specify the data alignment requirements in a table entry. You can specify alignment for implementation function arguments individually or collectively.
• Specify the data alignment capabilities and syntax for your compiler. Attach an AlignmentSpecification object to the TargetCharacteristics object of the registry entry specified in your rtwTargetInfo.m file.

Open the model rtwdemo_crlalign. The model shows three data alignment code replacement scenarios:

• **Add** - Alignment of exported and imported signals. You can specify an exact value for the alignment in the Signal Properties dialog box or allow the code generator to determine the best alignment based on usage by leaving the alignment value set to -1.

• **Product** - Alignment of virtual and nonvirtual bus types. You can specify an exact value for the alignment for the Alignment property of the Simulink.Bus object or allow the code generator to determine the best alignment based on usage by leaving the Alignment property set to -1.

• **EML.MMUL** - Alignment of local variables, global variables, and block parameters.

Use the buttons at the bottom of the model window to explore the files that define and register the code replacement mappings. Note that the model is configured to use a GCC, Clang, MSVC, or MinGW compiler.

For more information on specifying data alignment for code replacement, see “Data Alignment for Code Replacement” on page 54-136.

```matlab
open_system('rtwdemo_crlalign')
```
Code replacement supports alignment of exported and imported signals. You can specify either an exact value for the alignment in the signal properties dialog box or you can allow the code generator to determine the best alignment based on usage by leaving the alignment value set to -1.

Alignment of imported signals must be specified to allow use of that signal in a replaced function requiring alignment.

Code replacement supports alignment of virtual and non-virtual bus types. You can specify either an exact value for the alignment in the Alignment property of the Simulink.Bus object or you can allow the code generator to determine the best alignment based on usage by leaving the alignment property set to -1.

Code replacement supports alignment of local and global variables as well as block parameters.

This example shows how to specify the alignment of matrix operands using code replacement libraries. Alignment requirements are specified on the entry's arguments. The compiler's alignment syntax is specified on the registry in the sl_customization.m or the rtwTargetInfo.m file.

Note:
Select "Data Alignment Examples for Non-MinGW" CRL for GCC, Clang, and MSVC.
Select "Data Alignment Examples for MinGW" CRL for MinGW.
**Performance Gain from Data Alignment**

This example shows how code replacement data alignment can accelerate execution of a generated executable by enabling deployment of SIMD operations in generated code.

1. Open model `rtwdemo_crlalignperf`. This model illustrates a basic image processing algorithm, represented by subsystem `Root/Filtering/Process/ALGORITHM`. The algorithm slides a 5x5 template across the image one pixel at a time. The image area covered by the template forms another 5x5 matrix. This matrix is element-wise multiplied by the template matrix. The twenty-five elements in the resultant matrix are summed together to form the new value for that pixel. This element-wise matrix multiplication is performed for all pixels in an image, so its efficiency has a significant impact on the overall algorithm performance.

```matlab
perf = 'rtwdemo_crlalignperf';
open_system(perf)

cc = rtwprivate('getCompilerForModel',perf);
isDaDemoSupported = strcmpi(cc.comp.Manufacturer,'GNU') || ...
    strcmpi(cc.comp.Manufacturer,'Apple') || ...
    strcmpi(cc.comp.Manufacturer,'Microsoft');
if ~isDaDemoSupported
    recMsg = ['Use "mex -setup" to select either GCC, Clang,'...
        'MSVC, or MinGW and restart this example'];
    warning(['The model "%s" is configured to use GCC, Clang,'...
        'MSVC, or MinGW to create a Data Aligned Executable. %s.'],...
    perf,recMsg); %#ok<CTPCT>
end
```
This example shows how the code replacement data alignment capability can accelerate the execution of the generated program by enabling the deployment of SIMD operations in generated code.

This model example illustrates a basic image processing algorithm, represented by subsystem <Root/Filtering/Process/ALGORITHM>. The algorithm slides a 5x5 template across the image one pixel at a time. The image area covered by the template forms another 5x5 matrix. This matrix is element-wise multiplied by the template matrix. The twenty-five elements in the resultant matrix are summed together to form the new value for that pixel. This element-wise matrix multiply is performed for all of the pixels in an image, so its efficiency has a significant impact on the overall algorithm performance.

In this example, the model is compiled twice. First, the model is compiled to generate portable, ANSI-C code without data alignment. Next, the model is compiled using a SIMD CRL that does the element-wise matrix multiply using SIMD instructions. The data that the SIMD instructions operate on need to be aligned on a 16-byte boundary.

Double-click the blue button below to execute the example. For both compilations, the generated code is profiled by a profiling hook. After the compilations complete, a figure is displayed that compares the execution time of the subsystem <Root/Filtering/Process/ALGORITHM> with and without data alignment.

For details about how a profile hook works, please refer to example: rtwdemo_profile.

Note:
Select “SIMD Single 5x5 Element-wise Mul for Non-MinGW” CRL for GCC, Clang, and MSVC.
Select “SIMD Single 5x5 Element-wise Mul for MinGW” CRL for MinGW.
2. Use the buttons at the bottom of the model window to explore the files that define and register the code replacement mappings.

3. Execute the example by double-clicking **Start the Example**. Note that the model is configured to use a GCC, Clang, MSVC, or MinGW compiler. This example compiles the model twice. The first compilation produces portable, ANSI-C code without data alignment. The second compilation uses a SIMD code replacement library that does the element-wise matrix multiply using SIMD instructions. The data on which the SIMD instructions operate needs to be aligned on a 16-byte boundary. For both compilations, the generated code is profiled by a profiling hook. After the compilations complete, a figure appears to show a comparison of the execution time of the subsystem Root/Filtering/Process/ALGORITHM with and without data alignment.

4. Generate a baseline by selecting the ANSI® library, building the model, and then running the generated executable ten times. This model uses an element-wise matrix multiplication operation as part of an image processing algorithm. The matrix multiplication is executed numerous times as each pixel in the image is processed. Profiling hooks time the execution of the executable.

```matlab
if (isDaDemoSupported)
    % Create a temporary folder (in your system's temporary folder) for the
    % build and inspection process.
    currentDir = pwd;
    [~,cgDir] = rtwdemodir();

    set_param(perf, 'CodeReplacementLibrary','None'...
             , 'TargetLangStandard','C89/C90 (ANSI)');
    rtwbuild(perf);
    iterations = 10;
    T1 = zeros(iterations, 1);
    for idx = 1:iterations
        evalc(['!', fullfile('.', perf)]);
        evalc(['load ', fullfile('.', 'rtwdemo_crlalignperf.mat')]));
        T1(idx) = rt_yout.signals(1).values;
    end
    if exist('rtwdemo_crlalignperf_ANSI', 'dir')
        rmdir('rtwdemo_crlalignperf_ANSI', 's');
    end
    movefile('rtwdemo_crlalignperf_ert_rtw', 'rtwdemo_crlalignperf_ANSI');
else
    warning('Unable to build model "%s". %s.', perf,recMsg);
end
```
### Starting build procedure for model: rtwdemo_crlalignperf
### Successful completion of build procedure for model: rtwdemo_crlalignperf

5. Generate an optimized, data-aligned executable by selecting a library that maps element-wise matrix multiplication operations to SIMD intrinsic calls, and then building the model. The SIMD intrinsic calls impose an alignment requirement on data passed to the intrinsic. The optimized executable is run ten times. Profiling hooks again capture timing data.

```matlab
if (isDaDemoSupported)
    crl=getCorrectCrlForSelectedCompiler(perf);
    set_param(perf,'CodeReplacementLibrary',crl);
    rtwbuild(perf);
    T2 = zeros(iterations, 1);
    for idx=1:iterations
        evalc(['!', fullfile('.', perf)]);
        evalc(['load ', fullfile('.','rtwdemo_crlalignperf.mat')]);
        T2(idx) = rt_yout.signals(1).values;
    end
    if exist('rtwdemo_crlalignperf_SIMD', 'dir')
        rmdir('rtwdemo_crlalignperf_SIMD','s');
    end
    movefile('rtwdemo_crlalignperf_ert_rtw', 'rtwdemo_crlalignperf_SIMD');
else
    warning(...
        'The Data Aligned Executable for the model "%s" could not be generated. %s.'...
        ,perf,recMsg);
end
```

### Starting build procedure for model: rtwdemo_crlalignperf
### Successful completion of build procedure for model: rtwdemo_crlalignperf

6. Compare timing results of the baseline and data-aligned executables. The timing data captured from running the baseline and data-aligned executables is displayed in a graph. The graph illustrates that using SIMD operations with data alignment can effectively speed up execution of data-parallel operations.

```matlab
if (isDaDemoSupported)
    T1(T1<0) = NaN;    % The profile counter may overflow.
    T2(T2<0) = NaN;
    t = [min(T1), min(T2)];
    h = figure;
    bar([NaN, t(1), NaN, t(2), NaN]);
```

59-59
set(gca, 'XLim',[0.5, 5.5], 'XTickLabel',... 
{
'ANSI Multiply', '', 'SIMD Multiply', ''}, ... 
'TickLength', [0 0], 'YLim', [0, max(t) * 1.3], 'YTick', []);

ylabel('Execution Time (CPU Cycles)');

% annotate the plot
annotation('textbox', get(gca, 'Position'), ... 
'String', ['Execution Speed Increased By: ',... 
num2str((1 - t(2)/t(1))*100, '%2.0f'), '%'], ... 
'LineStyle', 'none', 'FitBoxToText', 'off',... 
'FitHeightToText', 'on', ... 
'FontWeight', 'bold', 'FontSize', 12, ...

% annotate first bar (simple multiply without alignment)

% annotate second bar (SIMD Multiply without alignment)

text('Position', [2, t(1)], 'String', int2str(t(1)),... 
'FontSize', 12, 'HorizontalAlignment', 'center',... 
'VerticalAlignment', 'bottom');

else
    warning(['The Data Alignment Performance Gain example'... 
        ' could not be executed. %s.'], recMsg);
end
**Code Replacement Library Exploration and Verification**

This example shows Code Replacement Viewer. You can use the Code Replacement Viewer to:

- Explore which code replacement library to use
- Verify the list of tables in a library and the entries in each table
- Review table entry specifications
- Troubleshoot code replacement misses

The following commands open the Code Replacement Viewer for code replacement table `crl_tablemuldiv`:

![Bar chart showing execution speed comparison between ANSI Multiply and SIMD Multiply](image)

Execution Time (CPU Cycles)

ANSI Multiply: 33135375
SIMD Multiply: 23678185

Execution Speed Increased By: 29%
crl = crl_table_muldiv;
crviewer(crl);
daRoot = DAStudio.Root;
me = daRoot.find('-isa', 'DAStudio.Explorer');

For more information on the Code Replacement Viewer, see “Verify Code Replacements” on page 54-79.

**Build Information**

For each entry in a code replacement table, you can specify build information such as the following, for replacements functions:

- Header file dependencies
- Source file dependencies
- Additional include paths
- Additional source paths
- Additional link flags

Additionally, you can specify `RTW.copyFileToBuildDir` to copy header, source, or object files, which are required to generate replacement code, to the build folder before code generation. You can specify `RTW.copyFileToBuildDir` by setting it as the value of:

- Property `GenCallback` in a call to `setTflCFunctionEntryParameters`, `setTflCOperationEntryParameters`, or `setTflCSemaphoreEntryParameters`.
- Argument `genCallback` in a call to `registerCFunctionEntry`, `registerCOperationEntry`, or `registerCSemaphoreEntry`.

**Note:** Models in this example are configured for code generation only because the implementations for the replacement functions are not provided.

For more information on specifying build information, see “Specify Build Information for Replacement Code” on page 54-61.

**Reserved Identifiers**

Each function implementation name defined by a code replacement table entry is reserved as a unique identifier. You can specify other identifiers with a table on a per-header-file basis. Providing additional reserved identifiers can help prevent duplicate symbols and other identifier related compile and link issues.
For more information on specifying reserved identifiers, see “Reserved Identifiers and Code Replacement” on page 54-157.

**Remove Example Code Replacement Libraries**

When you finish using the example models, remove the example code replacement libraries and close the example models with these commands:

```matlab
rmpath(fullfile(matlabroot,'toolbox','rtw','rtwdemos','crl_demo'));
sl_refresh_customizations;

close_system('rtwdemo_crladdsub', 0)
close_system('rtwdemo_crl.cbo.ca0', 0)

Improve Execution Efficiency by Reordering Block Operations in the Generated Code

To improve execution efficiency, the code generator can change the block execution order. In the Configuration Parameters dialog box, when you set the **Optimize Block Order** parameter to **Improved Execution Speed**, the code generator can change the block operation order to implement these optimizations:

- Eliminate data copies for blocks that perform inplace operations (that is, use the same input and output variable) and contain algorithm code with unnecessary data copies.
- Combine more for loops by executing blocks together that have the same size.
- Reuse the same variable for the input, output, and state of a Unit Delay block by executing the Unit Delay block before upstream blocks.

These optimizations improve execution speed and conserve RAM and ROM consumption.

**Example Model**

Open the model matlab:rtwdemo_optimizeblockorder. This model contains three subsystems for demonstrating how reordering block operations improves execution efficiency.
for Loop Fusion

The subsystem `LoopFusionScheduling` shows how the code generator reorders block operations so that blocks that have the same output size execute together. This
reordering enables for loop fusion. Set the **Optimize block order in the generated code** parameter to **Off**.

In your system's temporary folder, create a folder for the build and inspection process and build the model.

### Starting build procedure for model: rtwdemo_optimizeblockorder
### Successful completion of build procedure for model: rtwdemo_optimizeblockorder

View the generated code without the optimization. Code for the **LoopFusionScheduling** subsystem:

```c
/* Output and update for atomic system: '<Root>/LoopFusionScheduling' */
static void LoopFusionScheduling(const real_T rtu_In1[6], const real_T rtu_In2[6],
                                const real_T rtu_In3[6], const real_T rtu_In4[6],
                                real_T rty_Out1[6], real_T rty_Out2[9],
                                real_T rty_Out3[6], real_T rty_Out4[9])
{
    int32_T i;
    int32_T i_0;
    int32_T tmp;
    int32_T tmp_0;

    /* Bias: '<S2>/Bias' incorporates:
       * Gain: '<S2>/Gain'
    */
    for (i = 0; i < 6; i++) {
        rty_Out1[i] = -0.3 * rtu_In1[i] + 0.5;
    }

    /* End of Bias: '<S2>/Bias' */

    /* Product: '<S2>/Product' */
    for (i = 0; i < 3; i++) {
        for (i_0 = 0; i_0 < 3; i_0++) {
            tmp = i_0 + 3 * i;
            rty_Out2[tmp] = 0.0;
            tmp_0 = 3 * i + i_0;
            rty_Out2[tmp] = rty_Out2[tmp_0] + rtu_In2[i << 1] * rtu_In1[i_0];
            rty_Out2[tmp] = rtu_In2[(i << 1) + 1] * rtu_In1[i_0 + 3] + rty_Out2[tmp_0];
        }
    }

    /* End of Product: '<S2>/Product' */
```
/* Bias: '<S2>/Bias1' incorporates:
 *  Gain: '<S2>/Gain1'
 */
for (i = 0; i < 6; i++) {
    rty_Out3[i] = -0.3 * rtu_In3[i] + 0.5;
}

/* End of Bias: '<S2>/Bias1' */

/* Product: '<S2>/Product1' */
for (i = 0; i < 3; i++) {
    for (i_0 = 0; i_0 < 3; i_0++) {
        tmp = i_0 + 3 * i;
        rty_Out4[tmp] = 0.0;
        tmp_0 = 3 * i + i_0;
        rty_Out4[tmp] = rty_Out4[tmp_0] + rtu_In4[i << 1] * rtu_In3[i_0];
        rty_Out4[tmp] = rtu_In4[(i << 1) + 1] * rtu_In3[i_0 + 3] + rty_Out4[tmp_0];
    }
}

/* End of Product: '<S2>/Product1' */

With the default execution order, the blocks execute from left to right and from top to bottom. As a result, there are separate for loops for the two combinations of Gain and Bias blocks and the Product blocks.

Generate code with the optimization. Set the **Optimize block order in the generated code** parameter to **Improved Execution Speed** and build the model.

```makefile
### Starting build procedure for model: rtwdemo_optimizeblockorder
### Successful completion of build procedure for model: rtwdemo_optimizeblockorder
```

View the generated code with the optimization.

```c
/* Output and update for atomic system: '<Root>/LoopFusionScheduling' */
static void LoopFusionScheduling(const real_T rtu_In1[6], const real_T rtu_In2[6],
                                 const real_T rtu_In3[6], const real_T rtu_In4[6], real_T rty_Out1[6], real_T rty_Out2[9], real_T rty_Out3[6], real_T rty_Out4[9])
{
    int32_T i;
    int32_T i_0;
    int32_T tmp;
```
int32_T tmp_0;
for (i = 0; i < 3; i++) {
    for (i_0 = 0; i_0 < 3; i_0++) {
        /* Product: '<S2>/Product' incorporates:
         *  Product: '<S2>/Product1'
         */
        tmp = i_0 + 3 * i;
        rty_Out2[tmp] = 0.0;
        /* Product: '<S2>/Product1' */
        rty_Out4[tmp] = 0.0;
        /* Product: '<S2>/Product' incorporates:
         *  Product: '<S2>/Product1'
         */
        tmp_0 = 3 * i + i_0;
        rty_Out2[tmp] = rty_Out2[tmp_0] + rtu_In2[i << 1] * rtu_In1[i_0];
        /* Product: '<S2>/Product1' */
        rty_Out4[tmp] = rty_Out4[tmp_0] + rtu_In4[i << 1] * rtu_In3[i_0];
        /* Product: '<S2>/Product' */
        rty_Out2[tmp] = rtu_In2[(i << 1) + 1] * rtu_In1[i_0 + 3] + rty_Out2[tmp_0];
        /* Product: '<S2>/Product1' */
        rty_Out4[tmp] = rtu_In4[(i << 1) + 1] * rtu_In3[i_0 + 3] + rty_Out4[tmp_0];
    }
}
for (i = 0; i < 6; i++) {
    /* Bias: '<S2>/Bias' incorporates:
     *  Gain: '<S2>/Gain'
     */
    rty_Out1[i] = -0.3 * rtu_In1[i] + 0.5;
    /* Bias: '<S2>/Bias1' incorporates:
     *  Gain: '<S2>/Gain1'
     */
    rty_Out3[i] = -0.3 * rtu_In3[i] + 0.5;
}

In the optimized code, blocks with the same output size execute together. The two sets of Gain and Bias blocks have an output dimension size of 6, so they execute together. The
Product blocks have an output dimension size of 9, so they execute together. The fusion of for loops enables the code generator to set the value of the expression $3 \times i + i_0$ equal to the temporary variable tmp_0. This optimization also improves execution efficiency.

### Buffer Reuse for the Input, Output, and State of Unit Delay Blocks

The subsystem RegionScheduling shows how the code generator reorders block operations to enable buffer reuse for the input, output, and state of Unit Delay blocks. When computation is part of separate regions that connect only through Delay blocks, the code generator can change the block execution order so that the downstream regions execute before the upstream regions. This execution order enables maximum reuse of Delay block states and input and output variables. Set the Optimize block order in the generated code parameter to Off and build the model.

```plaintext
### Starting build procedure for model: rtwdemo_optimizeblockorder
### Successful completion of build procedure for model: rtwdemo_optimizeblockorder
```

View the generated code without the optimization. Code for the RegionScheduling subsystem:

```c
/* Output and update for atomic system: '<Root>/RegionScheduling' */
static void RegionScheduling(const real_T rtu_In1[6], const real_T rtu_In2[6],
  real_T rty_Out1[6], rtDW_RegionScheduling *localDW)
{
    int32_T i;
    real_T rtb_Sum;
    for (i = 0; i < 6; i++) {
      /* Sum: '<S3>/Sum' incorporates:
       *  UnitDelay: '<S3>/Delay'
       *  UnitDelay: '<S3>/UnitDelay'
       */
      rtb_Sum = localDW->Delay_DSTATE[i] + localDW->UnitDelay_DSTATE[i];

      /* UnitDelay: '<S3>/UnitDelay2' */
      rty_Out1[i] = localDW->UnitDelay2_DSTATE[i];

      /* Update for UnitDelay: '<S3>/UnitDelay' incorporates:
       *  Bias: '<S3>/Bias'
       */
      localDW->Delay_DSTATE[i] = rtu_In1[i] + 3.0;

      /* Update for UnitDelay: '<S3>/UnitDelay' incorporates:
       */
    }
}
```

59-70
With the default execution order, the generated code contains the extra, temporary variable `rtb_Sum` and a data copy.

Generate code with the optimization. Set the **Optimize block order in the generated code** parameter to **Improved Execution Speed** and build the model.

```c
/* Output and update for atomic system: '<Root>/RegionScheduling' */
static void RegionScheduling(const real_T rtu_In1[6], const real_T rtu_In2[6],
                              real_T rty_Out1[6], rtDW_RegionScheduling *localDW)
{
    int32_T i;
    for (i = 0; i < 6; i++) {
        /* UnitDelay: '<S3>/UnitDelay2' */
        rty_Out1[i] = localDW->UnitDelay2_DSTATE[i];

        /* Update for UnitDelay: '<S3>/UnitDelay2' incorporates:
         *  Sum: '<S3>/Sum'
         *  UnitDelay: '<S3>/Delay'
         *  UnitDelay: '<S3>/UnitDelay'
         */
        localDW->UnitDelay2_DSTATE[i] = localDW->Delay_DSTATE[i] +
                                         localDW->UnitDelay_DSTATE[i];

        /* Update for UnitDelay: '<S3>/Delay' incorporates:
         *  Bias: '<S3>/Bias'
         */
        localDW->Delay_DSTATE[i] = rtu_In1[i] + 3.0;

        /* Update for UnitDelay: '<S3>/UnitDelay' incorporates:
         *  Gain: '<S3>/Gain'
         */
        localDW->UnitDelay_DSTATE[i] = 2.0 * rtu_In2[i];
    }
}
```
In the optimized code, the blocks in Regions 3, 2, and 1 execute in that order. With that execution order, the generated code does not contain the temporary variable `rtb_Sum` and the corresponding data copy.

**Eliminate Data Copies for Blocks That Perform Inplace Operations**

The subsystem `InplaceScheduling` shows how the code generator reorders block operations to eliminate data copies for blocks that perform inplace operations. In the Configuration Parameters dialog box, set the **Optimize block order in the generated code** parameter to Off and build the model.

```plaintext
### Starting build procedure for model: rtwdemo_optimizeblockorder
### Successful completion of build procedure for model: rtwdemo_optimizeblockorder

View the generated code without the optimization. Code for the `InplaceScheduling` subsystem:

```c
static void InplaceScheduling(const real_T rtu_In1[6], real_T rtu_In3, const real_T rtu_In2[6], real_T rty_Out2[6], real_T rty_Out1[6], rtDW_InplaceScheduling *localDW)
{
    int32_T idx1;
    int32_T idx2;
    real_T acc;
    int32_T k;
    real_T rtb_Max[6];
    for (idx1 = 0; idx1 < 6; idx1++) {
        /* Sum: '<S1>/Sum2x3' incorporates:
         *  UnitDelay: '<S1>/Unit Delay'
         */
        localDW->UnitDelay_DSTATE[idx1] += rtu_In1[idx1];
        /* MinMax: '<S1>/Max'
         */
        if (2.0 > localDW->UnitDelay_DSTATE[idx1]) {
            rtb_Max[idx1] = 2.0;
        } else {
            rtb_Max[idx1] = localDW->UnitDelay_DSTATE[idx1];
        }
    }
}
```
With the default execution order, the Max block executes before the Product block. To hold the Sum block output, the generated code contains two variables, UnitDelay_DSTATE and rtb_Max.
Generate code with the optimization. Set the **Optimize block order in the generated code** parameter to **Improved Execution Speed** and build the model.

```text
### Starting build procedure for model: rtwdemo_optimizeblockorder
### Successful completion of build procedure for model: rtwdemo_optimizeblockorder
```

View the generated code with the optimization.

```c
/* Output and update for atomic system: '<Root>/InplaceScheduling' */
static void InplaceScheduling(const real_T rtu_In1[6], real_T rtu_In3, const
   real_T rtu_In2[6], real_T rty_Out2[6], real_T rty_Out1[6],
   rtDW_InplaceScheduling *localDW)
{
   int32_T idx1;
   int32_T idx2;
   real_T acc;
   int32_T k;
   for (idx1 = 0; idx1 < 6; idx1++) {
      /* Sum: '<S1>/Sum2x3' incorporates:
         * UnitDelay: '<S1>/Unit Delay'
      */
      localDW->UnitDelay_DSTATE[idx1] += rtu_In1[idx1];

      /* Product: '<S1>/Product' incorporates:
         * Bias: '<S1>/Bias'
      */
      rty_Out2[idx1] = (rtu_In3 + 1.0) * localDW->UnitDelay_DSTATE[idx1];

      /* MinMax: '<S1>/Max' */
      if (2.0 > localDW->UnitDelay_DSTATE[idx1]) {
         localDW->UnitDelay_DSTATE[idx1] = 2.0;
      }

      /* End of MinMax: '<S1>/Max' */
   }

/* S-Function (sdsp2norm2): '<S1>/Normalization' */
idx1 = 0;
idx2 = 0;
acc = 0.0;
for (k = 0; k < 6; k++) {
   acc += localDW->UnitDelay_DSTATE[idx1] * localDW->UnitDelay_DSTATE[idx1];
   idx1++;
}
```

59-74
acc = 1.0 / (sqrt(acc) + 1.0E-10);
for (k = 0; k < 6; k++) {
    rty_Out1[idx2] = localDW->UnitDelay_DSTATE[idx2] * acc;
    idx2++;
}

/* End of S-Function (sdsp2norm2): '<S1>/Normalization' */

/* Update for UnitDelay: '<S1>/Unit Delay' */
for (idx1 = 0; idx1 < 6; idx1++) {
    /* Switch: '<S1>/Switch' */
    if (rtu_In2[idx1] > 0.0) {
        localDW->UnitDelay_DSTATE[idx1] = 0.0;
    }
    /* End of Switch: '<S1>/Switch' */
}

/* End of Update for UnitDelay: '<S1>/Unit Delay' */

The optimized code does not contain the variable rtb_Max or the data copy. The generated code contains one variable, UnitDelay_DSTATE, for holding the Sum block output. The Product block reads from UnitDelay_DSTATE and the Max block reads from and writes to UnitDelay_DSTATE.

To implement buffer reuse, the code generator does not violate user-specified block priorities.

Optimize Generated Code Using Minimum and Maximum Values

To optimize the generated code for your model, you can choose an option to use input range information, also known as design minimum and maximum, that you specify on signals and parameters. These minimum and maximum values usually represent environmental limits, such as temperature, or mechanical and electrical limits, such as output ranges of sensors.

In the Configuration Parameters dialog box, on the Optimization tab, when you select the Optimize using specified minimum and maximum values check box, the software uses the minimum and maximum values to derive range information for downstream signals in the model. It then uses this derived range information to determine if it is possible to streamline the generated code by:

- Reducing expressions to constants
- Removing dead branches of conditional statements
- Eliminating unnecessary mathematical operations

This optimization results in:

- Reduced ROM and RAM consumption
- Improved execution speed

Configure Your Model

To make optimization more likely:

- Provide as much design minimum and maximum information as possible. Specify minimum and maximum values for signals and parameters in the model for:
  - Inport and Outport blocks
  - Block outputs
  - Block inputs, for example, for the MATLAB Function and Stateflow Chart blocks
  - Simulink.Signal objects
- Before generating code, test the minimum and maximum values for signals and parameters. Otherwise, optimization might result in numerical mismatch with
simulation. You can simulate your model with simulation range checking enabled. If errors or warnings occur, fix these issues before generating code.

**Enable Simulation Range Checking**

1. In your model, select **Simulation > Model Configuration Parameters** to open the Configuration Parameters dialog box.
2. In the Configuration Parameters dialog box, select **Diagnostics > Data Validity**.
3. On the **Data Validity** pane, under **Signals**, set **Simulation range checking** to **warning** or **error**.

- Provide design minimum and maximum information upstream of blocks as close to the inputs of the blocks as possible. If you specify minimum and maximum values for a block output, these values are most likely to affect the outputs of the blocks immediately downstream.

**Optimize Generated Code Using Specified Minimum and Maximum Values**

This example shows how the minimum and maximum values specified on signals and parameters in a model are used to optimize the generated code.

**Overview**

The specified minimum and maximum values usually represent environmental limits, such as temperature, or mechanical and electrical limits, such as output ranges of sensors.

This optimization uses these values to streamline the generated code. For example, it reduces expressions to constants or removes dead branches of conditional statements.

**NOTE:** Make sure the minimum and maximum values that you specify are valid limits. Otherwise, this optimization might result in numerical mismatch with simulation.

The benefits of optimizing the generated code are:

- Reducing the ROM and RAM consumption.
- Improving the execution speed.

**Review Minimum and Maximum Information**

Consider the model `rtwdemo_minmax`. In this model, there are minimum and maximum values specified on Inports and on the gain parameter of the Gain block.
model = 'rtwdemo_minmax';
open_system(model);

Generate Code Without This Optimization

First, generate code for this model without considering the min and max values.

currentDir = pwd;
[~,cgDir] = rtwdemodir();
rtwconfiguredemo(model,'ERT')
rtwbuild(model)
### Starting build procedure for model: rtwdemo_minmax
### Successful completion of build procedure for model: rtwdemo_minmax

A portion of `rtwdemo_minmax.c` is listed below.

```c
int32_T tmp;
/* Sum: '<Root>/Sum' incorporates:
   * Inport: '<Root>/U1'
   * Inport: '<Root>/U2'
   * Sum: '<Root>/Sum2'
   * Switch: '<Root>/Switch'
*/
tmp = U1 + U2;

/* Switch: '<Root>/Switch' incorporates:
   * Gain: '<Root>/Gain'
   * Inport: '<Root>/U3'
   * RelationalOperator: '<Root>/Relational Operator'
   * Sum: '<Root>/Sum'
*/
if (tmp <= k * U3) {
    /* Outport: '<Root>/Out1' incorporates:
       * Sum: '<Root>/Sum2'
    */
    rtY.Out1 = tmp + U3;
} else {
    /* Outport: '<Root>/Out1' incorporates:
       * Inport: '<Root>/U1'
       * Inport: '<Root>/U2'
       * Product: '<Root>/Product'
    */
    rtY.Out1 = U1 * U2 * U3;
}
```

Optimize Generated Code Using Minimum and Maximum Values
Enable This Optimization

1. Open the Configuration Parameters dialog box.
2. On the Optimization pane, select Optimize using the specified minimum and maximum values.

Alternatively, you can enable this optimization by setting the command-line parameter.

```matlab
set_param(model, 'UseSpecifiedMinMax', 'on');
```

Generate Code With This Optimization

In the model, with the specified minimum and maximum values for U1 and U2, the sum of U1 and U2 has a minimum value of 50. Considering the range of U3 and the specified minimum and maximum values for the Gain block parameter, the maximum value of the Gain block's output is 40.

The output of the Relational Operator block remains false, and the output of the Switch block remains the product of the three inputs.

Configure and build the model using Embedded Coder.

```matlab
rtwconfiguredemo(model,'ERT')
rtwbuild(model)
```

```text
### Starting build procedure for model: rtwdemo_minmax
### Successful completion of build procedure for model: rtwdemo_minmax
```

View the optimized code from rtwdemo_minmax.c.

```matlab
cfile = fullfile(cgDir,'rtwdemo_minmax_ert_rtw','rtwdemo_minmax.c');
rtwdemodbttype(cfile,'/* Model step', '/* Model initialize', 1, 0);
```

```c
/* Model step function */
void rtwdemo_minmax_step(void)
{
    /* Outport: '<Root>/Out1' incorporates:
       * Inport: '<Root>/U1'
       * Inport: '<Root>/U2'
       * Inport: '<Root>/U3'
       * Product: '<Root>/Product'
       * Switch: '<Root>/Switch'
    */
```
rtY.Out1 = U1 * U2 * U3;
}

Close the model and cleanup.

bdclose(model)
rtwdemoclean;
cd(currentDir)

**Limitations**

- This optimization does not take into account minimum and maximum values for:

  - Merge block inputs. To work around this issue, use a Simulink.Signal object on the Merge block output and specify the range on this object.
  - Bus elements.
  - Conditionally-executed subsystem (such as a triggered subsystem) block outputs that are directly connected to an Outport block.

  Outport blocks in conditionally-executed subsystems can have an initial value specified for use only when the system is not triggered. In this case, the optimization cannot use the range of the block output because the range might not cover the initial value of the block.

  - If you use Polyspace software to verify code generated using this optimization, it might mark code that was previously green as orange. For example, if your model contains a division where the range of the denominator does not include zero, the generated code does not include protection against division by zero. Polyspace might mark this code orange because it does not have information about the minimum and maximum values for the inputs to the division.

Polyspace Code Prover automatically captures some minimum and maximum values specified in the MATLAB workspace, for example, for Simulink.Signal and Simulink.Parameter objects. In this example, to provide range information to the Polyspace software, use a Simulink.Signal object on the input of the division and specify a range that does not include zero.

Polyspace Code Prover stores these values in a Data Range Specification (DRS) file. However, they do not capture all minimum and maximum values in your Simulink model. To provide additional minimum and maximum information to Polyspace, you can manually define a DRS file.
• If you are using double-precision data types and the Code Generation > Interface > Support non-finite numbers configuration parameter is selected, this optimization does not occur.

• If your model contains multiple instances of a reusable subsystem and each instance uses input signals with different minimum and maximum values, this optimization might result in different generated code for each subsystem so code reuse does not occur. Without this optimization, code is generated once for the subsystem and shares this code among the multiple instances of the subsystem.

• The Model Advisor DO-178C/DO-331 check Check safety-related optimization settings generates a warning if this option is selected. For many safety-critical applications, removing dead code automatically is unacceptable because doing so might make code untraceable. For more information about using the check to comply with DO-178C/DO-331, see Check safety-related optimization settings (Simulink Check).

Flat Structures for Reusable Subsystem Parameters

This example shows how to increase the efficiency of code generated for reusable subsystems by generating a single flat parameter structure instead of a hierarchy of nested parameter structures.

By default, the code generated for reusable subsystems contains a single flat parameter data structure. You can generate code for reusable subsystems that contains separate structures to define the parameters that each subsystem uses. If you use nested reusable subsystems, the generated code creates a hierarchy of nested parameter structures. Hierarchies of structures can reduce code efficiency due to compiler padding between word boundaries in memory.

This optimization is for only ERT-based targets. You must set the configuration parameter Default parameter behavior to Inlined.

Explore Example Model

Open the example model rtwdemo_paramstruct.

```matlab
model = 'rtwdemo_paramstruct';
open_system(model);
```

The model contains two nested reusable subsystems. Each subsystem uses two of the parameters A, B, C, and D that are defined in the base workspace.

Generate Code with Hierarchical Parameter Structures

Create a temporary folder to contain the model build files. Generate code for the model using the default hierarchical data structure for reusable subsystems.

```matlab
currentDir = pwd;
[~,cgDir] = rtwdemodir();
rtwbuild(model)
```

### Starting build procedure for model: rtwdemo_paramstruct
### Successful completion of build procedure for model: rtwdemo_paramstruct

In the code generation report, view the parameter structure definitions in the file rtwdemo_paramstruct.h.

```matlab
cfile = fullfile(cgDir,'rtwdemo_paramstruct_ert_rtw','rtwdemo_paramstruct.h');
rtwdemodbtype(cfile,'/* Parameters for system: ''<S1>/SubsysZ'',...
 ' /* Parameters (default storage)' , 1, 0);
```
The code defines a parameter structure for each reusable subsystem and nests the structures.

**Enable Optimization**

Open the Configuration Parameters dialog box. On the Optimization pane, select Nonhierarchical in the Parameter structure drop-down list.

Alternatively, enable the optimization at the command prompt.

```matlab
set_param(model, 'InlinedParameterPlacement', 'NonHierarchical');
```

**Generate Code with Flat Parameter Structure**

Generate code for the model using a flat parameter structure for reusable subsystems.

```matlab
rtwbuild(model)
```
### Starting build procedure for model: rtwdemo_paramstruct
### Successful completion of build procedure for model: rtwdemo_paramstruct

In the code generation report, view the parameter structure definition in the file `rtwdemo_paramstruct.h`.

```c
rtwdemodbtype(cfile,'/* Parameters (default storage) */','
   /* Real-time Model Data Structure */', 1, 0);

/* Parameters (default storage) */
struct P_ {
    uint16_T A;                          /* Variable: A
     * Referenced by: '<S1>/Gain1'
    */
    uint16_T B;                          /* Variable: B
     * Referenced by: '<S1>/Gain2'
    */
    uint16_T C;                          /* Variable: C
     * Referenced by: '<S2>/Gain3'
    */
    uint16_T D;                          /* Variable: D
     * Referenced by: '<S2>/Gain4'
    */
};

/* Parameters (default storage) */
typedef struct P_ P;
```

The code stores all of the parameters for the reusable subsystems in a single flat structure.

Close the model and delete build files.

```c
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

Reduce Global Variables in Nonreusable Subsystem Functions

Global variables can increase memory requirements and reduce execution speed. To reduce global RAM for a nonreusable subsystem, you can generate a function interface that passes data through arguments instead of global variables. The Subsystem block parameter “Function interface” (Simulink) provides this option. To compare the outputs for the Function interface options, first generate a function for a subsystem with a void-void interface, and then generate a function with arguments.

Generate void-void Function

By default, when you configure a Subsystem block as a nonreusable function, it generates a void-void interface.

1 Open the example model rtwdemo_roll.
2 Right-click the subsystem RollAngleReference. From the list select Block Parameter (Subsystem).
3 In the Block Parameters dialog box, confirm that the Treat as atomic unit check box is selected.
4 Click the Code Generation tab and set the Function packaging parameter to Nonreusable function.
5 The Function interface parameter is already set to void_void.
6 Click Apply and OK.
7 Repeat steps 2-6, for the other subsystems HeadingMode and BasicRollMode.
8 Generate code and the static code metrics report for rtwdemo_roll. This model is configured to generate a code generation report and to open the report automatically. For more information, see “Generate Static Code Metrics Report for Simulink Model” on page 38-37.

In the code generation report, in rtwdemo_roll.c, the generated code for subsystem RollAngleReference contains a void-void function definition:
void rtwdemo_roll_RollAngleReference(void)
{
    ...
}

In the static code metrics report, navigate to **Global Variables**. With the `void_void` option, the number of bytes for global variables is 55.

### 2. Global Variables [hide]

Global variables defined in the generated code.

<table>
<thead>
<tr>
<th>Global Variable</th>
<th>Size (bytes)</th>
<th>Reads / Writes</th>
<th>Reads / Writes in a Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>rtwdemo_roll_U</td>
<td>26</td>
<td>14</td>
<td>6</td>
</tr>
<tr>
<td>rtwdemo_roll_DW</td>
<td>9</td>
<td>17</td>
<td>14</td>
</tr>
<tr>
<td>rtwdemo_roll_B</td>
<td>8</td>
<td>17</td>
<td>10</td>
</tr>
<tr>
<td>rtwdemo_roll_M</td>
<td>8</td>
<td>0*</td>
<td>0*</td>
</tr>
<tr>
<td>rtwdemo_roll_Y</td>
<td>4</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td><strong>Total</strong></td>
<td>55</td>
<td>49</td>
<td></td>
</tr>
</tbody>
</table>

* The global variable is not directly used in any function.

Next, generate the same function with the `Allow arguments` option to compare the results.

**Generate Function with Arguments**

To reduce global RAM, improve ROM usage and execution speed, generate a function that allows arguments:

1. Open the Subsystem Block Parameter dialog box for `RollAngleReference`.
2. Click the **Code Generation** tab. Set the **Function interface** parameter to `Allow arguments`.
3. Click **Apply** and **OK**.
4. Repeat steps 2 and 3, for the other subsystems `HeadingMode` and `BasicRollMode`.
5. Generate code and the static code metrics report for `rtwdemo_roll`.
In the code generation report, in `rtwdemo_roll.c`, the generated code for subsystem `RollAngleReference` now has arguments:

```c
real32_T rtwdemo_roll_RollAngleReference(real32_T rtu_Phi, ...
    boolean_T rtu_AP_Eng, ...
    real32_T rtu_Turn_Knob)
{
...
}
```

In the static code metrics report, navigate to Global Variables. With the Allow arguments option set, the total number of bytes for global variables is now 47 bytes.

## 2. Global Variables

Optimize Generated Code By Packing Boolean Data Into Bitfields

This example shows how to optimize the generated code by packing Boolean data into bitfields. When you select the model configuration parameter **Pack Boolean data into bitfields**, Embedded Coder® packs the Boolean signals into 1-bit bitfields, reducing RAM consumption. By default, the optimization is enabled. This optimization reduces the RAM consumption. Be aware that this optimization can potentially increase code size and execution speed.

**Example Model**

Consider the model rtwdemo_pack_boolean.

```matlab
model = 'rtwdemo_pack_boolean';
open_system(model);
```

**Disable Optimization**

1. Open the Configuration Parameters dialog box.
2 On the **Optimization > Signals and Parameters** pane, clear **Pack Boolean data into bitfields**.

Alternatively, you can use the command-line API to disable the optimization:

```matlab
set_param(model,'BooleansAsBitfields','off');
```

Create a temporary folder (in your system temporary folder) for the build and inspection process.

```matlab
currentDir = pwd;
 [~,cgDir] = rtwdemodir();
```

### Generate Code Without Optimization

Build the model using Embedded Coder®.

```matlab
rtwbuild(model)
```

View the generated code without the optimization. These lines of code are in `rtwdemo_pack_boolean.h`.

```matlab
hfile = fullfile(cgDir,'rtwdemo_pack_boolean_ert_rtw','rtwdemo_pack_boolean.h');
rtwdemodbtype(hfile,'/* Block signals and states','/* External inputs',1,0);
```

```c
/* Block signals and states (default storage) for system '<Root>' */
typedef struct {
    boolean_T LogicalOp1;    /* '<Root>/Logical Op1' */
    boolean_T LogicalOp2;    /* '<Root>/Logical Op2' */
    boolean_T LogicalOp5;    /* '<Root>/Logical Op5' */
    boolean_T LogicalOp3;    /* '<Root>/Logical Op3' */
    boolean_T LogicalOp4;    /* '<Root>/Logical Op4' */
    boolean_T RelationalOperator; /* '<Root>/Relational Operator' */
    boolean_T UnitDelay_DSTATE; /* '<Root>/Unit Delay' */
} DW;
```

### Enable Optimization

1 Open the Configuration Parameters dialog box.

2 On the **Optimization > Signals and Parameters** pane, select **Pack Boolean data into bitfields**.
Alternatively, you can use the command-line API to enable the optimization:

```
set_param(model,'BooleansAsBitfields','on');
```

**Generate Code with Optimization**

Build the model using Embedded Coder®.

```
rtwbuild(model)
```

### Starting build procedure for model: rtwdemo_pack_boolean
### Successful completion of build procedure for model: rtwdemo_pack_boolean

View the generated code with the optimization. These lines of code are in `rtwdemo_pack_boolean.h`.

```
hfile = fullfile(cgDir,'rtwdemo_pack_boolean_ert_rtw','rtwdemo_pack_boolean.h');
rtwdemodbttype(hfile,'/* Block signals and states','/* External inputs',1,0);
```

```
/* Block signals and states (default storage) for system '<Root>' */
typedef struct {
    struct {
        uint_T LogicalOp1:1;       /* '<Root>/Logical Op1' */
        uint_T LogicalOp2:1;       /* '<Root>/Logical Op2' */
        uint_T LogicalOp5:1;       /* '<Root>/Logical Op5' */
        uint_T LogicalOp3:1;       /* '<Root>/Logical Op3' */
        uint_T LogicalOp4:1;       /* '<Root>/Logical Op4' */
        uint_T RelationalOperator:1;  /* '<Root>/Relational Operator' */
        uint_T UnitDelay_DSTATE:1;  /* '<Root>/Unit Delay' */
    } bitsForTID0;
} DW;
```

Selecting **Pack Boolean data into bitfields** enables model configuration parameter **Bitfield declarator type specifier**. To optimize your code further, select `uchar_t`. However, the optimization benefit of the **Bitfield declarator type specifier** setting depends on your choice of target.

Close the model and code generation report.
bdclose(model)
rtwdemoclean;
cd(currentDir)

Optimize Generated Code By Passing Reusable Subsystem Outputs as Individual Arguments

This example shows how passing reusable subsystem outputs as individual arguments instead of as a pointer to a structure stored in global memory optimizes the generated code. This optimization conserves RAM consumption and increases code execution speed by reducing global memory usage and eliminating data copies from local variables back to global block I/O structures.

Example Model

Consider the model rtwdemo_reusable_sys_outputs. In this model, the reusable subsystem outputs feed the root outputs of the model.

```matlab
model = 'rtwdemo_reusable_sys_outputs';
open_system(model);
```

Generate Code Without This Optimization

Generate code for this model while passing subsystem outputs as a structure reference. Create a temporary folder for the build and inspection process.

```matlab
currentDir = pwd;
[~, cgDir] = rtwdemodir();
```
Build the model.

rtwbuild(model)

### Starting build procedure for model: rtwdemo_reusable_sys_outputs
### Successful completion of build procedure for model: rtwdemo_reusable_sys_outputs

The code snippet shows portions of `rtwdemo_reusable_sys_outputs.c`. Notice the global block I/O structure and in the model step function a data copy from this structure.

cfile = fullfile(cgDir,'rtwdemo_reusable_sys_outputs_ert_rtw',...
            'rtwdemo_reusable_sys_outputs.c');
rtwdemodbtype(cfile,'/* Output and update for atomic system',...
            '/* Model initialize', 1, 0);

/* Output and update for atomic system: '<Root>/ReusableSubsystem' */
static void ReusableSubsystem(real_T rtu_In1, real_T rtu_In2, real_T rtu_In3,
                             DW_ReusableSubsystem *localDW)
{
    /* Gain: '<S1>/Gain' */
    localDW->Gain = 5.0 * rtu_In1;

    /* Gain: '<S1>/Gain1' */
    localDW->Gain1 = 6.0 * rtu_In2;

    /* Gain: '<S1>/Gain2' */
    localDW->Gain2 = 7.0 * rtu_In3;
}

/* Model step function */
void rtwdemo_reusable_sys_outputs_step(void)
{
    /* Outputs for Atomic SubSystem: '<Root>/ReusableSubsystem' */

    /* Inport: '<Root>/In1' incorporates:
        * Inport: '<Root>/In2'
        * Inport: '<Root>/In3'
    */
    ReusableSubsystem(rtU.In1, rtU.In2, rtU.In3, &rtDW.ReusableSubsystem_d);

    /* End of Outputs for SubSystem: '<Root>/ReusableSubsystem' */

    /* Outport: '<Root>/Out1' */
    rtY.Out1 = rtDW.ReusableSubsystem_d.Gain;
Enable This Optimization

1. Open the Configuration Parameters dialog box.
2. On the Optimization pane, set Pass reusable subsystem outputs as to Individual arguments.

Alternatively, you can use the command-line API to enable the optimization:

```plaintext
set_param(model, 'PassReuseOutputArgsAs', 'Individual arguments');
```

Generate Code With This Optimization

With this optimization, the ReusableSubsystem function has three output arguments, which are direct references to the external outputs. The rtDW global structure no longer exists, and the data copies from this structure to the rtY (external outputs) structure are not in the generated code.

Build the model.

```plaintext
rtwbuild(model)
```

### Starting build procedure for model: rtwdemo_reusable_sys_outputs
### Successful completion of build procedure for model: rtwdemo_reusable_sys_outputs

The code snippet below is a portion of rtwdemo_reusable_sys_outputs.c. Observe the optimized code.

```plaintext
rtwdemodbtype(cfile,'/* Output and update for atomic system','...'
'/* Model initialize', 1, 0);

/* Output and update for atomic system: '<Root>/ReusableSubsystem' */
static void ReusableSubsystem(real_T rtu_In1, real_T rtu_In2, real_T rtu_In3,
   real_T *rty_Out1, real_T *rty_Out2, real_T *rty_Out3)
{
   /* Gain: '<S1>/Gain' */
```
*rty_Out1 = 5.0 * rtu_In1;
/* Gain: '<S1>/Gain1' */
*rty_Out2 = 6.0 * rtu_In2;
/* Gain: '<S1>/Gain2' */
*rty_Out3 = 7.0 * rtu_In3;
}

/* Model step function */
void rtwdemo_reusable_sys_outputs_step(void)
{
/* Outputs for Atomic SubSystem: '<Root>/ReusableSubsytem' */

/* Inport: '<Root>/In1' incorporates:
 * Inport: '<Root>/In2'
 * Inport: '<Root>/In3'
 * Outport: '<Root>/Out1'
 * Outport: '<Root>/Out2'
 * Outport: '<Root>/Out3'
 */
ReusableSubsystem(rtU.In1, rtU.In2, rtU.In3, &rtY.Out1, &rtY.Out2, &rtY.Out3);

/* End of Outputs for SubSystem: '<Root>/ReusableSubsytem' */
}

Close the model and cleanup.
bdclose(model)
rtwdemoclean;
cd(currentDir)

Convert Data Copies to Pointer Assignments

The code generator optimizes generated code for vector signal assignments by trying to replace for loop controlled element assignments and memcpy function calls with pointer assignments. Pointer assignments avoid expensive data copies. Therefore, they use less stack space and offer faster execution speed than for loop controlled element assignments and memcpy function calls. If you assign large data sets to vector signals, this optimization can result in significant improvements to code efficiency.

Configure Model to Optimize Generated Code for Vector Signal Assignments

To apply this optimization:

1. Verify that your target supports the memcpy function.
2. Determine whether your model uses vector signal assignments (such as Y=expression) to move large amounts of data. For example, your model could use a Selector block to select input elements from a vector, matrix, or multidimension signal.
3. On the Optimization pane, the Use memcpy for vector assignment parameter, which is on by default, enables the associated Memcpy threshold (bytes) parameter.
4. Examine the setting of Memcpy threshold (bytes). By default, it specifies 64 bytes as the minimum array size for which memcpy function calls or pointer assignments can replace for loops in the generated code. Based on the array sizes in your application's vector signal assignments, and target environment considerations on the threshold selection, accept the default value or specify another array size.

Example Model

Consider the following model named rtwdemo_pointer_conversion. This model uses a Switch block to assign data to a vector signal. This signal then feeds into a Bus Selector block.
Generate Code without Optimization

1. In the Configuration Parameters dialog box, clear the **Use memcpy for vector assignment** parameter.
2. Create a temporary folder for the build and inspection process.
3. Press **Ctrl+B** to generate code.

```plaintext
### Starting build procedure for model: rtwdemo_pointer_conversion
### Successful completion of build procedure for model: rtwdemo_pointer_conversion

View the generated code without the optimization. Here is a portion of `rtwdemo_pointer_conversion.c`.

```c
/* Model step function */
void rtwdemo_pointer_conversion_step(void)
{
  int16_T rtb_dataX[100];
  int16_T rtb_dataY[100];
  int32_T i;

  /* Switch: '<Root>/Switch' incorporates:
   * Constant: '<Root>/Constant'
   * Constant: '<Root>/Constant1'
   * Constant: '<Root>/Constant2'
   * Constant: '<Root>/Constant3'
```
* Inport: '<Root>/In1'
*/
for (i = 0; i < 100; i++) {
    if (rtU.In1) {
        rtb_dataX[i] = rtCP_Constant_Value[i];
        rtb_dataY[i] = rtCP_Constant1_Value[i];
    } else {
        rtb_dataX[i] = rtCP_Constant2_Value[i];
        rtb_dataY[i] = rtCP_Constant3_Value[i];
    }
}

/* End of Switch: '<Root>/Switch' */

/* S-Function (sfix_look1_dyn): '<Root>/Lookup Table Dynamic' incorporates:
* Inport: '<Root>/In2'
* Outport: '<Root>/Out1'
*/
/* Dynamic Look-Up Table Block: '<Root>/Lookup Table Dynamic'
* Input0 Data Type: Integer        S16
* Input1 Data Type: Integer        S16
* Input2 Data Type: Integer        S16
* Output0 Data Type: Integer        S16
* Lookup Method: Linear_Endpoint
* */
LookUp_S16_S16( &(rtY.Out1), &rtb_dataY[0], rtU.In2, &rtb_dataX[0], 99U);
}

Without the optimization, the generated code contains for loop controlled element assignments.

**Enable Optimization and Generate Code**

1. In the Configuration Parameter dialog box, select the Use memcpy for vector assignment parameter.
2. Generate code.

```bash
### Starting build procedure for model: rtwdemo_pointer_conversion
### Successful completion of build procedure for model: rtwdemo_pointer_conversion
```

View the generated code without the optimization. Here is a portion of rtwdemo_pointer_conversion.c.
/* Model step function */
void rtwdemo_pointer_conversion_step(void)
{
    const int16_T *rtb_dataX_0;
    const int16_T *rtb_dataY_0;

    /* Switch: '<Root>/Switch' incorporates:
    * Inport: '<Root>/In1'
    */
    if (rtU.In1) {
        /* Switch: '<Root>/Switch' incorporates:
        * Constant: '<Root>/Constant'
        * Constant: '<Root>/Constant1'
        */
        rtb_dataX_0 = &rtCP_Constant_Value[0];
        rtb_dataY_0 = &rtCP_Constant1_Value[0];
    } else {
        /* Switch: '<Root>/Switch' incorporates:
        * Constant: '<Root>/Constant2'
        * Constant: '<Root>/Constant3'
        */
        rtb_dataX_0 = &rtCP_Constant2_Value[0];
        rtb_dataY_0 = &rtCP_Constant3_Value[0];
    }

Because the setting of the **Memcpy threshold (bytes)** parameter is below the array sizes in the generated code, the optimized code contains pointer assignments for the vector signal assignments.

Reuse Buffers of Different Sizes and Dimensions

You can reuse buffers for matrices that have different sizes and shapes. In the Configuration Parameters dialog box, you enable this optimization by selecting **Reuse buffers of different sizes and dimensions**. This optimization conserves RAM and ROM usage and improves code execution speed.

**Example Model**

The model `rtwdemo_differentsizereuse` contains signals of different sizes and dimensions.

```matlab
model='rtwdemo_differentsizereuse';
open_system(model);
```

Generate Code Without Optimization

In the Configuration Parameters dialog box, set **Reuse buffers of different sizes and dimension** parameter to off or in the MATLAB Command Window, enter:

```matlab
set_param('rtwdemo_differentsizereuse','DifferentSizesBufferReuse','off');
```

Create a folder for the build and inspection process.

```matlab
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Turn off comments and build the model.

```matlab
set_param('rtwdemo_differentsizereuse','GenerateComments','off');
rtwbuild('rtwdemo_differentsizereuse');
```

View the generated code without the optimization. The `D_Work` structure is:
The portion of `rtwdemo_differentsizereuse.c` is:

```c
#include "rtwdemo_differentsizereuse.h"
D_Work rtDWork;

            rty_z[x + 63 * y] = fabs(rtu_u[63 * y + x] - rtu_u[(y + 1) * 63 + x]);
        }
    }
}

static void NoninplaceableSS3(void)
{
    DeltaY(rtDWork.z_j, rtDWork.z_i);
    DeltaY(rtDWork.z_m, rtDWork.z);
}
void rtwdemo_differentsizereuse_step(void)
{
    int32_T i;
    for (i = 0; i < 16384; i++) {
        rtDWork.ComplextoRealImag_o1[i] = rtU.ComplexData[i].re;
        rtDWork.ComplextoRealImag_o2[i] = rtU.ComplexData[i].im;
    }

    NoninplaceableSS1();
    NoninplaceableSS2();
    NoninplaceableSS3();
    for (i = 0; i < 3969; i++) {
        rtY.Out1[i].re = rtDWork.z_i[i];
        rtY.Out1[i].im = rtDWork.z[i];
    }
}

The D_work structure contains eight global variables for holding the inputs and outputs of Downsample, DeltaX, and DeltaY. These variables have different sizes.

**Generate Code with Optimization**

1. In the Configuration Parameters dialog box, verify that Signal storage reuse is selected.

2. Set the Reuse buffers of different sizes and dimensions parameter to on or in the MATLAB Command Window, enter:

   ```
   set_param('rtwdemo_differentsizereuse','DifferentSizesBufferReuse','on');
   ```

Build the model.

```set_param('rtwdemo_differentsizereuse','GenerateComments','off');rtwbuild(model);
```  

### Starting build procedure for model: rtwdemo_differentsizereuse

### Successful completion of build procedure for model: rtwdemo_differentsizereuse

        for (y = 0; y < 63; y++) {
            rty_z[x + 63 * y] = fabs(rtu_u[63 * y + x] - rtu_u[(y + 1) * 63 + x]);
        }
    }
}

static void NoninplaceableSS3(void)
{
    DeltaY(&rtDWork.z_e[0], &rtDWork.z_i[0]);
    DeltaY(&rtDWork.z[0], &rtDWork.z_e[0]);
}

void rtwdemo_differentsizereuse_step(void)
{
    int32_T i;
    for (i = 0; i < 16384; i++) {

rtDWork.z_i[i] = rtU.ComplexData[i].re;
rtDWork.z_e[i] = rtU.ComplexData[i].im;
}

NoninplaceableSS1();
NoninplaceableSS2();
NoninplaceableSS3();
for (i = 0; i < 3969; i++) {
    rtY.Out1[i].re = rtDWork.z_i[i];
    rtY.Out1[i].im = rtDWork.z_e[i];
}
}

The D_work structure now contains three global variables instead of eight global variables for holding the inputs and outputs of Downsample, DeltaX, and DeltaY. The generated code uses these variables to hold the differently-sized inputs and outputs.

Close the model and code generation report.

bdclose(model)
rtwdemoclean;
cd(currentDir)

**Limitations**

- If you use a Reusable custom storage class to specify reuse on signals that have different sizes and shapes, you must select the *Reuse buffers of different sizes and dimensions* parameter. Otherwise, the model does not build.
- The code generator does not replace a buffer with a lower priority buffer that has a smaller size.
- The code generator does not reuse buffers that have different sizes and symbolic dimensions.

**See Also**

“Reuse buffers of different sizes and dimensions” (Simulink Coder)

Remove Reset and Disable Functions from the Generated Code

<table>
<thead>
<tr>
<th>In this section...</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Example Model” on page 60-37</td>
</tr>
<tr>
<td>“Generate Code” on page 60-38</td>
</tr>
<tr>
<td>“Enable Optimization” on page 60-39</td>
</tr>
</tbody>
</table>

This example shows how the code generator removes unreachable (dead code) instances of the reset and disable functions from the generated code for ERT-based systems that include model referencing hierarchies. Optimizing the generated code to remove unreachable code is a requirement for safety-critical systems. This optimization also improves execution speed and reduces ROM consumption.

If a model contains blocks with states, the generated code contains reset and disable functions. If the model is not part of a conditionally executed system, such as an enabled subsystem, the code generator can remove the disable function because the generated code does not call it. If the model is not part of a conditionally executed system that can reset states when a control input enables it, the code generator can remove the reset function because the generated code does not call it.

**Example Model**

A referenced model, `rtwdemo_optionalDisableResetFunc_bot`, is in `rtwdemo_optionalDisableResetFunc_top`. The referenced model contains two blocks with states, a Delay block and a Discrete-Time Integrator block.
Generate Code

1 Open the models. In the Command Window, type `rtwdemo_optionalDisableResetFunc_bot` and `rtwdemo_optionalDisableResetFunc_top`.
2 In your system temporary folder, create a temporary folder for the build and inspection process.
3 Build the model.
4 Open the `rtwdemo_optionalDisableResetFunc_top.c` and `rtwdemo_optionalDisableResetFunc_bot.c` files.
The `rtwdemo_optionalDisableResetFunc_bot.c` file contains these reset and disable functions.

```c
/* System reset for referenced model: 'rtwdemo_optionalDisableResetFunc_bot' */
void rtwdemo_optionalDisableResetFunc_bot_Reset(DW_rtwdemo_optionalDisableResetFunc_bot_f_T *localDW)
{
    /* InitializeConditions for Delay: '<Root>/Delay' */
    localDW->Delay_DSTATE = 0.0;

    /* InitializeConditions for DiscreteIntegrator: '<Root>/Discrete-Time Integrator' */
    localDW->DiscreteTimeIntegrator_DSTATE = 3.0;
}

/* Disable for referenced model: 'rtwdemo_optionalDisableResetFunc_bot' */
void rtwdemo_optionalDisableResetFunc_bot_Disable(real_T *rty_Out1, DW_rtwdemo_optionalDisableResetFunc_bot_f_T *localDW)
{
    /* Disable for DiscreteIntegrator: '<Root>/Discrete-Time Integrator' */
    localDW->DiscreteTimeIntegrator_DSTATE = *rty_Out1;
}
```

The `rtwdemo_optionalDisableResetFunc_bot.c` file contains these reset and disable functions.

The `rtwdemo_optionalDisableResetFunc_top_step` function does not call the `rtwdemo_optionalDisableResetFunc_bot_Disable` function because the model is not part of a conditionally executed system. The `rtwdemo_optionalDisableResetFunc_top_step` function does not call the `rtwdemo_optionalDisableResetFunc_bot_Reset` function because the model is not part of a conditionally executed system that can reset states when a control input enables it.

**Enable Optimization**

1. Open the Model Configuration Parameters dialog box for `rtwdemo_optionalDisableResetFunc_bot`.
2. Select **Remove Disable Function** and **Remove Reset Function**.

Open the `rtwdemo_optionalDisableResetFunc_bot.c` file. The code does not contain the `rtwdemo_optionalDisableResetFunc_bot_Reset` function or the `rtwdemo_optionalDisableResetFunc_bot_Disable` function.

Code Execution Profiling in Embedded Coder

- “Code Execution Profiling with SIL and PIL” on page 61-2
- “View and Compare Code Execution Times” on page 61-7
- “Analyze Code Execution Data” on page 61-16
- “Tips and Limitations” on page 61-19
You can configure a software-in-the-loop (SIL) or processor-in-the-loop (PIL) on page 67-2 simulation to produce execution-time metrics for tasks and functions in your generated code. The software calculates execution times from data that is obtained through code instrumentation added to the SIL or PIL application or the generated code under test. You can use the execution-time metrics to determine whether the generated code meets the requirements for real-time deployment on your target hardware.

For example, you can perform the following analysis:

1. Identify tasks that require the most time. Tasks are main entry points into the generated code. For example, the step function for a sample rate or the `model_initialize` function.
2. In these tasks, investigate code sections that require the most time.
3. Identify variations in execution time over time steps.

If you are trying to reduce execution times, the analysis results help you to focus on the most critical code sections. To observe performance changes for an updated model, rerun the SIL or PIL simulation and compare the new metrics against previous metrics.

**Note** Execution-time measurements depend greatly on the hardware that you use. For reliable results, collect execution-time metrics using hardware on which you plan to deploy the generated code, that is, run PIL simulations that execute code on your target hardware. SIL simulations, which execute code on your host computer, might not produce representative metrics.

When the SIL or PIL simulation is complete, you can:

- View execution-time metrics through a display window or report.
- Use the Simulation Data Inspector to view and compare the variation of execution times over a simulation.
- Analyze the measurements within the MATLAB environment.
Configure Code Execution Profiling

To configure code execution profiling for a SIL or PIL simulation:

1. In your top model, open the Configuration Parameters dialog box, and select the Code Generation > Verification pane.
2. Select the Measure task execution time check box.
3. If you also want function execution times, select the Measure function execution times check box.
4. In the Workspace variable field, specify a name. When you run the simulation, the software generates a variable with this name in the MATLAB base workspace. The variable contains the execution-time measurements, and is an object of type coder.profile.ExecutionTime.

   If you select the Data Import/Export > Single simulation output check box, the software creates the variable in the Simulink.SimulationOutput object that you specify.

5. From the Save options drop-down list, select one of the following:
   - Summary data only — If you want to generate only a report and reduce memory usage, for example, during a long simulation.
   - All data — Allows you to generate a report and store execution-time profiles in the base workspace. After the simulation, you can use methods from the coder.profile.ExecutionTime and coder.profile.ExecutionTimeSection classes to retrieve execution-time measurements for every call to each profiled section of code that occurs during the simulation.

6. Click OK.

For a PIL simulation, you must configure a hardware-specific timer. When you set up the connectivity configuration for your target, create a timer object. This action is not required for a SIL simulation.

If you select All data from the Save options drop-down list, the metrics display window and generated report display Simulation Data Inspector icons. When you click one of these icons, the software imports simulation results into the Simulation Data Inspector. You can then plot execution times and manage and compare plots from various simulations.
Profiling for Atomic Subsystems and Model Reference Hierarchies

To generate execution-time metrics for tasks only, on the Code Generation > Verification pane of the Configuration Parameters dialog box, select the Measure task execution time check box and clear the Measure function execution times check box.

To generate function execution data for atomic subsystems in the top model, on the Code Generation > Verification pane, select the Measure task execution time and Measure function execution times check boxes.

The generation of function execution data requires the insertion of measurement probes into the generated code. The software inserts measurement probes for an atomic subsystem only if you set the Function packaging field (on the Code Generation tab of the Function Block Parameters dialog box) to either Nonreusable function or Reusable function. If the field is set to Auto, then the insertion of probes depends on the packaging choice that results from the Auto setting. If the field is set to Inline, the software does not insert probes.

Note In the generated code, the software wraps each function call with measurement probes except when:

- The call site cannot be wrapped because of expression folding (see “Minimize Computations and Storage for Intermediate Results at Block Outputs” (Simulink Coder)).
- The call site is located in the shared utility code (see “Sharing Utility Code” (Simulink Coder)).

You might not want to generate profiles for specific subsystems. To disable code execution profiling for a subsystem in the top model:

1. Right-click the subsystem.
2. From the context menu, select Properties.
3. In the Block Properties dialog box, select the General tab.
4. In the Tag field, enter DoNotProfile.
5. Click OK.
To generate function execution data for model reference hierarchies:

1. In the top model, open the Configuration Parameters dialog box, and select the **Code Generation > Verification** pane.
2. Select the **Measure task execution time** check box.
3. For each Model block that you want to profile, select **Measure function execution times** only at the reference level for which you require function execution data.

For example, consider a top model that has Model block A, which in turn contains Model block B.

If you want to generate execution times for functions from model B, select **Measure task execution time** for the top model and **Measure function execution times** for model B.

These parameters of the top model override the corresponding parameters of referenced models:

- **Measure task execution time**. If you disable this parameter for the top model, you also disable function profiling for referenced models.
- **Workspace variable**
- **Save options**

If your top model has a PIL block, the execution profiling settings that apply to the PIL block are the settings from the original model that you used to create the PIL block. See “Simulation with Blocks From Subsystems” on page 67-19. The execution profiling settings of your top model do not apply to the PIL block.

View and Compare Code Execution Times

During a software-in-the-loop (SIL) or processor-in-the-loop (PIL) simulation, you can use the Simulation Data Inspector to observe streamed execution times. At the end of the simulation, you can:

- View execution-time metrics for a profiled model component.
- Open a report of execution-time metrics for all profiled components.
- Use the Simulation Data Inspector to plot and compare execution times from various simulations.

Consider the `rtwdemo_sil_topmodel` model, which has two subsystems `CounterTypeA` and `CounterTypeB`. To measure code execution times for the subsystems, on the **Configuration Parameters > Code Generation > Verification** pane:

1. Select the following check boxes:
   - **Measure task execution time** — Provides execution-time metrics for the task generated from the top model `rtwdemo_sil_topmodel`.
   - **Measure function execution times** — Provides execution-time metrics for the functions generated from the subsystems `CounterTypeA` and `CounterTypeB`.

2. Specify a **Workspace variable**, for example, `executionProfile`.

3. From the **Save options** drop-down list, select **All data**.

Running a simulation generates the variable `executionProfile` in the MATLAB base workspace.

**Note** If you select the **Data Import/Export > Single simulation output** check box, the simulation creates the variable in your specified `Simulink.SimulationOutput` object.

To view streamed execution times during the simulation, open the Simulation Data Inspector. On the Simulink Editor toolbar, click the Simulation Data Inspector button.

When the simulation is complete, the profiled model components are colored blue. To view execution-time metrics for a profiled component, click the component. For example, subsystem `CounterTypeB`.
The display window also has links to:

- The complete profiling report, which provides execution-time metrics for all profiled code sections.
- The profiled code section in the code generation report.
- The Simulation Data Inspector, which allows you to plot and compare execution-time measurements for the profiled code section.

For top-model SIL or PIL simulations, the Simulink Editor background is also colored blue. When you click the background, the display window shows execution-time metrics for top-model tasks.

If you close the model or display window, you can reopen the colored model and display window with this line command:
Code Execution Profiling Report

At the end of the simulation, you can open this report through the metrics display window or with this line command:

```matlab
>> annotate(executionProfile)
```

```matlab
>> report(executionProfile)
```

### Code Execution Profiling Report for rtwdemo_sil_topmodel

The code execution profiling report provides metrics based on data collected from a SIL or PIL execution. Execution times are calculated from data recorded by instrumentation probes added to the SIL or PIL test harness or inside the code generated for each component. See Code Execution Profiling for more information.

The report contains time measurements for:

- The model initialization function `rtwdemo_sil_topmodel_initialize`.
- A task represented by the step function `rtwdemo_sil_topmodel_step [0.1 0]`.
- Functions generated from the subsystems `CounterTypeA` and `CounterTypeB`.

You can go to a profiled code section in the Generated Code view of the Code Generation Report. In the Code Execution Profiling Report, on a code section row, click the icon . For example, if you click the icon for the `rtwdemo_sil_topmodel_initialize` task, you see the measurement probes around the call site in the SIL application.
If you click the icon for a function, the call site is highlighted.
From the Code Execution Profiling Report, you can trace the model component that produces a set of metrics. For example, in the Section column, if you click the CounterTypeA hyperlink, the Simulink Editor identifies the subsystem.

```c
/* Model step function */
void rtwdemo_sil_topmodel_step(void)
{
    /* Logic: '<Root>/Logical_Operator2' incorporates:
    * Inport: '<Root>/count_enable'
    * Inport: '<Root>/counter_mode'
    * Logic: '<Root>/Logical_Operator'
    */
    enableA = (!rtU.counter_mode) && rtU.count_enable);

    /* Outputs for Enabled SubSystem: '<Root>/CounterTypeA' */
    CounterTypeA();

    /* End of Outputs for SubSystem: '<Root>/CounterTypeA' */
```
By default, the report displays time in nanoseconds ($10^{-9}$ seconds). You can specify the time unit and numeric display format. For example, to display time in microseconds ($10^{-6}$ seconds), use the following command:

```matlab
>> report(executionProfile,'Units', 'Seconds', 'ScaleFactor', '1e-06', 'NumericFormat', '%0.3f')
```

The report displays time in seconds only if the timer is calibrated, that is, the number of timer ticks per second is known. On a Windows machine, the software determines this value for a SIL simulation. On a Linux machine, calibrate the timer manually. For example, if your processor speed is 1 GHz, specify the number of timer ticks per second:

```matlab
>> executionProfile.TimerTicksPerSecond = 1e9;
```

To display measured execution times for a task or function, click the Simulation Data Inspector icon on the corresponding row. Use the Simulation Data Inspector to manage and compare plots from various simulations.

**Note** To observe how code sections are invoked over the execution timeline, use the `timeline` function.

The following table describes the information provided in the code section profiles.

<table>
<thead>
<tr>

**More About**

- “Tips and Limitations” on page 61-19
Analyze Code Execution Data

After a SIL or PIL simulation, you can analyze execution-time data using methods from the `coder.profile.ExecutionTime` and `coder.profile.ExecutionTimeSection` classes.

1. Open `rtwdemo_sil_topmodel`.
2. On the **Configuration Parameters > Code Generation > Verification** pane, specify profiling options:
   - Select the **Measure task execution time** check box.
   - Specify a **Workspace variable**, for example, `myExecutionProfile`.
   - From the **Save options** drop-down list, select **All data**.
3. Run a SIL simulation.

The software generates the workspace variable `myExecutionProfile`, an `coder.profile.ExecutionTime` object.

To get the total number of code sections that have profiling data, use the `Sections` method.

```matlab
>> no_of_Sections = myExecutionProfile.Sections
```

```matlab
no_of_Sections =
```

```
1×2 ExecutionTimeTaskSection array with properties:
```

<table>
<thead>
<tr>
<th>Name</th>
<th>Number</th>
<th>ExecutionTimeInTicks</th>
<th>SelfTimeInTicks</th>
<th>TurnaroundTimeInTicks</th>
<th>TotalExecutionTimeInTicks</th>
<th>TotalSelfTimeInTicks</th>
<th>TotalTurnaroundTimeInTicks</th>
<th>MaximumExecutionTimeInTicks</th>
<th>MaximumExecutionTimeCallNum</th>
<th>MaximumSelfTimeInTicks</th>
<th>MaximumSelfTimeCallNum</th>
<th>MaximumTurnaroundTimeInTicks</th>
<th>MaximumTurnaroundTimeCallNum</th>
<th>NumCalls</th>
<th>ExecutionTimeInSeconds</th>
<th>Time</th>
</tr>
</thead>
</table>

To get the `coder.profile.ExecutionTimeSection` object for a profiled code section, use the method `Sections`.
FirstSectionProfile = myExecutionProfile.Sections(1)
SecondSectionProfile = myExecutionProfile.Sections(2)

FirstSectionProfile =
    ExecutionTimeTaskSection with properties:
        Name: 'rtwdemo_sil_topmodel_initialize'
        Number: 1
        ExecutionTimeInTicks: 1188
        SelfTimeInTicks: 1188
        TurnaroundTimeInTicks: 1188
        TotalExecutionTimeInTicks: 1188
        TotalSelfTimeInTicks: 1188
        TotalTurnaroundTimeInTicks: 1188
        MaximumExecutionTimeInTicks: 1188
        MaximumExecutionTimeCallNum: 1
        MaximumSelfTimeInTicks: 1188
        MaximumSelfTimeCallNum: 1
        MaximumTurnaroundTimeInTicks: 1188
        MaximumTurnaroundTimeCallNum: 1
        NumCalls: 1
        ExecutionTimeInSeconds: 5.4000e-07
        Time: 0

SecondSectionProfile =
    ExecutionTimeTaskSection with properties:
        Name: 'rtwdemo_sil_topmodel_step [0.1 0]' 
        Number: 2
        ExecutionTimeInTicks: [1x101 uint64]
        SelfTimeInTicks: [1x101 uint64]
        TurnaroundTimeInTicks: [1x101 uint64]
        TotalExecutionTimeInTicks: 70316
        TotalSelfTimeInTicks: 70316
        TotalTurnaroundTimeInTicks: 70316
        MaximumExecutionTimeInTicks: 2448
        MaximumExecutionTimeCallNum: 2
        MaximumSelfTimeInTicks: 2448
        MaximumSelfTimeCallNum: 2
        MaximumTurnaroundTimeInTicks: 2448
        MaximumTurnaroundTimeCallNum: 2
        NumCalls: 101
        ExecutionTimeInSeconds: [1x101 double]
        Time: [101x1 double]

Use coder.profile.ExecutionTimeSection methods to extract profiling information for a particular code section. For example, use Name to obtain the name of a profiled task.

>> name_of_section = SecondSectionProfile.Name
name_of_section =
If the timer is uncalibrated and you know the timer rate, for example 2.2 GHz, you can use the \texttt{coder.profile.ExecutionTime} method \texttt{TimerTicksPerSecond} to calibrate the timer:

\begin{verbatim}
>> myExecutionProfile.TimerTicksPerSecond = 2.2e9;
>> SecondSectionProfile = myExecutionProfile.Sections(2);
\end{verbatim}

Triggered Model Block

Consider the case where a triggered Model block is configured to run in the SIL or PIL simulation mode. The software generates one execution-time measurement each time the referenced model is triggered to run. If there are multiple triggers in a single time step, the software generates multiple measurements for the triggered Model block. Conversely, if there is no trigger in a given time step, the software generates no time measurements.

Outliers in Execution-Time Profiles

When you run a SIL simulation with execution time profiling enabled, you might see spikes in execution-time measurements.
The spikes are due to process preemption that occurs with a multitasking host operating system. If the operating system preempts the SIL process and runs another process, the measured execution time includes the time during which the SIL process is suspended. With a PIL simulation, you do not see spikes because code execution on the target is not preempted.

Counter wrapping produces execution-time measurements that are smaller than expected. For SIL, the counter wraps when an execution-time period is greater than $2^{64}$ ticks ($2^{32}$ ticks if the MEX compiler is LCC). For PIL, the wrapping point depends on the timer you specify and can be $2^8$, $2^{16}$, $2^{32}$, or $2^{64}$ ticks.

Consider a PIL example where the timer frequency is 20 MHz. For a 32-bit timer, wrapping occurs when the execution-time period is greater than $1/(20e6) \times (2^{32}-1)$, that is, 214.7 s. However, for a 16-bit timer, the point at which wrapping occurs is 0.0033 s.

For a real-time, multi-core application, the software accommodates synchronization discrepancies when recording timer values for different cores, which effectively reduces the timer measurement range.
Hardware-Specific Timer

If your target configuration does not already specify a timer, create a timer object that provides details of the hardware-specific timer and associated source files:

- For SIL simulation, the timer word length is 64 bits.
- For PIL simulation, you can specify an 8-, 16-, 32-, or 64-bit timer.

Task Context Switching Due to Preemption

Profiling instrumentation is intrusive and affects the quantity that it is meant to measure. Therefore, the design goal is to maximize code understanding with a minimum of instrumentation. For example, with a real-time system, there can be task context switches due to preemption. These context switches are not explicitly instrumented. To record the start and end of each task, the software must infer context switches from instrumentation. As a result, the software reports behavior that is an estimate. The estimate is subject to error because of incomplete instrumentation within the kernel.

In some cases, when the software cannot accurately determine behavior, the software generates a warning:

Warning: Analysis unsuccessful for one or more profiling data points. ...

For example, the software might generate this warning when not all mutex take system calls (associated with rate transitions) are instrumented. In the case of Simulink Real-Time, this situation might arise if you generate code for a model reference hierarchy without enabling function profiling for all referenced models (set_param(model, 'CodeProfilingInstrumentation', 'on')). If a mutex take system call is not instrumented, a task context switch might occur that is not visible to the execution profiling analysis.

In other cases, although the software cannot accurately determine behavior, the software does not generate a warning.

Subsystem Code Reuse

You cannot generate execution-time profiles for function call sites within subsystem code that is reused across a model or multiple models. For information about subsystem code reuse, see “Generate Reusable Code from Library Subsystems Shared Across Models” (Simulink Coder).
Cannot Load Execution-Time Measurements from Previous Release

You cannot load execution-time measurements saved with a previous release. For example, using R2014a, you save workspace variables to a MAT-file. One of the workspace variables contains execution-time measurements. In R2015b, if you try to load the MAT-file, you see this error:

Format of execution profiling data is invalid. This error can occur if you load data from a previous release. Loading data from a previous release is not supported.
Code Execution Profiling for MATLAB Coder

- “Execution Time Profiling for SIL and PIL” on page 62-2
- “Generate Execution Time Profile” on page 62-3
- “View Execution Times” on page 62-4
- “Analyze Execution Time Data” on page 62-7
Execution Time Profiling for SIL and PIL

During a software-in-the-loop (SIL) or processor-in-the-loop (PIL) execution, you can produce a profile of execution times for code generated from entry-point functions. The software calculates execution times from data that is obtained through instrumentation probes added to the SIL or PIL application.

Use the execution time profile to check whether your code runs within the required time on your target hardware:

- If code execution overruns, look for ways to reduce execution time.
- If your code easily meets time requirements, consider enhancing functionality to exploit the unused processing power.

At the end of the SIL or PIL execution, you can:

- View a report of code execution times.
- Use the Simulation Data Inspector to view and compare plots of function execution times.
- Access and analyze execution time profiling data.

**Note** SIL and PIL execution supports multiple entry-point functions. An entry-point function can call another entry-point function as a subfunction. However, the software generates execution time profiles only for functions that are called at the entry-point level. The software does not generate execution time profiles for entry-point functions that are called as subfunctions by other entry-point functions.

- “Analyze Execution Time Data” on page 62-7
Generate Execution Time Profile

Before running a software-in-the-loop (SIL) or processor-in-the-loop (PIL) execution, enable execution time profiling:

1. To open the MATLAB Coder app, on the MATLAB Toolstrip Apps tab, under Code Generation, click the app icon.

2. To open your project, click and then click Open existing project. Select the project.

4. Select the Enable entry point execution profiling for SIL/PIL check box.

Or, from the Command Window, specify the CodeExecutionProfiling property of your coder.EmbeddedCodeConfig object. For example:

```matlab
cfg.CodeExecutionProfiling = true;
```

More About

- “Execution Time Profiling for SIL and PIL” on page 62-2
View Execution Times

When you run a SIL or PIL execution with execution time profiling enabled, the software generates a message in the Test Output tab. For example:

Current plot held
### Starting SIL execution for 'kalman01'
   To terminate execution: clear kalman01_sil
   Execution profiling data is available for viewing. Open Simulation Data Inspector.
   Execution profiling report available after termination.
Current plot released

To observe streamed execution times while the execution runs, click the Simulation Data Inspector link.

To open the code execution profiling report:

1 Click the Stop SIL Verification link.

   The software terminates the execution process and displays a new link.

   ### Stopping SIL execution for 'kalman01'
   Execution profiling report: report(getCoderExecutionProfile('kalman01'))

2 Click the new link.

### Code Execution Profiling Report for kalman01

The code execution profiling report provides metrics based on data collected from a SIL or PIL execution. Execution times are calculated from data recorded by instrumentation probes added to the SIL or PIL test harness or inside the code generated for each component. See Code Execution Profiling for more information.

1. Summary

<table>
<thead>
<tr>
<th>Command</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Total time</td>
<td>325931</td>
</tr>
<tr>
<td>Unit of time</td>
<td>ms</td>

<tr>
<td>Time frequency (ticks per second)</td>
<td>3.501e+09</td>
</tr>
<tr>
<td>Profiling data created</td>
<td>05-Jul-2017 11:27:07</td>
</tr>
</tbody>
</table>

2. Profiled Sections of Code

<table>
<thead>
<tr>
<th>Section</th>
<th>Maximum Execution Time in ms</th>
<th>Average Execution Time in ms</th>
<th>Maximum Self Time in ms</th>
<th>Average Self Time in ms</th>
<th>Calls</th>
</tr>
</thead>
<tbody>
<tr>
<td>kalman01</td>
<td>953</td>
<td>953</td>
<td>953</td>
<td>953</td>
<td>1</td>
</tr>
<tr>
<td>kalman01</td>
<td>58603</td>
<td>10866</td>
<td>58603</td>
<td>10866</td>
<td>300</td>
</tr>
<tr>
<td></td>
<td>43</td>
<td>43</td>
<td>43</td>
<td>43</td>
<td>1</td>
</tr>
</tbody>
</table>

3. Definitions

   Execution Time: Time between start and end of code section.
   Self Time: Execution time, excluding time in child sections.

The report provides:
• A summary.
• Information about profiled code sections, which includes time measurements for:
  • The `entry_point_fn_initialize` function, for example, `kalman01_initialize`.
  • The entry-point function, for example, `kalman01`.
  • The `entry_point_fn_terminate` function, for example, `kalman01_terminate`.
• Definitions for metrics.

By default, the report displays time in nanoseconds ($10^{-9}$ seconds). You can specify the time unit and numeric display format. For example, to display time in microseconds ($10^{-6}$ seconds), use the `report` command:

```matlab
executionProfile = getCoderExecutionProfile('kalman01'); % Create workspace variable
report(executionProfile, ...
    'Units', 'Seconds', ...
    'ScaleFactor', '1e-06', ...
    'NumericFormat', '%0.3f')
```

The report displays time in seconds only if the timer is calibrated, that is, the number of timer ticks per second is established. On a Windows machine, the software determines this value for a SIL simulation. On a Linux machine, you must manually calibrate the timer. For example, if your processor speed is 1 GHz, specify the number of timer ticks per second:

```matlab
executionProfile.TimerTicksPerSecond = 1e9;
```

To display measured execution times for a code section, click the Simulation Data Inspector icon on the corresponding row. You can use the Simulation Data Inspector to manage and compare plots from various executions.

The following table lists the information provided in the code section profiles.

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Section</td>
<td>Name of function from which code is generated.</td>

- “Simulation Data Inspector in Your Workflow” (Simulink)
Analyze Execution Time Data

After a software-in-the-loop (SIL) or processor-in-the-loop (PIL) execution, you can analyze execution-time data using methods from the `coder.profile.ExecutionTime` and `coder.profile.ExecutionTimeSection` classes.

In the following example, you run a SIL execution and apply supplied methods to execution-time data.

Extract Execution Time Data for Kalman Estimator Code

1. Run SIL execution to generate execution time data

Copy MATLAB code to your working folder.

```matlab
src_dir = ...
    fullfile(docroot,'toolbox','coder','examples','kalman');

copyfile(fullfile(src_dir,'kalman01.m'), '.')
copyfile(fullfile(src_dir,'test01_ui.m'), '.')
copyfile(fullfile(src_dir,'plot_trajectory.m'), '.')
copyfile(fullfile(src_dir,'position.mat'), '.')
```

For a description of the Kalman estimator, see “C Code Generation at the Command Line” (MATLAB Coder).

Create a `coder.EmbeddedCodeConfig` object.

```matlab
config = coder.config('lib');
config.GenerateReport = true; % HTML report
```

Configure the object for SIL and enable execution time profiling.

```matlab
config.VerificationMode = 'SIL';
config.CodeExecutionProfiling = true;
```

Generate library code for the `kalman01` MATLAB function and the SIL interface.

```matlab
codegen('-config', config, '-args', {zeros(2,1)}, 'kalman01');
```

Run the MATLAB test file `test01_ui` with `kalman01_sil`. `kalman01_sil` is the SIL interface for `kalman01`.

```matlab
coder.runTest('test01_ui', ['kalman01_sil.mexext']);
```
You see the following message.

```bash
### Starting SIL execution for 'kalman01'
To terminate execution: clear kalman01_sil
    Execution profiling data is available for viewing. Go to Simulation Data Inspector.
    Execution profiling report available after termination.
Current plot released

Terminate the SIL execution process. Click the link clear kalman01_sil.
```  

### Stopping SIL execution for 'kalman01'

```bash
### Stopping SIL execution for 'kalman01'
    Execution profiling report: report(getCoderExecutionProfile('kalman01'))
```

2 **Create workspace variable that holds execution time data**

Use the `getCoderExecutionProfile` function to create a workspace variable that holds execution time profiling data.

```matlab
executionProfile = getCoderExecutionProfile('kalman01');
```

3 **Extract code sections**

Use the `Sections` method.

```matlab
allSections = executionProfile.Sections
```

The software displays the number of code sections and a list of properties.

```matlab
allSections =
    1x3 ExecutionTimeTaskSection array with properties:
        Name         Number ExecutionTimeInTicks SelfTimeInTicks TurnaroundTimeInTicks TotalExecutionTimeInTicks TotalSelfTimeInTicks TotalTurnaroundTimeInTicks MaximumExecutionTimeInTicks MaximumExecutionTimeCallNum MaximumSelfTimeInTicks MaximumSelfTimeCallNum MaximumTurnaroundTimeInTicks MaximumTurnaroundTimeCallNum NumCalls ExecutionTimeInSeconds Time
```

4 **Extract execution time data from specific code section**

Specify the code section that you want to examine.
secondSectionProfile = executionProfile.Sections(2)

The software displays profile data for the code section.

secondSectionProfile =

ExecutionTimeTaskSection with properties:
    Name: 'kalman01'
    Number: 2
    ExecutionTimeInTicks: [1x300 uint64]
    SelfTimeInTicks: [1x300 uint64]
    TurnaroundTimeInTicks: [1x300 uint64]
    TotalExecutionTimeInTicks: 6641016
    TotalSelfTimeInTicks: 6641016
    TotalTurnaroundTimeInTicks: 6641016
    MaximumExecutionTimeInTicks: 48864
    MaximumSelfTimeInTicks: 48864
    MaximumTurnaroundTimeInTicks: 48864
    MaximumExecutionTimeCallNum: 158
    MaximumSelfTimeCallNum: 158
    MaximumTurnaroundTimeCallNum: 158
    NumCalls: 300
    ExecutionTimeInSeconds: [1x300 double]
    Time: [300x1 double]

You can extract specific properties, for example, the name of a profiled function.

nameOfSection = secondSectionProfile.Name

The software displays the name.

nameOfSection =

kalman01

The following table lists the information that you can extract from each code section.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name of entry-point function</td>
</tr>
<tr>
<td>Number</td>
<td>Code section number</td>
</tr>
<tr>
<td>ExecutionTimeInTicks</td>
<td>Vector of execution times, measured in timer ticks. Each element contains the difference between the timer reading at the start and at the end of the code section. The data type is the same data type as the data type of the timer used on the target, which allows you to infer the maximum range of the timer measurements.</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>

Simulation and Code Comparison in Simulink Coder
Simulation and Code Comparison

In this section...

“Configure Signal Data for Logging” on page 63-2
“Log Simulation Data” on page 63-3
“Run Executable and Load Data” on page 63-5
“Visualize and Compare Results” on page 63-6
“Compare States for Simulation and Code Generation” on page 63-8

This example shows how to verify the answers computed by code generated from the slexAircraftExample model. It shows how to capture and compare two sets of output data. Simulating the model produces one set of output data. Executing the generated code produces a second set of output data.

Note To obtain a valid comparison between model output and the generated code, use the same Solver selection and Step size for the simulation run and the build process.

Configure Signal Data for Logging

Configure the model for logging and recording signal data.

1 Make sure that slexAircraftExample is closed. Clear the base workspace to eliminate the results of previous simulation runs. In the Command Window, type:

```
clear
```

The clear operation clears variables created during previous simulations and all workspace variables, some of which are standard variables that the slexAircraftExample model requires.

2 In the Command Window, enter slexAircraftExample to open the model.

3 In the model window, choose File > Save As, navigate to the working folder, and save a copy of the slexAircraftExample model as myAircraftExample.

4 Set up your model to log signal data for signals: Stick, alpha, rad, and q, rad/sec. For each signal:

   a Right-click the signal. From the context menu, select Properties.
b In the Signal Properties dialog box, select Log signal data.

c In the Logging name section, from the drop-down list, select Custom.

d In the text field, enter the logging name for the corresponding signal.

<table>
<thead>
<tr>
<th>Signal Name</th>
<th>Logging Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stick</td>
<td>Stick_input</td>
</tr>
<tr>
<td>alpha, rad</td>
<td>Alpha</td>
</tr>
<tr>
<td>q, rad/sec</td>
<td>Pitch_rate</td>
</tr>
</tbody>
</table>

e Click Apply and OK.

For more information, see “Export Signal Data Using Signal Logging” (Simulink).

5 Select Simulation > Model Configuration Parameters to open the Configuration Parameters dialog box.

6 Select the Solver pane and in the Solver selection section, specify the Type parameter as Fixed-step.

7 On the Data Import/Export pane:

• Specify the Format parameter as Structure with time.
• Clear the States parameter check box.
• Select the Signal logging parameter.
• Select the Record logged workspace data in Simulation Data Inspector parameter to enable logged signal data to send to the Simulation Data Inspector after the simulation is finished.

8 Save the model.

Proceed to “Log Simulation Data” on page 63-3.

**Log Simulation Data**

Run the simulation, log the signal data, and view the data in the Simulation Data Inspector.

1 Run the model. When the simulation is done, on the Simulink Editor toolbar, the Simulation Data Inspector button is highlighted to indicate that new simulation output is available in the Simulation Data Inspector.
2 Click the **Simulation Data Inspector** button to open the Simulation Data Inspector.

3 Group the signals:
   
   a On the **Visualize** tab, click **Group Signals**.
   
   b In the Group Signals dialog box, select **Data Hierarchy** from the **Then By** list.

   ![Group Signals Dialog Box]

   c Click **OK**.

4 Click the **Logsout** expander to view the logged signals.

5 Click the **Format** tab.

6 Click the **Subplots** button and select **3x1** to show three subplots.

7 For each signal:
   
   a Click the top subplot. A blue border indicates the plot selection.
   
   b Select the check box next to the **Alpha** signal name. The signal data appears in the subplot.
   
   c Plot the **Pitch_rate** signal in the middle subplot.
   
   d Plot the **Stick_input** signal in the bottom subplot.
Proceed to “Run Executable and Load Data” on page 63-5.

**Run Executable and Load Data**

You must rebuild and run the `myAircraftExample` executable to obtain a valid data file because you have modified the model.

1. Select **Simulation > Model Configuration Parameters** to open the Configuration Parameters dialog box.
2. Select the **Code Generation > Interface** pane.
3. Set the **MAT-file variable name modifier** parameter to `rt_`. `rt_` is prefixed to each variable that you selected for logging in the first part of this example.
4. Click **Apply** and **OK**.
5. Save the model.
6. On the Simulink Editor toolbar, click the **Build Model** button to generate code.
7. When the build is finished, run the standalone program from the Command Window.

`!myAircraftExample`
The executing program writes the following messages to the Command Window.

```
** starting the model **
** created myAircraftExample.mat **
```

8 Load the data file myAircraftExample.mat.

```
load myAircraftExample
```

**Tip** For UNIX platforms, run the executable in the Command Window with the syntax `./executable_name`. If preferred, run the executable from an OS shell with the syntax `./executable_name`. For more information, see “Run External Commands, Scripts, and Programs” (MATLAB).

Proceed to “Visualize and Compare Results” on page 63-6.

**Visualize and Compare Results**

When you follow the example sequence that began in “Configure Signal Data for Logging” on page 63-2, you obtain data from a Simulink run of the model and from a run of the program generated from the model.

1 To view the execution output for \textit{alpha, rad}, import the data into the Simulation Data Inspector.

\begin{itemize}
  \item[a] On the Simulation Data Inspector \textbf{Visualize} tab, click the \textbf{Import} button to open the Import dialog.
  \item[b] Specify \textbf{Import from} as \textit{Base workspace}.
  \item[c] Specify \textbf{Import to} as \textit{New run}.
  \item[d] To the left of \textbf{Signal Name}, click the check mark to clear the check boxes.
  \item[e] Select the check box for the \textit{alpha, rad} data where the \textbf{Time Series Root} is \textit{rt_yout}.
  \item[f] Click \textbf{Import}.
\end{itemize}
The selected data is now under **Run 2: Imported_Data**.

2 View a plot of the executed data.

   a Click the rt_yout expander.

   b Click the top subplot and select the check box next to the **alpha, rad** signal name. The signal data appears in the top subplot.

The **alpha, rad** signal from Run 1 and Run 2 overlap in the subplot because the signals are equivalent.
It is possible to see a very small difference between simulation and code generation results. A slight difference can be caused by many factors, including:

- Different compiler optimizations
- Statement ordering
- Run-time libraries

For example, a function call such as \( \sin(2.0) \) can return a slightly different value depending on which C library you use. Such variations can also cause differences between your results and these results.

### Compare States for Simulation and Code Generation

The order in which Simulink logs states during simulation is different than the order in which Simulink Coder logs states during code generation. If you want to compare states between simulation and code generation, sort the states by block name.

For example, by default, Simulink exports state data to the MATLAB variable, `xout`. Simulink Coder exports state data to the variable `rt_xout`. To sort the state data for these variables, enter the following commands in the MATLAB Command Window:
\[\text{~,idx1}=\text{sort}({\text{xout.signals.blockName}});\]
\[\text{xout\_sorted}=[\text{xout.signals(idx1).values}];\]
\[\text{~,idx2}=\text{sort}({\text{rt\_xout.signals.blockName}});\]
\[\text{rt\_xout\_sorted}=[\text{rt\_xout.signals(idx2).values}];\]

You can confirm that the logging order is the same between code generation and simulation by entering the following command in the MATLAB Command Window:

\[\text{isequal(xout\_sorted, rt\_xout\_sorted)}\]

Code tracing (traceability) uses hyperlinks to navigate between a line of generated code and its corresponding elements in a model. To find the lines of code and their corresponding elements, you can also right-click an element or elements in a model. This two-way navigation is bidirectional traceability.

Using code tracing, you can:

- Verify that generated code is as you expect. You can identify which model elements correspond to a line of code. You can track code from different elements that you have or have not reviewed.
- Verify that generated code meets the design requirements. You can link requirements to the model element and use code tracing to verify that the generated code for a model element meets the assigned requirements.

The HTML code generation report includes resources that support code tracing:

- Code element hyperlinks (indicated by underlining when you hover over the code) to trace variables or types in the generated code to their declarations or definitions in the header files.
- Tags in code comments that identify elements in a model from which lines of code are generated.
- Line number hyperlinks that link to the model component from which the line of code was generated.

**Traceable Elements**

Bidirectional traceability is supported for Simulink blocks and these Stateflow elements:
• States
• Transitions
• State transition tables
• MATLAB functions. Traceability is not supported for external code that you call from a
MATLAB function.
• Truth table blocks
• Graphical functions
• Simulink functions

Traceability in one direction is supported for these Stateflow elements:

• Events (code-to-model)

  Code-to-model traceability works for explicit events, but not implicit events. Clicking a
  hyperlink for an explicit event in the generated code highlights that item in the
  Contents pane of the Model Explorer.

• Junctions (model-to-code)

  Model-to-code traceability works for junctions with at least one outgoing transition.
  Right-clicking such a junction in the Stateflow Editor highlights the line of code that
  corresponds to the first outgoing transition for that junction.

For more information, see “Trace Stateflow Elements in Generated Code” on page 64-13.

MATLAB Function blocks that you insert directly into a Simulink model are also traceable.
For more information, see “Use Traceability in MATLAB Function Blocks” (Simulink).

Traceability in Code Generation Report

This example shows how to create an HTML code generation report that includes links for
tracing between the source code and the Simulink model.

1. Open the model and make sure that it is configured for an ERT target.

2. Select **Create code generation report** if it is not already selected. By default, **Open
report automatically**, **Code-to-model**, and **Model-to-code** are selected.

3. If your model contains referenced models and you want to enable traceability for the
referred model's code generation report, repeat step 2 for each referenced model.
4 Press Ctrl+B to generate code for your model. The build process opens the code generation report in a MATLAB web browser.

5 In the left navigation pane, select a source code file. The source code and line numbers in the right pane contain hyperlinks to blocks in the model.

6 Click a comment or line number hyperlink. The Simulink Editor displays and highlights the corresponding block or blocks in the model.

7 To highlight the generated code for a block in your Simulink model, right-click the block and select C/C++ Code > Navigate to C/C++ Code. The generated code for the block is then highlighted in the HTML code generation report. To highlight the generated code for multiple blocks that you select, hold the SHIFT key, select multiple blocks, and then right-click any one block to select C/C++ Code > Navigate to C/C++ Code. The generated code for the blocks is then highlighted in the HTML code generation report.

8 If you have a referenced model in your model, in the left navigation pane, under Reference Models, click the link to a referenced model. The code generation report for the referenced model is now displayed in the MATLAB web browser.

9 In the left navigation pane, you can click the Back button to go back to the previous code generation report.

**Traceability Tags**

A traceability tag appears in a comment above the corresponding line of generated code. The format of the tag is `<system>/block_name`.

- **system** is one of the following:
  - The text Root
  - A unique system number assigned by the Simulink engine

- **block_name** is the name of the source block.

The code generator documents the tags for a model in the comments section of the generated header file `model.h`. For example, this comment appears in the header file for a model, `foo`, that has a subsystem `Outer` and a nested subsystem `Inner`:

```c
/* Here is the system hierarchy for this model. *
 *<Root> : foo
 *<S1>   : foo/Outer
```
This code shows a tag comment above the generated line of code. A Gain block at the root level of a source model generates this code:

```cpp
/* Gain: '<Root>/UnDeadGain1' */
rtb_UnDeadGain1_h = dead_gain_U.In1 * dead_gain_P.UnDeadGain1_Gain;
```

This code shows a tag comment above the generated line of code. A Gain block within a subsystem one level below the root level of the source model generates this code:

```cpp
/* Gain: '<S1>/Gain' */
dead_gain_B.temp0 *= (dead_gain_P.s1_Gain_Gain);
```

## Operator Traceability

The HTML code generation report provides traceability between operators in the generated code and Simulink blocks, Stateflow elements, or MATLAB Function blocks.

To verify the generated code by using operator traceability, in the HTML report window, click an operator hyperlink to highlight the source block in the model.

These operators are supported.

<table>
<thead>
<tr>
<th>Operator Type</th>
<th>Operators</th>
</tr>
</thead>
<tbody>
<tr>
<td>Arithmetic</td>
<td>+, -, *, /, %</td>

<td>new, new[]</td>
</tr>
<tr>
<td></td>
<td>delete, delete[]</td>
</tr>
</tbody>
</table>

**Traceability Limitations**

These limitations apply to reports generated by Embedded Coder software:

- Under the following conditions, model-to-code traceability is disabled for a block if the block name contains:
  - A single quote (`'`).
  - An asterisk (`*`) that causes a name-mangling ambiguity relative to other names in the model. This name-mangling ambiguity occurs if in a block name or at the end of a block name, an asterisk precedes or follows a slash (`/`).
  - The character ÿ (`char(255)`).
  - If a block name contains a newline character (`\n`), the generated code comment for the block path hyperlink replaces the newline character with a space for readability.
  - You cannot trace blocks representing these types of subsystems to generated code:
    - Virtual subsystems
    - Masked subsystems
    - Nonvirtual subsystems for which code has been removed due to optimization

If you cannot trace a subsystem at subsystem level, you can trace individual blocks within the subsystem.
• If you open a model on a platform that is different from the platform used to generate code, you cannot use model-to-code and code-to-model traceability.

Related Examples
• “Trace Simulink Model Elements in Generated Code” on page 64-8
Trace Simulink Model Elements in Generated Code

To verify the generated code, Embedded Coder provides bidirectional traceability between the Simulink model and the code generation report. You can use either method for traceability:

- **Code-to-model**: The code generation report displays these hyperlinks in comment lines in the generated code:
  - Block/subsystems names
  - Line numbers
  - Operators

  To highlight the corresponding block or subsystem in the Simulink Editor, click the hyperlinks.

- **Model-to-code**: You can select single or multiple blocks of a model in the Simulink Editor and navigate to the corresponding generated code in the code generation report.

### Code-to-Model Traceability

To use hyperlinks for tracing code-to-model elements:

1. Open the model and make sure that it is configured for an ERT target.
2. On the **Code Generation > Report** pane, verify that you have selected these parameters:
   - **Create code generation report** (Simulink Coder)
   - **Open report automatically** (Simulink Coder)
   - **Code-to-model** (Simulink Coder)
   - **Model-to-code** (Simulink Coder)
3. Build or generate code for the model. An HTML code generation report is displayed in the MATLAB web browser.
4. In the HTML report window, click hyperlinks to highlight source blocks. For example, generate an HTML report for the model `rtwdemo_hyperlinks`. In the generated code for the model step function in `rtwdemo_hyperlinks.c`, click the first UnitDelay: '<Root>/X' block hyperlink.
In the model window, the corresponding UnitDelay block is highlighted.

To use line numbers for tracing code-to-model elements:

1. In the previous model, `rtwdemo_hyperlinks`, click the hyperlink at line number 147. The line numbers can differ from the numbers that appear in your code generation report.

2. In the model window, the Chart subsystem is highlighted and contains the functionality on line 147.
Model-to-Code Traceability

To trace model elements to their corresponding generated code:

1. Complete steps 1 and 2 as in “Code-to-Model Traceability” on page 64-8
2. Verify that you have selected the **Model-to-code** parameter. This parameter enables the **Configure** (Simulink Coder) button, which opens a dialog box for loading existing traceability information. For more information, see “Reload Existing Traceability Information” on page 64-34.
3. Build or generate code for the model. An HTML code generation report is displayed in the MATLAB web browser.
4. In the model window, right-click a model element. To select multiple blocks, hold the **SHIFT** key and select additional blocks.
5. From the context menu, select **C/C++ Code > Navigate to C/C++ Code**. In the HTML code generation report, you see the first instance of highlighted code that is generated for the model element. In the left pane of the report, numbers that appear to the right of generated file names indicate the total number of highlighted lines in each file. This figure shows the result of tracing the Unit Delay block in model *rtwdemo_hyperlinks*. 
At the top of the code window, use the navigation bar to move forward and backward through multiple instances of highlighted lines. Use the navigation sidebar to go directly to a line of code.

If you close and reopen a model, the **Navigate to Code** context menu option might not be available because Embedded Coder cannot find a build folder for your model in the current working folder. Do one of the following:

- Reset the current working folder to the parent folder of the existing build folder.
- Select **Model-to-code** and rebuild the model. Rebuilding the model regenerates the build folder into the current working folder.
- Click **Configure**. In the Model-to-code navigation dialog box, reload the existing traceability information by specifying the original build folder.

<tr>
<td>“Format of Traceability Comments for Stateflow Elements” on page 64-25</td>
</tr>
</tbody>
</table>

To verify the generated code for your Stateflow elements, you can trace Stateflow elements in your model to the code generation report by using these types of navigation:

- **Code-to-model**: Trace generated code from the code generation report back to the model by clicking hyperlinks in the comments or the hyperlinked line numbers, which highlights the corresponding model element in the Simulink Editor.
- **Model-to-code**: Trace the model elements in the Simulink Editor to corresponding lines in generated code by right-clicking the model element and navigating to the generated code.

These examples illustrate how to trace different Stateflow elements.

## Inline Traceability for Stateflow Elements

Inline traceability refers to the line-level traceability available in the code generation report. You can click the hyper-linked line numbers to trace single or multiple Stateflow elements at the same time.

1. At the command prompt, type `old_sf_car`.
2. Select **Simulation > Model Configuration Parameters**.
3. In the **Code Generation** pane, go to the **Target selection** section and enter `ert.tlc` for the system target file. Click **Apply**.
4. On the **Code Generation > Report** pane, verify that you have selected these parameters:
• Create code generation report (Simulink Coder)
• Open report automatically (Simulink Coder)
• Code-to-model (Simulink Coder)
• Model-to-code (Simulink Coder)

5 Go to the Code Generation > Interface pane. In the Software environment section, select continuous time. Click Apply. Before generating code, you must perform this step because this model contains a block with a continuous sample time.

6 Press Ctrl+B.

After the code generation process is complete, the code generation report appears.

7 In the report, on the left navigation pane, click the old_sf_car.c hyperlink.

8 To view the inline traceability hyperlinks, scroll through the code. These line numbers can differ from the numbers that appear in your code generation report.

```
185 /* Function for Chart: '<Root>/shift_logic' */
186 static void old_sf_car_gear_state(const int32_T *sfEvent)
187 {
188     switch (old_sf_car_dw.is_gear_state) {
189         case old_sf_car_IN_first:
190             old_sf_car_B.gear = 1.0;
191             if (*sfEvent == old_sf_car_event_UP) {
192                 old_sf_car_dw.is_gear_state = old_sf_car_IN_second;
193                 old_sf_car_B.gear = 2.0;
194             }
195         break;
```

9 Click the hyperlink on line number 190. The corresponding element is highlighted.
Bidirectional Traceability for States and Transitions

1. At the command prompt, type `old_sf_car`.
2. Select **Simulation > Model Configuration Parameters**.
3. In the **Code Generation** pane, go to the **Target selection** section and enter `ert.tlc` for the system target file. Click **Apply**. Traceability comments appear in generated code only for embedded real-time targets.
4. Verify that you have selected these parameters on the **Code Generation > Report** pane:
   - Create code generation report
   - Open report automatically
   - Code-to-model
   - Model-to-code
5 Go to the **Code Generation > Comments** pane and select **Stateflow object comments**. This parameter enables the traceability comments for Stateflow elements.

6 Go to the **Code Generation > Interface** pane. In the **Software environment** section, select **continuous time**. Click **Apply**. Before generating code, you must perform this step because this model contains a block with a continuous sample time.

7 Press **Ctrl+B** to generate source code and header files for the old_sf_car model that contains the **shift_logic** chart. After the code generation process is complete, the code generation report appears.

8 In the report, click the **old_sf_car.c** hyperlink.

**View Results**

1 To see the traceability comments, scroll through the code. These line numbers can differ from the numbers that appear in your code generation report.

```c
185 /* Function for Chart: '<Root>/shift_logic' */
186 static void old_sf_car_gear_state(const int32_T *sfEvent)
187 {
188     /* During 'gear_state': '<S5>:2' */
189     switch (old_sf_car_FW.is_gear_state) {
190         case old_sf_car_IN_first:
191             /* During 'first': '<S5>:6' */
192                 if (*sfEvent == old_sf_car_event_UP) {
193                     /* Transition: '<S5>:12' */
194                     old_sf_car_FW.is_gear_state = old_sf_car_IN_second;
195                 
196                 /* Entry 'second': '<S5>:4' */
197                 old_sf_car_B.gear = 2.0;
198     }
199     }
200 }
```

2 Click the `<S5>:2` hyperlink in this traceability comment:

```c
/* During 'gear_state': '<S5>:2' */
```

The corresponding state appears highlighted in the chart.

3 Click the `<S5>:12` hyperlink in this traceability comment:

```c
/* Transition: '<S5>:12' */
```

The corresponding transition appears highlighted in the chart. To remove highlighting from an element in the chart, select **Display > Remove Highlighting**.
4 You can also trace elements in the model to lines of generated code. In the chart, right-click the element gear_state and select C/C++ Code > Navigate to C/C++ Code.

The code for that state appears highlighted in old_sf_car.c.

```c
108  /* Function for Stateflow: '<Root>/shift_logic' */
109  static void old_sf_car_gear_state (void)
110  {
111   // During 'gear_state': '<S5>:2' */
112   if (old_sf_car_bWork.is_active_gear_state != 0) {
113     switch (old_sf_car_bWork.is_gear_state) {
114       case old_sf_car_IN_first:
115         /* During 'first': '<S5>:6' */
```

5 In the chart, right-click the transition with the condition [speed > up_th] and select C/C++ Code > Navigate to C/C++ Code.

The code for that transition appears highlighted in old_sf_car.c.

```c
446       case old_sf_car_IN_steady_state:
447         /* During 'steady_state': '<S5>:8' */
448       if (old_sf_car_b.mph > old_sf_car_S.interp_up) {
449         /* Transition: '<S5>:18' */
480         /* Exit 'steady_state': '<S5>:9' */
```

**Note** For a list of the Stateflow elements in your model that are traceable, click the Traceability Report hyperlink in the code generation report.

### Bidirectional Traceability for State Transition Tables

This example shows how to navigate bidirectionally between elements in a state transition table and the generated C/C++ and HDL code for traceability.

1 At the command prompt, type sf_cdplayer_STT. This model is already configured for traceability. For more information on these configurations, see “Traceability of Stateflow Objects in Generated Code” (Stateflow).

2 Press Ctrl+B to generate source code and header files for the sf_cdplayer_STT model. After the code generation process is complete, the code generation report appears.

3 Click the sf_cdplayer_STT.c hyperlink in the report.
To see the traceability comments, scroll through the code. The line numbers shown can differ from the numbers that appear in your code generation report.

```c
/* Function for State Transition Table: 'root/cdPlayerModeManager' */
static void sf_cdplayer_S_enter_internal_ON(void)
{
    /* Entry Internal 'ON': '<S2>:58' */
    switch (sf_cdplayer_STT_DWork.bitsForTID1.was_ON) {
        case sf_cdplayer_STT_IN_AMMode:
            sf_cdplayer_STT_DWork.bitsForTID1.is_ON = sf_cdplayer_STT_IN_AMMode;
            sf_cdplayer_STT_DWork.bitsForTID1.was_ON = sf_cdplayer_STT_IN_AMMode;
        break;
    }
}
```

Click the `<S2>:58` hyperlink in this traceability comment:

```c
/* Entry Internal 'ON': '<S2>:58' */
```

The corresponding state 'ON' appears highlighted in the state transition table.
6 Right-click the highlighted state and select **View state element**. The state 'ON' also appears highlighted in the underlying state transition diagram.

7 You can trace a state or transition from the state transition table to the generated code. Right-click the state **Standby** and select **C/C++ Code > Navigate to C/C++ Code**.

The entry code for the state **Standby** is highlighted in the generated code.
Bi-directional Traceability for Truth Table Blocks

1. At the command prompt, type `sf_climate_control`
2. Complete steps 2 through 6 in “Bi-directional Traceability for States and Transitions” on page 64-15.
3. To build the model, press **Ctrl+B**.
4. In the code generation report, click the `sf_climate_control.c` hyperlink.
5. To see the traceability comments, scroll through the code. These line numbers can differ from the numbers that appear in your code.
6. Click the `<S1>:1:47` hyperlink in this traceability comment:

```
/* Action '3': '<S1>:1:47' */
```

In the Truth Table Editor, row 3 of the Action Table appears highlighted.
You can also trace a condition, decision, or action in the table to a line of generated code. For example, right-click a cell in the column D2 and select C/C++ Code > Navigate to C/C++ Code.

The code for that decision appears highlighted in sf_climate_control.c.
Tip To select C/C++ Code > Navigate to C/C++ Code for a condition, decision, or action, right-click a cell in the row or column that corresponds to that truth table element.

### Bidirectional Traceability for Graphical Functions

1. At the command prompt, type `sf_clutch_enabled_subsystems`.
2. Complete steps 2 through 6 in “Bidirectional Traceability for States and Transitions” on page 64-15.
3. In the Model Configuration Parameters dialog box, go to the Solver pane. In the Solver selection section, select Fixed-step in the Type field. Click Apply. Before generating code, you must perform this step because the model does not work with variable-step solvers.
4. To build the model, press Ctrl+B.
5. In the code generation report, click the `sf_clutch_enabled_subsystems.c` hyperlink.
6. To see the traceability comments, scroll through the code. These line numbers can differ from the numbers that appear in your code generation report.

7. Click the `<S1>:3` hyperlink in this traceability comment:

   ```
   /* Graphical Function 'getSlipTorque': '<S1>:3' */
   ```

   In the chart, the graphical function `getSlipTorque` appears highlighted.
8. You can trace a graphical function in the chart to a line of generated code. For example, right-click the graphical function `detectSlip` and select C/C++ Code > Navigate to C/C++ Code.
The code for that graphical function appears highlighted in `sf_clutch_enabled_subsystems.c`.

```c
184  case sf_clutch_IN_LOCKED:
185      /* Graphical Function 'detectSlip': '<S1>:16' */
186      /* Transition: '<S1>:18' */
```

**Code-to-Model Traceability for Events**

1. At the command prompt, type `sf_security`.
2. Complete steps 2 through 6 in “Bidirectional Traceability for States and Transitions” on page 64-15.
3. To build the model, press **Ctrl+B**.
4. In the code generation report, click the `sf_security.c` hyperlink.
5. To see this traceability comment, scroll through the code. These numbers can differ from the numbers that appear in your code generation report.

```c
236      /* Event 'Pending': '<S3>:5' */
237      /* Event: '<S3>:56' */
238      sf_security_HW.SoundEventCounter++;
239  }
240  break;
```
6. Click the `<S3>:56` hyperlink in this traceability comment:

```c
/* Event: '<S3>:56' */
```

In the **Contents** pane of the Model Explorer, the event `Sound` appears highlighted.
Model-to-Code Traceability for Junctions

1. At the command prompt, type `sf_abs`.

2. Complete steps 2 through 6 in “Bidirectional Traceability for States and Transitions” on page 64-15.

3. In the Model Configuration Parameters dialog box, go to the Solver pane. In the Solver selection section, select Fixed-step in the Type field. Click Apply. Before generating code, you must perform this step because the model does not work with variable-step solvers.

4. To build the model, press Ctrl+B.
In the code generation report, open the AbsoluteValue chart.

Right-click the left junction and select C/C++ Code > Navigate to C/C++ Code.

The code for the first outgoing transition of that junction appears highlighted in sf_abs.c.

```c
/* Entry Internal: AbsoluteValue */
/* Transition: '<S1>:5' */
if (SinWave1 >= 0.0) {
  /* Transition: '<S1>:6' */
  stateChanged = true;
  sf_abs_DW.is_c1_sf_abs = sf_abs_IN_P;
} else {
  /* Transition: '<S1>:7' */
  /* Transition: '<S1>:8' */
  stateChanged = true;
  sf_abs_DW.is_c1_sf_abs = sf_abs_IN_N;
}
```

**Format of Traceability Comments for Stateflow Elements**

The format of a traceability comment depends on the Stateflow element type.

**State**

**Syntax**

`/* <ActionType> '<StateName>': '<elementHyperlink>' */`

**Example**

`/* During 'gear_state': '<S5>:2' */`

This comment refers to the during action of the state gear_state, which has the hyperlink <S5>:2.

**Transition**

**Syntax**

`/* Transition: '<elementHyperlink>' */`

**Example**

`/* Transition: '<S5>:12' */`
This comment refers to a transition, which has the hyperlink <S5>:12.

**MATLAB Function**

**Syntax**

/* MATLAB Function '<Name>': '<elementHyperlink>' */

Within the inlined code for a MATLAB function, comments that link to individual lines of the function have this syntax:

/* '<elementHyperlink>' */

**Examples**

/* MATLAB Function 'test_function': '<S50>:99' */

/* '<S50>:99:20' */

The first comment refers to the MATLAB function named test_function, which has the hyperlink <S50>:99.

The second comment refers to line 20 of the MATLAB function in your chart.

**Truth Table Block**

**Syntax**

/* Truth Table Function '<Name>': '<elementHyperlink>' */

Within the inlined code for a Truth Table block, comments for conditions, decisions, and actions have this syntax:

/* Condition '#<Num>': '<elementHyperlink>' */
/* Decision 'D<Num>': '<elementHyperlink>' */
/* Action '<Num>': '<elementHyperlink>' */

<Num> is the row or column number that appears in the Truth Table Editor.

**Examples**

/* Truth Table Function 'truth_table_default': '<S10>:100' */

/* Condition '#1': '<S10>:100:8' */
/* Decision 'D1': '<S10>:100:16' */
/* Action '1': '<S10>:100:31' */
The first comment refers to a Truth Table block named truth_table_default, which has the hyperlink <S10>:100.

The other three comments refer to elements of that Truth Table block. Each condition, decision, and action in the Truth Table block has a unique hyperlink.

**Truth Table Function**

For syntax and examples, see “Truth Table Block” on page 64-26.

**Graphical Function**

Syntax

`/* Graphical Function '<Name>': '<elementHyperlink>' */`

Example

`/* Graphical Function 'hello': '<S1>:123' */`

This comment refers to a graphical function named hello, which has the hyperlink <S1>:123.

**Simulink Function**

Syntax

`/* Simulink Function '<Name>': '<elementHyperlink>' */`

Example

`/* Simulink Function 'simfcn': '<S4>:10' */`

This comment refers to a Simulink function named simfcn, which has the hyperlink <S4>:10.

**Event**

Syntax

`/* Event: '<elementHyperlink>' */`

Example

`/* Event: '<S3>:33' */`

This comment refers to an event, which has the hyperlink <S3>:33.

Link Generated Code to Requirements

Link generated code to model element requirements. Using configuration parameters, you can specify whether to include requirement descriptions as comments in the generated code.

Open Model

Open the rtwdemo_requirements model. The model contains Simulink® and Stateflow® elements with associated requirements.

```matlab
model='rtwdemo_requirements';
open_system(model);
```

**Requirements in Generated Code**

Requirements attached to various Simulink and Stateflow objects can appear in code generated by Embedded Coder(R) within their respective comments. The two steps are:

1) Add requirements to model.
2) Check option in configuration parameters.

**Step 1: Add Requirements to Model**

Requirements can be added to numerous types of objects in Simulink and Stateflow using the Requirements entry from the context menu. The following are requirements entered in this model (double-click to open):

- Simulink Block
- Simulink Signal Builder
- Stateflow State
- Stateflow Transition
- Stateflow Graphical Function

**Step 2: Check Requirements Options**

Open the model’s configuration parameters and navigate to the Requirements section of the Code Generation settings. Double-click below to see these settings.

- Open Requirements Settings

**Additional Documentation**

Additional documentation is available for integrating requirements into generated code by double-clicking the link below.

- Requirements Documentation
**View Requirements**

You can view requirements linked to the model by using the Requirements Editor. In the Simulink Editor, select Analysis > Requirements > Requirements Editor. You can view requirements specific to model objects by using the object context menu. Right-click an element and select Requirements > Open Outgoing Links dialog .... To view the requirements, use these commands:

1. To view the requirements for the DiscretePulseGenerator block, right click on the DiscretePulseGenerator block and select Requirements > Open Outgoing Links dialog ... to open Outgoing Links Editor. Using Outgoing Links Editor, you can create, edit, and delete requirements traceability links.

   ```
clockblock='rtwdemo_requirements/clock';
clockblockh=get_param(clockblock,'handle');
rmi('edit',clockblockh);
```

2. To view the requirements, open the Signal Builder block by double clicking on it.

   ```
sigbblock='rtwdemo_requirements/Signal Builder';
open_system(sigbblock)
```
3. To view the requirements for the Stateflow® state, open the Outgoing Links Editor.

```matlab
state=find(sfroot,'-isa','Stateflow.State','-and','Tag','req_state');
rmi('edit',state.id);
```

4. To view the requirements for the Stateflow transition, open the Outgoing Links Editor.

```matlab
trans=find(sfroot,'-isa','Stateflow.Transition','-and','Tag','req_trans');
rmi('edit',trans.id);
```

5. To view the requirements for the Stateflow function, open the Outgoing Links Editor.
func=find(sfroot,'-isa','Stateflow.Function','-and','Tag','req_function');
rm('edit',func.id);

Close the open windows.

close_system(sigbblock);

**Set Configuration Parameters**

Open the Configuration Parameters dialog box **Code Generation > Comments** pane. View the configuration parameter settings.

model = bdroot;
slCfigPrmDlg(model,'Open');
slCfigPrmDlg(bdroot,'TurnToPage','Comments');

**Generate Code**

Generate code for the model.

rtwbuild('rtwdemo_requirements')

### Starting build procedure for model: rtwdemo_requirements
### Successful completion of build procedure for model: rtwdemo_requirements

In the generated code, view the comments containing the requirements. To view all the requirements, click the hyperlinked requirement comment.

rtwdemodbtype('rtwdemo_requirements_ert_rtw/rtwdemo_requirements.c','...
"/* Function for Chart:','return result;',1,0);

/* Function for Chart: '<Root>/rebound_elimination' */
static real_T rebound_fcn(real_T prev_in, real_T prev_out, real_T curr_in) {
   real_T result;

   /* Graphical Function 'rebound_fcn': '<S2>:2':
    *  1. Result Computation
    */
   /* Transition: '<S2>:4' */
   if (prev_in == curr_in) {
      /* Transition: '<S2>:5' */
      result = curr_in;
   } else {
/ * Transition: '<S2>:6' */
/* Transition: '<S2>:7' */
result = prev_out;

For requirement traceability, see “Link Blocks and Requirements” (Simulink Requirements).

Close Model

rtwdemoclean;
close_system('rtwdemo_requirements',0);
Reload Existing Traceability Information

When you build a model, the traceability information is stored in the build folder. The format of the build folder for an ERT-based target is *model_ert_rtw*.

**Model-to-code** (Simulink Coder) parameter should be selected in the original build to be able to reload the traceability information in a new Simulink session. To reload existing traceability information for a model:

1. Reset the current working folder to the parent folder of the existing build folder.
2. In the Configuration Parameters dialog box, next to **Model-to-code**, click **Configure** (Simulink Coder).
3. In the Model-to-code navigation dialog box, in the **Build folder** field, type or browse to the build folder that contains the existing traceability information.

If you close and reopen a model, the **Navigate to Code** context menu option might not be available because Embedded Coder cannot find a build folder for your model in the current working folder. In that case, perform these steps:

1. To open the Model-to-code navigation dialog box, click **Configure**.
2. In the Model-to-code navigation dialog box, click **Browse**.
3. Browse to the build folder for your model and select the folder. The build folder path is displayed in the **Build folder** field.
If you selected **Model-to-code** for the build, clicking **Apply** or **OK** loads traceability information from the earlier build into your Simulink session.

To open the context menu and trace a model element to corresponding code, right-click a model element and select **C/C++ Code > Navigate to C/C++ Code**.

Customize Traceability Reports

Even a relatively small model can generate hundreds of lines of C/C++ code. To help you navigate more easily between the generated code and your source model, Embedded Coder provides the traceability report section. When you enable traceability, Embedded Coder creates and displays an HTML code generation report. You can generate reports in the Configuration Parameters dialog box or at the command line.

In the Configuration Parameters dialog box, the Code Generation > Report pane lists parameters that you can select and clear to customize the content of your traceability reports.

Select or clear any combination of these parameters. These parameters are on by default.

- **Eliminated / virtual blocks** (Simulink Coder) (account for blocks that are untraceable)
- **Traceable Simulink blocks** (Simulink Coder)
- **Traceable Stateflow elements** (Simulink Coder)
- **Traceable MATLAB functions** (Simulink Coder)

If you select all parameters, you get a complete mapping between model elements and the generated code.

This figure shows the top section of the traceability report, which is generated when you select all traceability content parameters for model rtwdemo_hyperlinks.

Generate a Traceability Matrix

The traceability matrix provides traceability among model elements, generated code, and model requirements in a Microsoft Excel® file format.

If you have DO Qualification Kit software or IEC Certification Kit software and are using a Windows host, you can generate a traceability matrix into Microsoft Excel format directly from the traceability report.

Go to the Traceability Report section of the HTML code generation report and click Generate Traceability Matrix.

To select an existing matrix file to update or specify a matrix file to create, use the options in the Generate Traceability Matrix dialog box. Optionally, you can select and create an order to the columns that appear in the generated matrix. After specifying the location where you want the matrix file, click the Generate button.

For more information, see "Generating a Traceability Matrix" in either the DO Qualification Kit documentation (DO Qualification Kit) or the IEC Certification Kit documentation (IEC Certification Kit).

Component Verification in Embedded Coder
Component Verification in Target Environment

After you generate production code for a component design, you need to integrate, compile, link, and deploy the code as a complete application on the embedded system. One approach is to manually integrate the code into an existing software framework that consists of an operating system, device drivers, and support utilities. The algorithm can include externally written legacy or custom code.

An easier approach to verifying a component in a target environment is to use processor-in-the-loop (PIL) simulation. For information about PIL simulations, see “SIL and PIL Simulations” on page 67-2.

Goals of Component Verification

Assuming that you have generated production source code and integrated required externally written code, such as drivers and a scheduler, you can verify that the integrated software operates as expected by testing it in the target environment. During testing, you can achieve either of the following goals, depending on whether you export code that is strictly ANSI C/C++ or mixes ANSI C/C++ with code optimized for a target environment.

<table>
<thead>
<tr>
<th>Goal</th>
<th>Type of Code Export</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximize code portability and configurability</td>
<td>ANSI C/C++</td>
</tr>
<tr>
<td>Simplify integration and maximize use of processor resources and code efficiency</td>
<td>Mixed code</td>
</tr>
</tbody>
</table>

Regardless of your goal, you must integrate required external drivers and scheduling software. To achieve real-time execution, you must integrate the real-time scheduling software.

To maximize code portability and configurability, limit the application code to ANSI/ISO C or C++ code only, as the following figure shows.
To simplify code integration and maximize code efficiency for a target environment, use Embedded Coder features for:

- Controlling code interfaces
- Exporting subsystems
- Including target-specific code, including compiler optimizations

The following figure shows a mix of ANSI C/C++ code with code that is optimized for a target environment.
Run Component Tests

The workflow for running software component tests in the target environment is:

1. Integrate external code, for example, for device drivers and a scheduler, with the generated C or C++ code for your component model. For more information, see “S-Functions and Code Generation” (Simulink Coder). For more specific references that depend on your verification goals, see the following table.
<table>

- “Real-Time Software Component Testing” on page 66-6
Real-Time Software Component Verification

One approach to verifying a software component is to build the component into a complete software system that can execute in real time in the target environment. A complete software system includes:

- Algorithm for the software component
- Scheduling algorithms
- Calls to drivers for board-specific devices

This single build approach is more time consuming to set up, but makes it easier to get the complete application running in the target environment.

The following figure shows code generated for an algorithm being built into a complete system executable for the target environment.
The workflow for testing component software as part of a complete real-time target environment is:

1. Develop a component model and generate source code for production.

For information on building in scheduling and real-time system support, see:

- “Time-Based Scheduling and Code Generation” (Simulink Coder) and “Modeling for Multitasking Execution” (Simulink Coder). For an example, open rtwdemos and navigate to the Multirate Support folder.

What Are SIL and PIL Simulations?

With Embedded Coder, you can run software-in-the-loop (SIL) and processor-in-the-loop (PIL) simulations of your model. These simulations generate source code for either the top model or part of the model. A SIL simulation compiles and runs the generated code on your development computer. A PIL simulation cross-compiles source code on your development computer, and then downloads and runs the object code on a target processor or an equivalent instruction set simulator.

With SIL and PIL simulations, you can:

- Test whether your model and generated code are numerically equivalent.
- Observe code coverage.
- Perform code execution profiling.

Why Use SIL and PIL

Through SIL and PIL, you can early on test and fix defects. For example, you can model and test a system component in normal mode. Then, you can reuse your test suites in a SIL or PIL simulation that runs compiled generated code. To check numerical equivalence, you compare normal and SIL or PIL simulation results. You thereby avoid leaving the Simulink environment to test generated code on a separate infrastructure.

This table describes situations where you can use SIL and PIL.
<table>

## How SIL and PIL Simulations Work

In a SIL or PIL simulation, code is generated for either the top model or part of the model. With SIL, this code is compiled for and executed on your development computer. With PIL, the code is cross-compiled for the target hardware and runs on the target processor.

Through a communication channel, Simulink sends stimulus signals to the code on your computer or target processor for each sample interval of the simulation.

- For a top model, Simulink uses stimulus signals from the base or model workspace.
- If you have designated only part of the model to simulate in SIL or PIL mode, then a part of the model remains in Simulink and code is not generated for this part of the

---

**Note** The SIL and PIL simulation modes are not designed for the reduction of model simulation times. If you want to speed up the simulation of your model, use the rapid accelerator mode. For more information, see “What Is Acceleration?” (Simulink).

Normal simulation techniques do not account for restrictions and requirements that the hardware imposes, such as limited memory resources or behavior of target-specific optimized code.

For information about running PIL simulations on specific targets, see “Sample Custom Targets” (Simulink Coder) in the Simulink Coder documentation.
model. Typically, you configure this part of the model to provide test vectors for the software executing on the hardware. This part of the model can represent other parts of the algorithm or the environment in which the algorithm operates.

When your computer or target processor receives signals from Simulink, the processor executes the SIL or PIL algorithm for one sample step. The SIL or PIL algorithm returns output signals calculated during this step to Simulink through a communication channel. One sample cycle of the simulation is complete, and Simulink proceeds to the next sample interval. The process keeps repeating itself and the simulation progresses. SIL and PIL simulations do not run in real time. In each sample period, Simulink and the object code exchange I/O data.

**Type of SIL or PIL Simulation** | **What Happens in SIL Simulation** | **What Happens in PIL Simulation**
--- | --- | ---
Use SIL or PIL block created from subsystem. | • Simulation runs compiled object code through S-function. S-function communicates with object code executing as standalone application on development computer. SIL block execution is independent of the MATLAB process.  
• Execution is host/host and nonreal time. | • Simulation runs cross-compiled object code through S-function on development computer. S-function communicates with object code executing as standalone application on target processor or instruction set simulator.  
• Execution is host/target and nonreal time.

---

**Code Interfaces for SIL and PIL**

You generate standalone code when you perform, for example, a top-model or right-click subsystem build for a single deployable component. You can compile and link standalone code into a standalone executable or integrate it with other code. For more information on the standalone code interface, see “Configure Code Generation for Model Entry-Point Functions” (Simulink Coder).

When you generate code for a referenced model hierarchy, the software generates standalone executable code for the top model and a library module called a model reference target for each referenced model. When the code executes, the standalone executable invokes the applicable model reference targets to compute the referenced model outputs. For more information, see “Build Model Reference Targets” (Simulink Coder).

To integrate generated code with legacy code, use standalone code because the standalone code interface is documented.

---

**Note** SIL and PIL simulations do not provide direct support for custom code interfaces. You can incorporate these interfaces into Simulink as an S-function, for example, using the Legacy Code Tool, S-Function Builder, or handwritten code. Then, you can verify the custom code by using SIL and PIL simulations.
This table provides the interfaces that SIL and PIL simulations generate.

<table>
<thead>
<tr>
<th>SIL/PIL Simulation</th>
<th>Code Interface</th>
</tr>
</thead>
<tbody>
<tr>
<td>Top-model</td>
<td>SIL/PIL simulation generates the standalone code interface. If code exists, simulation calls standalone code for the model. If code does not exist, simulation generates standalone code.</td>
</tr>
</tbody>
</table>
| Model block        | If you set **Code interface** block parameter to **Top model**, SIL/PIL simulation generates standalone code interface. Simulation calls standalone code for the model if it exists. Otherwise, simulation generates standalone code by using `slbuild('model')` command.  
If you set **Code interface** block parameter to **Model reference**, SIL/PIL simulation generates model reference code interface. Simulation calls model reference target for Model block if it exists. Otherwise, simulation generates model reference target by using `slbuild('model', 'ModelReferenceRTWTarget')` command. |
| SIL or PIL block   | Block uses standalone code interface. |
## Scheduling Considerations

</table>
| Exported functions in feedback loops | If your model has function-call subsystems and you export a subsystem that has context-dependent inputs (for example, feedback signals), the results of a SIL/PIL simulation with the generated code and the results of the normal mode simulation of your model can differ. One approach to make SIL/PIL and normal mode simulations yield identical results is to use Function-Call Feedback Latch blocks in your model. You can make context-dependent inputs become context-independent. Embedded Coder generates a warning identifying context-dependent inputs of exported function-call subsystems if you set **Configuration Parameters > Diagnostics > Connectivity > Context-dependent inputs** to one of the following:  
  - Enable all as warnings  
  - Use local settings  
  - Disable all  
  For more information, see:  
    - “Control Generation of Subsystem Functions” (Simulink Coder)  
    - Function-Call Feedback Latch  
    - “Context-dependent inputs” (Simulink) |
# Imported Data and Function Definitions

<table>
<thead>
<tr>
<th>Item</th>
<th>Information</th>
</tr>
</thead>
</table>
| Imported data               | In SIL and PIL simulations, you can use signals, parameters, and data stores that specify storage classes with imported data definitions. The simulations define storage for imported data associated with:  
- Signals at the root level of the component (on the I/O boundary)  
- Parameters  
- Global data stores  

SIL and PIL simulations do not define storage for other imported data. For example, the simulations do not define storage for imported data associated with:  
- Internal signals (not on the I/O boundary)  
- Local data stores  

In these cases, define the storage through custom code included by the component under test or through the PIL rtw.pil.RtI0StreamApplicationFramework API.  

See also “Tunable Parameters and SIL/PIL” on page 67-68.                                                                                   |
| GetSet custom storage class | SIL and PIL simulations support the GetSet custom storage class. The SIL/PIL test harness provides C definitions of the Get and Set functions that are used during simulations. For more information, see “Access Data Through Functions with Custom Storage Class GetSet” on page 26-42.                          |
You can use top-model and Model block SIL/PIL and SIL/PIL block simulations to perform model-based testing of an AUTOSAR software component. The generated code for the AUTOSAR software component is linked with a basic component-specific AUTOSAR Runtime Environment (RTE) to create a test application. This application tests AUTOSAR API calls made by the AUTOSAR software component.

**Note** For Model block SIL/PIL, to test the AUTOSAR interface, set the Code interface block parameter to Top model.

For more information, see “Verify AUTOSAR C Code with SIL and PIL”.

</tr>
<tr>
<td>“Summary” on page 67-14</td>
</tr>
</tbody>
</table>

Consider a top model that consists of components A, B, C, and D:

- A and B are existing components for which code has previously been generated and tested.
- C, a referenced model, and D, a subsystem, are new components.

With software-in-the-loop (SIL) and processor-in-the-loop (PIL) simulations, you can use the following approaches to numerical equivalence testing:

For some forms of testing, you require a test harness model. The test harness model:
• Generates test vectors or stimulus inputs that feed the block under test.
• Makes it possible for you to observe or capture output from the block.

The following example shows a simple test harness model.

The block under test is a Model block. The Sine Wave block generates the input for the Model block. Through the Scope block, you can observe the output from the Model block.

**Test Top-Model Code**

To test code generated from the top-model components together (A, B, C, and D), you can use top-model SIL/PIL or Model block SIL/PIL.

• Top-model SIL/PIL:

  1. Create test vectors or stimulus inputs in the MATLAB workspace (Simulink).
  2. Run the top model in normal, SIL, and PIL simulation modes. The software loads the test vectors or stimulus inputs from the MATLAB workspace.
  3. For each simulation mode, observe or capture outputs.
  4. Verify numerical equivalence by comparing normal outputs against SIL and PIL outputs.

• Model block SIL/PIL:

  1. Create a Model block that contains the top-model components.
  2. Insert the Model block in a simulation model, for example, your test harness model.
  3. Run simulations, switching the Model block between normal, SIL, and PIL modes. For the SIL and PIL simulation modes, set the **Code interface** Model block parameter to **Top model**.
  4. Verify numerical equivalence by comparing normal outputs against SIL and PIL outputs.
Test Referenced Model Code

To test code generated from the component C as part of a model reference hierarchy, use the Model block SIL/PIL approach:

- Insert the Model block C in a simulation model, for example, your test harness model.
- Run simulations, switching the Model block between normal, SIL, and PIL modes. For the SIL and PIL simulation modes, set the Code interface Model block parameter to Model reference.
- Verify numerical equivalence by comparing normal outputs against SIL and PIL outputs.

Test Subsystem Code

To test code generated from the subsystem D, use the SIL or PIL block approach:

1. Insert the subsystem in a simulation model, for example, your test harness model.
2. Run a normal mode simulation, capturing the outputs.
3. Create a SIL or PIL block from the subsystem.
4. In the model, replace the subsystem with the SIL or PIL block.
5. Run a simulation of the model, capturing the outputs.
6. Verify numerical equivalence by comparing normal mode subsystem outputs against SIL or PIL block outputs.

Configure and Run SIL Simulation

There are three ways of running SIL and PIL simulations. You can use:

- The top model.
- Model blocks.
- SIL and PIL blocks that you create from subsystems.

Simulation with Top Model

To configure and run a top-model SIL or PIL simulation:

1. Open your model.
2. Select either Simulation > Mode > Software-in-the-Loop (SIL) or Simulation > Mode > Processor-in-the-Loop (PIL). This option is available only if the model is configured for an ERT or AUTOSAR target. See “Model Configuration Parameters: Code Generation” (Simulink Coder) and “Generate AUTOSAR C Code and XML Component Descriptions” for configuration information.
3. If you have not already done so, in the Configuration Parameters dialog box, on the Data Import/Export pane:
   - In the Input check box and field, specify stimulus signals (or test vectors) for your top model.
   - Configure logging for model outputs, with either output logging or signal logging:
• In the **Output** check box and field, specify *output logging*.
• In the **Signal logging** check box and field, specify *signal logging*.
• Disable logging of Data Store Memory variables. The software does not support this option for this simulation mode. If you do not clear the **Data stores** check box, the software produces a warning when you run the simulation.

4 If you are configuring a SIL simulation, specify the portable word sizes option. You can then switch seamlessly between the SIL and PIL modes. Select **Code Generation > Verification > Enable portable word sizes**.

5 If required, configure:
   • Code coverage.
   • Code execution profiling.
   • Creation of code generation report and static code metrics.

6 Start the simulation.

---

**Note** On a Windows operating system, the Windows Firewall can potentially block a SIL or PIL simulation. To allow the simulation, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

You cannot:

• Close the model while the simulation is running. To interrupt the simulation, in the Command Window, press **Ctrl+C**.
• Alter the model during the simulation. You can move blocks and lines as long as it does not alter the behavior of the model.

You can run a top-model SIL or PIL simulation with the command `sim(model)`. The software supports the `sim` command option `SrcWorkspace` for the value 'base'.

For a PIL simulation, you control the way code compiles and executes in the target environment through connectivity configurations.

With a top-model SIL or PIL simulation, Simulink creates a hidden model, `modelName_wrapper`. The simulation generates code for the model and uses the hidden model to call this code at each time step. As a result, in some circumstances, logged signals can have a `_wrapper` suffix. The simulation can also generate warnings that refer to the hidden model. For example:
Simulation with Model Blocks

To configure a Model block for a SIL or PIL simulation:

1. Open your model, for example, `rtwdemo_sil_modelblock`.
2. Right-click your Model block, for example, Counter A. In the context menu, select **Block Parameters (ModelReference)**, which opens the Function Block Parameters dialog box.
3. From the **Simulation Mode** drop-down list, select the required mode, for example, **Software-in-the-loop (SIL)**.
4. From the **Code interface** drop-down list, specify the code that you want to test, for example, **Model reference**.
5. Click **OK**. The software displays the simulation mode as a block label.

If you select **Top model**, the software displays the block label (**SIL: Top**).

6. If you are configuring a SIL simulation, specify the portable word sizes option. You can then switch seamlessly between the SIL and PIL modes. Select **Code Generation > Verification > Enable portable word sizes**.

7. If required, configure:
   - Code coverage.
   - Code execution profiling for your Model block, by configuring execution profiling for the top model.
   - Creation of code generation report and static code metrics.
8 Start the simulation.

**Note** On a Windows operating system, the Windows Firewall can potentially block a SIL or PIL simulation. To allow the simulation, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

For a PIL simulation, you control the way code compiles and executes in the target environment through connectivity configurations.

**Simulation with Blocks From Subsystems**

To create a SIL or PIL block from a subsystem and use this block to test the code generated from the subsystem:

1 From the **Configuration Parameters > Code Generation > Advanced Parameters > Create block** drop-down list, select either SIL or PIL.
2 If required, configure code execution profiling.
3 Click **OK**.
4 In your model window, right-click the subsystem that you want to simulate.
5 Select **C/C++ Code > Build This Subsystem**.
6 Click **Build**, which starts the subsystem build process that creates a SIL or PIL block for the generated subsystem code.
7 Add the generated block to an environment or test harness model that supplies test vectors or stimulus input.
8 Run simulations with the environment or test harness model.

**Note** On a Windows operating system, the Windows Firewall can potentially block a SIL or PIL simulation. To allow the simulation, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

You cannot create a SIL or PIL block if you do one of the following:

- Disable the `CreateSILPILBlock` property.
- Select a code coverage tool.
Create block appears dimmed.

For a PIL simulation, you control the way code compiles and executes in the target environment through connectivity configurations.

**Configure Hardware Implementation Settings**

For a SIL simulation, you must configure hardware implementation settings, which enables generated code compilation for your development computer. These settings can differ from the hardware implementation settings that you use when building the model for your production hardware. Use one of these approaches.

### Approach Details

Numerical results can differ between generated code executing in a SIL simulation and generated code executing on the production hardware under one of these conditions:

- Your model contains blocks implemented in TLC, for which C integral promotion in expressions can behave differently between the MATLAB host and the production hardware target. Normal and PIL simulation results match, but SIL simulation results can differ.
- Your production hardware implements rounding to **Floor** for signed integer division, and divisions in your model use rounding mode **Ceiling**, **Floor**, **Simplest**, or **Zero**. Normal and PIL simulation results match, but SIL simulation results can differ.
- The byte ordering for your production hardware is **Big Endian**. Normal and PIL simulation results match, but SIL simulation results can differ. For example, when generated code depends on byte order and generated production code is implemented with the aim that its behavior matches normal simulation behavior.
- You use custom code with the Stateflow product. In this case, type conversion statements are not inserted into the custom code, which target overflow behavior on the host can require. Normal and PIL simulation results match, but SIL simulation results can differ.

### Test hardware

Use this approach only when you want to work around a limitation of portable word sizes.

Set:

- **PortableWordSizes** to 'off'.
- **ProdEqTarget** to 'off'.
- **TargetHWDeviceType** to 'Custom Processor->MATLAB Host Processor'.

| Approach   | Details                                                                 |
**Approach** | **Details**
--- | ---
Production hardware | Use this approach only when the production hardware settings match your development computer architecture.  
Set:  
• PortableWordSizes to 'off'.  
• ProdEqTarget to 'on'.  
• ProdHWDeviceType to match your development computer architecture.

For information about test and production targets, see “Configure Run-Time Environment Options” (Simulink Coder) in the Simulink Coder documentation.

**Log Internal Signals of a Component**

SIL and PIL component outputs are available for observation and comparison with other simulation mode outputs. If you want to examine an internal signal, you can enable internal signal logging for top-model or Model block SIL or PIL. With signal logging, you can:

• Collect signal logging outputs during SIL/PIL simulations, for example, logsout.
• Log the internal signals and the root-level outputs of a SIL/PIL component.
• Manage the SIL/PIL signal logging settings with the Simulink Signal Logging Selector.
• Use the Simulation Data Inspector to:
  • Observe streamed signals during normal, SIL, and PIL simulations.
  • Compare logged signals from normal, SIL, and PIL simulations.

For SIL and PIL signal logging:

• Set Configuration Parameters > Data Import/Export > Format to Dataset.
• Select the Configuration Parameters > Code Generation > Interface > Generate C API for: signals check box.

  The C API determines the addresses of the internal signals that require logging.

You can use other methods to examine internal signals of the SIL or PIL component:
• Manually route the signal to the top level.
• Use global data stores to access internal signals:
  1. Inside the component, connect a Data Store Write block to the required signal.
  2. Outside the component, use a Data Store Read block to access the signal value.
• Use MAT-file logging. Note that:
  • MAT-file logging does not support signal logging. If signal logging is enabled, 
    
  • For PIL, the target environment must support MAT-file logging.

For more information, see:
• “Test Points” (Simulink)
• “Export Signal Data Using Signal Logging” (Simulink)
• “Local and Global Data Stores” (Simulink)
• “Global Data Store Example” (Simulink)
• “Log Program Execution Results” (Simulink Coder)

Prevent Code Changes in Multiple Simulations

Use Model block SIL/PIL or the SIL/PIL block with fast restart when you want to run
multiple SIL or PIL simulations with:

• Varying test vectors (parameter sets and input data).
• Unchanged generated code, that is, none of the simulations regenerate or rebuild code
  after the initial build. For example, you want to avoid the incremental code generation
  that an initial value change can trigger.

For Model block SIL/PIL, you can also use one of these methods:

• In your test harness model, set Configuration Parameters > Model Referencing >
  Rebuild to Never. If the Model block Code interface parameter is Model
  reference, the software does not rebuild the referenced model code. (If the Code
  interface parameter is Top model, the software ignores the Rebuild setting.)
• Create a protected model and generate source or binary code. Then, insert the
  protected model in your test harness model. With this method, you can verify top-
  model code (with the standalone code interface) or model reference code.
For the alternative methods of running Model block SIL/PIL, the following table summarizes code generation behavior after the initial build.

<table>
<thead>
<tr>
<th>SIL and PIL Approach</th>
<th>Code Generation Behavior After Initial Build</th>
</tr>
</thead>
<tbody>
<tr>
<td>Model block</td>
<td>1 Component (algorithm) code from initial build is not regenerated.</td>
</tr>
<tr>
<td></td>
<td>2 Component code makefile is not called.</td>
</tr>
<tr>
<td></td>
<td>3 SIL/PIL application files from initial build are not regenerated.</td>
</tr>
<tr>
<td></td>
<td>4 SIL/PIL application makefile is called.</td>
</tr>
<tr>
<td>Model block (protected model)</td>
<td>You observe the same behavior except for feature 2. In this case, the component code makefile is run. The component code is recompiled and linked to produce new object code.</td>
</tr>
<tr>
<td>Source code from protected model.</td>
<td>You observe features 1-4.</td>
</tr>
<tr>
<td>Binary code from protected model.</td>
<td></td>
</tr>
</tbody>
</table>

For more information, see:

- “Model Configuration Parameters: Model Referencing” (Simulink)
- “Create a Protected Model” (Simulink Coder)

**Speed Up Testing**

If your model has SIL/PIL blocks or Model blocks in SIL/PIL mode, you can speed up SIL/PIL testing by:

- Running the top-model simulation in accelerator mode (Simulink). This mode accelerates the simulation of model components that are not in SIL or PIL mode.
• Turning on fast restart (Simulink) with the **Fast restart** button on the Simulink Editor toolbar. After the first simulation, you can tune parameters and rerun simulations without model recompilation.

**Note** The SIL and PIL simulation modes are not designed for the reduction of model simulation times. If you want to speed up the simulation of your model, use the rapid accelerator mode. For more information, see “What Is Acceleration?” (Simulink).

### Simulation with Function Calls

Use the Simulink Function block and Function Caller block when you want to:

- Generate code that makes a function-call to external code, for example, driver or legacy code.
- Provide a subsystem that behaves like the external code in normal, SIL, or PIL simulations.

The example in “Configure Calls to AUTOSAR NVRAM Manager Service” shows how you can configure client calls to Basic Software (BSW) NVRAM Manager (NvM) service interfaces from your AUTOSAR software component. In a simulation, Simulink implements the BSW NvM calls through Simulink Function and preconfigured Function Caller blocks. For the final system, you link function-call stubs with external BSW function code that runs in the AUTOSAR Runtime Environment (RTE).

For more information, see “Simulink Function Blocks and Code Generation” (Simulink Coder).

- The top model.
- Model blocks.
- SIL and PIL blocks that you create from subsystems.

**Simulation with Top Model**

To configure and run a top-model SIL or PIL simulation:

1. Open your model.
2. Select either Simulation > Mode > Software-in-the-Loop (SIL) or Simulation > Mode > Processor-in-the-Loop (PIL). This option is available only if the model is configured for an ERT or AUTOSAR target. See “Model Configuration Parameters: Code Generation” (Simulink Coder) and “Generate AUTOSAR C Code and XML Component Descriptions” for configuration information.
3. If you have not already done so, in the Configuration Parameters dialog box, on the Data Import/Export pane:
   - In the Input check box and field, specify stimulus signals (or test vectors) for your top model.
   - Configure logging for model outputs, with either output logging or signal logging:
     - In the Output check box and field, specify output logging.
• In the **Signal logging** check box and field, specify *signal logging*.

• Disable logging of Data Store Memory variables. The software does not support this option for this simulation mode. If you do not clear the **Data stores** check box, the software produces a warning when you run the simulation.

4 If you are configuring a SIL simulation, specify the portable word sizes option. You can then switch seamlessly between the SIL and PIL modes. Select **Code Generation > Verification > Enable portable word sizes.**

5 If required, configure:

• Code coverage.

• Code execution profiling.

• Creation of code generation report and static code metrics.

6 Start the simulation.

---

**Note** On a Windows operating system, the Windows Firewall can potentially block a SIL or PIL simulation. To allow the simulation, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access.**

You cannot:

• Close the model while the simulation is running. To interrupt the simulation, in the Command Window, press **Ctrl+C**.

• Alter the model during the simulation. You can move blocks and lines as long as it does not alter the behavior of the model.

You can run a top-model SIL or PIL simulation with the command `sim(model)`. The software supports the `sim` command option `SrcWorkspace` for the value `'base'`.

For a PIL simulation, you control the way code compiles and executes in the target environment through connectivity configurations.

With a top-model SIL or PIL simulation, Simulink creates a hidden model, `modelName_wrapper`. The simulation generates code for the model and uses the hidden model to call this code at each time step. As a result, in some circumstances, logged signals can have a `_wrapper` suffix. The simulation can also generate warnings that refer to the hidden model. For example:

**Warning:** The model `'modelName_wrapper'` has the 'Configuration Parameters' ...

---

67-29
Simulation with Model Blocks

To configure a Model block for a SIL or PIL simulation:

1. Open your model, for example, `rtwdemo_sil_modelblock`.
2. Right-click your Model block, for example, `Counter A`. In the context menu, select **Block Parameters (ModelReference)**, which opens the Function Block Parameters dialog box.
3. From the **Simulation Mode** drop-down list, select the required mode, for example, **Software-in-the-loop (SIL)**.
4. From the **Code interface** drop-down list, specify the code that you want to test, for example, **Model reference**.
5. Click **OK**. The software displays the simulation mode as a block label.

If you select **Top model**, the software displays the block label (**SIL: Top**).

6. If you are configuring a SIL simulation, specify the portable word sizes option. You can then switch seamlessly between the SIL and PIL modes. Select **Code Generation > Verification > Enable portable word sizes**.

7. If required, configure:
   - Code coverage.
   - Code execution profiling for your Model block, by configuring execution profiling for the top model.
   - Creation of code generation report and static code metrics.

8. Start the simulation.
Note On a Windows operating system, the Windows Firewall can potentially block a SIL or PIL simulation. To allow the simulation, use the Windows Security Alert dialog box. For example, in Windows 7, click Allow access.

For a PIL simulation, you control the way code compiles and executes in the target environment through connectivity configurations.

Simulation with Blocks From Subsystems

To create a SIL or PIL block from a subsystem and use this block to test the code generated from the subsystem:

1. From the Configuration Parameters > Code Generation > Advanced Parameters > Create block drop-down list, select either SIL or PIL.
2. If required, configure code execution profiling.
3. Click OK.
4. In your model window, right-click the subsystem that you want to simulate.
5. Select C/C++ Code > Build This Subsystem.
6. Click Build, which starts the subsystem build process that creates a SIL or PIL block for the generated subsystem code.
7. Add the generated block to an environment or test harness model that supplies test vectors or stimulus input.
8. Run simulations with the environment or test harness model.

Note On a Windows operating system, the Windows Firewall can potentially block a SIL or PIL simulation. To allow the simulation, use the Windows Security Alert dialog box. For example, in Windows 7, click Allow access.

You cannot create a SIL or PIL block if you do one of the following:

- Disable the CreateSILPILBlock property.
- Select a code coverage tool.

Create block appears dimmed.
For a PIL simulation, you control the way code compiles and executes in the target environment through connectivity configurations.

**Log Internal Signals of a Component**

SIL and PIL component outputs are available for observation and comparison with other simulation mode outputs. If you want to examine an internal signal, you can enable internal signal logging for top-model or Model block SIL or PIL. With signal logging, you can:

- Collect signal logging outputs during SIL/PIL simulations, for example, `logout`.
- Log the internal signals and the root-level outputs of a SIL/PIL component.
- Manage the SIL/PIL signal logging settings with the Simulink Signal Logging Selector.
- Use the Simulation Data Inspector to:
  - Observe streamed signals during normal, SIL, and PIL simulations.
  - Compare logged signals from normal, SIL, and PIL simulations.

For SIL and PIL signal logging:

- Set **Configuration Parameters** > **Data Import/Export** > **Format** to **Dataset**.
- Select the **Configuration Parameters** > **Code Generation** > **Interface** > **Generate C API for: signals** check box.

  The C API determines the addresses of the internal signals that require logging.

You can use other methods to examine internal signals of the SIL or PIL component:

- Manually route the signal to the top level.
- Use global data stores to access internal signals:
  1. Inside the component, connect a Data Store Write block to the required signal.
  2. Outside the component, use a Data Store Read block to access the signal value.
- Use MAT-file logging. Note that:
  - MAT-file logging does not support signal logging. If signal logging is enabled, `logout` is generated but not stored in the MAT-file.
  - For PIL, the target environment must support MAT-file logging.
For more information, see:

- “Test Points” (Simulink)
- “Export Signal Data Using Signal Logging” (Simulink)
- “Local and Global Data Stores” (Simulink)
- “Global Data Store Example” (Simulink)
- “Log Program Execution Results” (Simulink Coder)

### Prevent Code Changes in Multiple Simulations

Use Model block SIL/PIL or the SIL/PIL block with fast restart when you want to run multiple SIL or PIL simulations with:

- Varying test vectors (parameter sets and input data).
- Unchanged generated code, that is, none of the simulations regenerate or rebuild code after the initial build. For example, you want to avoid the incremental code generation that an initial value change can trigger.

For Model block SIL/PIL, you can also use one of these methods:

- In your test harness model, set **Configuration Parameters > Model Referencing > Rebuild** to **Never**. If the Model block **Code interface** parameter is **Model reference**, the software does not rebuild the referenced model code. (If the Code interface parameter is **Top model**, the software ignores the **Rebuild** setting.)
- Create a protected model and generate source or binary code. Then, insert the protected model in your test harness model. With this method, you can verify top-model code (with the standalone code interface) or model reference code.

For the alternative methods of running Model block SIL/PIL, the following table summarizes code generation behavior after the initial build.
### SIL and PIL Approach

<table>
<thead>
<tr>
<th>Model block</th>
<th>Configuration Parameters &gt; Model Referencing &gt; Rebuild of test harness model set to Never.</th>
<th>1</th>
<th>Component (algorithm) code from initial build is not regenerated.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>2</td>
<td>Component code makefile is not called.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>3</td>
<td>SIL/PIL application files from initial build are not regenerated.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>4</td>
<td>SIL/PIL application makefile is called.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Model block (protected model)</th>
<th>Source code from protected model.</th>
<th>You observe the same behavior except for feature 2. In this case, the component code makefile is run. The component code is recompiled and linked to produce new object code.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Binary code from protected model.</td>
<td>You observe features 1–4.</td>
<td></td>
</tr>
</tbody>
</table>

For more information, see:
- “Model Configuration Parameters: Model Referencing” (Simulink)
- “Create a Protected Model” (Simulink Coder)

### Speed Up Testing

If your model has SIL/PIL blocks or Model blocks in SIL/PIL mode, you can speed up SIL/PIL testing by:

- Running the top-model simulation in accelerator mode (Simulink). This mode accelerates the simulation of model components that are not in SIL or PIL mode.
- Turning on fast restart (Simulink) with the Fast restart button on the Simulink Editor toolbar. After the first simulation, you can tune parameters and rerun simulations without model recompilation.
Note The SIL and PIL simulation modes are not designed for the reduction of model simulation times. If you want to speed up the simulation of your model, use the rapid accelerator mode. For more information, see “What Is Acceleration?” (Simulink).

Simulation with Function Calls

Use the Simulink Function block and Function Caller block when you want to:

- Generate code that makes a function-call to external code, for example, driver or legacy code.
- Provide a subsystem that behaves like the external code in normal, SIL, or PIL simulations.

The example in “Configure Calls to AUTOSAR NVRAM Manager Service” shows how you can configure client calls to Basic Software (BSW) NVRAM Manager (NvM) service interfaces from your AUTOSAR software component. In a simulation, Simulink implements the BSW NvM calls through Simulink Function and preconfigured Function Caller blocks. For the final system, you link function-call stubs with external BSW function code that runs in the AUTOSAR Runtime Environment (RTE).

For more information, see “Simulink Function Blocks and Code Generation” (Simulink Coder).

Simulation Mode Override Behavior in Model Reference Hierarchy

When the top model contains a Model block, the simulation mode of the top model can override the simulation mode of the Model block. The Model block itself can be a parent block containing child Model blocks at lower levels of its reference hierarchy. The simulation mode of the parent block can override the simulation mode of the child block.

You can specify the simulation mode of a top model to be normal, accelerator, rapid accelerator, SIL, or PIL. With a Model block, you can specify all modes except rapid accelerator. This table shows how the software determines the effective simulation mode of a Model block in a reference hierarchy.

<table>
<thead>
<tr>
<th>Mode of Top Model or Parent Block</th>
<th>Mode of Parent or Child Block in Reference Hierarchy</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Normal</td>
</tr>
<tr>
<td>Normal</td>
<td>Equivalent</td>
</tr>
<tr>
<td>Accelerator</td>
<td>Override</td>
</tr>
<tr>
<td>Rapid accelerator</td>
<td>Override</td>
</tr>
<tr>
<td>SIL</td>
<td>Override</td>
</tr>
<tr>
<td>PIL</td>
<td>Override</td>
</tr>
</tbody>
</table>

The different types of behavior are:

- Equivalent — Both parent and child Model block run in the same simulation mode.
- Compatible — The software simulates the child block in the mode specified for the child block, for example, when the simulation mode of the top model is normal or accelerator.
- Error — The simulation produces an error. For example, if a top model has simulation mode rapid accelerator but contains a child block in SIL or PIL mode, then running a simulation produces an error: the rapid accelerator mode cannot override the SIL and
PIL mode of child blocks. This behavior avoids the risk of “false positives”, that is, the simulation of a model in rapid accelerator mode does not lead to the conclusion that generated source or object code of child Model blocks is tested or verified.

- **Override** — The simulation mode of the top model or parent Model block overrides the simulation mode of the child block. For example, if a top model or parent Model block that you configured for a SIL simulation contains a child Model block with normal or accelerator simulation mode, then the software simulates the child block in SIL mode. The override behavior:
  
  - Allows a Model block in the reference hierarchy to have the SIL or PIL mode.
  - Makes lower-level referenced models execute in SIL or PIL mode if you simulate the top model or parent Model block in SIL or PIL mode. You do not have to switch the simulation mode of every model component in the hierarchy.

**Note** You can view your model hierarchy in the Model Dependency Viewer. In the Referenced Model Instances view, the software displays Model blocks differently to indicate their simulation modes, for example, normal, accelerator, SIL, and PIL. In this view, the software does not indicate the simulation mode of the top model.

Debug Generated Code During SIL Simulation

If a software-in-the-loop (SIL) simulation fails or you notice differences between the outputs of your original functions and the generated code, you can rerun the SIL simulation with a debugger enabled. By inserting breakpoints, you can observe the behavior of code sections, which can help you to understand the cause of the issue.

For a SIL simulation failure, you can also view information from the standard output and standard error streams in the Diagnostic Viewer. For example:

- Output from printf statements in your code.
- Error messages sent to stderr.
- Some low-level system messages.

During a SIL simulation, the SIL application redirects the stdout and stderr streams. When the application terminates, the Diagnostic Viewer displays the information from the redirected streams. The SIL application also provides a basic signal handler, which captures the POSIX® signals SIGFPE, SIGILL, SIGABRT, and SIGSEV. For this signal handler, the SIL application includes the file signal.h.

A SIL simulation supports these debuggers:

- On Windows, Microsoft Visual Studio® debugger.
- On Linux, GNU Data Display Debugger (DDD).

**Note** You can perform SIL debugging only if the Simulink product family supports your Microsoft Visual C++ or GNU GCC compiler. For more information, see supported compilers.

To enable your debugger for a SIL simulation, on the Configuration Parameters > Code Generation > Verification pane, select the Enable source-level debugging for SIL check box.

If your top model has Model blocks, the Enable source-level debugging for SIL parameter for the top model overrides the corresponding parameter for referenced models.
When you run the SIL simulation, for example on a Windows computer, your `model.c` or `model.cpp` file opens in the Microsoft Visual Studio IDE with debugger breakpoints at the start of the `model_initialize` and `model_step` functions.

You can now use the debugger features to observe code behavior. For example, you can step through code and examine variables.

To end the debugging session:

1. Remove all breakpoints.
2. Click the Continue button (F5).

The SIL simulation runs to completion and the Microsoft Visual Studio IDE closes.

**Note** In the Microsoft Visual Studio IDE, if you select **Debug > Stop Debugging**, the SIL simulation times out with the following error message:
The timeout of 1 seconds for receiving data from the rtiostream interface has been exceeded. There are multiple possible causes for this failure.

Target Connectivity Configurations for PIL

Use target connectivity configurations and the target connectivity API to customize processor-in-the-loop (PIL) simulation for your target environments.

Through a target connectivity configuration, you specify:

- A configuration name for a target connectivity API implementation.
- Settings that define the set of compatible Simulink models. For example, the set of models that have a particular system target file, template makefile, and hardware implementation.

A PIL simulation requires a target connectivity API implementation that integrates third-party tools for:

- Cross-compiling generated code, creating the PIL application that runs on the target hardware.
- Downloading, starting, and stopping the application on the target.
- Communicating between Simulink and the target.

You can have many different target connectivity configurations for PIL simulation. Register a connectivity configuration with Simulink by creating an `sl_customization.m` file and placing it on the MATLAB search path.

When you run a PIL simulation, the software determines which of the available connectivity configurations to use. The software looks for a connectivity configuration that is compatible with the model under test. If the software finds multiple or no
compatible connectivity configurations, the software generates an error message with information about resolving the problem.

**Create a Target Connectivity API Implementation**

This diagram shows the components of the PIL target connectivity API.

You must provide implementations of the three API components:

- **Build API** — Specify the Simulink Coder toolchain or template makefile approach for building generated code.
- **Launcher API** — Control how Simulink starts and stops the PIL executable.
- **Communications API** — Customize connectivity between Simulink and the PIL target. Embedded Coder provides host-side support for TCP/IP and serial communications, which you can adapt for other protocols.
These steps outline how you create a target connectivity API implementation. The example code shown in the steps is taken from `ConnectivityConfig.m` in “Configure Processor-In-The-Loop (PIL) for a Custom Target”.

   
   ```
   ConnectivityConfig < rtw.connectivity.Config
   ```

2. In the subclass:
   
   - Instantiate `rtw.connectivity.MakefileBuilder`, which configures the build process.
     
     ```
     builder = rtw.connectivity.MakefileBuilder(componentArgs, ...
            targetApplicationFramework, ...
            exeExtension);
     ```
   - Create a subclass of `rtw.connectivity.Launcher`, which downloads and executes the application using a third-party tool.
     
     ```
     launcher = mypil.Launcher(componentArgs, builder);
     ```

3. Configure your `rtiostream` API implementation of the host-target communications on page 67-48 channel.
   
   - For the target side, you must provide the driver code for communications, for example, TCP/IP or serial communications. To integrate this code into the build process, create a subclass of `rtw.pil.RtIOStreamApplicationFramework`.
   - For the host side, you can use a supplied library for TCP/IP or serial communications. Instantiate `rtw.connectivity.RtIOStreamHostCommunicator`, which loads and initializes the library that you specify.
     
     ```
     hostCommunicator = rtw.connectivity.RtIOStreamHostCommunicator(componentArgs, ...
                           launcher, ...
                           rtiostreamLib);
     ```

4. If you require execution-time profiling of generated code, create a timer object that provides details of the hardware-specific timer and associated source files. See “Specify Hardware Timer” on page 67-54.

**Note** Each time you modify a connectivity implementation, close and reopen the models to refresh them.
Register a Connectivity API Implementation

To register a target connectivity API implementation as a target connectivity configuration in Simulink:

1. Create or update an `sl_customization.m` file. In this file:
   - Create a target connectivity configuration object that specifies, for example, the configuration name for a target connectivity API implementation and compatible models.
   - Invoke `registerTargetInfo`.

2. Add the folder containing `sl_customization.m` to the search path and refresh your customizations.

   ```matlab
   addpath(sl_customization_path);
   sl_refresh_customizations;
   
   For more information, see `rtw.connectivity.ConfigRegistry`.

Verify Target Connectivity Configuration

To verify your target connectivity configuration early on and independently of your model development and code generation, use the supplied `piltest` function. With the function, you can run a suite of tests. In the tests, the function runs various normal, SIL, and PIL simulations. The function compares results and produces errors if it detects differences between simulation modes.

Target Connectivity API Examples

For step-by-step examples, see:

- “Configure Processor-In-The-Loop (PIL) for a Custom Target”

  This example shows you how to create a custom PIL implementation using the target connectivity APIs. You can examine the code that configures the build process to support PIL, a downloading and execution tool, and a communication channel between host and target. To activate a full host-based PIL configuration, follow the steps in the example.

- “Create a Target Communication Channel for Processor-In-The-Loop (PIL) Simulation”
This example shows you how to implement a communication channel for use with the Embedded Coder product and your embedded target. This communication channel enables exchange of data between different processes. PIL simulation requires exchange of data between the Simulink software running on your development computer and deployed code executing on target hardware.

The `rtiostream` interface provides a generic communication channel that you can implement in the form of target connectivity drivers for a range of connection types. The example shows how to configure your own target-side driver for TCP/IP, to operate with the default host-side TCP/IP driver. The default TCP/IP communications allow high-bandwidth communication between host and target, which you can use for transferring data such as video.

**Note** If you customize the `rtiostream` TCP/IP implementation for your PIL simulations, you must turn off Nagle's algorithm for the server side of the connection. If Nagle's algorithm is not turned off, your PIL simulations can run at a significantly slower speed. The `matlabroot/rtw/c/src/rtiostream/rtiostreamtcpip/rtiostream_tcpip.c` file shows how you can turn off Nagle's algorithm:

```c
/* Disable Nagle's Algorithm*/
option = 1;
sockStatus = setsockopt(lFd,IPPROTO_TCP,TCP_NODELAY,(char*)&option,sizeof(option));
```

The code for your custom TCP/IP implementation can require modification.

The example also shows how to implement custom target connectivity drivers, for example, using serial, CAN, or USB for both host and target sides of the communication channel.

Host-Target Communication for PIL

In this section...

“Communications rtiostream API” on page 67-48
“Synchronize Host and Target” on page 67-49
“Test an rtiostream Driver” on page 67-50
“Word Addressable Target Hardware” on page 67-52

Communications rtiostream API

The rtiostream API supports communications for the target connectivity API. Use the rtiostream API to implement a communication channel that enables data exchange between different processes.

PIL simulation requires a host-target communications channel. This communications channel comprises driver code that runs on the host and target. The rtiostream API defines the signature of target-side and host-side functions that this driver code must implement.

The API is independent of the physical layer that sends the data. Possible physical layers include RS232, Ethernet, or Controller Area Network (CAN).

A full rtiostream implementation requires both host-side and target-side drivers. Code generation software includes host-side drivers for the default TCP/IP implementation and a version for serial communications. To use:

• The TCP/IP rtiostream communications channel, you must provide, or obtain from a third party, target-specific TCP/IP device drivers.
• The serial communications channel, you must provide, or obtain from a third party, target-specific serial device drivers.

For other communication channels and platforms, the code generation software does not provide default implementations. You must provide both the host-side and the target-side drivers.

The rtiostream API comprises the following functions:

• rtIOStreamOpen
• rtIOStreamSend
• rtIOStreamRecv
• rtIOStreamClose

For information about:

• Using rtiostream functions in a connectivity implementation, see “Create a Target Connectivity API Implementation” on page 67-43.
• Testing the rtiostream shared library methods from MATLAB code, see rtiostream_wrapper.
• Debugging and verifying the behavior of custom rtiostream interface implementations, see “Test an rtiostream Driver” on page 67-50.

**Synchronize Host and Target**

If you use the rtiostream API to implement the communications channel, the host and target must be synchronized, which prevents Simulink from transmitting and receiving data before the target application is fully initialized.

To synchronize the host and target for TCP/IP rtiostream implementations, use the setInitCommsTimeout method from rtw.connectivity.RtIOStreamHostCommunicator. This approach works well for connection-oriented TCP/IP rtiostream implementations because Simulink automatically waits until the target server is running.

With other rtiostream implementations, for example, serial, the Simulink side of the rtiostream connection opens without waiting for the target to be fully initialized. In this case, you must make your Launcher implementation wait until the target application is fully initialized. Use one of the following approaches to synchronize your host and target:

• Add a pause at the end of the Launcher implementation that makes the Launcher wait until target initialization is complete.
• In the Launcher implementation, use third-party downloader or debugger APIs that wait until target initialization is complete.
• Implement a handshaking mechanism in the Launcher/rtiiostream implementation that confirms completion of target initialization.
Test an rtiostream Driver

Use a test suite to debug and verify the behavior of custom rtiostream interface implementations.

The test suite has the following advantages:

- Reduces time for integrating custom hardware that does not have built-in rtiostream support.
- Reduces time for testing custom rtiostream drivers.
- Helps analyze the performance of custom rtiostream drivers.

The test suite has two parts. One part of the test suite runs on the target.

**Note** After building the target application, download it to the target and run it.

To start this part, compile and link the following files, which are in the folder `matlabroot/toolbox/coder/rtiostream/src/rtiostreamtest (open).`

- `rtiostreamtest.c`
- `rtiostreamtest.h`
- `rtiostream.h`, located in the folder `matlabroot/rtw/c/src (open)`
- `rtiostream implementation under investigation` (for example, `rtiostream_tcpip.c`)
- `main.c`

To run the MATLAB part of the test suite, invoke `rtiostreamtest`. The syntax is as follows:

```plaintext
rtiostreamtest(connection, param1, param2)
```

- `connection` is a character vector indicating the communication method. It can have values 'tcp' or 'serial'.
- `param1` and `param2` have different values depending on the value of `connection`.
  - If `connection` is 'tcp', then `param1` and `param2` are hostname and port, respectively. For example, `rtiostreamtest('tcp', 'localhost', 2345).`
• If connection is 'serial', then param1 and param2 are COM port and baud rate, respectively. For example, rtiostreamtest('serial', 'COM1', 9600).

You can run the MATLAB part of the test suite as follows:

```matlab
rtiostreamtest('tcp','localhost','2345')
```

An output in the following format appears in the MATLAB window:

```plaintext
### Test suite for rtiostream ###
Initializing connection with target...

### Hardware characteristics discovered
Size of char    : 8 bit
Size of short   : 16 bit
Size of int     : 32 bit
Size of long    : 32 bit
Size of float   : 32 bit
Size of double  : 64 bit
Size of pointer : 64 bit
Byte ordering   : Little Endian

### rtiostream characteristics discovered
Round trip time : 0.96689 ms
rtIOStreamRecv behavior : non-blocking

### Test results
Test 1 (fixed size data exchange): ......... PASS
Test 2 (varying size data exchange): ......... PASS

### Test suite for rtiostream finished successfully ###

Furthermore, the following profile appears.
Word Addressable Target Hardware

On the Hardware Implementation pane, when you specify Device vendor and Device type settings, you provide PIL simulations with memory addressing information about the target hardware.
For example, consider the case when **Device vendor** is set to **Texas Instruments** and **Device type** is set to **C5000**.

The settings specify that the target hardware uses 16-bit word addresses and big-endian word order. The rtiostream implementation operates with 16-bit words.

On the target hardware, if an **rtIStream** function specifies a size of 1, then the target hardware must send or receive one 16-bit word (2 bytes). **sizeof(char)** and **sizeof(short)** return 1, which corresponds to one 16-bit word. The **rtIStream** function expects the byte order within the word to be little-endian, that is, less significant bytes are transmitted before more significant bytes.

**rtiostreamtest** identifies the target hardware and handles data in terms of 16-bit words, for example, a byte value is transferred as a 16-bit word value.

Specify Hardware Timer

For processor-in-the-loop (PIL) code execution profiling, you must create a timer object that provides details of the hardware-specific timer and associated source files. You can use the Code Replacement Tool or the code replacement library API to specify this hardware-specific timer.

To specify the timer with the Code Replacement Tool:

1. Open the Code Replacement Tool. In the Command Window, enter crtool.
3. Create a new function entry. Under Tables List, right-click the new table. Then, from the context-menu, select New entry > Function.
4. In the middle view, select the new unnamed function.
5. On the Mapping Information pane:
   a. From the Function drop-down list, select code_profile_read_timer.
   b. Specify the count direction for your timer. For example, from the Count direction drop-down list, select Up.
   c. In the Ticks per second field, specify the number of ticks per second for your timer, for example, 1e+09.

   The default value is 0. In this case, the software reports time measurements in terms of ticks, not seconds.
   d. In the Name field, specify a replacement function name, for example, MyTimer.
   e. Click Apply.
To validate the function entry, click **Validate entry**.

6 On the **Build Information** pane, specify the required build information. See “Specify Build Information for Replacement Code” on page 54-61.

7 Save the table (**Ctrl+S**). When you save the table for the first time, use the Save As dialog box to specify the file name and location.

You must save the table in a location that is on the MATLAB search path. For example, you can save this file in the folder for your subclass of `rtw.connectivity.Config`.

The software stores your timer information as a code replacement library table.

8 Assuming you save the table as `MyCrlTable.m`, in your subclass of `rtw.connectivity.Config`, add the following line:

```matlab
setTimer(this, 'MyCrlTable')
```

A processor-in-the-loop (PIL) simulation cross-compiles production source code, and then downloads and runs object code on your target hardware. The connectivity configuration that you create controls the way code is compiled and executed on the target. This table describes the sequence of stages in a PIL simulation.

<table>
<thead>
<tr>
<th>Stage</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Start</td>
</tr>
<tr>
<td></td>
<td>For top-model PIL, on the Simulink Editor toolbar, you select the Processor-in-the-Loop (PIL) mode, and then click the Run button. For Model block PIL, you set the Simulation mode parameter of the Model block to Processor-in-the-loop (PIL), and then run a simulation of the harness model that contains the Model block. For the PIL block, you run a simulation of the harness model that contains the PIL block.</td>
</tr>
<tr>
<td>2</td>
<td>Validate target connectivity</td>
</tr>
<tr>
<td></td>
<td>The software verifies that a target connectivity configuration is registered for PIL. Otherwise, the software produces an error.</td>
</tr>
<tr>
<td>3</td>
<td>Generate production source code and build object code for target</td>
</tr>
</tbody>
</table>
|       | The generated source code is identical to the code that is produced when you run the slbuild command.  
  - For top-model PIL or Model block PIL with block parameter Code interface set to Top model, the generated code is identical to the code produced when you run slbuild('model').  
  - For Model block PIL with block parameter Code interface set to Model reference, the generated code is identical to the code produced when you run slbuild('model', 'ModelReferenceRTWTarget'). The model reference simulation target is also produced.  
  The software builds object code for the target by using the template makefile or toolchain that you specify. |
<table>
<thead>
<tr>
<th>Stage</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>Create instances of PIL API components</td>
</tr>
<tr>
<td>5</td>
<td>Generate PIL files</td>
</tr>
</tbody>
</table>
| 6     | Build target application | The software:  
- Uses your instance of `rtw.connectivity.MakefileBuilder` to build the target application.  
- Compiles the PIL interface file, `xil_interface.c`, and other PIL files into the target executable file. On a Windows system, for example, this file is called `modelName.exe`. The object code, including the executable file, is in the `pil` folder.  
- If configured, produces the code generation report. |
| 7     | Start target application | The software uses `rtw.connectivity.Launcher` to start the application on the target. |
| 8     | Simulink engine interacts with PIL S-function | The Simulink engine interacts with the PIL S-function in the same way that it interacts with a C S-function.  
From the host-side, the PIL S-function communicates with the target executable code through `rtI0Stream` commands. On the target side, `xil_interface` executes generated code. |
<p>| 9     | Stop target application | The software uses <code>rtw.connectivity.Launcher</code> to stop the application on the target. |</p>
<table>
<thead>
<tr>
<th>Stage</th>
<th>Description</th>
</tr>
</thead>
</table>
| 10    | End PIL simulation | For top-model PIL, at the end of the simulation, the software destroys the `rtw.connectivity.Config` instance.  
For Model block PIL and PIL block, the block creates and owns the `rtw.connectivity.Config` instance, which is not destroyed at the end of the simulation. You can rerun the simulation, which now does not require the creation of another `rtw.connectivity.Config` instance. If you want to destroy the instance, close the parent model. |

Verification of Code Generation Assumptions

At the start of a processor-in-the-loop (PIL) simulation, the software verifies some configuration parameter settings with reference to the target hardware.

For example, the settings on the **Configuration Parameters > Hardware Implementation** pane specify target behavior, which result in the implementation of implicit assumptions in the generated code. Incorrect settings can lead to:

- Suboptimal code
- Code execution failure, incorrect code output, and nondeterministic code behavior

The software checks:

- The correctness of settings. For example, the integer bit length in the **Number of bits**: *int* field.
- Whether the settings are optimized. For example, the rounding of signed integer division in the **Signed integer division rounds to** field.

If required, the software generates warnings and errors.

This table provides information about the checks performed.
<table>

View SIL and PIL Files in Code Generation Report

With top-model and Model block SIL and PIL simulations, you can produce a code generation report and static code metrics that cover SIL and PIL files. The information helps you to:

• Understand and review the SIL and PIL testing process.
• See how your registered custom target connectivity files fit into the target application that runs during a SIL or PIL simulation.

This capability is not supported for simulations that you run with the PIL block.

To configure the creation of a code generation report and static code metrics, on the Configuration Parameters > Code Generation > Report pane, select the Create code generation report, Open report automatically, and Static code metrics check boxes. Then click OK.

At the end of the simulation, in the Code Generation Report window:

• To review code metrics, in the Contents view, click Static Code Metrics Report.
• To review SIL and PIL files, in the Generated Code view, expand the SIL/PIL files node. For example:
  • To review the S-function that runs on the host, click modelName_sbs.c or modelName_pbs.c.
  • To view the SIL or PIL interface that runs on the target, click xil_interface.c.
Note Do not use the SIL or PIL files in code development as these files can change over releases. Use supplied APIs for code development.

| “SIL/PIL Block Limitations” on page 67-81 |

About SIL and PIL Limitations

With Embedded Coder, you can run software-in-the-loop (SIL) and processor-in-the-loop (PIL) simulations in three ways:

- Top-model SIL/PIL — Set the top-model simulation mode to **Software-in-the-Loop (SIL)** or **Processor-in-the-Loop (PIL)**.
- Model block SIL/PIL — Set the Model block parameter **Simulation mode** to **Software-in-the-loop (SIL)** or **Processor-in-the-loop (PIL)**.
- SIL/PIL block — Use SIL or PIL blocks in the model.

The following sections describe modeling and code generation features that are either unsupported or partially supported by SIL and PIL simulations.

General SIL and PIL Limitations

Tunable Parameters and SIL/PIL

For Model block SIL/PIL and SIL/PIL block simulations, you can tune tunable *workspace* parameters but not tunable *dialog box* parameters. For information about tuning parameters, see “Tune and Experiment with Block Parameter Values” (Simulink).

For a top model with tunable parameters, you can run a SIL/PIL simulation but you cannot tune the parameters during the simulation.

The software cannot define, initialize, or tune the following types of tunable workspace parameters.
### Parameter description

<table>
<thead>
<tr>
<th>Parameter description</th>
<th>Software response</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parameters with storage class that applies &quot;static&quot; scope or &quot;const&quot; keyword. For example, Custom, Const, or ConstVolatile</td>
<td>Warning Warning Warning</td>
</tr>
<tr>
<td>Parameters with multiword, fixed-point data types</td>
<td>Warning Error Warning</td>
</tr>
<tr>
<td>Parameters with data types that have different sizes on host and target</td>
<td>Warning Error Warning</td>
</tr>
</tbody>
</table>

For C++ class code, SIL/PIL you can tune tunable workspace parameters when **Parameter visibility** is public. If **Parameter visibility** is private or protected, tuning is supported only if **Parameter access** is Method or Inlined method.

For top-model SIL/PIL and the SIL/PIL block, consider the case where all of the following conditions apply:

- **Code Generation > Interface > Code interface packaging** is Reusable function.
- **Code Generation > Interface > Use dynamic memory allocation for model initialization** is not selected.
- **Optimization > Default parameter behavior** is Tunable.
- In the Code Mapping Editor for the model, the default storage class for the **Global parameters** or **Local parameters** category is set to Default, and the model contains corresponding parameters that use the storage classes Auto or Model default.

If the SIL/PIL component cannot dynamically initialize tunable parameters in the **rtP model** parameter structure, you see an error message like the following:

```
Parameter Dialog:InitialOutput in 'rtwdemo_sil_topmodel/CounterTypeA/count'
is part of the imported "rtP" structure in the generated code but cannot be
initialized by SIL or PIL. To avoid this error, make sure the parameter
corresponds to a tunable workspace variable. Alternatively, set
"Configuration Parameters > Code Generation > Interface > Code interface packaging"
to "Nonreusable function", or search for "Use dynamic memory allocation"
```
for model initialization' in the Configuration Parameters dialog box and select the checkbox.

If you select Code Generation > Interface > Use dynamic memory allocation for model initialization, this limitation does not apply.

For Model block SIL/PIL, if you specify the code under test to be Top model, you can tune parameters while a simulation runs. If you tune parameters between successive runs of the simulation, the software generates new code for the later run. The new code uses your latest settings as initial parameter values.

For top model or Model block SIL/PIL, if you change the value of a MATLAB variable or parameter object (such as Simulink.Parameter) that you store in a workspace, Simulink Coder regenerates the C code.

Global and Local Data Stores

SIL/PIL supports global data stores. For components that are not export-function models, top-model SIL/PIL and SIL/PIL block simulations that access global data stores must be single rate. Otherwise, the software produces an error.

SIL/PIL does not support local data stores.

Model block SIL/PIL does not support local Data Store Memory blocks that have these parameter settings:

- Share across model instances – Selected.
- Storage class – Auto or Model default.

You cannot create SIL/PIL blocks from models that use local Data Store Memory blocks with the Share across model instances parameter selected.

SIL/PIL Does Not Check Simulink Coder Error Status

SIL/PIL does not check the Simulink Coder error status of the generated code under test. This error status flags exceptional conditions during execution of the generated code.

Blocks in the model can also set the Simulink Coder error status, for example, custom blocks that you create. SIL/PIL does not check this error status and report errors.

Missing Code Interface Description File Errors

SIL/PIL requires a code interface description file, which is created during code generation for the component under test. If the code interface description file is missing, the SIL/PIL
simulation cannot proceed. You see an error reporting that the file does not exist. If you select the unsupported option **Classic call interface**, this error can occur. Therefore, do not select the option.

**To Workspace Block**

If you enable MAT-file logging, top-model SIL/PIL and SIL/PIL blocks support To Workspace blocks.

Model block SIL/PIL does not support To Workspace blocks.

**Cannot Connect SIL/PIL Outputs to Merge Block**

If you connect Model block SIL/PIL or SIL/PIL block outputs to a Merge block, you see an error because S-function memory is not reusable.

**Variant Condition Propagation with Variant Source and Variant Sink Blocks**

Top-model SIL/PIL and SIL/PIL block simulations do not support the propagation of variant conditions across component boundaries.

**Unsupported Blocks**

SIL/PIL does not support the following blocks:

- Scope blocks, and all types of run-time display. For example, display of port values and signal values.
- Stop blocks. SIL/PIL ignores the Stop Simulation block and continues simulating.

**Multiword Fixed-Point I/O**

You cannot run SIL and PIL simulations of models that have multiword, fixed-point signals across component boundaries.

**Fixed-Point Data Types Wider Than 32 Bits**

SIL/PIL supports fixed-point data types that are wider than 32 bits. For example:

- 64-bit `long` and `long long`
- 64-bit execution profiling timer data type
- `int64` and `uint64` in MATLAB Coder SIL execution.
The following constraints apply:

- For 64-bit data type support, the data type must be representable as `long` or `long long` on the MATLAB host and the target. Otherwise, the software uses the multiword, fixed-point approach, which SIL/PIL does not support.
- The software does not support the 40-bit `long` data type of the TI’s C6000™ target.

Through the Configuration > Hardware Implementation pane, you can enable support for the 64-bit `long` `long` data type. For data types with widths between 33 and 40 bits (inclusive), the software implements the data types using the 40-bit `long` data type, which SIL/PIL does not support.

### Data Type Replacement

The software does not support replacement data type names that you define for the built-in data type `boolean` if these names map to the `int` or `uint` built-in data type.

### Continuous Sample Times

Top-model SIL/PIL and SIL/PIL block do not support continuous sample times at the SIL or PIL component boundary. However, they support continuous sample times within the component.

Model block SIL/PIL does not support continuous sample times.

### Variable-Size Signals

Model block SIL/PIL simulations support variable-size signals only if Diagnostics > Model Referencing > Propagate sizes of variable-size signals is During execution.

Top-model SIL/PIL and SIL/PIL block simulations treat variable-size signals at the I/O boundary of the SIL/PIL component as fixed-size signals, which can lead to errors during propagation of signal sizes. To avoid such errors, use only fixed-size signals at the I/O boundary of the SIL/PIL component.

There can be cases where no error occurs during propagation of signal sizes. In these cases, the software treats variable-size input signals as zero-size signals.

### Internal Signal Logging

SIL/PIL blocks do not support signal logging. For a workaround, see “Log Internal Signals of a Component” on page 67-23.
The following internal signal logging limitations apply to top-model and Model block SIL/PIL simulations.

<table>
<thead>
<tr>
<th>Limitation</th>
<th>Applies To</th>
</tr>
</thead>
<tbody>
<tr>
<td>Only signals that are included in the C API are logged during SIL/PIL simulation. To observe the signals in the generated code, you can configure the signals as test points. For each signal, select the <strong>Signal Properties &gt; Test point</strong> check box.</td>
<td>Yes</td>
</tr>
<tr>
<td>Signals feeding merge blocks are not supported for logging in normal simulation but are logged in SIL/PIL mode. The logged values during SIL/PIL are the same as the logged values for the output of the merge block.</td>
<td>Yes</td>
</tr>
<tr>
<td>Top-model normal simulation logs data at a periodic rate but top-model SIL/PIL simulation logs data at a constant rate under these circumstances:</td>
<td>Yes</td>
</tr>
<tr>
<td>- <strong>Default parameter behavior</strong> is Tunable.</td>

<td>No</td>
</tr>
</tbody>
</table>

**Unsupported Implementation Errors**

If you use a custom storage class (CSC) with a **Type** property that is **Other** or if you use a data store, signal, or parameter implementation that SIL/PIL does not support, you can see errors like the following:

The following *data interfaces* have implementations that are not supported by SIL or PIL.

*data interfaces* can be global data stores, *inports*, *outports*, or *parameters*.

The model output port has been optimized through virtual output port optimization. See “Virtualized Output Ports Optimization” on page 58-17. The error occurs because the properties (for example, data type, dimensions) of the signal or signals entering the
virtual root output port have been modified by routing the signals in one of the following ways:

- Through a Mux block.
- Through a block that changes the signal data type. To check the consistency of data types in the model, display Port Data Types by selecting **Display > Signals & Ports > Port Data Types** (see “Port Data Types” (Simulink)).
- Through a block that changes the signal dimensions. To check the consistency of data types in the model, display dimensions by selecting **Display > Signal & Ports > Signal Dimensions**.

Dimension changes from scalar (1) to matrix [1x1], and, matrix [1x1] to scalar (1), can lead to this error. It is difficult to inspect the model for such changes because **Display > Signal & Ports > Signal Dimensions** does not distinguish between (1) and [1x1] dimensions. Both signals are displayed as scalar signals. Check your model and workspace objects carefully. Make sure that you specify scalar dimensions consistently.

The following model causes this error by changing the output port signal data type.

**Hardware Implementation**

PIL does not support multiword data types where the word order differs from the target byte order. The PIL simulation fails, displaying undefined behavior.
PIL requires that you configure the correct **Hardware Implementation** settings for the target environment, including byte ordering for targets. If you do not specify the correct byte ordering, the PIL simulation fails, displaying undefined behavior.

**Non-ASCII Characters in Folder Name**

If the name of the current working folder contains non-ASCII characters, you cannot run a SIL simulation.

**State Logging**

SIL/PIL does not support state logging (Simulink).

**Bus Elements Mapped to Imported Bit-Field Definitions**

If you map Simulink bus elements to bit fields through an imported header file, a SIL or PIL simulation produces a build error. For example, if your model has an Inport block connected to a bus that is a Simulink.Bus object with these properties:

- **Name** — myBus
- **Bus elements** — An array of Simulink.BusElement objects with these properties.

<table>
<thead>
<tr>
<th>Name</th>
<th>DataType</th>
<th>Complexity</th>
<th>Dimensions</th>
</tr>
</thead>
<tbody>
<tr>
<td>bitField0</td>
<td>boolean</td>
<td>real</td>
<td>1</td>
</tr>
<tr>
<td>bitField1</td>
<td>boolean</td>
<td>real</td>
<td>1</td>
</tr>
<tr>
<td>bitField2</td>
<td>boolean</td>
<td>real</td>
<td>1</td>
</tr>
<tr>
<td>bitField3</td>
<td>boolean</td>
<td>real</td>
<td>1</td>
</tr>
<tr>
<td>bitField4</td>
<td>boolean</td>
<td>real</td>
<td>1</td>
</tr>
<tr>
<td>bitField5</td>
<td>boolean</td>
<td>real</td>
<td>1</td>
</tr>
</tbody>
</table>

- **Data scope** — Imported
- **Header file** — busSpecification.h. This file contains myBus, which defines C bit-field data types for the bus elements.

```c
typedef struct myBus
{
    unsigned int bitField0 : 1;
    unsigned int bitField1 : 1;
    unsigned int bitField2 : 1;
    unsigned int bitField3 : 1;
    unsigned int bitField4 : 1;
    unsigned int bitField5 : 1;
} myBus;
```
(unsigned int bitField4 : 1;
    unsigned int bitField5 : 1;
} myBus;

Size Mismatch Between Simulink and Target Hardware Data Types

When a Simulink data type and the corresponding target hardware data type differ in size, a SIL or PIL simulation produces an error. This size mismatch can occur if you map a Simulink data type to the target hardware data type through definitions in an imported header file. For example, if you create a data type alias, T_BOOL, which is a Simulink.AliasType object with these properties:

- **Base type** — boolean.
- **Mode** — Built in, boolean.
- **Data scope** — Imported.
- **Header file** — myDefinitions.h. This file defines T_BOOL as an enumerated data type:

```c
typedef enum _BOOL_TYPE
{
    FALSE           = 0,
    TRUE            = 1
} BOOL_TYPE;

dtypedef BOOL_TYPE T_BOOL;
```

In this case, the compiler for the target hardware determines the size of T_BOOL, which can differ from the size of the Simulink data type, boolean.

SIL Simulations with Target-Specific Custom Code

Target-specific custom code that is not portable for execution on your development computer can produce compilation or run-time failures during a SIL simulation.

For example, SIL does not support the use of custom code that explicitly casts pointers to integer-type variables that are smaller than the length of a pointer variable on your development computer. Consider using one of these alternatives:

- Run a PIL simulation.
- If you have custom code that casts pointers to a 32-bit integer type, for your development computer, set up a PIL target connectivity configuration that uses a toolchain that is configured to build a 32-bit binary application.
Top-Model SIL/PIL Limitations

Top-Model Root-Level Logging

Top-model SIL/PIL supports signal logging for signals connected to root-level inports and outports. The C API is not required. Root-level logging has the following limitations:

• The characteristics of the logged data such as data type, sample time, and dimensions must match the characteristics of the root-level inports and outports (rather than the characteristics of the connected signal).

In some cases, there can be differences in data type and dimensions between the signal being logged and the root inport or outport that the signal is connected to. Consider the following examples.

• If a signal being logged has matrix dimensions [1x5] but the outport connected to the signal has vector dimensions (5), then the data logged during a SIL or PIL simulation has vector dimensions (5).

• If a signal being logged has scalar dimensions but the outport connected to the signal has matrix dimensions [1x1], then the data logged during a SIL or PIL simulation has matrix dimensions [1x1].

• Signals connected to duplicated inports are not logged during SIL/PIL simulation. No warning is issued.

During normal simulation, signals connected directly to duplicated inports are logged.

• The Signal Logging Selector / DataLoggingOverride override mechanism is not supported.

• Normal and SIL/PIL simulations log bus signals with names that are different when all of the following conditions apply:

  • The SaveOutput or SignalLogging configuration parameter is on.
  • The names of the elements in the bus signal are different from the corresponding names in the bus object. For example, when the InheritFromInputs parameter for a Bus Creator block is set to 'on'.

  • The software inserts the suffix, _wrapper for output logging, if the save format is Structure, Structure with time, or Dataset and you run the sim command without specifying the single-output format. The software adds _wrapper to the block name for signals in yout. If the save format is Array, the software does not add the suffix. For example:
To avoid this behavior, run command-line simulations with the `sim` command specifying the single-output format. See “Run Simulations Programmatically” (Simulink).

**Model in Compiled State During Top-Model SIL/PIL**

During a top-model SIL/PIL simulation, the software places the model in a compiled state – see `model`. This action can result in a conflict over global resources between the model and the generated SIL/PIL code. In this case, differences between normal mode and SIL/PIL simulation outputs can result.

For example, consider a model that uses UDP blocks from the DSP System Toolbox. These blocks open UDP sockets, which can lead to resource contention between the model and the generated SIL/PIL code.

**Callback Support**

SIL/PIL does not support the callbacks (model or block) `StartFcn` and `StopFcn`.

**Note** Top-model SIL/PIL supports the callback `InitFcn`.

**Incremental Build**

When you start a top-model SIL/PIL simulation, the software regenerates code if it detects changes to your model. The software detects changes by using a checksum for the model. The software does not detect changes that you make to:

- The `HeaderFile` property of a `Simulink.AliasType` object
- Legacy S-functions

If you make these changes, build (**Ctrl-B**) your model again before starting the next PIL simulation.

```
>> yout.signals

ans =

    values: [11x1 double]
    dimensions: 1
    label: 'SignalLogging'
    blockName: 'sillogging_wrapper/OutputLogging'
```
Model Block SIL/PIL Limitations

Top-Model Code Testing

The following limitations apply:

- The Model Variants block does not support the block parameter `CodeInterface`. The software behaves as if `CodeInterface` is set to 'Model reference'. To work around this limitation, use the Variant Subsystem block. Through this block, you can incorporate Model blocks for which `CodeInterface` is set to 'Top model'.
- Because model arguments do not apply to a top model, when the `Code interface` block parameter is set to 'Top model', the software does not support the `Model arguments` block parameter.
- Conditional execution does not apply to a top model. If a Model block is set up to execute conditionally and the `Code interface` block parameter is set to 'Top model', the software produces an error when you run a SIL or PIL simulation.
- For sample time independent models, you must set `Configuration Parameters > Solver > Periodic sample time constraint` to Ensure sample time independent.
- Simulation results from top-model code and model reference code can differ when a root-level Inport is connected to a root-level Outport by a signal that has a signal object with an initial value.

For top-model code, the software associates the signal object with the Inport. The software can apply the initial value for the signal object to the Inport. See “Initialization Behavior Summary for Signal Objects” (Simulink).

For model reference code, the software associates the signal object with the Outport. The software does not apply the initial value for the signal object to the Inport.

Conditionally Executed Subsystem

You see an error if:

- You place your Model block, in either SIL or PIL simulation mode, in a conditionally executed subsystem and the referenced model is multirate (that is, has multiple sample times). Single-rate, referenced models (with only a single sample time) are not affected.
- Your Model block, in either SIL or PIL simulation mode, has blocks that depend on absolute time and is conditionally executed.
**Outputs with Constant Sample Time**

If the block parameter **Code interface** is **Top model**, Model block SIL/PIL supports outputs with constant sample time.

**Noninlined S-Functions**

Model-block SIL/PIL simulations do not support noninlined S-functions.

**Referenced Models That Use Same Target Connectivity Configuration**

Consider a top model with two or more Model blocks that reference models that use the same target connectivity configuration. If the Model blocks are in PIL mode simultaneously, you cannot run a simulation of the top model. An error occurs.

**SIL and PIL Instances of a Referenced Model**

Consider a top model that contains two instances of a Model block that reference the same model. If one instance is in SIL mode and the other instance is in PIL mode, you cannot run a simulation of the top model. An error occurs.

**SIL/PIL Block Limitations**

**PIL Block Mux**

The PIL block supports mux signals, except mixed data-type mux signals that expand into individual signals during a right-click subsystem build.

**Code Coverage**

SIL block simulations do not support the generation of code coverage results. PIL block support for code coverage depends on your target connectivity configuration and third-party product support.

**Subsystem with Inherited Sample Time Blocks**

When you create a SIL/PIL block from a subsystem that has blocks with inherited sample times, the generated code and SIL/PIL wrapper acquire the sample time of the original parent model. If you use the SIL/PIL block in a context that does not allow explicit sample times, for example, within a triggered subsystem, you see an error.

Try one of these workarounds:
Before you create the SIL/PIL block, in the parent model, set Configuration Parameters > Solver > Periodic sample time constraint to ensure sample time independent.

Using the subsystem, create a Model block that is independent of sample time. With this block, run Model block SIL/PIL simulations.

• “Choose a SIL or PIL Approach” on page 67-12
**Check Configuration**

Use the `cgv.Config` class to check model settings for a SIL or PIL simulation. You can review your model configuration and determine the settings that you must change. By default, `cgv.Config` changes configuration parameter values to the value that it recommends, but does not save the model. Alternatively, you can:

- Change configuration parameter values to the values that `cgv.Config` recommends, and save the model. Specify this approach using the `SaveModel` property.
- List the values that `cgv.Config` recommends for the configuration parameters, but not change the configuration parameters or the model. Specify this approach using the `ReportOnly` property.

**Note**

- Execution in the target environment can require additional modifications to configuration parameter values or the model.
- Do not use referenced configuration sets in models that you are changing using `cgv.Config`. If the model uses a referenced configuration set, update the model with a copy of the configuration set. Use the `getRefConfigSet` method of the `Simulink.ConfigSetRef` class.
- If you use `cgv.Config` on a model that executes a callback function, the callback function can change configuration parameter values each time the model loads. The callback function can revert changes that `cgv.Config` makes. For more information, see “Callbacks for Customized Model Behavior” (Simulink).

To verify that your model is configured for SIL or PIL:

1. Construct a `cgv.Config` object that changes the configuration parameter values without saving the model. For example, to configure your model for SIL:

   ```
c = cgv.Config('vdp', 'connectivity', 'sil');
   ```

**Tip**

- You can obtain a list of changes without changing the configuration parameter values. When you construct the object, include the 'ReportOnly', 'on' property name and value pair:
You can change the configuration parameter values and save the model. When you construct the object, include the 'SaveModel', 'on' property name and value pair.

2 Determine and change the configuration parameter values that the object recommends using the configModel method. For example:

```matlab
c.configModel();
```

3 Display a report of the changes that configModel makes. For example:

```matlab
c.displayReport();
```

4 Review the changes.

5 To apply the changes to your model, save the model.

- “Verify Numerical Equivalence with CGV” on page 67-85
- “Verify Numerical Equivalence Between Two Modes of Execution of a Model” on page 67-87
Verify Numerical Equivalence with CGV

Before verifying numerical equivalence:

- Configure your model for SIL or PIL simulation.
- Use the `cgv.Config` class of the CGV API to verify the model configuration for SIL or PIL simulation.
- Configure your model for code generation. For more information, see “Configure Model for Code Generation Objectives by Using Code Generation Advisor” on page 32-2.
- Save your model. If you modify a model without saving it, CGV can issue an error.

To verify numerical equivalence:

- Set up the tests for the first execution environment. For example, simulation.
- Use `run` to run the tests for the first execution environment.
- Set up the tests for the second execution environment. For example, top-model PIL.
- Use `cgv.CGV.run` to run the tests for the second execution environment.
- Use `getOutputData` to get the output data for each execution environment.
- Use `getSavedSignals` to display the signal names in the output data. (optional)
- Build a list of signal names for input to other `cgv.CGV` methods. (optional)
- Use `createToleranceFile` to create a file correlating tolerance information with output signal names. (optional)
- Use `compare` to compare the output signals of the first and second execution environments for numerical equivalence.

**Note** Simulink Test is a separate product that provides additional capabilities for SIL and PIL testing, for example, test sequence construction and test management.

The following example describes configuring, executing, and comparing the results of the rtwdemo_cgv model in normal and software-in-the-loop (SIL) simulation modes.

Configure the Model

The first task for verifying numerical equivalence is to check the configuration of your model.

1. Open the rtwdemo_cgv model.

   ```matlab
cgvModel = 'rtwdemo_cgv';
   load_system(cgvModel);
   ```

2. Save the model to a working directory.

   ```matlab
   save_system(cgvModel, fullfile(pwd, cgvModel));
   close_system(cgvModel); % avoid original model shadowing saved model
   ```

3. Use the `cgv.Config` to create a `cgv.Config` object. Specify parameters that check and modify configuration parameter values and save the model for top-model SIL mode of execution.

   ```matlab
cgvCfg = cgv.Config('rtwdemo_cgv', 'connectivity', 'sil', 'SaveModel', 'on');
   ```

4. Use the `configModel` method to review your model configuration and to change the settings to configure your model for SIL. When 'connectivity' is set to 'sil', the system target file is automatically set to 'ert.tlc'. If you specified the parameter/value pair, ('SaveModel', 'on') when you created the `cgvCfg` object, the `cgv.Config.configModel` method saves the model.
Note  CGV runs on models that are open. If you modify a model without saving it, CGV can issue an error.

cgvCfg.configModel(); % Evaluate, change, and save your model for SIL

5  Display a report of the changes that cgv.Config.configModel makes to the model.
   cgvCfg.displayReport(); % In this example, this reports no changes

Execute the Model

Use the CGV API to execute the model in two modes. The two modes in this example are normal mode simulation and SIL mode. In each execution of the model, the CGV object for each mode captures the output data and writes the data to a file.

1  If you have not already done so, follow the steps described in “Configure the Model” on page 67-87.

2  Create a cgv.CGV object that specifies the rtwdemo_cgv model in normal mode simulation.
   cgvSim = cgv.CGV(cgvModel, 'connectivity', 'sim');

Note  When the top model is set to normal simulation mode, the CGV API sets referenced models in PIL mode to accelerator mode.

3  Provide the input file to the cgvSim object.
   cgvSim.addInputData(1, [cgvModel '_data']);

4  Before execution of the model, specify the MATLAB files to execute or MAT-files to load. This step is optional.
   cgvSim.addPostLoadFiles({[cgvModel '_init.m']});

5  Specify a location where the object writes all output data and metadata files for execution. This step is optional.
   cgvSim.setOutputDir('cgv_output');

6  Execute the model.
   result1 = cgvSim.run();

7  Get the output data associated with the input data.
   outputDataSim = cgvSim.getOutputData(1);
For the next mode of execution, SIL, repeat steps 2–7.

```matlab
cgvSil = cgv.CGV(cgvModel, 'Connectivity', 'sil');
cgvSil.addInputData(1, [cgvModel '_data']);
cgvSil.addPostLoadFiles({[cgvModel '_init.m']});
cgvSil.setOutputDir('cgv_output');
result2 = cgvSil.run();
```

**Compare All Output Signals**

After setting up and running the test, compare the outputs by doing the following:

1. If you have not already done so, configure and test the model, as described in “Configure the Model” on page 67-87 and “Execute the Model” on page 67-88.

2. Test that the execution result of the model:

   ```matlab
   if ~result1 || ~result2
       error('Execution of model failed.);
   end
   ```

3. Use the `getOutputData` method to get the output data from the `cgv.CGV` objects.

   ```matlab
   simData = cgvSim.getOutputData(1);
silData = cgvSil.getOutputData(1);
   ```

4. Display a list of signals by name using the `getSavedSignals` method.

   ```matlab
cgvSim.getSavedSignals(simData);
   ```

5. Using the list of signals, build a list of signals in a cell array of character vectors. The signal list can contain a number of signals.

   ```matlab
   signalList = {'simData.getElement(4).Values.Data'};
   ```

6. Use the `createToleranceFile` method to create a file, in this example, 'localtol', correlating tolerance information with output signal names.

   ```matlab
toleranceList = {{'absolute', 0.5}};
cgv.CGV.createToleranceFile('localtol', signalList, toleranceList);
   ```

7. Compare the output data signals. By default, the `compare` method looks at all signals which have a common name between both executions. If a tolerance file is present, `cgv.CGV.compare` uses the associated tolerance for a specific signal during comparison; otherwise the tolerance is zero. In this example, the 'Plot' parameter is set to 'mismatch'. Therefore, only mismatched signals produce a plot.

   ```matlab
   [matchNames, ~, mismatchNames, ~] = ...;
cgv.CGV.compare(simData, silData, 'Plot', 'mismatch', ...'
   'ToleranceFile', 'localtol');
   fprintf('%d Signals match, %d Signals mismatch\n', ... length(matchNames), length(mismatchNames));
   ```
disp('Mismatched Signal Names:');
disp(mismatchNames);

At the MATLAB command line, you see:

14 Signals match, 1 Signals mismatch
Mismatched Signal Names:
 'simData.getElement(4).Values.Data'

A plot results from the signal mismatch.

The lower plot displays the numeric difference between the results.

**Compare Individual Output Signals**

After setting up and running the test, compare the outputs of individual signals by doing the following:
1. If you have not already done so, configure and test the model, as described in “Configure the Model” on page 67-87 and “Execute the Model” on page 67-88.

2. Use the `getOutputData` method to get the output data from the `cgv.CGV` objects.

   ```matlab
   simData = cgvSim.getOutputData(1);
silData = cgvSil.getOutputData(1);
   ```

3. Use the `getSavedSignals` method to display the output data signal names. Build a list of specific signal names in a cell array of character vectors. The signal list can contain a number of signals.

   ```matlab
cgv.CGV.getSavedSignals(simData);
   signalList = {'simData.getElement(3).Values.hi1.mid0.lo1.Data', ...
                  'simData.getElement(3).Values.hi1.mid0.lo2.Data', ...
                  'simData.getElement(2).Values.Data(:,3)'};
   ```

4. Use the specified signals as input to the `compare` method to compare the signals from separate runs.

   ```matlab
   [matchNames, ~, mismatchNames, ~] = ...
cgv.CGV.compare(simData, silData, 'Plot', 'mismatch', ...
                  'signals', signalList);
   ```

   At the MATLAB command line, the result is:

   ```
   3 Signals match, 0 Signals mismatch
   ```

**Plot Output Signals**

After setting up and running the test, use the `plot` method to plot output signals.

1. If you have not already done so, configure and test the model, as described in “Configure the Model” on page 67-87 and “Execute the Model” on page 67-88.

2. Use the `getOutputData` method to get the output data from the `cgv.CGV` objects.

   ```matlab
   simData = cgvSim.getOutputData(1);
   ```

3. Use the `getSavedSignals` method to display the output data signal names. Build a list of specific signal names in a cell array of character vectors. The signal list can contain a number of signals.

   ```matlab
cgv.CGV.getSavedSignals(simData);
   signalList = {'simData.getElement(2).Values.Data(1)'};
   ```
4 Use the specified signal list as input to the `plot` method to compare the signals from separate runs.

```matlab
[signalNames, signalFigures] = cgv.CGV.plot(simData, ...
   'Signals', signalList);
```

Related Examples

- “Verify Numerical Equivalence with CGV” on page 67-85
- “Check Configuration” on page 67-83
Using Code Generation Verification API

Configure and run normal, software-in-the-loop (SIL), and processor-in-the-loop (PIL) simulations, and compare results.

Note: Simulink Test is a separate product that provides additional capabilities for SIL and PIL testing, for example, test sequence construction and test management.

Review the Model

The rtwdemo_cgv model uses buses, scalars, and vectorized data, plus error injection to create differences between test executions.

Note: Before executing the code in this example, change to a writable folder. If you are not working in a writable folder, code generation errors occur.

To open rtwdemo_cgv, in the MATLAB® Command Window, enter the following commands.

```matlab
baseVars = who;  % For future cleanup.
cgvModel = 'rtwdemo_cgv';
close_system(cgvModel,0);
open_system( cgvModel);
```
The model contains a hierarchical bus with three nested buses. This arrangement of buses produces complex hierarchical data at the first logged output port. At the second output port, the model injects errors in the signal at fixed intervals. These errors produce different results between two runs. The signal at the third output port is a vector of four values per sample to help show the comparison support.

**Verify the Model Configuration**

CGV provides a class, cgv.Config, to check whether models have a configuration that is compatible with execution in a SIL or PIL environment using an ert target. This model has already been modified using the cgv.Config class.
**Execute Under CGV**

**Run in Normal and SIL Modes**

The model executes in three modes under CGV: normal, SIL, and PIL. In each case, the CGV object captures the output data and writes it to a file. For more information, see CGV Documentation. To execute the model in normal and SIL simulation modes, enter:

```matlab
cgvSim = cgv.CGV( cgvModel, 'Connectivity', 'Normal');
cgvSim.addInputData(1, [cgvModel '_data']);
% This next CGV function, addPostLoadFiles(), allows you to specify MATLAB(R)
% programs to execute, or mat-files to load, before execution of the model.
cgvSim.addPostLoadFiles({[cgvModel '_init.m']});
cgvSim.setOutputDir('cgv_output');
cgvSim.activateConfigSet( 'CS1_default');
result1 = cgvSim.run();
```

% CGV provides methods to simplify numerical equivalence checking.
% The copySetup method creates an exact duplicate of an existing CGV object without
% results data. You can change the SimulationMode using setMode() and then
% execute again.

cgvSil = cgvSim.copySetup();
cgvSil.setMode( 'SIL');
% You can provide a baseline file to CGV for comparing the simulation
% output. In this example, the comparison results set the status to
% 'failed', because the ErrorsInjected signal differs between simulations.
cgvSil.addBaseline( 1, 'rtwdemo_cgv_results');
result2 = cgvSil.run();

% To see the name(s) of the signal(s) that did match, use getMismatches.
% Mismatched signal names are only available if a baseline was added and
% the comparison failed.
if strcmp( cgvSil.getStatus( 1), 'failed')
    disp( 'Mismatched Signal Names:');
    [signalNames, plotFiles] = cgvSil.getMismatches( 1);
    fprintf( 1, 'Signal Names: %s\n', signalNames{:} );
    fprintf( 1, 'Path to plot files: %s\n', plotFiles{1});
    assert(numel(signalNames)==1,'Expected exactly one mismatch');
end

Applying Configuration Set:
    CS1_default
Applying PostLoad file:
    B:\matlab\toolbox\rtw\rtwdemos\rtwdemo_cgv_init.m
Starting execution:
Run in PIL Mode

Next, the model runs a PIL simulation, using your embedded processor. A universal embedded processor does not exist. Therefore, PIL support is provided by using the host computer where MATLAB® is running. The host processor is treated as an embedded target.

A customization file is executed that maps this model's PIL execution onto the SIL infrastructure. After the customization file is executed, CGV execution displays PIL messages for the mode. SIL messages display the connectivity target.

The configuration set for the model is already configured with: Hardware Implementation > Test hardware > Test hardware is the same as production hardware is checked. Code Generation > Verification > Enable portable word sizes is checked. These settings work in SIL and in PIL when PIL is mapped onto the SIL connectivity target.

```matlab
% Copy the PIL customization file
copyfile( which( 'rtwdemo_cgv_sl_customization.m'),...
          fullfile( pwd, 'sl_customization.m'),'f');
```
sl_refresh_customizations();

cgvPil = cgvSim.copySetup();
cgvPil.setMode( 'PIL');
result3 = cgvPil.run();

Applying PostLoad file:
   B:\matlab\toolbox\rtw\rtwdemos\rtwdemo_cgv_init.m
Starting execution:
   ComponentType: topmodel
   Connectivity: pil
   InputData:
      B:\matlab\toolbox\rtw\rtwdemos\rtwdemo_cgv_data.mat
### Starting build procedure for model: rtwdemo_cgv
### Successful completion of build procedure for model: rtwdemo_cgv
### Preparing to start PIL simulation ... 
Building with 'Microsoft Visual C++ 2015 (C)'.
MEX completed successfully.
### Connectivity configuration for "C:\TEMP\Bdoc18a_815039_17936\ib0BF173\10\tp9d4138e7\ex96023632\rtwdemo_cgv_ert_rtw": CS1_default ###
### Updating code generation report with PIL files ... 
### Starting application: 'rtwdemo_cgv_ert_rtw\pil\rtwdemo_cgv.exe'
End CGV execution: status completed.

Remove Customization

To prevent problems with other models, immediately remove the customization used to
show PIL mode.

delete( 'sl_customization.m');
sl_refresh_customizations();

Check that execution did not terminate with an error

The run() function returns a Boolean value, which is true if the execution completes
without model compilation or simulation error. Before accessing the data, check the result
returned from each execution.

if ~result1 || ~result2 || ~result3
    disp('Execution of model failed.');
end

simData   = cgvSim.getOutputData(1);
silData   = cgvSil.getOutputData(1);
pilData   = cgvPil.getOutputData(1);
**Compare Results**

The executions are now complete. Compare the results. The comparison code supports a plot with filters. Plots display both the data and the difference.

CGV functions display signals names (as used in the command window) and create a file correlating tolerance information with signal names.

**Show Signal Names from Normal Simulation**

Display a list of signal names from the saved data.

Note: cgv.CGV.compare ignores signals that appear in only one data set. For example, the compare function ignores a logged internal signal hi0 that appears in the output of a normal simulation, but does not appear in the output of a SIL simulation.

```matlab
cgv.CGV.getSavedSignals( simData);
```

```matlab
simData.getElement(1).Values.Data(:,1)
simData.getElement(1).Values.Data(:,2)
simData.getElement(2).Values.Data(:,1)
simData.getElement(2).Values.Data(:,2)
simData.getElement(2).Values.Data(:,3)
simData.getElement(2).Values.Data(:,4)
simData.getElement(3).Values.hi0.Data(:,1)
simData.getElement(3).Values.hi0.Data(:,2)
simData.getElement(3).Values.hl1 mid0.lo0.Data(1,1,:)
simData.getElement(3).Values.hl1 mid0.lo0.Data(2,1,:)
simData.getElement(3).Values.hl1 mid0.lo0.Data(1,2,:)
simData.getElement(3).Values.hl1 mid0.lo0.Data(2,2,:)
simData.getElement(3).Values.hl1 mid1.lo1.Data
simData.getElement(3).Values.hl1 mid0.lo2.Data
simData.getElement(3).Values.hl1 mid1.Data(:,1)
simData.getElement(3).Values.hl1 mid1.Data(:,2)
simData.getElement(4).Values.Data
```

**Create a Tolerance File**

The CGV createToleranceFile function creates a file correlating tolerance information with signal names. For the options available to configure tolerances, see cgv.CGV.createToleranceFile. By default, tolerances are zero. Therefore the signals must match exactly. This example allows a delta of 0.5 on the ErrorsInjected signal.
signalList = {'simData.ErrorsInjected.Data' };  
toleranceList = { { 'absolute', 0.5}};  
cgv.CGV.createToleranceFile( 'localtol', signalList, toleranceList );

**Compare Signals**

By default, the `cgv.CGV.compare` function looks at signals that have a common name between both executions. In the following code, the `simData.hi0.Data` signals are not compared, because the signals do not appear in `silData`.

The second and fourth return parameters of the `compare` function are for matched figures and mismatched figures. Tildes (~) represent these parameters because this example does not use the return values.

A plot results from the mismatch on signal `simData.ErrorsInjected.Data`.

```
[matchNames, ~, mismatchNames, ~] = ...  
cgv.CGV.compare( simData, silData, 'Plot', 'mismatch', ...  
    'Tolerancefile', 'localtol');  
fprintf( '%d Signals match, %d Signals mismatch
', ...  
    length(matchNames), length(mismatchNames));  
assert(length(mismatchNames) == 1,'Expected exactly one mismatch');  
assert(length(matchNames) == 14, 'Expected exactly 14 matches');

disp( 'Mismatched Signal Names:');  
disp(mismatchNames');

14 Signals match, 1 Signals mismatch
Mismatched Signal Names:
    'simData.getElement(4).Values.Data'
```
Compare Individual Signals

The cgv.CGV.compare function also compares only the specified signals. In this example, the function compares only three signals.

```matlab
[matchNames, ~, mismatchNames, ~] = ... 
  cgv.CGV.compare( simData, silData, 'Plot', 'mismatch', ... 
  'Signals', {'simData.getElement(3).Values.hi1.mid0.lo1.Data',... 
  'simData.getElement(3).Values.hi1.mid0.lo2.Data', ... 
  'simData.getElement(2).Values.Data(:,3)');
fprintf( '%d Signals match, %d Signals mismatch
', length(matchNames), length(mismatchNames));
assert(isempty(mismatchNames),'Expected no mismatches');
if ~isempty(mismatchNames)
  disp( 'Mismatched Signal Names:
  disp(mismatchNames');
```
% Since a mismatch does not occur for these signals, a plot is not generated.
3 Signals match, 0 Signals mismatch

Additional Plotting Support

To create a plot of a list of signals, call cgv.CGV.plot. For example,

```matlab
[signalNames, signalFigures] = cgv.CGV.plot( simData, ...
    'Signals', {'simData.getElement(2).Values.Data(:,1)'});
```

View Signal Data in the Simulation Data Inspector Tool

To open the Simulation Data Inspector tool, at the MATLAB® command line, enter Simulink.sdi.view. To import the signal data, in the Simulation Data Inspector tool, select
**File > Import Data**, which opens the Data Import tool. Select **Import from > Base workspace**, to view and select the signals saved in simData and silData.

**Clear Your Workspace**

Clear the variables from the workspace:

```matlab
newBaseVars = who;
addedVars = setdiff( newBaseVars, baseVars);
clearCmd = ['clear ' sprintf( '%s ', addedVars{:})];
eval( clearCmd);
clear newBaseVars addedVars clearCmd
rtwdemoclean;
```

**Numerical Consistency**

In the Model-Based Design workflow (Simulink Code Inspector), you use MathWorks products to generate code for numerical applications that employ fixed-point and floating-point arithmetic.

- To develop models, you use MATLAB, Simulink, and Stateflow.
- To generate source code, you use Simulink Coder and Embedded Coder.
- To test numerical equivalence between your model and generated code, you compare model and generated code simulation results. For example, normal mode simulation results compared with software-in-the-loop (SIL) simulation results.

The results from the model and generated code simulations are numerically consistent if:

- In fixed-point applications, the results agree in a bit-wise comparison.
- In floating-point applications, the results agree with an error tolerance that you specify.

Use the Simulation Data Inspector to compare results. To determine whether discrepancies exist or are significant, you can specify absolute and relative tolerance values:

- For fixed-point applications, you can specify an absolute tolerance of zero.
- For floating-point applications, you can specify tolerance with respect to a reference value or signal. The choice of reference depends on your application. Consider these examples:
  - An algorithm that solves a linear algebraic equation by iterative, feed-forward error calculations. You can specify tolerance with respect to \( \text{eps} \).
• A Proportional-Integral-Derivative (PID) controller for a closed-loop system. For transient behavior, you can specify tolerance with criteria from a standard. For steady-state behavior, you can specify tolerance with reference to the PID controller characteristics.

Programmatically, you can specify absolute and relative tolerance values through the absTol and relTol properties of the Simulink.sdi.Signal object.

**Numerical Consistency in Complex Systems**

For complex systems, numerical differences between model and generated code simulations can be a result of block-level differences propagating through the system. If you observe numerical differences at the system level:

1. Identify blocks for which block-level numerical differences exceed the error tolerance.
2. Investigate each identified block.

Consider the following plant-controller model.
• T produces reference or test signals.
• C is the controller component. The controller output is the plant input. C can be a Model block that comprises multiple Model blocks.
• P is the plant component. The plant output is subtracted from the reference signal to produce the controller input.

To test numerical equivalence between the model controller and the generated code version:

1. Run the model in normal mode, and, using the Simulation Data Inspector, record the output of C.
2. Specify SIL mode for C. Rerun the simulation, recording the output of C.
3. Using the Simulation Data Inspector, compare normal and SIL mode outputs with reference to your specified error tolerance.
If the Simulation Data Inspector comparison indicates a match, the model and generated code results are numerically consistent.

If the normal and SIL mode outputs do not match:

1. Within C, enable signal logging for block outputs.
2. Run the model in normal mode.
3. Rerun the simulation with C in SIL mode.
4. Using the Simulation Data Inspector, compare the logged output signals with reference to your specified error tolerance. See “Compare Simulation Data” (Simulink).
5. Identify blocks for which normal and SIL mode output differences exceed the error tolerance.
6. Analyze each identified block and look for the cause. For example, the generated code might use a different math library than MATLAB.

Note: If the comparison of a large number of signals is required, you can automate the workflow with Simulink Test. See “Code Generation Verification Workflow with Simulink Test” (Simulink Test).

Reasons for Block-Level Numerical Differences

In fixed-point and floating-point application development, there are factors that can affect numerical agreement between block-level results from model and generated code simulations.

Some factors can affect both fixed-point and floating-point applications. For example, the use of:

- Code generation optimization.
- Custom code.
- Code replacement library entries whose results differ from MATLAB results.
- Code replacement libraries that implement different algorithms.

Other factors affect only floating-point applications. For example:

- Numerical soundness of algorithm.
• Algorithm sensitivity to input.
• Closed loop and open loop behavior.

Code Verification Through Software-in-the-Loop and Processor-in-the-Loop Execution

MATLAB Coder supports software-in-the-loop (SIL) and processor-in-the-loop (PIL) execution, which enables you to verify production-ready source code and compiled object code. With these execution modes, you can reuse test vectors developed for your MATLAB functions to verify the numerical behavior of library code.

In SIL execution, through a MATLAB SIL interface, the software compiles and runs library code on your development computer. In PIL execution, through a MATLAB PIL interface, the software cross-compiles and runs production object code on a target processor or an equivalent instruction set simulator. Before you run a PIL execution, you must set up a PIL connectivity configuration for your target.

The workflow for generating and verifying code is:

1. Set up MATLAB Coder.
2. Fix errors detected at design time.
3. Generate MEX function.
4. Test MEX function.
5. Generate C/C++ library code.
6. Verify generated C/C++ code through SIL or PIL execution — requires Embedded Coder license.

In step 4, you verify code that is generated for execution within MATLAB. However, this code is different from the standalone code generated for libraries. In step 6, with an Embedded Coder license, you use SIL or PIL execution to verify the standalone code.

Software-in-the-Loop Execution with the MATLAB Coder App

Use software-in-the-loop (SIL) execution to verify the numerical behavior of the generated C/C++ code with reference to your original MATLAB functions.

1. To open the MATLAB Coder app, on the MATLAB Toolstrip Apps tab, under Code Generation, click the app icon.

2. To open your project, click , and then click Open existing project. Select the project. For example, kalman_filter01.prj.

3. On the Generate Code page, click the Generate arrow .

4. In the Generate dialog box:
   a. Set Build type to Static Library or Dynamic Library.
   b. In the Output file name field, use the default value. For example, kalman01.
   c. Specify Language.
   d. Clear the Generate code only check box.
   e. In the Hardware Board field, use the default value (MATLAB Host Computer).

You do not have to specify the Toolchain setting. By default, the MATLAB Coder app locates an installed toolchain.

5. To generate the C or C++ code, click Generate.

6. Click Verify Code.

7. In the command field, specify the test file that calls the original MATLAB functions, for example, test01_ui.m.

8. If required, select the Enable source-level debugging for SIL check box.

9. To start the SIL execution, click Run Generated Code.

The MATLAB Coder app:

• Generates a standalone library, for example, codegen\lib\kalman01.
• Generates SIL interface code, for example, codegen\lib\kalman01\sil.
• Runs the test file, replacing calls to the MATLAB function with calls to the generated code in the library.
• Displays messages from the SIL execution in the Test Output tab.

10 Verify that the results from the SIL execution match the results from the original MATLAB functions.

11 To terminate the SIL execution process, click Stop SIL Verification. Alternatively, on the Test Output tab, click the link that follows To terminate execution.

Note On a Windows operating system, the Windows Firewall can potentially block a SIL or PIL execution. To allow the execution, use the Windows Security Alert dialog box. For example, in Windows 7, click Allow access.

More About
Software-in-the-Loop Execution From Command Line

Use software-in-the-loop (SIL) execution to verify the numerical behavior of the generated C/C++ code with reference to your original MATLAB functions.

To set up and start a SIL execution from the command line:

2. Configure the object for SIL.
3. Use the `codegen` function to generate library code for your MATLAB function and the SIL interface.
4. Use the `coder.runTest` function to run the test file for your original MATLAB function.

To terminate the SIL execution, use the `clear function_sil` or `clear mex` command.

The following example shows how you can set up and run a SIL execution from the command line.

**SIL Execution of Code Generated for a Kalman Estimator**

1. **Copy MATLAB code for Kalman estimator**

   From `docroot\toolbox\coder\examples\kalman`, copy the following files to your working folder:
   - `kalman01.m` — MATLAB function for the Kalman estimator
   - `test01_ui.m` — MATLAB file to test `kalman01.m`
   - `plot_trajectory.m` — File that plots actual target trajectory and Kalman estimator output
   - `position.mat` — Input data

   ```matlab
   src_dir = ...
   fullfile(docroot,'toolbox','coder','examples','kalman');
   copyfile(fullfile(src_dir,'kalman01.m'), '.')
   copyfile(fullfile(src_dir,'test01_ui.m'), '.')
   copyfile(fullfile(src_dir,'plot_trajectory.m'), '.')
   copyfile(fullfile(src_dir,'position.mat'), '.')
   ```
For a description of the Kalman estimator in this example, see “C Code Generation at the Command Line” (MATLAB Coder).

2 Configure SIL execution

   a From your working folder, create a `coder.EmbeddedCodeConfig` object.

      ```matlab
      config = coder.config('lib');
      config.GenerateReport = true; % Optional, documents code in HTML report
      ```

   b Configure the object for SIL.

      ```matlab
      config.VerificationMode = 'SIL';
      % Check that production hardware setting is the default
      % i.e. 'Generic->MATLAB Host Computer'
      disp(config.HardwareImplementation.ProdHWDeviceType);
      ```

   c If required, enable the Microsoft Visual Studio debugger for SIL execution:

      ```matlab
      config.SILDebugging = true;
      ```

3 Generate code and run SIL execution

Generate library code for the `kalman01` MATLAB function and the SIL interface, and run the MATLAB test file, `test01_ui`. The test file uses `kalman01_sil`, the generated SIL interface for `kalman01`.

```matlab
codegen -config config -args {zeros(2,1)} kalman01 -test test01_ui
```

The software creates the following output folders:

- `codegen\lib\kalman01` — Standalone code for `kalman01`.
- `codegen\lib\kalman01\sil` — SIL interface code for `kalman01`.

Verify that the output of this run matches the output from the original `kalman01.m` function.

**Note** On a Windows operating system, the Windows Firewall can potentially block a SIL or PIL execution. To allow the execution, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.
4 Debug code during SIL execution

If you enable the Microsoft Visual Studio debugger, then running the test file opens the Microsoft Visual Studio IDE with debugger breakpoints at the start of the kalman01.initialize and kalman01 functions.

You can use the debugger features to observe code behavior. For example, you can step through code and examine variables.

To end the debugging session:

a Remove all breakpoints.
b Click the Continue button (F5).

The SIL execution runs to completion.

5 Terminate SIL execution

Terminate the SIL execution process.

clear kalman01_sil;

You can also use the command clear mex, which clears MEX functions from memory.

More About

Debug Generated Code During SIL Execution

If a SIL execution fails or you notice differences between the outputs of your original functions and the generated code, you can rerun the SIL execution with a debugger enabled. By inserting breakpoints, you can observe the behavior of code sections, which might help you to understand the cause of the problem.

For a SIL execution failure, you can also view information from the standard output and standard error streams in the MATLAB Command Window. For example:

- Output from printf statements in your code.
- If you enable run-time error detection, messages sent to stderr.
- Some low-level system messages.

**Note** During a SIL execution, the SIL application redirects the stdout and stderr streams. When the application terminates, the MATLAB Command Window displays the information from the redirected streams. The SIL application also provides a basic signal handler, which captures the POSIX signals SIGFPE, SIGILL, SIGABRT, and SIGSEV. For this signal handler, the SIL application includes the file signal.h.

A SIL execution supports the following debuggers:

- On Windows, Microsoft Visual Studio debugger.
- On Linux, GNU Data Display Debugger (DDD).

**Note** You can perform SIL debugging only if your Microsoft Visual C++ or GNU GCC compiler is supported by the MATLAB product family. For more information, see supported compilers.

To run a SIL execution with debugging enabled:

1. On the **Generate Code** page, click **Verify Code**.
2. Select the **Enable source-level debugging for SIL** check box.
3. Click **Run Generated Code**.
On a Windows computer, your `user_fn.c` or `user_fn.cpp` file opens in the Microsoft Visual Studio IDE with debugger breakpoints at the start of the `user_fn_initialize` and `user_fn` functions.

You can now use the debugger features to observe code behavior. For example, you can step through code and examine variables.

To end the debugging session:

1. Remove all breakpoints.
2. Click the **Continue** button (F5).

   The SIL execution runs to completion.

3. To terminate the SIL execution process, on the **Test Output** tab, click the link that follows **To terminate execution**, for example, `clear kalman01_sil`.

   The Microsoft Visual Studio IDE closes automatically.

**Note** If you select **Debug > Stop Debugging**, the SIL execution times out with the following error message:
Communications error: failed to send data to the target. There might be multiple reasons for this failure.

Create PIL Target Connectivity Configuration for MATLAB

In this section...

| “Target Connectivity Configurations for PIL” on page 69-12 |
| “Create a Target Connectivity API Implementation” on page 69-13 |
| “Register Target Connectivity Configuration” on page 69-14 |
| “Verify Target Connectivity Configuration” on page 69-15 |

Target Connectivity Configurations for PIL

Use target connectivity configurations and the target connectivity API to customize processor-in-the-loop (PIL) execution for your target environments.

Through a target connectivity configuration, you specify:

- A target connectivity configuration name for a target connectivity API implementation.
- Settings that define compatible MATLAB code. For example, the code that is generated for a particular hardware implementation.

A PIL execution requires a target connectivity PIL API implementation that integrates third-party tools for:

- Building the PIL application that runs on the target hardware
- Downloading, starting, and stopping the application on the target
- Communicating between MATLAB and the target

You can have many different connectivity configurations for PIL execution. Register a connectivity configuration with MATLAB by creating an `rtwTargetInfo.m` file and placing it on the MATLAB search path.

In a PIL execution, the software determines which of the available connectivity configurations to use. The software looks for a connectivity configuration that is compatible with the MATLAB code under test. If the software finds multiple or no compatible connectivity configurations, the software generates an error message with information about resolving the problem.
Create a Target Connectivity API Implementation

This diagram shows the components of the PIL target connectivity API.

You must provide implementations of the three API components:

- **Build API** — Specify a toolchain approach for building generated code.
- **Launcher API** — Control how MATLAB starts and stops the PIL executable.
- **Communications API** — Customize connectivity between MATLAB and the PIL target. Embedded Coder provides host-side support for TCP/IP and serial communications, which you can adapt for other protocols.

These steps outline how you create a target connectivity API implementation. The example code shown in the steps is taken from the `ConnectivityConfig.m` file used in “Processor-in-the-Loop Execution From Command Line” on page 69-28.

   ```matlab
   ConnectivityConfig < rtw.connectivity.Config
   ```

2. In the subclass:
• Instantiate `rtw.connectivity.MakefileBuilder`, which configures the build process.

```matlab
builder = rtw.connectivity.MakefileBuilder(componentArgs, ...
    targetApplicationFramework, ...
    exeExtension);
```

• Create a subclass of `rtw.connectivity.Launcher`, which downloads and executes the application using a third-party tool.

```matlab
launcher = mypil.Launcher(componentArgs, builder);
```

3 Configure your `rtiostream` API implementation of the host-target communications on page 69-16 channel.

• For the target side, you must provide the driver code for communications, for example, code for TCP/IP or serial communications. To integrate this code into the build process, create a subclass of `rtw.pil.RtIOStreamApplicationFramework`.

• For the host side, you can use a supplied library for TCP/IP or serial communications. Instantiate `rtw.connectivity.RtIOStreamHostCommunicator`, which loads and initializes the library that you specify.

```matlab
hostCommunicator = rtw.connectivity.RtIOStreamHostCommunicator(...
    componentArgs, ...
    launcher, ...
    rtiostreamLib);
```

4 If you require execution-time profiling of generated code, create a timer object that provides details of the hardware-specific timer and associated source files. See “Specify Hardware Timer” on page 69-22.

**Register Target Connectivity Configuration**

To register a target connectivity API implementation as a target connectivity configuration in MATLAB:

1 Create or update an `rtwTargetInfo.m` file. In this file:

   • Create a target connectivity configuration object that specifies, for example, the configuration name for a target connectivity API implementation and compatible MATLAB code.
   • Invoke `registerTargetInfo`.
Add the folder containing `rtwTargetInfo.m` to the search path and refresh the MATLAB Coder library registration information.

For more information, see `rtw.connectivity.ConfigRegistry`.

### Verify Target Connectivity Configuration

To verify your target connectivity configuration early on and independently of your algorithm development and code generation, use the `piltest` function. With the function, you can run a suite of tests. The function:

- Runs the MATLAB function and performs PIL executions.
- Compares results and produces errors if it detects differences.

For an example, see “PIL Execution of Code Generated for a Kalman Estimator” on page 69-28.

Host-Target Communication for PIL

Communications rtiostream API

The rtiostream API supports communications for the target connectivity API. Use the rtiostream API to implement a communication channel that enables data exchange between different processes.

PIL verification requires a host-target communications channel. This communications channel comprises driver code that runs on the host and target. The rtiostream API defines the signature of target-side and host-side functions that must be implemented by this driver code.

The API is independent of the physical layer that sends the data. Possible physical layers include RS232, Ethernet, or Controller Area Network (CAN).

A full rtiostream implementation requires both host-side and target-side drivers. Code generation software includes host-side drivers for the default TCP/IP implementation as well as a version for serial communications. To use:

- The TCP/IP rtiostream communications channel, you must provide, or obtain from a third party, target-specific TCP/IP device drivers.
- The serial communications channel, you must provide, or obtain from a third party, target-specific serial device drivers.

For other communication channels and platforms, the code generation software does not provide default implementations. You must provide both the host-side and the target-side drivers.

The rtiostream API comprises the following functions:

- rtiostreamOpen
- rtiostreamSend
• rtIOStreamRecv
• rtIOStreamClose

For information about:

• Using rtiostream functions in a connectivity implementation, see “Create a Target Connectivity API Implementation” on page 69-13.
• Testing the rtiostream shared library methods from MATLAB code, see rtiostream_wrapper.
• Debugging and verifying the behavior of custom rtiostream interface implementations, see “Test an rtiostream Driver” on page 69-18.

**Synchronize Host and Target**

If you use the rtiostream API to implement the communications channel, the host and target must be synchronized, which prevents MATLAB from transmitting and receiving data before the target application is fully initialized.

To synchronize the host and target for TCP/IP rtiostream implementations, use the setInitCommsTimeout method from rtw.connectivity.RtIOStreamHostCommunicator. This approach works well for connection-oriented TCP/IP rtiostream implementations because MATLAB automatically waits until the target server is running.

With other rtiostream implementations, for example, serial, the MATLAB side of the rtiostream connection opens without waiting for the target to be fully initialized. In this case, you must make your Launcher implementation wait until the target application is fully initialized. Use one of the following approaches to synchronize your host and target:

• Add a pause at the end of the Launcher implementation that makes the Launcher wait until target initialization is complete.
• In the Launcher implementation, use third-party downloader or debugger APIs that wait until target initialization is complete.
• Implement a handshaking mechanism in the Launcher / rtiostream implementation that confirms completion of target initialization.
Test an rtiostream Driver

Use a test suite to debug and verify the behavior of custom rtiostream interface implementations.

The test suite has the following advantages:

- Reduces time for integrating custom hardware that does not have built-in rtiostream support.
- Reduces time for testing custom rtiostream drivers.
- Helps analyze the performance of custom rtiostream drivers.

The test suite has two parts. One part of the test suite runs on the target.

Note After building the target application, download it to the target and run it.

To start this part, compile and link the following files, which are in the folder matlabroot/toolbox/coder/rtiostream/src/rtiostreamtest (open).

- rtiostreamtest.c
- rtiostreamtest.h
- rtiostream.h, located in the folder matlabroot/rtw/c/src (open)
- rtiostream implementation under investigation (for example, rtiostream_tcpip.c)
- main.c

To run the MATLAB part of the test suite, invoke rtiostreamtest. The syntax is as follows:

rtiostreamtest(connection,param1,param2)

- connection is a character vector indicating the communication method. It can have values 'tcp' or 'serial'.
- param1 and param2 have different values depending on the value of connection.
  - If connection is 'tcp', then param1 and param2 are hostname and port, respectively. For example, rtiostreamtest('tcp', 'localhost', 2345).
- If connection is 'serial', then param1 and param2 are COM port and baud rate, respectively. For example, rtiostreamtest('serial', 'COM1', 9600).

You can run the MATLAB part of the test suite as follows:

```matlab
rtiostreamtest('tcp','localhost','2345')
```

An output in the following format appears in the MATLAB window:

```plaintext
### Test suite for rtiostream ###
Initializing connection with target...

### Hardware characteristics discovered
Size of char : 8 bit
Size of short : 16 bit
Size of int : 32 bit
Size of long : 32 bit

Specify Hardware Timer

For processor-in-the-loop (PIL) code execution profiling, you must create a timer object that provides details of the hardware-specific timer and associated source files. You can use the Code Replacement Tool or the code replacement library API to specify this hardware-specific timer.

To specify the timer with the Code Replacement Tool:

1. Open the Code Replacement Tool. In the Command Window, enter `crtool`.
2. Create a new code replacement table. Select **File > New table**.
3. Create a new function entry. Under **Tables List**, right-click the new table. Then, from the context-menu, select **New entry > Function**.
4. In the middle view, select the new unnamed function.
5. On the **Mapping Information** pane:
   a. From the **Function** drop-down list, select `code_profile_read_timer`.
   b. Specify the count direction for your timer. For example, from the **Count direction** drop-down list, select **Up**.
   c. In the **Ticks per second** field, specify the number of ticks per second for your timer, for example, `1e+09`.
      
      The default value is 0. In this case, the software reports time measurements in terms of ticks, not seconds.
   d. In the **Name** field, specify a replacement function name, for example, `MyTimer`.
   e. Click **Apply**.
To validate the function entry, click **Validate entry**.

6 On the **Build Information** pane, specify the required build information. See “Specify Build Information for Replacement Code” on page 54-61.

7 Save the table (**Ctrl+S**). When you save the table for the first time, use the Save As dialog box to specify the file name and location.

You must save the table in a location that is on the MATLAB search path. For example, you can save this file in the folder for your subclass of `rtw.connectivity.Config`.

The software stores your timer information as a code replacement library table.

8 Assuming you save the table as **MyCrlTable.m**, in your subclass of `rtw.connectivity.Config`, add the following line:

```matlab
setTimer(this, MyCrlTable)
```

More About
• “What Is Code Replacement?” on page 41-2
• “What Is Code Replacement Customization?” on page 54-3
Use processor-in-the-loop (PIL) execution to verify the numerical behavior of cross-compiled object code with reference to your original MATLAB functions.

Before you run a PIL execution, you must define a target connectivity configuration. In “Processor-in-the-Loop Execution From Command Line” on page 69-28, steps 1 and 2 of the example PIL Execution of Code Generated for a Kalman Estimator show how you can set up and register a connectivity configuration for PIL execution on your development computer.

1. To open the MATLAB Coder app, on the MATLAB Toolstrip Apps tab, under Code Generation, click the app icon.
2. To open your project, click , and then click Open existing project. Select the project. For example, kalman_filter.prj.
3. On the Generate Code page, click the Generate arrow .
4. In the Generate dialog box:
   a. Set Build type to Static Library or Dynamic Library.
   b. In the Output file name field, use the default value. For example, kalman01.
   c. Clear the Generate code only check box.
   d. From the Hardware Board drop-down list, select None - Select device below.
   e. In the Device fields, specify vendor and type. These settings must match the target hardware settings in the rtwTargetInfo.m file of your target connectivity configuration. For host-based PIL, select settings that match your host computer. For example:
      - For a Windows 64-bit system, set Device vendor to Intel and Device type to x86-64 (Windows64). In addition, set Enable long long to Yes.
      - For a Linux 64-bit system, set Device vendor to Intel and Device type to x86-64 (Linux 64).
      - For a Mac OS X system, set Device vendor to Intel and Device type to x86-64 (Mac OS X).
You do not have to specify the **Toolchain** setting. By default, the MATLAB Coder app locates an installed toolchain.

5 To generate the C or C++ code, click **Generate**.

6 Click **Verify Code**.

7 In the command field, specify the test file that calls the original MATLAB functions, for example, *test01_ui.m*.

8 To start the PIL execution, click **Run Generated Code**.

The MATLAB Coder app:

- Generates a standalone library, for example, *codegen\lib\kalman01*.
- Generates PIL interface code, for example, *codegen\lib\kalman01\pil*.
- Runs the test file, replacing calls to the MATLAB function with calls to the generated code in the library.
- Displays messages from the PIL execution in the **Test Output** tab.

9 Verify that the results from the PIL execution match the results from the original MATLAB functions.

10 To terminate the PIL execution process, click **Stop PIL Verification**. Alternatively, on the **Test Output** tab, click the link that follows To terminate execution.

**Note** On a Windows operating system, the Windows Firewall can potentially block a SIL or PIL execution. To allow the execution, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

More About

Processor-in-the-Loop Execution From Command Line

Use processor-in-the-loop (PIL) execution to verify code that you intend to deploy in production.

To set up and start a PIL execution from the command line:

1. Create, register, and verify your target connectivity configuration.
2. Create a `coder.EmbeddedCodeConfig` object.
3. Configure the object for PIL.
4. Use the `codegen` function to generate library code for your MATLAB function and the PIL interface.
5. Use the `coder.runTest` function to run the test file for your original MATLAB function.

To terminate the PIL execution, use the `clear function_pil` or `clear mex` command.

The following example shows how you can use line commands to set up and run a PIL execution on your development computer.

PIL Execution of Code Generated for a Kalman Estimator

1. **Create a target connectivity API implementation**
   a. In your current working folder, make a local copy of the connectivity classes.

```
src_dir = ...
    fullfile(matlabroot,'toolbox','coder','simulinkcoder','+coder','+mypil');
if exist(fullfile('.','+mypil'),'dir')
    rmdir('+mypil','s')
end
mkdir +mypil
mkdir 'LP
copyfile(fullfile(src_dir,'Launcher.m'), '+mypil');
copyfile(fullfile(src_dir,'TargetApplicationFramework.m'), '+mypil');
copyfile(fullfile(src_dir,'ConnectivityConfig.m'), '+mypil');
```

b. Make the copied files writable.

```
fileattrib(fullfile('+mypil', '*'),'+w');
```

c. Update the package name to reflect the new location of the files.
coder.mypil.Utils.UpdateClassName(...
   './+mypil/ConnectivityConfig.m',...
   'coder.mypil',...
   'mypil');

d  Check that you now have a folder +mypil in the current folder, which includes three files, Launcher.m, TargetApplicationFramework.m, and ConnectivityConfig.m.

dir './+mypil'

e  Review the code that starts the PIL application. The mypil.Launcher class configures a tool for starting the PIL executable. Open this class in the editor.

edit(which('mypil.Launcher'))

Review the content of this file. For example, consider the setArgString method. This method allows additional command line parameters to be supplied to the application. These parameters can include a TCP/IP port number. For an embedded processor implementation, you might have to hard code these settings.

f  The class mypil.ConnectivityConfig configures target connectivity.

eedit(which('mypil.ConnectivityConfig'))

Review the content of this file. For example:

- The creation of an instance of rtw.connectivity.RtIOStreamHostCommunicator that configures the host side of the TCP/IP communications channel.
- A call to the setArgString method of Launcher that configures the target side of the TCP/IP communications channel.
- A call to setTimer that configures a timer for execution time measurement. To define your own target-specific timer for execution time profiling, you must use the Code Replacement Library to specify a replacement for the function code_profile_read_timer.

g  Review the target-side communication drivers.

rtiostreamtcpip_dir=fullfile(matlabroot,'rtw','c','src','rtiostream',...
   'rtiostreamtcpip');
edit(fullfile(rtiostreamtcpip_dir,'rtiostream_tcppip.c'))

Scroll down to the end of this file. The file contains a TCP/IP implementation of the functions rtIOStreamOpen, rtIOStreamSend, and rtIOStreamRecv.
These functions are required for target communication with the host. For each of these functions, you must provide an implementation that is specific to your target hardware and communication channel.

The `mypil.TargetApplicationFramework` class adds target-side communication drivers to the connectivity configuration.

```matlab
edit(which('mypil.TargetApplicationFramework'))
```

The file specifies additional files to include in the build.

2 **Register a target connectivity configuration**

Use an `rtwTargetInfo.m` file to:

- Create a target connectivity configuration object.
- Invoke `registerTargetInfo`, which registers the target connectivity configuration.

The target connectivity configuration object specifies, for example:

- The configuration name and associated API implementation. See `rtw.connectivity.ConfigRegistry`.
- A toolchain for your target hardware. This example assumes that the target hardware is your host computer, and uses the toolchain supplied for host-based PIL verification. For information about toolchains, see “Custom Toolchain Registration” (MATLAB Coder).

a Insert the following code into your `rtwTargetInfo.m` file, and save the file in the current working folder or in a folder that is on the MATLAB search path:

```matlab
function rtwTargetInfo(tr)

% Register PIL connectivity config: mypil.ConnectivityConfig

tr.registerTargetInfo(@loc_createConfig);

% local function
function config = loc_createConfig

% Create object for connectivity configuration
config = rtw.connectivity.ConfigRegistry;
% Assign connectivity configuration name
config.ConfigName = 'My PIL Example';
% Associate the connectivity configuration with the connectivity
% API implementation
config.ConfigClass = 'mypil.ConnectivityConfig';

% Specify toolchains for host-based PIL
config.Toolchain = rtw.connectivity.Utils.getHostToolchainNames;

% Through the HardwareBoard and TargetHWDeviceType properties,
% define compatible code for the target connectivity configuration
config.HardwareBoard = {}; % Any hardware board
config.TargetHWDeviceType = {'Generic->32-bit x86 compatible' ...
'Generic->Custom' ...
'Intel->x86-64 (Windows64)', ...
'Intel->x86-64 (Mac OS X)', ...
'Intel->x86-64 (Linux 64)'};

b Refresh the MATLAB Coder library registration information.
RTW.TargetRegistry.getInstance('reset');

3 Verify target connectivity configuration

Use the supplied pilstest function to verify your target connectivity configuration.

a Create a coder.EmbeddedCodeConfig object for verifying the target
connectivity configuration.

configVerify = coder.config('lib');

b Specify the manufacturer and test hardware type. For example, PIL execution on
a 64-bit Windows development computer requires:

    configVerify.HardwareImplementation.TargetHWDeviceType = ...
       'Intel->x86-64 (Windows64)';
    configVerify.HardwareImplementation.ProdLongLongMode = true;

c Run pilstest.

    pilstest(configVerify, 'ConfigParam', {'ProdLongLongMode'} )

4 Copy MATLAB code for Kalman estimator

Copy the MATLAB code to your working folder.

src_dir = ...
    fullfile(docroot,'toolbox','coder','examples','kalman');

    copyfile(fullfile(src_dir,'kalman01.m'), '.')
For a description of the Kalman estimator in this example, see “C Code Generation at the Command Line” (MATLAB Coder).

5 Configure the PIL execution

a Create a `coder.EmbeddedCodeConfig` object.
   
   ```
   config = coder.config('lib');
   ```

b Configure the object for PIL.
   
   ```
   config.VerificationMode = 'PIL';
   ```

c Specify production hardware, which must match one of the test hardware settings in `rtwTargetInfo.m`. For PIL execution on your development computer, specify settings that match the computer. For example, if your computer is a Windows 64-bit system, specify:
   
   ```
   config.HardwareImplementation.ProdHWDeviceType = ...
   'Intel->x86-64 (Windows64)';
   config.HardwareImplementation.ProdLongLongMode = true;
   ```

   For a Linux 64-bit system, set `ProdHWDeviceType` to `'Intel->x86-64 (Linux 64)'`.

   For a Mac OS X system, set `ProdHWDeviceType` to `'Intel->x86-64 (Mac OS X)'`.

6 Generate code and run PIL execution

Generate library code for the `kalman01` MATLAB function and the PIL interface, and run the MATLAB test file, `test01_ui`. The test file uses `kalman01_pil`, the generated PIL interface for `kalman01`.

```
codegen -config config -args {zeros(2,1)} kalman01 -test test01_ui
```  

The software creates the following output folders:

- `codegen\lib\kalman01` — Standalone code for `kalman01`.
- `codegen\lib\kalman01\pil` — PIL interface code for `kalman01`.

Verify that the output of this run matches the output from the original `kalman01.m` function.
Note On a Windows operating system, the Windows Firewall can potentially block a SIL or PIL execution. To allow the execution, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

7 **Terminate PIL execution**

Terminate the PIL execution process.

clear kalman01_pil;

**More About**
Verification of Code Generation Assumptions

The settings on the More Settings > Hardware tab specify target behavior, which result in the implementation of implicit assumptions in the generated code. Incorrect settings can lead to:

- Suboptimal code
- Code execution failure, incorrect code output, and nondeterministic code behavior

At the start of a processor-in-the-loop (PIL) execution, the software verifies the Hardware tab settings with reference to the target hardware. The software checks:

- The correctness of settings. For example, the integer bit length in the Sizes > int field.
- Whether the settings are optimized. For example, the rounding of signed integer division in the Signed integer division rounds to field.

If required, the software generates warnings and errors.

**Related Examples**

Speed Up SIL/PIL Execution by Disabling Constant Input Checking and Global Data Synchronization

By default, a SIL or PIL execution performs constant input checking and global data synchronization. Constant input checking compares the value that a test file provides for a constant input argument with the value specified at code generation time. If the values do not match, an error occurs. Global data synchronization makes the values of global variables in the SIL or PIL execution environment consistent with the values in the MATLAB workspace. If a global variable is constant and its value in the SIL or PIL execution environment differs from its value in the MATLAB workspace, an error occurs.

It is possible to speed up a SIL or PIL execution by disabling constant input checking or global data synchronization. However, if you disable these features, the SIL or PIL execution results might differ from the results in MATLAB.

Disable Constant Input Checking or Global Data Synchronization at the Command Line

In a coder.EmbeddedCodeConfig object that you configured for SIL or PIL execution:

- To disable constant input checking, set the SILPILCheckConstantInputs property to false. For example, for an object cfg, use this code:

  ```
  cfg.SILPILCheckConstantInputs = false;
  ```

- To disable global data synchronization, set the SILPILSyncGlobalData property to false. For example, for an object cfg, use this code:

  ```
  cfg.SILPILSyncGlobalData = false;
  ```

Disable Constant Input Checking or Global Data Synchronization in the MATLAB Coder App

In the settings for a project that you set up for SIL or PIL execution, on the Debugging tab:

- To disable constant input checking, set Check constant inputs in SIL/PIL to No.
- To disable global data synchronization, set Synchronize global data in SIL/PIL to No.

Simulink Code Coverage Metrics

In this section...

| “Statement Coverage for Code Coverage” on page 70-2 |
| “Condition Coverage for Code Coverage” on page 70-3 |
| “Decision Coverage for Code Coverage” on page 70-3 |
| “Modified Condition/Decision Coverage (MCDC) for Code Coverage” on page 70-4 |
| “Cyclomatic Complexity for Code Coverage” on page 70-5 |
| “Relational Boundary for Code Coverage” on page 70-5 |

If you have a Simulink Coverage license, you can run a SIL or PIL simulation that produces code coverage metrics for generated model code. The simulation performs several types of code coverage analysis.

Statement Coverage for Code Coverage

Statement coverage determines the number of source code statements that execute when the code runs. Use this type of coverage to determine whether every statement in the program has been invoked at least once.

Statement coverage = (Number of executed statements / Total number of statements) *100

Statement Coverage Example

This code snippet contains five statements. To achieve 100% statement coverage, you need at least three test cases. Specifically, tests with positive x values, negative x values, and x values of zero.

```c
if (x > 0)
    printf( "x is positive" );
else if (x < 0)
    printf( "x is negative" );
else
    printf( "x is 0" );
```
Condition Coverage for Code Coverage

Condition coverage analyzes statements that include conditions in source code. Conditions are C/C++ Boolean expressions that contain relation operators (<, >, <=, or >=), equation operators (!= or ==), or logical negation operators (!), but that do not contain logical operators (&& or ||). This type of coverage determines whether every condition has been evaluated to all possible outcomes at least once.

Condition coverage = (Number of executed condition outcomes / Total number of condition outcomes) *100

Condition Coverage Example

In this expression:

\[ y = x \leq 5 \land x \neq 7; \]

there are these conditions:

- \[ x \leq 5 \]
- \[ x \neq 7 \]

Decision Coverage for Code Coverage

Decision coverage analyzes statements that represent decisions in source code. Decisions are Boolean expressions composed of conditions and one or more of the logical C/C++ operators && or ||. Conditions within branching constructs (if/else, while, do-while) are decisions. Decision coverage determines the percentage of the total number of decision outcomes the code exercises during execution. Use this type of coverage to determine whether all decisions, including branches, in your code are tested.

Note The decision coverage definition for DO-178C compliance differs from the Simulink Coverage definition. For decision coverage compliance with DO-178C, select the Condition Decision structural coverage level for Boolean expressions not containing && or || operators.

Decision coverage = (Number of executed decision outcomes / Total number of decision outcomes) *100
Decision Coverage Example

This code snippet contains three decisions:

\[
y = x \leq 5 \land x \neq 7; \quad \text{// decision #1}
\]

\[
\text{if}( x > 0 ) \quad \text{// decision #2}
\]

\[
\quad \text{printf( "decision #2 is true" );}
\]

\[
\text{else if}( x < 0 \land y ) \quad \text{// decision #3}
\]

\[
\quad \text{printf( "decision #3 is true" );}
\]

\[
\text{else}
\]

\[
\quad \text{printf( "decisions #2 and #3 are false" );}
\]

Modified Condition/Decision Coverage (MCDC) for Code Coverage

Modified condition/decision coverage (MCDC) is the extent to which the conditions within decisions are independently exercised during code execution.

- All conditions within decisions have been evaluated to all possible outcomes at least once.
- Every condition within a decision independently affects the outcome of the decision.

MCDC coverage = \( \frac{\text{Number of conditions evaluated to all possible outcomes affecting the outcome of the decision}}{\text{Total number of conditions within the decisions}} \) \times 100

Modified Condition/Decision Coverage Example

For this decision:

\[
X \lor ( Y \land Z )
\]

the following set of test cases delivers 100% MCDC coverage.

<table>
<thead>
<tr>
<th></th>
<th>X</th>
<th>Y</th>
<th>Z</th>
</tr>
</thead>
<tbody>
<tr>
<td>Test case #1</td>
<td>0</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>Test case #2</td>
<td>0</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>Test case #3</td>
<td>0</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>Test case #4</td>
<td>1</td>
<td>0</td>
<td>1</td>
</tr>
</tbody>
</table>
Cyclomatic Complexity for Code Coverage

Cyclomatic complexity is a measure of the structural complexity of code that uses the McCabe complexity measure. To compute the cyclomatic complexity of code, code coverage uses this formula:

\[ c = \sum_{1}^{N} (o_n - 1) \]

\( N \) is the number of decisions in the code. \( o_n \) is the number of outcomes for the \( n^{th} \) decision point. Code coverage adds 1 to the complexity number for each C/C++ function.

Coverage Example

For this code snippet:

```c
void evalNum( int x ){
    if (x > 0)
        printf( "x is positive" );
    else if (x < 0)
        printf( "x is negative" );
    else
        printf( "x is 0" );
}
```

the cyclomatic complexity is 3.

Relational Boundary for Code Coverage

Relational boundary code coverage examines code that has relational operations. Relational boundary code coverage metrics align with those for model coverage, as described in “Relational Boundary Coverage” (Simulink Coverage). Fixed-point values in your model are integers during code coverage.
See Also

Related Examples

If you have Embedded Coder and Simulink Coverage, you can analyze coverage for generated code during a software-in-the-loop (SIL) or processor-in-the-loop (PIL) simulation.

In this section...

- “Enable SIL or PIL Code Coverage for a Model” on page 70-7
- “Simulink Coverage Code Coverage Measurement Workflows” on page 70-8
- “Review the Coverage Results for Models in SIL or PIL Mode” on page 70-9
- “Limitations” on page 70-10

Enable SIL or PIL Code Coverage for a Model

To record SIL or PIL code coverage for a model:

1. In the Configuration Parameters dialog box, on the left pane, click **Code Generation**. From the list, select **Verification**.
2. Under **Code profiling**, clear **Measure function execution times**.
3. Under **Code coverage for SIL or PIL**, for the **Third-party tool** select None (use Simulink Coverage).
Simulink Coverage Code Coverage Measurement Workflows

To measure code coverage, use either of these workflows:

- The top model is in SIL mode or PIL mode. Simulink Coverage measures code coverage for the top model, depending on `RecordCoverage`. Simulink Coverage also measures code coverage for referenced models, depending on `CovModelRefEnable`.
- The top model is in Normal mode and contains at least one reference model in SIL or PIL mode. Simulink Coverage measures code coverage for the referenced model if
CovModelRefEnable is 'on', 'all', or 'filtered' and RecordCoverage is 'off'.

**Review the Coverage Results for Models in SIL or PIL Mode**

In the code coverage report, each hyperlink opens a report with more details on the coverage analysis for the model. The code coverage results in these reports are similar to the coverage results for C/C++ code in S-function blocks, as described in “View Coverage Results for C/C++ Code in S-Function Blocks” (Simulink Coverage). You can navigate from code coverage results to the associated model blocks by using the links within the detailed code coverage reports.

Each detailed code coverage report also contains syntax highlighted code with coverage information.
Limitations

Coverage for models in SIL and PIL mode has these limitations:

• The model must meet the requirements listed in “Enable SIL or PIL Code Coverage for a Model” on page 70-7.

• Code coverage results must not include external C/C++ files in read-only folders.

See Also

Related Examples

• “Software-in-the-Loop Code Coverage” (Simulink Coverage)
Configure Code Coverage with Third-Party Tools

During a top-model or Model block SIL or PIL simulation, you can collect code coverage metrics for generated code using a third-party tool. Embedded Coder supports the following tools:

- LDRA Testbed from LDRA Software Technology. For information about installing and using this tool, go to www.ldra.com.
  
The software supports LDRA Testbed code coverage for SIL and PIL.

- BullseyeCoverage from Bullseye Testing Technology. For information about installing and using this tool, go to www.bullseye.com.
  
The software supports BullseyeCoverage code coverage for SIL and, in certain cases, PIL.

To configure a code coverage tool for a top-model or Model block SIL or PIL simulation:

1. Select Simulation > Model Configuration Parameters > Code Generation > Verification.
2. From the Third-party tool drop-down list, select a tool, for example, BullseyeCoverage or LDRA Testbed.
3. Click Configure to open the Code Coverage Settings dialog box.
4. In the Installation folder field, specify the location where your coverage tool is installed. If you click Browse, the Select Installation Folder dialog box opens, which allows you to navigate to the folder where your coverage tool is installed. The software detects and displays the tool version.

![Code coverage tool dialog box]

By default, the following parameters are enabled:
• **Code coverage for this model** — Generate coverage data for the current (top) model.

• **Code coverage for referenced models** — Generate data for models referenced by the current (top) model.

If your top model has Model blocks, these parameters of the top model override the corresponding parameters of referenced models.

5 Click **OK**. You return to the **Verification** pane.

6 To view cumulative code coverage results within a code generation report, in the **Configuration Parameters > Code Generation > Report** pane, select the following check boxes:

- **Create code generation report**
- **Open report automatically**

7 Click **OK**. You return to the model window.

With LDRA Testbed:

- The evaluation of cumulative code coverage begins from the point when you last added a new file to the existing set of source files. For example, existing code coverage results are deleted when you:
  - Run a simulation with a new model using the existing code generation folder.
  - Run a simulation that results in additional source code files being instrumented.
- If you switch between SIL and PIL simulations of a model, the software generates separate cumulative code coverage results for the SIL and PIL simulations.

For a model in a reference hierarchy, the software does not support simultaneous function execution time measurement and code coverage.

If you configure third-party code coverage for a SIL or PIL simulation, when the simulation is complete, the code generation report opens automatically and you see hyperlinks in the Command Window.

View LDRA Testbed Results

If you specified the LDRA Testbed, you see three links in the Command Window:

```plaintext
### Starting SIL simulation for component: rtwdemo_sil_topmodel
### Stopping SIL simulation for component: rtwdemo_sil_topmodel
### Starting analysis of coverage data
### Use the following links to view code coverage results:
  LDRA Testbed GUI
  LDRA Testbed Code Coverage Overview Report
  HTML code generation report with code coverage annotations
### Completed code coverage analysis
```

To go to the LDRA Testbed GUI, click the LDRA Testbed GUI link.

To open the LDRA Testbed Report with your Web browser, click the LDRA Testbed Code Coverage Overview Report link.
For information about using this report, refer to the LDRA Testbed documentation.

LDRA Testbed analysis results for all code in the current code generation folder belong to a set. In this set, you can find analysis results for models that share the same code generation folder. The LDRA Testbed Code Coverage Overview Report link identifies the location of the LDRA Testbed analysis results, which is determined by:

- The LDRA Testbed configuration.
- The name of the LDRA Testbed set associated with the current code generation folder.

To view summary data and code annotations with coverage information in the code generation report, click the HTML code generation report with code coverage annotations link.
View BullseyeCoverage Results

If you specified the BullseyeCoverage tool, you see two links in the Command Window:

```plaintext
### Starting SIL simulation for component: rtwdemo_sil_topmodel
### Stopping SIL simulation for component: rtwdemo_sil_topmodel
### Processing code coverage data
### Use the following links to view code coverage results:
   BullseyeCoverage browser (coverage for last run)
   HTML code generation report (cumulative coverage)
### Completed code coverage analysis
>>
```

To view the coverage report using the BullseyeCoverage Browser, click the BullseyeCoverage browser (coverage for last run) link.

The BullseyeCoverage Browser shows coverage data for instrumented files associated with your latest top-model simulation. The coverage data shown in the browser is not cumulative and pertains only to the most recent simulation. For information about the BullseyeCoverage Browser, go to www.bullseye.com.

To view summary data and code annotations with coverage information in the code generation report, click the HTML code generation report (cumulative coverage) link.

Configure Code Coverage Programmatically

You can configure code coverage for your model using command-line APIs. A typical workflow with BullseyeCoverage is:

1. Using `get_param`, retrieve the object containing coverage settings for the current model, for example, `gcs`.

   ```
   >> covSettings = get_param(gcs, 'CodeCoverageSettings')
   covSettings =
   CodeCoverageSettings with properties:
   TopModelCoverage: 'on'
   ReferencedModelCoverage: 'off'
   CoverageTool: 'BullseyeCoverage'
   ```

   The property `TopModelCoverage` determines whether the software generates code coverage data for just the top model, while `ReferencedModelCoverage` determines whether the software generates coverage data for models referenced by the top model. If neither property is 'on', then no code coverage data is generated during a SIL simulation.

   If LDRA Testbed is the specified code coverage tool, then the property `CoverageTool` is 'LDRA Testbed'.

   When you save your model, the properties `TopModelCoverage`, `ReferencedModelCoverage`, and `CoverageTool` are also saved.

2. Check the class of `covSettings`.

   ```
   >> class(covSettings)
   ans =
   coder.coverage.CodeCoverageSettings
   ```

3. Turn on coverage for referenced models.

   ```
   >> covSettings.ReferencedModelCoverage='on';
   ```

4. Using `set_param`, apply the new coverage settings to the model.

   ```
   >>set_param(gcs,'CodeCoverageSettings', covSettings);
   ```

5. Assuming you have installed the BullseyeCoverage tool, specify the installation path.

   ```
   >>coder.coverage.BullseyeCoverage.setPath('C:\Program Files\BullseyeCoverage')
   ```
For LDRA Testbed, use `coder.coverage.LDRA.setPath('C:\...').`

6 Check that the path is saved as a preference.

```python
>> coder.coverage.BullseyeCoverage.getPath
```

For LDRA Testbed, use `coder.coverage.LDRA.getPath`.

Code Coverage Summary and Annotations

In this section...

“LDRA Testbed Coverage” on page 70-20
“BullseyeCoverage Information” on page 70-23

If you specify a code coverage tool for a SIL or PIL simulation, the software produces a code generation report that provides summary data and code annotations with coverage information. Each code annotation is associated with a code feature and indicates the nature of the feature coverage during code execution.

The code generation report also allows you to navigate easily between blocks in your model and the corresponding sections in the source code.

LDRA Testbed Coverage

The cumulative coverage data in a code generation report is derived from instrumented files associated with your latest top-model simulation and coverage data collected from simulations with other top models that share referenced models with your current top model.

The software provides LDRA Testbed annotations in the code generation report to help you to review code coverage.
**Note** Do not use the code generation report alone to verify that you have achieved your coverage goals. You must refer to the LDRA Testbed Report.

This example shows three kinds of annotations. On lines 134, 139, 140, and 141, the annotation • indicates that statement coverage for each of these lines of code is not complete.

```c
134 if (setWork.bitsForTID0.Logicaloperator) {
135     ... 
136     // Switch: 'APP/Switch' incorporated;
137     // Constant: 'APP/CT'
138     // Import: 'SET/Reset'
139     //
140     if (SET/reset) {
141
codeWork.PreviousOutput_STATE = 0;
142       }
```

Placing the cursor over the annotation =>b produces a tooltip.

This tooltip indicates that only one branch destination is covered. The code within the curly brackets, which starts at column 45 of line 134, is not executed. As the if statement on line 139 lies within this code, the corresponding annotation => states that the branch is not covered.

This table describes the LDRA Testbed code annotations that you might see in a code generation report produced by a SIL and PIL simulations.

<table>

</table>
BullseyeCoverage Information

The cumulative coverage data in a code generation report is derived from instrumented files associated with your latest top-model simulation and coverage data collected from simulations with other top models that share referenced models with your current top model.

The software provides BullseyeCoverage annotations in the code generation report to help you to review code coverage.

This example shows two kinds of annotations. At line 41, TF indicates that the if decision had both true and false outcomes during the simulation. At line 52, =>F indicates that the if decision was false only during the simulation.

This table describes the BullseyeCoverage code annotations that you might see in a code generation report produced by a SIL simulation.
<table>

Tips and Limitations

**Model Build and SIL/PIL Blocks Not Supported**

Code coverage does not support:

- The model build process, for example, the Ctrl+B command.
- SIL or PIL blocks.

Code coverage settings are ignored by the Ctrl+B command and SIL or PIL blocks.

**BullseyeCoverage License Wait**

When you build your model, you might have to wait for a BullseyeCoverage license. If you want to see information about the wait, before you build your model, select `Configuration Parameters > Verbose build`.

**Current Working Folder Cannot be UNC Path**

If your MATLAB current working folder is a Universal Naming Convention (UNC) path, code coverage fails.

**Characters in matlabroot and File Path**

If `matlabroot` or the path to your generated files contains a space or the . (period) character, code coverage might fail.

**Header Files with Identical Names**

Consider a model that is configured for LDRA Testbed code coverage. During the build process, if the software detects two header files with the same name in the folder for generated code, the software generates an error.

**Code Coverage for Source Files in Shared Utility Folders**

The software supports code coverage for source files generated in shared utility folders. If you configure code coverage for a model that uses shared utility code generation, when
you build the model, you also build all source files in the shared utilities folder with code coverage enabled.

Whenever you build a model, the code coverage settings of the model must be consistent with source files that you previously built in the shared utilities folder. Otherwise, the software reports that code in the shared utilities folder is inconsistent with the current model configuration and must be rebuilt. For example, if you run a SIL simulation for a model with code coverage enabled and then run a SIL simulation for another model with code coverage disabled, the software must rebuild all source files in the shared utilities folder.

**BullseyeCoverage Behavior with Inline Macros**

The BullseyeCoverage tool, by default, does not provide code coverage data for inline macros.

For example, if a model generates a file `slprj/ert/_sharedutils/rt_SATURATE.h` that contains the macro

```c
#define rt_SATURATE(sig,ll,ul) (((sig) >= (ul)) ? (ul) : (((sig) <= (ll)) ? (ll) : (sig)) )
```

and the macro is in `sat_ert_rtw/sat.c`, then the coverage report provides a measurement for `sat.c`, but no coverage data for the conditions within the macro `rt_SATURATE`.

To configure the BullseyeCoverage tool to provide code coverage data for inline macros:

1. Open the BullseyeCoverage Browser.
2. Select **Tools > Options** to open the Options dialog box.
3. On the **Build** tab, select the **Instrument macro expansions** check box.
4. Click **OK**.
5. Rerun your simulation.

Alternatively, you can add the text `-macro` to the BullseyeCoverage configuration file. For more information, go to [www.bullseye.com/help](http://www.bullseye.com/help).

**SIL and PIL Simulations with Open LDRA Testbed**

If you enable code coverage with the LDRA Testbed tool, you must verify that the LDRA Testbed GUI is not open when you run your SIL or PIL simulation. If the set name in the
LDRA Testbed GUI differs from the set name used by the SIL or PIL simulation, the SIL or PIL simulation fails.

**Minor SIL and PIL Differences for LDRA Testbed**

The target connectivity API supports code coverage with LDRA Testbed for top-model and Model block PIL.

There are minor differences in the code coverage information collected during SIL and PIL simulations. In particular, with PIL, the software does not explicitly show function exit point coverage. However, you can infer the coverage of function exit points by examining statement coverage.

**PIL Zero Coverage LDRA Testbed Annotations**

For a PIL simulation with LDRA Testbed code coverage specified, there might be some source files where the recorded coverage is zero. In this case, the software provides summary information indicating that:

- There is coverage to measure.
- The coverage is zero.
You do not see information for individual probes on each line. The displayed summary information has an associated annotation tooltip:

0 out of $N$ coverage probes were exercised (detailed breakdown unavailable)

**PIL Support for BullseyeCoverage**

Code coverage with BullseyeCoverage is available for top-model and Model block PIL provided your PIL application can write directly to the host file system. Your target for the PIL application must provide `fopen` and `fread` access to the host file system.

If code coverage is not available when you run the PIL application on your target hardware, you might be able to collect code coverage measurements by running the PIL application on an instruction set simulator that supports direct file I/O with the host file system.

**Modify Legacy Code**

If you modify legacy code and rerun a SIL or PIL simulation, the legacy code is recompiled. However, the code from the model may be up-to-date. In this case, the code generation report is not updated and does not show the modified legacy code. Instead, the code coverage information for the modified legacy code is displayed with reference to the original legacy code. You must regenerate the report. For more information, see “Limitation” (Simulink Coder).

**IDE Link Does Not Support LDRA Testbed**

When you generate code for IDE Link, you cannot use LDRA Testbed for SIL or PIL code coverage. Specifically, this limitation applies when you use the following settings together:

- **Configuration Parameters > Code Generation > System target file:** idelink_ert.tlc
- **Configuration Parameters > Code Generation > Verification > Third-party tool:** LDRA Testbed.

**About ASAP2 File Customization**

The Embedded Coder product provides a number of Target Language Compiler (TLC) files to enable you to customize the ASAP2 file generated from a Simulink model.

**ASAP2 File Structure on the MATLAB Path**

The ASAP2 related files are organized within the folders identified below:

- **TLC files for generating ASAP2 file**
  
The `matlabroot/rtw/c/tlc/mw` (open) folder contains TLC files that generate ASAP2 files, `asamlib.tlc`, `asap2lib.tlc`, `asap2main.tlc`, and `asap2grouplib.tlc`. These files are included by the selected System target file. (See “Targets Supporting ASAP2” on page 47-3.)

- **ASAP2 target files**
  
The `matlabroot/toolbox/rtw/targets/asap2/asap2` (open) folder contains the ASAP2 system target file and other control files.

- **Customizable TLC files**
  
The `matlabroot/toolbox/rtw/targets/asap2/asap2/user` (open) folder contains files that you can modify to customize the content of your ASAP2 files.

- **ASAP2 templates**
  
The `matlabroot/toolbox/rtw/targets/asap2/asap2/user/templates` (open) folder contains templates that define each type of CHARACTERISTIC in the ASAP2 file.
Customize the Contents of the ASAP2 File

The ASAP2 related TLC files enable you to customize the appearance of the ASAP2 file generated from a Simulink model. Most customization is done by modifying or adding to the files contained in the `matlabroot/toolbox/rtw/targets/asap2/asap2/user` (open) folder. This section refers to this folder as the `asap2/user` folder.

The user-customizable files provided are divided into two groups:

- The *static* files define the parts of the ASAP2 file that are related to the environment in which the generated code is used. They describe information specific to the user or project. The static files are not model dependent.
- The *dynamic* files define the parts of the ASAP2 file that are generated based on the structure of the source model.

The procedure for customizing the ASAP2 file is as follows:

1. Make a copy of the `asap2/user` folder before making modifications.
2. Remove the old `asap2/user` folder from the MATLAB path, or add the new `asap2/user` folder to the MATLAB path above the old folder. The MATLAB session uses the ASAP2 setup file, `asap2setup.tlc`, in the new folder.

   `asap2setup.tlc` specifies the folders and files to include in the TLC path during the ASAP2 file generation process. Modify `asap2setup.tlc` to control the folders and folders included in the TLC path.

3. Modify the static parts of the ASAP2 file. These include
   - Project and header symbols, which are specified in `asap2setup.tlc`
   - Static sections of the file, such as file header and tail, `A2ML`, `MOD_COMMON`, and so on. These are specified in `asap2userlib.tlc`.
   - Specify the appearance of the dynamic contents of the ASAP2 file by modifying the existing ASAP2 templates or by defining new ASAP2 templates. Sections of the ASAP2 file affected include
     - `RECORD_LAYOUT`: modify parts of the ASAP2 template files.
     - `CHARACTERISTIC`: modify parts of the ASAP2 template files. For more information on modifying the appearance of `CHARACTERISTIC` records, see “ASAP2 Templates” on page 72-4.
• MEASUREMENT: These are specified in `asap2userlib.tlc`.
• COMPU_METHOD: These are specified in `asap2userlib.tlc`.

**ASAP2 Templates**

The appearance of CHARACTERISTIC records in the ASAP2 file is controlled using a different template for each type of CHARACTERISTIC. The `asap2/user` folder contains template definition files for scalars, 1-D Lookup Table blocks and 2-D Lookup Table blocks. You can modify these template definition files, or you can create additional templates as required.

The procedure for creating a new ASAP2 template is as follows:

1. Create a template definition file. See “Create Template Definition Files” on page 72-4.
2. Include the template definition file in the TLC path. The path is specified in the ASAP2 setup file, `asap2setup.tlc`.

**Create Template Definition Files**

This section describes the components that make up an ASAP2 template definition file. This description is in the form of code examples from `asap2lookup1d.tlc`, the template definition file for the `Lookup1D` template. This template corresponds to the `Lookup1D` parameter group.

**Note** When creating a new template, use the corresponding parameter group name in place of `Lookup1D` in the code shown.

**Template Registration Function**

The input argument is the name of the parameter group associated with this template:

```%<LibASAP2RegisterTemplate("Lookup1D")>```

**RECORD_LAYOUT Name Definition Function**

Record layout names (aliases) can be arbitrarily specified for each data type. This function is used by the other components of this file.

```%function ASAP2UserFcnRecordLayoutAlias_Lookup1D(dtId) void
  %switch dtId```
%case tSS_UINT8
  %return "Lookup1D_UBYTE"
...
%endswitch
%endfunction

**Function to Write RECORD_LAYOUT Definitions**

This function writes RECORD_LAYOUT definitions associated with this template. The function is called by the built-in functions involved in the ASAP2 file generation process. The function name must be defined as shown, with the template name after the underscore:

```%function ASAP2UserFcnWriteRecordLayout_Lookup1D() Output
   /begin RECORD_LAYOUT
   %<ASAP2UserFcnRecordLayoutAlias_Lookup1D(tSS_UINT8)>
   ...
   /end   RECORD_LAYOUT
%endfunction```

**Function to Write the CHARACTERISTIC**

This function writes the CHARACTERISTIC associated with this template. The function is called by the built-in functions involved in the ASAP2 file generation process. The function name must be defined as shown, with the template name after the underscore.

The input argument to this function is a pointer to a parameter group record. The example shown is for a Lookup1D parameter group that has two members. The references to the associated x and y data records are obtained from the parameter group record as shown.

This function calls a number of built-in functions to obtain the required information. For example, `LibASAP2GetSymbol` returns the symbol (name) for the specified data record:

```%function ASAP2UserFcnWriteCharacteristic_Lookup1D(paramGroup) Output
   %assign xParam = paramGroup.Member[0].Reference
   %assign yParam = paramGroup.Member[1].Reference
   %assign dtId = LibASAP2GetDataTypeId(xParam)
   /begin CHARACTERISTIC
   /* Name */              %<LibASAP2GetSymbol(xParam)>
   /* Long identifier */   "%<LibASAP2GetLongID(xParam)>"
   ...
```
Customize Computation Method Names

In generated ASAP2 files, computation methods translate the electronic control unit (ECU) internal representation of measurement and calibration quantities into a physical model oriented representation. Simulink Coder software provides the ability to customize the names of computation methods. You can provide names that are more intuitive, enhancing ASAP2 file readability, or names that meet organizational requirements.

To customize computation method names, use the MATLAB function getCompuMethodName, which is defined in matlabroot/toolbox/rtw/targets/asap2/asap2/user/getCompuMethodName.m.

The getCompuMethodName function constructs a computation method name. The function prototype is

\[
\text{cmName} = \text{getCompuMethodName}(\text{dataTypeName}, \text{cmUnits})
\]

where \textit{dataTypeName} is the name of the data type associated with the computation method, \textit{cmUnits} is the units as specified in the Unit property of a Simulink.Parameter or Simulink.Signal object (for example, rpm or m/s), and \textit{cmName} returns the constructed computation method name.

The default constructed name returned by the function has the format

\[
<\text{localPrefix}><\text{datatype}>_<\text{cmUnits}>
\]

where

- \textit{<local\_Prefix>} is a local prefix, CM_, defined in matlabroot/toolbox/rtw/targets/asap2/asap2/user/getCompuMethodName.m.
- \textit{<datatype>} and \textit{<cmUnits>} are the arguments you specified to the getCompuMethodName function.

Additionally, in the generated ASAP2 file, the constructed name is prefixed with \textit{<ASAP2CompuMethodName\_Prefix>}, a model prefix defined in matlabroot/toolbox/rtw/targets/asap2/asap2/user/asap2setup.tlc.

For example, if you call the getCompuMethodName function with the \textit{dataTypeName} argument 'int16' and the \textit{cmUnits} argument 'm/s', and generate an ASAP2 file for a
model named `myModel`, the computation method name would appear in the generated file as follows:

```plaintext
/begin COMPU_METHOD
  /* Name of CompuMethod */ myModel_CM_int16_m_s
  /* Units */ "m/s"
  ...
/end COMPU_METHOD
```

**Suppress Computation Methods for FIX_AXIS**

Versions 1.51 and later of the ASAP2 specification state that for certain cases of lookup table axis descriptions (integer data type and no doc units), a computation method is not required and the Conversion Method parameter must be set to the value `NO_COMPU_METHOD`. You can control whether or not computation methods are suppressed when not required using the Target Language Compiler (TLC) option `ASAP2GenNoCompuMethod`. This TLC option is disabled by default. If you enable the option, ASAP2 file generation does not generate computation methods for lookup table axis descriptions when not required, and instead generates the value `NO_COMPU_METHOD`. For example:

```plaintext
/begin CHARACTERISTIC
  /* Name            */
  luld_fix_axisTable_data
  ...
/begin AXIS_DESCR
  ...
    /* Conversion Method */
    NO_COMPU_METHOD
  ...
/end CHARACTERISTIC
```

The `ASAP2GenNoCompuMethod` option is defined in `matlabroot/toolbox/rtw/targets/asap2/asap2/user/asap2setup.tlc`.

Control Build Process Compiling and Linking

After generating code for a model, the build process determines whether to compile and link an executable program. Various factors guide this determination:

- **Generate code only** option
  
  When you select this option, the code generator produces code for the model, including a makefile.

- **Generate makefile** option
  
  When you clear this option, the code generator does not produce a makefile for the model. You must specify post code generation processing, including compilation and linking, as a user-defined command, as explained in “Customize Post-Code-Generation Build Processing” on page 73-14.

- **Makefile-only target**
  
  The Microsoft Visual C++ Project Makefile versions of the grt and Embedded Coder target configurations generate a Visual C++ project makefile (model.mak). To build an executable, you must open model.mak in the Visual C++ IDE and compile and link the model code.

- **HOST template makefile variable**
  
  The template makefile variable HOST identifies the type of system upon which your executable is intended to run. The variable can be set to one of three possible values: PC, UNIX, or ANY.

  By default, HOST is set to UNIX in template makefiles designed for use with The Open Group UNIX platforms (such as grt_unix.tmf), and to PC in the template makefiles designed for use with development systems for the PC (such as grt_vc.tmf).

  If the Simulink software is running on the same type of system as the system specified by the HOST variable, then the executable is built. Otherwise,

  - If HOST = ANY, an executable is still built. This option is useful when you want to cross-compile a program for a system other than the one that the Simulink software is running on.
  
  - Otherwise, processing stops after generating the model code and the makefile; the following message is displayed on the MATLAB command line.

    ```
    ### Make will not be invoked - template makefile is for a different host
    ```
• TGT_FCN_LIB template makefile variable

The template makefile variable TGT_FCN_LIB specifies compiler command-line options. The line in the makefile is TGT_FCN_LIB = |TGT_FCN_LIB|. Use this token in a makefile conditional statement to specify a standard math library as a compiler option. Possible |TGT_FCN_LIB| token values are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Generates Calls To</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name of custom CRL</td>
<td>ISO®/IEC 9899:1990 C (ANSI_C) standard math library</td>
</tr>
<tr>
<td>GNU</td>
<td>GNU extensions to the ISO/IEC 9899:1999 C standard math library</td>
</tr>
</tbody>
</table>
Cross-Compile Code Generated on Microsoft Windows

To generate code with the code generator on a Microsoft Windows system but compile the generated code on a different supported platform, you can do so by modifying your TMF and model configuration parameters. For example, you would need to follow this process if you develop applications with the MATLAB and Simulink products on a Windows system, but you run your generated code on a Linux system.

To set up a cross-compilation development environment, do the following (here a Linux system is the destination platform):

1. On your Windows system, copy the UNIX TMF for your target to a local folder. This folder is your working folder for initiating code generation. For example, you could copy the file `matlabroot/rtw/c/grt/grt_unix.tmf` to `D:/work/my_grt_unix.tmf`.

2. Make the following changes to your copy of the TMF:
   - Add the following line near the `SYS_TARGET_FILE =` line:
     ```
     MAKEFILE_FILESEP = /
     ```
   - Search for the line `ifeq ($(OPT_OPTS),$(DEFAULT_OPT_OPTS))` and, for each occurrence, remove the conditional logic and retain only the `else` code. That is, remove everything from the `if` to the `else`, inclusive, and the closing `endif`. Only the lines from the `else` portion remain. This logic forces the run-time libraries to build for a Linux system.

3. Open your model and make the following changes in the Code Generation pane of the Configuration Parameters dialog box:
   - Specify the name of your new TMF in the “Template makefile” (Simulink Coder) text box (for example, `my_grt_unix.tmf`).
   - Select Generate code only and click Apply.

4. Generate the code.

5. If the build folder (folder from which the model was built) is not already Linux accessible, copy it to a Linux accessible path. For example, if your build folder for the generated code was `D:\work\mymodel_grt_rtw`, copy that entire folder tree to a path such as `/home/user/mymodel_grt_rtw`.

6. If the MATLAB folder tree on the Windows system is Linux accessible, skip this step. Otherwise, copy the include and source folders to a Linux accessible drive partition, for example, `/home/user/myinstall`. These folders appear in the makefile after
MATLAB_INCLUDES = and ADD_INCLUDES = and can be found by searching for $(MATLAB_ROOT). Paths that contain $(MATLAB_ROOT) must be copied. Here is an example list (your list varies depending on your model):

- $(MATLAB_ROOT)/rtw/c/grt
- $(MATLAB_ROOT)/extern/include
- $(MATLAB_ROOT)/simulink/include
- $(MATLAB_ROOT)/rtw/c/src
- $(MATLAB_ROOT)/rtw/c/tools

Also, paths containing $(MATLAB_ROOT) in the build rules (lines with %.o :) must be copied. For example, based on the build rule

%.o : $(MATLAB_ROOT)/rtw/c/src/ext_mode/tcpip/%.c

copy the following folder:

- $(MATLAB_ROOT)/rtw/c/src/ext_mode/tcpip

**Note** The path hierarchy relative to the MATLAB root must be maintained. For example, c:\MATLAB\rtw\c\tools\* would be copied to /home/user/mlroot/rtw/c/tools/*.

For some blocksets, it is easiest to copy a higher-level folder that includes the subfolders listed in the makefile. For example, the DSP System Toolbox product requires the following folders to be copied:

- $(MATLAB_ROOT)/toolbox/dspblks
- $(MATLAB_ROOT)/toolbox/rtw/dspblks

7 Make the following changes to the generated makefile:

- Set both MATLAB_ROOT and ALT_MATLAB_ROOT equal to the Linux accessible path to matlabroot (for example, home/user/myinstall).
- Set COMPUTER to the computer value for your platform, such as GLNX86. Enter help computer in the MATLAB Command Window for a list of computer values.
- In the ADD_INCLUDES list, change the build folder (designating the location of the generated code on the Windows system) and parent folders to Linux accessible include folders. For example, change D:\work\mymodel_grt_rtw\ to /home/user/mymodel_grt_rtw.

Also, if matlabroot is a UNC path, such as \my-server\myapps\matlab, replace the hard-coded MATLAB root with $(MATLAB_ROOT).
8 From a Linux shell, compile the code you generated on the Windows system. You can compile by running the generated `model.bat` file or by typing the make command line as it appears in the `.bat` file.

**Note** If errors occur during makefile execution, you can run the `dos2unix` utility on the makefile (for example, `dos2unix mymodel.mk`).

**Related Examples**
- Use packNGo to Relocate Code to Another Development Environment (Simulink Coder)
Control Library Location and Naming During Build

When you generate precompiled, non-precompiled, and model reference libraries, you can control the library location and library name by using configuration parameters. These parameters control values in generated makefiles during model builds:

- For build processes that use the toolchain approach, control the generated library location by using the `TargetPreCompLibLocation` configuration parameter.
- For build processes that use the template makefile approach, control the generated library location by using the `TargetPreCompLibLocation` configuration parameter and control the generated library name by using the `TargetLibSuffix` configuration parameter.

Library Control Parameters

Use the library control parameters to:

- Specify the location of precompiled libraries, such as blockset libraries or the Simulink Coder block library. Typically, a target has cross-compiled versions of these libraries and places them in a target-specific folder.
- Control the suffix applied to library file names (for example, `_target.a` or `_target.lib`).

Targets can set the parameters inside the system target file (STF) select callback. For example:

```matlab
function mytarget_select_callback_handler(varargin)
    hDig=varargin{1};
    hSrc=varargin{2};
    slConfigUISetVal(hDig, hSrc, 'TargetPreCompLibLocation', ...
        'c:\mytarget\precomplibs');
    slConfigUISetVal(hDig, hSrc, 'TargetLibSuffix', ...
        '_target.library');
```

The TMF has corresponding expansion tokens:

```matlab
|>EXPAND_LIBRARY_LOCATION<|
|>EXPAND_LIBRARY_SUFFIX<|
```

Alternatively, you can use a call to the `set_param` function. For example:

```matlab
set_param(model,'TargetPreCompLibLocation',...
    'c:\mytarget\precomplibs');
```
Note If your model contains referenced models, you can use the make option
USE_MDLREF_LIBPATHS to control whether libraries used by the referenced models are
copied to the build folder of the parent model. For more information, see “Control the
Location of Model Reference Libraries” on page 73-10.

Identify Library File Type for Toolchain Approach

The toolchain approach for model builds does not use the value of the TargetLibSuffix
configuration parameter to select the library file name suffix and extension.

With the toolchain approach, the final binary name is composed of the modelname, the
compilername, and the extension provided by the build tool description in the
toolchain definition:

model_compilername.extension

You can identify the static library file name extension from the build tool description in
the toolchain definition. To get this information for the default toolchain, use this
procedure:

1 Get the default toolchain name. For example, enter:

   tc_name = coder.make.getDefaultToolchain()

2 Get the default toolchain handle. For example, enter:

   tc = coder.make.getToolchainInfoFromRegistry(tc_name)

3 Get the handle to the toolchain object. For example, enter:

   tool_archiver = tc.getBuildTool('Archiver');

4 Get the extension. For example, enter:

   ext_archiver = tool_archiver.getFileExtension('Static Library');

Note If you do not set the TargetLibSuffix parameter, template makefile and
toolchain approaches produce the same static library file name extension. See
“Customize Library File Suffix and File Type” (Simulink Coder).

Specify the Location of Precompiled Libraries

Use the TargetPreCompLibLocation configuration parameter to:
- Override the precompiled library location specified in the `rtwmakecfg.m` file (see “Use `rtwmakecfg.m` API to Customize Generated Makefiles” on page 73-26 for details)
- Precompile and distribute target-specific versions of product libraries (for example, the DSP System Toolbox product)

For a precompiled library, such as a blockset library or the Simulink Coder block library, the location specified in `rtwmakecfg.m` is typically a location specific to the blockset or the Simulink Coder product. The code generator expects that the library exists in this location and links against the library during builds.

For some applications, such as custom targets, it is preferable to locate the precompiled libraries in a target-specific or other alternate location rather than in the location specified in `rtwmakecfg.m`. For a custom target, the code generator expects that the target-specific cross-compiler creates the library, and you place the library in the target-specific location. Compile and place libraries supported by the target in the target-specific location, so they can be used during the build process.

You can set up the `TargetPreCompLibLocation` parameter in its select callback. The path that you specify for the parameter must be a fully qualified, absolute path to the library location. Relative paths are not supported. For example:

```plaintext
slConfigUISetVal(hDlg, hSrc, 'TargetPreCompLibLocation',...
    'c:\mytarget\precomplibs');
```

Alternatively, you set the parameter with a call to the `set_param` function. For example:

```plaintext
set_param(model,'TargetPreCompLibLocation',...
    'c:\mytarget\precomplibs');
```

During makefile generation, the build process replaces the tokens with the location from the `rtwmakecfg.m` file. For example, if the library name in the `rtwmakecfg.m` file is `'rtwlib'`, the template makefile build approach expands the token from:

```plaintext
LIBS += |>EXPAND_LIBRARY_LOCATION<|\|>EXPAND_LIBRARY_NAME<|\_target.library
```

to:

```plaintext
LIBS += c:\mytarget\precomplibs\rtwlib_target.library
```

By default, `TargetPreCompLibLocation` is an empty character vector. The build process uses the location in `rtwmakecfg.m` for the token replacement.
Control the Location of Model Reference Libraries

On platforms other than the Apple Macintosh platform, when building a model that uses referenced models, the default build process includes:

- Copy libraries that the referenced models use to the build folder of the parent model.
- Assign the file names of the libraries to `MODELREF_LINK_LIBS` in the generated makefile.

For example, if a model includes a referenced model `sub`, the build process assigns the library name `sub_rtwlib.lib` to `MODELREF_LINK_LIBS`. The build process copies the library file to the build folder of the parent model. This definition is then used in the final link line, which links the library into the final product (usually an executable). This technique minimizes the length of the link line.

On the Macintosh platform, and optionally on other platforms, the build process includes:

- No copying of libraries that the referenced models use to the build folder of the parent model.
- Assign the relative paths and file names of the libraries to `MODELREF_LINK_LIBS` in the generated makefile.

When using this technique, the build process assigns a relative path such as `../slprj/grt/sub/sub_rtwlib.lib` to `MODELREF_LINK_LIBS`. The build process uses the path to gain access to the library file at link time.

To change to the nondefault behavior on platforms other than the Macintosh platform, select the `Configuration Parameters > Code Generation > Make command` field. Enter:

```
make_rtw USE_MDLREF_LIBPATHS=1
```

If you specify other Make command arguments, such as `OPTS="-g"`, the order in which you specify the multiple arguments does not matter.

To return to the default behavior, set `USE_MDLREF_LIBPATHS` to 0, or remove it.

Control the Suffix Applied to Library File Names

With the template makefile approach for model builds, use the `TargetLibSuffix` configuration parameter to control the suffix applied to library names (for example,
_target.lib or _target.a). The specified suffix scheme must include a period (.). You can apply TargetLibSuffix to the following libraries:

- Libraries on which a target depends, as specified in the rtwmakecfg.m API. You can use TargetLibSuffix to change the suffix of both precompiled and non-precompiled libraries configured from the rtwmakecfg API. For details, see “Use rtwmakecfg.m API to Customize Generated Makefiles” on page 73-26.

In this case, a target can set the parameter in its select callback. For example:

    slConfigUISetVal(hDlg, hSrc, 'TargetLibSuffix', ...'_target.library');

Alternatively, you can use a call to the set_param function. For example:

    set_param(model,'TargetLibSuffix','_target.library');

During the TMF-to-makefile conversion, the build process replaces the token | >EXPAND_LIBRARY_SUFFIX< | with the specified suffix. For example, if the library name specified in the rtwmakecfg.m file is 'rtwlib', the TMF expands from:

    LIBS += | >EXPAND_LIBRARY_LOCATION< | | >EXPAND_LIBRARY_NAME< | | >EXPAND_LIBRARY_SUFFIX< |

    to:

    LIBS += c:\mytarget\precomplibs\rtwlib_target.library

By default, TargetLibSuffix is set to an empty character vector. In this case, the build process replaces the token | >EXPAND_LIBRARY_SUFFIX< | with an empty character vector.

- Shared utility library and the model libraries created with model reference. For these cases, associated makefile variables do not require the | >EXPAND_LIBRARY_SUFFIX< | token. Instead, the build process includes TargetLibSuffix implicitly. For example, for a top model named topmodel with referenced models named refmodel1 and refmodel2, the TMF of the top model is expanded from:

    SHARED_LIB = | >SHARED_LIB< |

    MODELLIB = | >MODELLIB< |

    MODELREF_LINK_LIBS = | >MODELREF_LINK_LIBS< |

    to:

    SHARED_LIB = \ ..\slprj\rt\_sharedutils\rtshared_target.library

    MODELLIB = topmodellib_target.library
MODELREF_LINK_LIBS = \n  refmodel1_rtwlib_target.library refmodel2_rtwlib_target.library

By default, the TargetLibSuffix parameter is an empty character vector. In this
case, the build process chooses a default suffix for these three tokens using a file
extension of .lib on Windows hosts and .a on UNIX hosts. (For model reference
libraries, the default suffix also includes _rtwlib.) For example, on a Windows host,
the expanded makefile values are:

    SHARED_LIB = ..\slprj\ert\sharedutils\rtwshared.lib
    MODELLIB = topmodellib.lib
    MODELREF_LINK_LIBS = refmodel1_rtwlib.lib refmodel2_rtwlib.lib
Recompile Precompiled Libraries

You can recompile precompiled libraries included as part of the code generator, such as rtwlib or dsplib, by using a supplied MATLAB function, rtw_precompile_libs. You can consider recompiling precompiled libraries to customize compiler settings for various platforms or environments. For details on using rtw_precompile_libs, see “Precompile S-Function Libraries” on page 42-48.
Customize Post-Code-Generation Build Processing

The code generator provides a set of tools, including a build information object, you can use to customize build processing that occurs after code generation. You can use such customizations for target development or the integration of third-party tools into your application development environment.

Workflow for Setting Up Customizations

The following figure and the steps that follow show the general workflow for setting up post-code-generation customizations.

1. Program the post code generation command on page 73-15.
2. Define the post code generation command on page 73-16.
3  Suppress makefile generation on page 73-20, if applicable.
4  Build the model.
5  Modify the command and rebuild the model until the build results are acceptable.

**Build Information Object**

At the start of a model build, the build process logs the following build option and dependency information to a temporary build information object:

- Compiler options
- Preprocessor identifier definitions
- Linker options
- Source files and paths
- Include files and paths
- Precompiled external libraries

You can retrieve information from and add information to this object by using an extensive set of functions. For a list of available functions and detailed function descriptions, see “Build Process Customization” (Simulink Coder). “Program a Post Code Generation Command” on page 73-15 explains how to use the functions to control post code generation build processing.

**Program a Post Code Generation Command**

For certain applications, you could want to control aspects of the build process after the code generation. For example, you can use this approach if you develop your own target, or you want to apply an analysis tool to the generated code before continuing with the build process. You can apply this level of control to the build process by programming and then defining a post code generation command.

A post code generation command is a MATLAB language file that typically calls functions that get data from or add data to the build information object of the model. You can program the command as a script or function.
If you program the command as a:

<table>
<thead>
<tr>
<th></th>
<th>Then the:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Script</td>
<td>Script can gain access to the model name and the build information directly</td>
</tr>
<tr>
<td>Function</td>
<td>Function can pass the model name and the build information as arguments</td>
</tr>
</tbody>
</table>

If your post code generation command calls user-defined functions, make sure that the functions are on the MATLAB path. If the build process cannot find a function you use in your command, the build process errors out.

You can then call a combination of build information functions, as listed in “Build Process Customization” (Simulink Coder), to customize the post code generation build processing of the model.

The following example shows a fragment of a post code generation command that gets the file names and paths of the source and include files generated for a model for analysis.

```matlab
function analyzegencode(buildInfo)
    % Get the names and paths of source and include files
    % generated for the model and then analyze them.
    % buildInfo - build information for my model.
    % Define cell array to hold data.
    MyBuildInfo={};
    % Get source file information.
    MyBuildInfo.srcfiles=getSourceFiles(buildInfo, true, true);
    MyBuildInfo.srcpaths=getSourcePaths(buildInfo, true);
    % Get include (header) file information.
    MyBuildInfo.incfiles=getAttributeFiles(buildInfo, true, true);
    MyBuildInfo.incpaths=getIncludePaths(buildInfo, true);
    % Analyze generated code.
    .
    .
    .
```

Define a Post Code Generation Command

After you program a post code generation command, inform the build process that the command exists and to add it to the build processing of the model. Define the command with the PostCodeGenCommand model configuration parameter. When you define a post
code generation command, the build process evaluates the command after generating and writing the generated code to disk and before generating a makefile.

As the following syntax lines show, the arguments that you specify when setting the configuration parameter varies depending on whether you program the command as a script, function, or set of functions.

**Note** When defining the command as a function, you can specify an arbitrary number of input arguments. To pass the name and build information of the model to the function, specify identifiers `modelName` and `buildInfo` as arguments.

### Script

```matlab
set_param(model, 'PostCodeGenCommand',...
'pcgScriptName');
```

### Function

```matlab
set_param(model, 'PostCodeGenCommand',...
'pcgFunctionName(modelName)');
```

### Multiple Functions

```matlab
pcgFunctions=...
'pcgFunction1Name(modelName)';...
pcgFunction2Name(buildInfo);...
set_param(model, 'PostCodeGenCommand',...
'pcgFunctions');
```

The following call to `set_param` defines `PostCodeGenCommand` to evaluate the function `analyzegenencode`.

```matlab
set_param(model, 'PostCodeGenCommand',...
'analyzegenencode(buildInfo)');
```

**Customize Build Process with PostCodeGenCommand and Relocate Generated Code to an External Environment**

This example shows how to use the Build Information API and the **Post Code Generation Command** parameter, `PostCodeGenCommand`.

The `PostCodeGenCommand` parameter value is `rtwdemo_buildinfo_data`. This value directs the build process to invoke the function after code generation.
The example also demonstrates how to use the `rtwmakecfg.m` API. For more information, click on the documentation links in the model.

**Open Example Model**

Open the example model `rtwdemo_buildinfo`.

```matlab
open_system('rtwdemo_buildinfo');
```

**Build Process Integration in Simulink Coder**

**Generate Code from Model**

Double-click on the **Generate Code Using Simulink Coder** button to generate code for the GRT target.

Or, if Embedded Coder is installed, double-click on the **Generate Code Using Embedded Coder** button to generate code for the ERT target.
The build process generates a BuildInfo.html file to document the build information object.

**Examine the Build Process Customizations and Output**

Use the links in the model to examine the build process customizations and the post code generation query of the build information object.

To view the BuildInfo.html file in a Web browser, click on **Open BuildInfo.html**.

The example uses the PostCodeGenCommand parameter of the model to generate the html file from the build information object. The file provides hyperlinks to open the source files (generated code) from the model. To view the PostCodeGenCommand parameter value, type:

```
get_param('rtwdemo_buildinfo','PostCodeGenCommand');
```

This value indicates a function to execute in the **Post Code Gen Command** stage.

```
rtwdemo_buildinfo_data(buildInfo);
```

To study how the example uses the rtwmakecfg API, click on **Open rtwmakecfg.m** or type:

```
edit rtwmakecfg.m;
```

To study the API for the buildInfo.mat object, click on **Open rtwdemo_buildinfo_data.m** or type:

```
edit rtwdemo_buildinfo_data.m;
```

The buildInfo.mat object is available at:

```
rtwdemo_<target>_rtw\buildInfo.mat
```

At the end of the rtwdemo_buildinfo_data.m post code generation function, the function invokes packNGo to package the source and objects identified in the buildInfo object for relocation.

**Further Study Topics**

- “Build Process Customization” (Simulink Coder)
- “Customize Post-Code-Generation Build Processing” (Simulink Coder)
• “Use rtwmakecfg.m API to Customize Generated Makefiles” (Simulink Coder)
• “Relocate Code to Another Development Environment” (Simulink Coder)

**Suppress Makefile Generation**

The code generator lets you suppress makefile generation during the build process. For example, you can use this support when you integrate tools into the build process that do not use makefiles.

To instruct the code generator not to produce a makefile, do one of the following:

- Clear the **Generate makefile** option on the **Code Generation** pane of the Configuration Parameters dialog box.
- Set the value of the configuration parameter **GenerateMakefile** to **off**.

When you suppress makefile generation,

- You cannot explicitly specify a make command or template makefile.
- Specify your own instructions for a post code generation processing, including compilation and linking, in a post code generation command as explained in “Program a Post Code Generation Command” on page 73-15 and “Define a Post Code Generation Command” on page 73-16.
Configure Generated Code with TLC

In this section...

| “About Configuring Generated Code with TLC” on page 73-21 |
| “Assigning Target Language Compiler Variables” on page 73-21 |
| “Set Target Language Compiler Options” on page 73-23 |

About Configuring Generated Code with TLC

You can use the Target Language Compiler (TLC) to fine-tune your generated code. TLC supports extended code generation variables and options in addition to parameters available on the Code Generation pane on the Configuration Parameters dialog box. There are two ways to set TLC variables and options, as described in this section.

Note  Do not customize TLC files in the folder {matlabroot}/rtw/c/tlc even though the capability exists to do so. It is possible that such TLC customizations are not applied during the code generation process. Such customizations can lead to unpredictable results.

Assigning Target Language Compiler Variables

The %assign statement lets you assign a value to a TLC variable, as in:

%assign MaxStackSize = 4096

This assignment is also known as creating a parameter name/parameter value pair.

For a description of the %assign statement, see “Target Language Compiler Directives” (Simulink Coder). Write your %assign statements in the Configure RTW code generation settings section of the system target file.

The following table lists the code generation variables you can set with the %assign statement.
## Target Language Compiler Optional Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MaxStackSize(=N)</td>
<td>When the <strong>Enable local block outputs</strong> check box is selected, the total allocation size of local variables that are declared by block outputs in the model cannot exceed (\text{MaxStackSize}) (in bytes). (\text{MaxStackSize}) can be a positive integer. If the total size of local block output variables exceeds this maximum, the remaining block output variables are allocated in global, rather than local, memory. The default value for (\text{MaxStackSize}) is (\text{rtInf}), that is, unlimited stack size. <strong>Note:</strong> Local variables in the generated code from sources other than local block outputs, such as from a Stateflow diagram or MATLAB Function block, and stack usage from sources such as function calls and context switching are not included in the (\text{MaxStackSize}) calculation. For overall executable stack usage metrics, do a target-specific measurement by using run-time (empirical) analysis or static (code path) analysis with object code.</td>
</tr>
<tr>
<td>MaxStackVariableSize(=N)</td>
<td>When the <strong>Enable local block outputs</strong> check box is selected, this selection limits the size of a local block output variable declared in the code to (N) bytes, where (N&gt;0). A variable whose size exceeds (\text{MaxStackVariableSize}) is allocated in global, rather than local, memory. The default is 4096.</td>
</tr>
</tbody>
</table>
| WarnNonSaturatedBlocks\(=value\) | Flag to control display of overflow warnings for blocks that have saturation capability, but have it turned off (not selected) in their dialog box. Options include:  
  - 0 — Warning is not displayed.  
  - 1 — Displays one warning for the model during code generation  
  - 2 — Displays one warning that contains a list of offending blocks |
Set Target Language Compiler Options

You can specify TLC command-line options for code generation using the model parameter TLCOptions in a set_param function call. For information about these options, see “Specify TLC for Code Generation” (Simulink Coder) and “Configure TLC” (Simulink Coder).
Use makecfg to Customize Generated Makefiles for S-Functions

With the toolchain and template makefile approach for building code, you can customize generated makefiles for S-functions. Through the customization, you can specify additional items for the S-function build process:

• Source files and folders
• Include files and folders
• Library names
• Preprocessor macro definitions
• Compiler flags
• Link objects

1 To customize the generated makefile:
   • For all S-functions in the build folder (Simulink Coder), create a makecfg.m file.
   • For a specific S-function in the build folder, create a specificSFunction_makecfg.m file.

2 In the file that you create, use RTW.BuildInfo (Simulink Coder) functions to specify additional items for the S-function build process. For example, you can use:
   • addCompileFlags to specify compiler options.
   • addDefines to specify preprocessor macro definitions.

3 Save the created file in the build folder.

After code generation, in the build folder, the code generator searches for makecfg.m and specificSFunction_makecfg.m files. If the files are present in the build folder, the code generator uses these files to customize the generated makefile, model.mk.

For example, consider a build folder that contains signalConvert.mexa64 (S-function binary file) and signalConvert.tlc (inlined S-function implementation) after the TLC phase (Simulink Coder) of the build process. The S-function requires an additional source code file, filterV1.c, which is located in anotherFolder. You can create a file, signalConvert_makecfg.m, that uses RTW.BuildInfo functions to specify filterV1.c for the build process.

function signalConvert_makecfg(objBuildInfo)
absolute = fullfile('$START_DIR', 'anotherFolder');

addIncludePaths(objBuildInfo, absolute);
addSourcePaths(objBuildInfo, absolute);
addSourceFiles(objBuildInfo,'filterV1.c');

Use rtwmakecfg.m API to Customize Generated Makefiles

Both the toolchain approach and the template makefile approach for builds let you add the following items to generated makefiles:

- Source folders
- Include folders
- Library names
- Module objects

About the rtwmakecfg Function

Using an rtwmakecfg function, you add this information to the makefile during the build operation for S-functions. The rtwmakecfg function is useful when specifying added sources and libraries to build a model that contains one or more of your S-function blocks.

To add information pertaining to an S-function to the makefile:

1. Create the MATLAB language rtwmakecfg function in the rtwmakecfg.m file. The code generator associates this file with your S-function based on its folder location. “Create the rtwmakecfg Function” on page 73-26 describes the requirements for the rtwmakecfg function and the data it returns.

2. If you are using the template makefile approach, modify the TMF of your target such that it supports macro expansion for the information that the rtwmakecfg function returns. “Modify the Template Makefile for rtwmakecfg” on page 73-29 describes the required modifications. If you are using the toolchain approach, the information that the rtwmakecfg function returns is used by the generated makefile; no further configuration is required.

After the TLC phase of the build process, when generating a makefile, the code generator searches for an rtwmakecfg.m file in the folder that contains the S-function MEX file. If it finds the file, the build process calls the rtwmakecfg function.

Create the rtwmakecfg Function

Create the rtwmakecfg.m file containing the rtwmakecfg function in the same folder as your S-function component (a MEX-file with a platform-dependent extension, such
as `.mexext` on Microsoft Windows systems). The function must return a structured array that contains these fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>makeInfo.includePath</td>
<td>A cell array that specifies additional include folder names, organized as a row vector. The build process expands the folder names into include instructions in the generated makefile.</td>
</tr>
<tr>
<td>makeInfo.sourcePath</td>
<td>A cell array that specifies additional source folder names, organized as a row vector. Include the folder names of files entered into the <strong>S-function modules</strong> field on the S-Function Block Parameters dialog box or into the <code>SFunctionModules</code> parameter of the block if they are not in the same folder as the S-function. The build process expands the folder names into make rules in the generated makefile.</td>
</tr>
<tr>
<td>makeInfo.sources</td>
<td>A cell array that specifies additional source file names (C or C++), organized as a row vector. Do not include the name of the S-function or any files entered into the <strong>S-function modules</strong> field on the S-Function Block Parameters dialog box or into the <code>SFunctionModules</code> parameter of the block. The build process expands the file names into make variables that contain the source files. Specify only file names (with extension). Specify path information with the <code>sourcePath</code> field.</td>
</tr>
<tr>
<td>makeInfo.linkLibsObjs</td>
<td>A cell array that specifies additional, fully qualified paths to object or library files against which the generated code links. The build process does not compile the specified objects and libraries. However, it includes them when linking the final executable. This inclusion can be useful for incorporating libraries that you do not want the build process to recompile or for which the source files are not available. You can also use this element to integrate source files from languages other than C and C++. This integration is possible if you first create a C compatible object file or library outside of the build process.</td>
</tr>
</tbody>
</table>
Field | Description
--- | ---
makeInfo.precompile | A Boolean flag that indicates whether the libraries specified in the rtwmakecfg.m file exist in a specified location (precompile==1) or if you must create the libraries in the build folder during the build process (precompile==0).

makeInfo.library | A structure array that specifies additional run-time libraries and module objects, organized as a row vector. The build process expands the information into make rules in the generated makefile. For a list of the library fields, see the next table.

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>makeInfo.library(n).Name</td>
<td>A character array that specifies the name of the library (without an extension).</td>
</tr>
<tr>
<td>makeInfo.library(n).Location</td>
<td>A character array that specifies the folder in which the library is located when precompiled. For more information, see the description of makeInfo.precompile in the preceding table. A target can use the TargetPreCompLibLocation parameter to override this value. See “Specify the Location of Precompiled Libraries” (Simulink Coder).</td>
</tr>
<tr>
<td>makeInfo.library(n).Modules</td>
<td>A cell array that specifies the C or C++ source file base names (without an extension) that comprise the library. Do not include the file extension. The makefile appends the object extension.</td>
</tr>
</tbody>
</table>

**Note** The makeInfo.library field must fully specify each library and how to build it. The modules list in the makeInfo.library(n).Modules element cannot be empty. To specify a link-only library, use the makeInfo.linkLibsObjs field instead.

**Example:**

```matlab
disp(['Running rtwmakecfg from folder: ',pwd]);
makeInfo.includePath = { fullfile(pwd, 'somedir2') };
makeInfo.sourcePath = {fullfile(pwd, 'somedir2'), fullfile(pwd, 'somedir3')};
makeInfo.sources = { 'src1.c', 'src2.cpp'};
```
Note If a path that you specify in the `rtwmakecfg.m` API contains spaces, the build process does not convert the path to its nonspace equivalent. If the build environments you intend to support do not support spaces in paths, refer to “Enable Build Process for Folder Names with Spaces” (Simulink Coder).

Modify the Template Makefile for `rtwmakecfg`

To expand the information that an `rtwmakecfg` function generates, modify the following sections in the TMF of your target:

- Include Path
- C Flags and/or Additional Libraries
- Rules

It is possible that these TMF code examples do not apply to your make utility. For additional examples, see the GRT or ERT TMFs located in `matlabroot/rtw/c/grt` (open) or `matlabroot/rtw/c/ert` (open).

**Add Folder Names to the Makefile Include Path**

The following TMF code example adds folder names to the include path in the generated makefile:

```
ADD_INCLUDES = \n|>START_EXPAND_INCLUDES<| -I|>EXPAND_DIR_NAME<| \n|>END_EXPAND_INCLUDES<|
```

Also, the `ADD_INCLUDES` macro must be added to the `INCLUDES` line.

```
INCLUDES = -I. -I.. $(MATLAB_INCLUDES) $(ADD_INCLUDES) $(USER_INCLUDES)
```

**Add Library Names to the Makefile**

The following TMF code example adds library names to the generated makefile.

```
LIBS = \n|>START_PRECOMP_LIBRARIES<|
```
For more information, see “Control Library Location and Naming During Build” on page 73-7.

Add Rules to the Makefile

The TMF code example adds rules to the generated makefile.

```bash
LIBS += |>EXPAND_LIBRARY_NAME|.a |>END_PRECOMP_LIBRARIES<|
|>START_EXPAND_LIBRARIES<|
LIBS += |>EXPAND_LIBRARY_NAME|.a |>END_EXPAND_LIBRARIES<|

For more information, see “Control Library Location and Naming During Build” on page 73-7.

Add Rules to the Makefile

The TMF code example adds rules to the generated makefile.

```bash
LIBS += |>EXPAND_LIBRARY_NAME|.a |>END_PRECOMP_LIBRARIES<|
|>START_EXPAND_LIBRARIES<|
LIBS += |>EXPAND_LIBRARY_NAME|.a |>END_EXPAND_LIBRARIES<|

For more information, see “Control Library Location and Naming During Build” on page 73-7.

Add Rules to the Makefile

The TMF code example adds rules to the generated makefile.

```bash
LIBS += |>EXPAND_LIBRARY_NAME|.a |>END_PRECOMP_LIBRARIES<|
|>START_EXPAND_LIBRARIES<|
LIBS += |>EXPAND_LIBRARY_NAME|.a |>END_EXPAND_LIBRARIES<|

For more information, see “Control Library Location and Naming During Build” on page 73-7.

Add Rules to the Makefile

The TMF code example adds rules to the generated makefile.

```bash
LIBS += |>EXPAND_LIBRARY_NAME|.a |>END_PRECOMP_LIBRARIES<|
|>START_EXPAND_LIBRARIES<|
LIBS += |>EXPAND_LIBRARY_NAME|.a |>END_EXPAND_LIBRARIES<|

For more information, see “Control Library Location and Naming During Build” on page 73-7.

Add Rules to the Makefile

The TMF code example adds rules to the generated makefile.

```bash
LIBS += |>EXPAND_LIBRARY_NAME|.a |>END_PRECOMP_LIBRARIES<|
|>START_EXPAND_LIBRARIES<|
LIBS += |>EXPAND_LIBRARY_NAME|.a |>END_EXPAND_LIBRARIES<|

For more information, see “Control Library Location and Naming During Build” on page 73-7.

Add Rules to the Makefile

The TMF code example adds rules to the generated makefile.

```bash
LIBS += |>EXPAND_LIBRARY_NAME|.a |>END_PRECOMP_LIBRARIES<|
|>START_EXPAND_LIBRARIES<|
LIBS += |>EXPAND_LIBRARY_NAME|.a |>END_EXPAND_LIBRARIES<|

For more information, see “Control Library Location and Naming During Build” on page 73-7.

Add Rules to the Makefile

The TMF code example adds rules to the generated makefile.

```bash
LIBS += |>EXPAND_LIBRARY_NAME|.a |>END_PRECOMP_LIBRARIES<|
|>START_EXPAND_LIBRARIES<|
LIBS += |>EXPAND_LIBRARY_NAME|.a |>END_EXPAND_LIBRARIES<|

For more information, see “Control Library Location and Naming During Build” on page 73-7.

Add Rules to the Makefile

The TMF code example adds rules to the generated makefile.

```bash
LIBS += |>EXPAND_LIBRARY_NAME|.a |>END_PRECOMP_LIBRARIES<|
|>START_EXPAND_LIBRARIES<|
LIBS += |>EXPAND_LIBRARY_NAME|.a |>END_EXPAND_LIBRARIES<|

For more information, see “Control Library Location and Naming During Build” on page 73-7.
Customize Build Process with STF_make_rtw_hook File

The build process lets you supply optional custom code in hook methods that are executed at specified points in the code generation and make process. You can use hook methods to add target-specific actions to the build process.

**STF_make_rtw_hook File**

You can modify hook methods in a file generically referred to as `STF_make_rtw_hook.m`, where `STF` is the name of a system target file, such as `ert` or `mytarget`. This file implements a function, `STF_make_rtw_hook`, that dispatches to a specific action, depending on the `hookMethod` argument passed in.

The build process calls `STF_make_rtw_hook`, passing in the `hookMethod` argument and other arguments. You implement only those hook methods that your build process requires.

If your model contains reference models, you can implement an `STF_make_rtw_hook.m` for each reference model as required. The build process calls each `STF_make_rtw_hook` for reference models, processing these files recursively (in dependency order).

**Conventions for Using the STF_make_rtw_hook File**

For the build process to call the `STF_make_rtw_hook`, check that the following conditions are met:

- The `STF_make_rtw_hook.m` file is on the MATLAB path.
- The file name is the name of your system target file (STF), appended to the text `make_rtw_hook.m`. For example, if you generate code with a custom system target file `mytarget.tlc`, name your hook file `mytarget_make_rtw_hook.m`, and name the hook function implemented within the file `mytarget_make_rtw_hook`.
- The hook function implemented in the file uses the function prototype described in “STF_make_rtw_hook.m Function Prototype and Arguments” on page 73-31.

**STF_make_rtw_hook.m Function Prototype and Arguments**

The function prototype for `STF_make_rtw_hook` is:

```matlab
function STF_make_rtw_hook(hookMethod, modelName, rtwRoot, templateMakefile, buildOpts, buildArgs, buildInfo)
```

73-31
The arguments are defined as:

- **hookMethod**: Character vector specifying the stage of build process from which the `STF_make_rtw_hook` function is called. The following flow chart summarizes the build process, highlighting the hook points. Valid values for `hookMethod` are 'entry', 'before_tlc', 'after_tlc', 'before_make', 'after_make', 'exit', and 'error'. The `STF_make_rtw_hook` function dispatches to the relevant code with a switch statement.
- `modelName`: Character vector specifying the name of the model. Valid at all stages of the build process.
- `rtwRoot`: Reserved.
- `templateMakefile`: Name of template makefile.
- `buildOpts`: A MATLAB structure containing the fields described in the following list. Valid for the 'before_make', 'after_make', and 'exit' stages only. The `buildOpts` fields include:
  - `modules`: Character vector specifying a list of additional files to compile.
  - `codeFormat`: Character vector specifying the value of the CodeFormat TLC variable for the target. (ERT-based targets must use the 'Embedded-C' value for the CodeFormat TLC variable and use the corresponding 'ert.tlc' value in the rtwgensettings.DerivedFrom field.)
  - `noninlinedSFcns`: Cell array specifying a list of noninlined S-functions in the model.
  - `compilerEnvVal`: Character vector specifying the compiler environment variable value (for example, `C:\Applications\Microsoft Visual`).
  - `buildArgs`: Character vector containing the argument to `make_rtw`. When you invoke the build process, `buildArgs` is copied from the argument following "make_rtw" in the Configuration Parameters + Code Generation + Make command field.

For example, the following make arguments from the Make command field

```
make_rtw VAR1=0 VAR2=4
```

generate the following:

```
% make -f untitled.mk VAR1=0 VAR2=4
```

The `buildArgs` argument does not apply for toolchain approach builds because these builds do not allow adding make arguments to the `make_rtw` call. On the compiler command line, to provide custom definitions (for example, `VAR1=0 VAR2=4`) that apply for both TMF approach and toolchain approach builds, use the Configuration Parameters > Code Generation > Custom Code > Defines field.

- `buildInfo`: The MATLAB structure that contains the model build information fields. Valid for the 'after_tlc', 'before_make', 'after_make', and 'exit' stages only. For information about these fields and functions to access them, see “Build Process Customization” (Simulink Coder).
Applications for STF_make_rtw_hook.m

Here are some examples of how to apply the STF_make_rtw_hook.m hook methods.

In general, you can use the 'entry' hook to initialize the build process, for example, to change or validate settings before code is generated. One application for the 'entry' hook is to rerun the auto-configuration script that initially ran at target selection time to compare model parameters before and after the script executes, for validation purposes.

The other hook points, 'before_tlc', 'after_tlc', 'before_make', 'after_make', 'exit', and 'error' are useful for interfacing with external tool chains, source control tools, and other environment tools.

For example, you could use the STF_make_rtw_hook.m file at a stage after 'entry' to obtain the path to the build folder. At the 'exit' stage, you could then locate generated code files within the build folder and check them into your version control system. You can use 'error' to clean up static or global data used by the hook function when an error occurs during code generation or the build process.

Note The build process temporarily changes the MATLAB working folder to the build folder for stages 'before_make', 'after_make', 'exit', and 'error'. Your STF_make_rtw_hook.m file must not make incorrect assumptions about the location of the build folder. At a point after the 'entry' stage, you can obtain the path to the build folder. In the following MATLAB code example, the build folder path is returned as a character vector to the variable buildDirPath.

buildDirPath = rtwprivate('get_makertwsettings',gcs,'BuildDirectory');

Control Code Regeneration Using STF_make_rtw_hook.m

When you rebuild a model, by default, the build process performs checks to determine whether changes to the model or relevant settings require regeneration of the top model code. (For details on the criteria, see “Control Regeneration of Top Model Code” on page 43-43.) If the checks determine that top model code generation is required, the build process fully regenerates and compiles the model code. If the checks indicate that the top model generated code is current with respect to the model, and model settings do not require full regeneration, the build process omits regeneration of the top model code.

Regardless of whether the top model code is regenerated, the build process subsequently calls the build process hooks, including STF_make_rtw_hook functions and the post
code generation command. The following mechanisms allow you to perform actions related to code regeneration in the \textit{STF\_make\_rtw\_hook} functions:

- To force code regeneration, use the following function call from the 'entry' hook:
  \begin{verbatim}
  rtw.targetNeedsCodeGen('set', true);
  \end{verbatim}
- In hooks from 'before\_tlc' through 'exit', the buildOpts structure passed to the hook has a Boolean field codeWasUpToDate. The field is set to \texttt{true} if model code was up to date and code was not regenerated, or \texttt{false} if code was not up to date and code was regenerated. You can customize hook actions based on the value of this field. For example:

  \begin{verbatim}
  case 'before\_tlc'
    if buildOpts.codeWasUpToDate
      \%Perform hook actions for up to date model
    else
      \%Perform hook actions for full code generation
    end
  \end{verbatim}

**Use \textit{STF\_make\_rtw\_hook}\texttt{.m} for Your Build Procedure**

To create a custom \textit{STF\_make\_rtw\_hook} hook file for your build procedure, copy and edit the example \texttt{ert\_make\_rtw\_hook.m} file, which is located in the folder \texttt{matlabroot/toolbox/coder/embeddedcoder} (open), as follows:

1. Copy \texttt{ert\_make\_rtw\_hook.m} to a folder in the MATLAB path. Rename it in accordance with the naming conventions described in “Conventions for Using the \textit{STF\_make\_rtw\_hook} File” on page 73-31. For example, to use it with the GRT target \texttt{grt.tlc}, rename it to \texttt{grt\_make\_rtw\_hook.m}.

2. Rename the \texttt{ert\_make\_rtw\_hook} function within the file to match the file name.

3. Implement the hooks that you require by adding code to case statements within the \texttt{switch hookMethod} statement.
Customize Build Process with sl_customization.m

The Simulink customization file sl_customization.m is a mechanism that allows you to use MATLAB to customize the build process interface. The Simulink software reads the sl_customization.m file, if present on the MATLAB path, when it starts and the customizations specified in the file are applied to the Simulink session. For more information on the sl_customization.m customization file, see “Registering Customizations” (Simulink).

The sl_customization.m File

The sl_customization.m file can be used to register installation-specific hook functions to be invoked during the build process. The hook functions that you register through sl_customization.m complement System Target File (STF) hooks (described in “Customize Build Process with STF_make_rtw_hook File” on page 73-31) and post-code generation commands (described in “Customize Post-Code-Generation Build Processing” on page 73-14).

The following figure shows the relationship between installation-level hooks and the other available mechanisms for customizing the build process.
Start build process

Simulink Coder verification

Entry
- STF 'entry' hook
- Installation 'entry' hook

Before TLC
- STF 'before_tlc' hook
- Installation 'before_tlc' hook

After TLC
- STF 'after_tlc' hook
- Installation 'after_tlc' hook

Before Make
- STF 'before_make' hook
- Installation 'before_make' hook

After Make
- STF 'after_make' hook
- Installation 'after_make' hook

Exit
- STF 'exit' hook
- Installation 'exit' hook

End build process
Register Build Process Hook Functions Using
sl_customization.m

To register installation-level hook functions that are invoked during the build process, you
create a MATLAB function called sl_customization.m and include it on the MATLAB
path of the Simulink installation that you want to customize. The sl_customization
function accepts one argument: a handle to a customization manager object. For example,

```matlab
function sl_customization(cm)
```

As a starting point for your customizations, the sl_customization function must first
get the default (factory) customizations, using the following assignment statement:

```matlab
hObj = cm.RTWBuildCustomizer;
```

You then invoke methods to register your customizations. The customization manager
object includes the following method for registering build process hook customizations:

- `addUserHook(hObj, hookType, hook)`

  Registers the MATLAB hook script or function specified by hook for the build process
  stage represented by hookType. The valid values for hookType are 'entry',
  'before_tlc', 'after_tlc', 'before_make', 'after_make', and 'exit'.

Use this method to register installation-specific hook functions in your instance of the
sl_customization function.

The Simulink software reads the sl_customization.m file when it starts. If you
subsequently change the file, you must restart the Simulink session or enter the following
command in the Command Window to enable the changes:

```matlab
sl_refresh_customizations
```

Variables Available for sl_customization.m Hook Functions

The following variables are available for sl_customization.m hook functions to use:

- `modelName` — The name of the Simulink model (valid for all stages)
- `dependencyObject` — An object containing the dependencies of the generated code
  (valid only for the 'after_make' stage)

A hook script can directly access the valid variables. A hook function can pass the valid
variables as arguments to the function. For example:
Example of Build Process Customization with sl_customization.m

The sl_customization.m file shown in the example, sl_customization.m for Build Process Customizations, uses the addUserHook method to specify installation-specific build process hooks to be invoked at the 'entry' and 'after_tlc' stages of the build process. For the hook function source code, see the CustomRTWEntryHook.m and CustomRTWPostProcessHook.m examples.

Example 73.1. sl_customization.m for Build Process Customizations

```matlab
function sl_customization(cm)
% Register user customizations

% Get default (factory) customizations
hObj = cm.RTWBuildCustomizer;

% Register build process hooks
hObj.addUserHook('entry', 'CustomRTWEntryHook(modelName);');
end
```

Example 73.2. CustomRTWEntryHook.m

```matlab
function [str, status] = CustomRTWEntryHook(modelName)
str = sprintf('Custom entry hook for model ''%s.'', modelName);
disp(str)
status = 1;
```

Example 73.3. CustomRTWPostProcessHook.m

```matlab
function [str, status] = CustomRTWPostProcessHook(modelName)
str = sprintf('Custom post process hook for model ''%s.'', modelName);
disp(str)
status = 1;
```

If you include the above three files on the MATLAB path of the Simulink installation that you want to customize, the coded hook function messages appear in the displayed output for builds. For example, if you open the ERT-based model rtwdemo_udt, open the Code Generation pane of the Configuration Parameters dialog box, and press Ctrl+B to initiate a build, the following messages are displayed:

```plaintext
>> rtwdemo_udt
### Starting build procedure for model: rtwdemo_udt
```
Custom entry hook for model 'rtwdemo_udt.'
Custom post process hook for model 'rtwdemo_udt.'
### Successful completion of build procedure for model: rtwdemo_udt
>>
Replace STF_rtw_info_hook Supplied Target Data

Prior to MATLAB Release 14, custom targets supplied target-specific information with a hook file (referred to as `STF_rtw_info_hook.m`). The `STF_rtw_info_hook` specified properties such as word sizes for integer data types (for example, `char`, `short`, `int`, and `long`), and C implementation-specific properties of the custom target.

The `STF_rtw_info_hook` mechanism has been replaced by the **Hardware Implementation** pane of the Configuration Parameters dialog box. Using this dialog box, you can specify properties that were formerly specified in your `STF_rtw_info_hook` file.

For backward compatibility, existing `STF_rtw_info_hook` files are available. However, you should convert your target and models to use of the **Hardware Implementation** pane. See “Configure Production and Test Hardware” (Simulink Coder).

About Embedded Target Development

Target files bundled with the code generator are suitable for many different applications and development environments. Third-party targets provide additional versatility. In addition, you have the option of implementing a custom target.

To implement a target based on the ARM Cortex-A or ARM Cortex-M processor, install the corresponding support package and see the Target SDK: Embedded Coder Support Package for ARM Cortex-A Processors, “Develop a Target” (Embedded Coder Support Package for ARM Cortex-A Processors) or Embedded Coder Support Package for ARM Cortex-M Processors, “Develop a Target” (Embedded Coder Support Package for ARM Cortex-M Processors). Otherwise, use these functions and topics.

Custom Targets

You might want to implement a custom target for one of the following reasons:

• To enable end users to generate executable production code for a specific CPU or development board, using a specific development environment (compiler/linker/debugger).

• To support I/O devices on the target hardware by incorporating custom device driver blocks into your models.

• To configure the build process for a special compiler (such as a cross-compiler for an embedded microcontroller or DSP board) or development/debugging environment.

The code generator provides a point of departure for the creation of custom embedded targets, for the basic purposes above. This manual covers the tasks and techniques you need to implement a custom embedded target.

Types of Targets

The following sections describe several types of targets intended for different use cases

• “About Target Types” on page 74-3
• “Rapid Prototyping Targets” on page 74-3
• “Production Targets” on page 74-3
• “Verifying Targets With SIL and PIL Simulation” on page 74-4
About Target Types

There is a progression of capabilities from baseline or rapid prototyping targets to production targets. Initially, you might want to implement a rapid prototyping target. Later, you can enhance the target to be more full-featured. For example, you might want to add support for software-in-the-loop (SIL) or processor-in-the-loop (PIL) simulation at some point for verifying your embedded target. The target types are not mutually exclusive. An embedded target can support more than one of these use cases, or additional uses not outlined here.

The discussion of target types is followed by “Recommended Features for Embedded Targets” on page 74-4, which contains a suggested list of features and general guidelines for embedded target development.

Rapid Prototyping Targets

A rapid prototyping target or baseline target offers a starting point for targeting a production processor. A rapid prototyping target integrates coded generator software with one or more popular cross-development environments (compiler/linker/debugger tool chains). A rapid prototyping target provides a starting point from which you can customize the target for application needs.

Target files provided for this type of target should be readable, easy to understand, and fully commented and documented. Specific attention should be paid to the interface to the intended cross-development environment. This interface should be implemented using the preferred approach for that particular development system. For example, some development environments use traditional make utilities, while others are based on project-file builds that can be automated under control of the code generator.

When you use a rapid prototyping target, you need to include your own device driver and legacy code and modify linker memory maps to suit your needs. You should be familiar with the targeted development system.

Production Targets

A production target supports embedded application development for a production processor. It includes the capability to create program executables that interact immediately with the external world. In general, ease of use is more important than simplicity or readability of generated code files, because it is assumed that you do not want or need to modify the files.
Desirable features for a production target include:

- Significant I/O driver support, provided out of the box
- Easy downloading of generated standalone executable programs with third-party debuggers
- User-controlled placement of an executable in FLASH or RAM memory
- Support for code visibility and tuning on target hardware

**Verifying Targets With SIL and PIL Simulation**

You can use software-in-the-loop (SIL) or processor-in-the-loop (PIL) simulation to verify generated code and validate the target compiler/processor environment.

You can use SIL and PIL simulation modes to verify automatically generated code by comparing the results with a normal mode simulation. With SIL, you can easily verify the behavior of production-intent source code on your host computer; however, it is generally not possible to verify exactly the same code that will subsequently be compiled for your target hardware because the code must be compiled for your host platform (i.e. a different compiler and different processor architecture than the target). With PIL simulation, you can verify exactly the same code that you intend to deploy in production, and you can run the code either on real target hardware or on an instruction set simulator.

For examples describing how to run processor-in-the-loop testing to verify a custom target, see “Sample Custom Targets” on page 74-9.

For more information on SIL and PIL simulation, see “SIL and PIL Simulations” on page 67-2.

**HIL Simulation**

A specialized use case is the generation of executables intended for use in hardware-in-the-loop (HIL) simulations. In a HIL simulation, parts of a pure simulation are gradually replaced with hardware components as components are refined and fabricated. HIL simulation offers an efficient design process that eliminates costly iterations of part fabrication.

**Recommended Features for Embedded Targets**

- “Basic Target Features” on page 74-5
Basic Target Features

You can base targets on the generic real-time (GRT) target or the Embedded Real-Time (ERT) target that is included in the Embedded Coder product.

If your target is based on the ERT target, it should use 'Embedded-C' value for the CodeFormat TLC variable, and it should inherit the options defined in the ERT target's system target file with the following lines in the TLC file:

```
%% Assign code format
%assign CodeFormat = "Embedded-C"
%%----------------------------
/
BEGIN_RTW_OPTIONS
  rtwgensettings.DerivedFrom = 'ert.tlc';
END_RTW_OPTIONS
%/  
%%----------------------------
```

By following these recommendations, your target has the production code generation capabilities of the ERT target.

See “Customize System Target Files” on page 74-28 for further details on the inheritance mechanism, setting the CodeFormat, and other details.

The most fundamental requirement for an embedded target is that it generate a real-time executable from a model or subsystem. Typically, an embedded target generates a timer interrupt-based, bareboard executable (although targets can be developed for an operating system environment as well).

Your target should support code generator concepts of single-tasking and multitasking solver modes for model execution. Tasking support is available with the ERT target, but you should thoroughly understand how it works before implementing an ERT-based target.

For information on timer interrupt-based execution, see “Absolute and Elapsed Time Computation” (Simulink Coder) and “Asynchronous Events” (Simulink Coder).

You should generate the target executable's main program module, rather than using a static main module (such as the static rt_main.c or rt_cppclass_main.cpp module provided with the software). A generated main.c or .cpp can be made much
more readable and more efficient, since it omits preprocessor checks and other extra code.

For information on generated and static main program modules, see “Deploy Generated Standalone Executable Programs To Target Hardware” on page 52-2.

- Follow the guidelines in “Folder and File Naming Conventions” on page 74-11.

**Integration with Target Development Environments**

- Most cross-development systems run under a Microsoft Windows PC host. Your target should support the Windows operating system as the host environment.

  Some cross-development systems support one or more versions of The Open Group UNIX platforms, allowing for UNIX host support as well.

- Your embedded target must support at least one embedded development environment. The interface to a development environment can take one of several forms. The toolchain approach and template makefile approach generate standard makefiles to work with your development environment. For general information about these build approaches, see “Choose Build Approach and Configure Build Process” (Simulink Coder). For detailed information about the structure of template makefiles, see “Customize Template Makefiles” on page 74-62.

Another approach with IDE-based tools is to create a Microsoft Visual Studio Solution from your target for integration within a Visual Studio project.

It is important to consider the license requirements and restrictions of the development environment vendor. You may need to modify files provided by the vendor and ship them as part of the embedded target.

See “Interface to Development Tools” on page 74-104 for further information.

**Observing Execution of Target Code**

- Your target should support a mechanism you can use to observe the target code as it runs in real time (outside of a debugger).

You can use the rtiostream API to implement a communication channel to enable exchange of data between different processes. For an example of creating a communication channel for target connectivity, see “Create a Target Communication Channel for Processor-In-The-Loop (PIL) Simulation”. This rtiostream communication channel is required to enable processor-in-the-loop (PIL) on a new target. See “Communications rtiostream API” on page 67-48.
One industry-standard approach is to use the CAN bus, with an ASAP2 file and CAN Calibration Protocol (CCP). There are several host-based graphical front-end tools available that connect to a CCP-enabled target and provide data viewing and parameter tuning. Supporting these tools requires implementation of CAN hardware drivers and CCP protocol for the target, as well as ASAP2 file generation. Your target can leverage the ASAP2 support provided with the code generator.

Another option is to support Simulink external mode simulation. For more information, see the “Host-Target Communication with External Mode Simulation” (Simulink Coder).

**Deployment and Hardware Issues**

- Device driver support is an important issue in the design of an embedded target. Device drivers are Simulink blocks that support either hardware I/O capabilities of the target CPU, or I/O features of the development board.

If you are developing a rapid prototyping target, consider providing minimal driver support, on the assumption that end users develop their own drivers. If you are developing a production target, you should provide full driver support.

See “Device Drivers” (Simulink Coder).

- Automatic download of generated code to the target hardware makes a target easier to use. Typically a debugger utility is used; if the chosen debugger supports command script files, this can be straightforward to implement. “STF_make_rtw_hook.m” on page 74-20 describes a mechanism to execute code from the build process. You can use this mechanism to make `system()` calls to invoke utilities such as a debugger. You can invoke other simple downloading utilities in a similar fashion.

If your development system supports COM automation, you can control the download process by that mechanism. Using COM automation is discussed in “Interface to Development Tools” on page 74-104.

- Executables that are mapped to RAM memory are typical. You can provide optional support for FLASH or RAM placement of the executable by using your target’s code generation options. To support this capability, you might need multiple linker command files, multiple debugger scripts, and possibly multiple makefiles or project files. Also include the ability to automatically switch between these files, depending on the RAM/FLASH option value.

- Select a popular, widely available evaluation or prototype board for your target processor. Consider enclosed and ruggedized versions of the target board.
consider board level support for the various on-chip I/O capabilities of the target CPU, and the availability of development systems that support the selected board.

Sample Custom Targets

There are technical solutions on the MathWorks Web site that you can use as a starting point to create your own target solution. The solutions provide guides to the following tasks for creating custom targets:

- Methods of embedding code onto a custom processor
- Creating a system target file
- Customizing the makefile and main file
- Adding compiler, chip, and board specific information
- Integrating legacy code and device drivers
- Creating blocks and libraries
- Implementing processor-in-the-loop (PIL) testing.

1. Start by downloading the embedded targets development guide .zip file from this web page:

   Is there an example guide on developing an embedded target...?

   The .zip file provides example files and a guide to developing a custom embedded target. The guide is divided into two parts, one on creating a generic custom target and another on creating a target for the Freescale™ S12X processor using the Cosmic Compiler.

   Read the example guide along with this document to understand the tasks for developing embedded targets.

2. For more detailed example files for specific processors, see:

   - Is there an example Freescale S12X target... using the Cosmic Compiler?
   - Is there an example Freescale S12X target... using the CodeWarrior Compiler?

   These example kits contain example models, code generation files, and instruction guides on generating and testing code for the processor. The Cosmic example illustrates the use of the target connectivity API for processor-in-the-loop (PIL) testing. The CodeWarrior example does not have PIL but shows CAN Calibration Protocol (CCP) and Simulink external mode.

   The intent of the example kits is to provide working examples that you can use as a base to create your own target solution. The intent is not to provide a full featured...
and maintained Embedded Target product like those provided by MathWorks or third-party products, as listed on the Embedded Coder Hardware Support Web page.

3 You can watch videos showing overviews of both the example kits at the following links:

• www.mathworks.com/videos/programming-the-freescale-s12x-target-68811.html
• www.mathworks.com/videos/programming-arm9-using-the-hitex-str9-comstick-68812.html

For another example target for the ARM9 (STR9) processor, see Is there an example ARM9 (STR9) target... using the GNU ARM Compiler and Hitex STR9-comStick?.

If you have questions on specific targets, please email mytarget@mathworks.com.

The example kits and this document describe Embedded Coder features such as customized ert system target files and processor-in-the-loop testing, but you can study the examples as a starting point for use with Simulink Coder targets.

Target Development Folders, Files, and Builds

Target development mechanics work with a number of folder and file types. The following topics provide the information to develop custom targets, configure folder usage, and use custom targets in the build process.

Folder and File Naming Conventions

You can use a single folder for your custom target files, or if desired you can use subfolders, for example containing files associated with specific development environments or tools.

For a custom target implementation, the recommended folder and file naming conventions are

- Use only lowercase in folder names, filenames, and extensions.
- Do not embed spaces in folder names. Spaces in folder names cause errors with many third-party development environments.
- Include desired folders in the MATLAB path
- Do not place your custom target folder anywhere in the MATLAB folder tree (that is, in or under the `matlabroot` folder). If you place your folder under `matlabroot` you risk losing your work if you install a new MATLAB version (or reinstall the current version).

The following sections explain how to organize your target folders and files and add them to your MATLAB path. They also provide high-level descriptions of the files.

In this document, `mytarget` is a placeholder name that represents folders and files that use the target's name. The names `dev_tool1`, `dev_tool2`, and so on represent subfolders containing files associated with development environments or tools. This document describes an example structure where the folder `mytarget` contains subfolders for `mytarget`, `blocks`, `dev_tool1`, `dev_tool2`. The top level folder `mytarget` is the target root folder.

Components of a Custom Target

- “Overview” on page 74-12
- “Code Components” on page 74-12
- “Control Files” on page 74-14
Overview

The components of a custom target are files located in a hierarchy of folders. The top-level folder in this structure is called the *target root folder*. The target root folder and its contents are named, organized, and located on the MATLAB path according to conventions described in “Folder and File Naming Conventions” on page 74-11.

The components of a custom target include

- Code components: C source code that supervises and supports execution of generated model code.
- Control files:
  - A system target file (STF) to control the code generation process.
  - File(s) to control the building of an executable from the generated code. In a traditional make-based environment, a template makefile (TMF) generates a makefile for this purpose. Another approach is to generate project files in support of a modern integrated development environment (IDE) such as the Freescale Semiconductor CodeWarrior IDE.
- Hook files: Optional TLC and MATLAB program files that can be invoked at well-defined stages of the build process. Hook files let you customize the build process and communicate information between various phases of the process.
- Other target files: Files that let you integrate your target into the MATLAB environment. For example, you can provide an *info.xml* file to make your target block libraries and examples available from a MATLAB session.

The next sections introduce key concepts and terminology you need to know to develop each component. References to more detailed information sources are provided.

Code Components

An executable program containing code generated from a Simulink model consists of a number of code modules and data structures. These fall into two categories.

Application Components

Application components are those which are specific to a particular model; they implement the functions represented by the blocks in the model. Application components are not specific to the target. Application components include

- Modules generated from the model
• User-written blocks (S-functions)
• Parameters of the model that are visible, and can be interfaced to, external code

**Execution Support Files**

A number of code modules and data structures, referred to collectively as the *execution support files*, are responsible for managing and supporting the execution of the generated program. The execution support files modules are not automatically generated. Depending on the requirements of your target, you must implement certain parts of the execution support files. Execution Support Files summarizes the execution support files.

### Execution Support Files

<table>
<thead>
<tr>
<th>You Provide...</th>
<th>The Code Generator Provides...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Customized main program</td>
<td>Generic main program</td>
</tr>
<tr>
<td>Timer interrupt handler to run model</td>
<td>Execution engine and integration solver (called by timer interrupt handler)</td>
</tr>
<tr>
<td>Other interrupt handlers</td>
<td>Example interrupt handlers (Asynchronous Interrupt blocks)</td>
</tr>
<tr>
<td>Device drivers</td>
<td>Example device drivers</td>
</tr>
<tr>
<td>Data logging, parameter tuning, signal monitoring, and external mode support</td>
<td>Data logging, parameter tuning, signal monitoring, and external mode APIs</td>
</tr>
</tbody>
</table>

**User-Written Execution Support Files**

The code generator provides most of the execution support files. Depending on the requirements of your target, you must implement some or all of the following elements:

- A timer *interrupt service routine* (ISR). The timer runs at the program's base sample rate. The timer ISR is responsible for operations that must be completed within a single clock period, such as computing the current output sample. The timer ISR usually calls the `rt_OneStep` function.

  If you are targeting a real-time operating system (RTOS), your generated code usually executes under control of the timing and task management mechanisms provided by the RTOS. In this case, you may not have to implement a timer ISR.

- The *main program*. Your main program initializes the blocks in the model, installs the timer ISR, and executes a background task or loop. The timer periodically interrupts
the main loop. If the main program is designed to run for a finite amount of time, it is also responsible for cleanup operations — such as memory deallocation and masking the timer interrupt — before terminating the program.

If you are targeting a real-time operating system (RTOS), your main program most likely spawns tasks (corresponding to the sample rates used in the model) whose execution is timed and controlled by the RTOS.

Your main program typically is based on a generated or static main program. For details on the structure of the execution support files, code execution, and guidelines for customizing main programs, see “Deploy Generated Standalone Executable Programs To Target Hardware” on page 52-2.

- **Device drivers.** Drivers communicate with I/O devices on your target hardware. In production code, device drivers are normally implemented as inlined S-functions.
- **Other interrupt handlers.** If your models need to support asynchronous events, such as hardware generated interrupts and asynchronous read and write operations, you must supply interrupt handlers. The Interrupt Templates library provides examples.
- **Data logging, parameter tuning, signal monitoring, and external mode support.** It is atypical to implement rapid prototyping features such as external mode support in an embedded target. However, it is possible to support these features by using standard code generator APIs. See “Data Exchange Interfaces” (Simulink Coder) for details.

**Control Files**

The code generation and build process is directed by a number of TLC and MATLAB files collectively called **control files.** This section introduces and summarizes the main control files.

**Top-Level Control File (make_rtw)**

The build process is initiated when you press Ctrl+B. At this point, the build process parses the **Make command** field of the Code Generation pane of the Configuration Parameters dialog box, expecting to find the name of a MATLAB command that controls the build process (as well as optional arguments to that command). The default command is make_rtw, and the default top-level control file for the build process is make_rtw.m.

**Note** make_rtw is an internal MATLAB command used by the build process. Normally, target developers do not need detailed knowledge of how make_rtw works. (The details for target developers are described in “Target Development and the Build Process” on
You should not invoke `make_rtw` directly from MATLAB code, and you should not customize `make_rtw.m`.

The `make_rtw.m` file contains the logic required to execute your target-specific control files, including a number of hook points for execution of your custom code. `make_rtw` does the following:

- Passes optional arguments in to the build process
- Performs required preprocessing before code generation
- Executes the STF to perform code generation (and optional HTML report generation)
- Processes the TMF to generate a makefile
- Invokes a make utility to execute the makefile and build an executable
- Performs required post-processing (such as generating calibration data files or downloading the generated executable to the target)

**System Target File (STF)**

The Target Language Compiler (TLC) generates target-specific C or C++ code from a partial description of your Simulink block diagram (`model.rtw`). The Target Language Compiler reads `model.rtw` and executes a program consisting of several target files (.tlc files.) The STF, at the top level of this program, controls the code generation process. The output of this process is a number of source files, which are fed to your development system's make utility.

You need to create a customized STF to set code generation parameters for your target. You should copy, rename, and modify the standard ERT system target file (`matlabroot/rtw/c/ert/ert.tlc`).

The detailed structure of the STF is described in “Customize System Target Files” on page 74-28.

**Note** The STF selects whether the target supports the toolchain approach or template makefile approach for code generation. See “Customize System Target Files” on page 74-28.
**Template Makefile (TMF)**

A TMF provides information about your model and your development system. The build process uses this information to create a makefile (.mk file) that builds an executable program.

Some targets implement more than one TMF, in order to support multiple development environments (for example, two or more cross-compilers) or multiple modes of code generation (for example, generating a binary executable versus generating a project file for your compiler).

The Embedded Coder software provides a large number of TMFs suitable for different types of development computer systems. These TMFs are located in `matlabroot/rtw/c/ert` (open). The standard TMFs are described in “Template Makefiles and Make Options” (Simulink Coder).

The detailed structure of the TMF is described in “Customize Template Makefiles” on page 74-62.

**Note** The STF selects whether the target supports the toolchain approach or template makefile approach for code generation. See “Customize System Target Files” on page 74-28.

**Hook Files**

The build process allows you to supply optional *hook files* that are executed at specified points in the code generation and make process. You can use hook files to add target-specific actions to the build process.

The hook files must follow well-defined naming and location requirements. “Folder and File Naming Conventions” on page 74-11 describes these requirements.

**Key Folders Under Target Root (mytarget)**

- “Target Root Folder (mytarget)” on page 74-17
- “Target Folder (mytarget/mytarget)” on page 74-17
- “Target Block Folder (mytarget/blocks)” on page 74-17
- “Development Tools Folder (mytarget/dev_tool1, mytarget/dev_tool2)” on page 74-18
• “Target Source Code Folder (mytarget/src)” on page 74-19

Target Root Folder (mytarget)

This folder contains the key subfolders for the target (see “Folder and File Naming Conventions” on page 74-11). You can also locate miscellaneous files (such as a readme file) in the target root folder. The following sections describe required and optional subfolders and their contents.

Target Folder (mytarget/mytarget)

This folder contains files that are central to the target, such as the system target file (STF) and template makefile (TMF). “Key Files in Target Folder (mytarget/mytarget)” on page 74-19 summarizes the files that should be stored in mytarget/mytarget, and provides pointers to detailed information about these files.

Note mytarget/mytarget should be on the MATLAB path.

Target Block Folder (mytarget/blocks)

If your target includes device drivers or other blocks, locate the block implementation files in this folder. mytarget/blocks contains

• Compiled block MEX-files
• Source code for the blocks
• TLC inlining files for the blocks
• Library models for the blocks (if you provide your blocks in one or more libraries)

Note mytarget/blocks should be on the MATLAB path.

You can also store example models and supporting files in mytarget/blocks. Alternatively, you can create a mytarget/mytargetdemos folder, which should also be on the MATLAB path.

To display your blocks in the standard Simulink Library Browser and/or integrate your example models into the MATLAB session environment, you can create the files described below and store them in mytarget/blocks.
mytarget/blocks/slblocks.m

This file allows a group of blocks to be integrated into the Simulink Library and Simulink Library Browser.

**Example 74.1. Example slblocks.m File**

```matlab
function blkStruct = slblocks
% Information for "Blocksets and Toolboxes" subsystem
blkStruct.Name = sprintf('Embedded Target
for MYTARGET');
blkStruct.OpenFcn = 'mytargetlib';
blkStruct.MaskDisplay = 'disp(''MYTARGET'')';

% Information for Simulink Library Browser
Browser(1).Library = 'mytargetlib';
Browser(1).Name    = 'Embedded Target for MYTARGET';
Browser(1).IsFlat  = 1;% Is this library "flat" (i.e. no subsystems)?

blkStruct.Browser = Browser;
```

mytarget/blocks/demos.xml

This file provides information about the components, organization, and location of example models. MATLAB software uses this information to place the example in the MATLAB session environment.

**Example 74.2. Example demos.xml File**

```xml
<?xml version="1.0" encoding="utf-8"?>
<demos>
  <name>Embedded Target for MYTARGET</name>
  <type>simulink</type>
  <icon>$toolbox/matlab/icons/boardicon.gif</icon>
  <description source = "file">mytarget_overview.html</description>

  <demosection>
    <label>Multirate model</label>
    <demoitem>
      <label>MYTARGET demo</label>
      <file>mytarget_overview.html</file>
      <callback>mytarget_model</callback>
    </demoitem>
  </demosection>
</demos>
```

**Development Tools Folder (mytarget/dev_tool1, mytarget/dev_tool2)**

These folders contain files associated with specific development environments or tools (dev_tool1, dev_tool2, etc.). Normally, your target supports at least one such development environment and invokes its compiler, linker, and other utilities during the
build process. mytarget/dev_tool1 includes linker command files, startup code, hook functions, and other files required to support this process.

For each development environment, you should provide a separate folder.

**Target Source Code Folder (mytarget/src)**

This folder is optional. If the complexity of your target requires it, you can use mytarget/src to store common source code and configuration code (such as boot and startup code).

**Key Files in Target Folder (mytarget/mytarget)**

- “Introduction” on page 74-19
- “mytarget.tlc” on page 74-19
- “mytarget.tmf” on page 74-20
- “mytarget_genfiles.tlc” on page 74-20
- “mytarget_main.c” on page 74-20
- “STF_make_rtw_hook.m” on page 74-20
- “STF_rtw_info_hook.m (obsolete)” on page 74-21
- “info.xml” on page 74-21
- “mytarget_overview.html” on page 74-21

**Introduction**

The target folder mytarget/mytarget contains key files in your target implementation. These include the system target file, template makefile, main program module, and optional M and TLC hook files that let you add target-specific actions to the build process. The following sections describe the key target folder files.

**mytarget.tlc**

mytarget.tlc is the system target file (STF). Functions of the STF include

- Making the target visible in the System Target File Browser
- Definition of code generation options for the target (inherited and target-specific)
- Providing an entry point for the top-level control of the TLC code generation process

You should base your STF on ert.tlc, the STF provided by Embedded Coder software.
“Customize System Target Files” on page 74-28 gives detailed information on the structure of the STF, and also gives instructions on how to customize an STF to

• Display your target in the System Target File Browser
• Add your own target options to the Configuration Parameters dialog box
• Tailor the code generation and build process to the requirements of your target

**mytarget.tmf**

*mytarget.tmf* is the template makefile for building an executable for your target.

For basic information on the structure and operation of template makefiles, see “Customize Template Makefiles” on page 74-62.

If your target development environment requires automation of a modern integrated development environment (IDE) rather than use of a traditional make utility, see “Interface to Development Tools” on page 74-104.

**mytarget_genfiles.tlc**

This file is optional. *mytarget_genfiles.tlc* is useful as a central file from which to invoke target-specific TLC files that generate additional files as part of your target build process. For example, your target may create sub-makefiles or project files for a development environment, or command scripts for a debugger to do automatic downloads. See “Using mytarget_genfiles.tlc” on page 74-45 for details.

**mytarget_main.c**

A main program module is required for your target. To provide a main module, you can either

• Modify the *rt_main.c* or *rt_cppclass_main.cpp* module provided by the software
• Generate *mytarget_main.c* or *.cpp* during the build process

For a description of the operation of main programs, see “Deploy Generated Standalone Executable Programs To Target Hardware” on page 52-2. The section also contains guidelines for generating and modifying a main program module.

**STF_make_rtw_hook.m**

*STF_make_rtw_hook.m* is an optional hook file that you can use to invoke target-specific functions or executables at specified points in the build process. *STF_make_rtw_hook.m*
implements a function that dispatches to a specific action depending on the method argument that is passed into it.

“Customize Build Process with STF_make_rtw_hook File” (Simulink Coder) describes the operation of the `STF_make_rtw_hook.m` hook file in detail.

**STF_rtw_info_hook.m (obsolete)**

Prior to Release 14, custom targets supplied target-specific information with a hook file (referred to as `STF_rtw_info_hook.m`). The `STF_rtw_info_hook` specified properties such as word sizes for integer data types (for example, `char`, `short`, `int`, and `long`), and C implementation-specific properties of the custom target.

The `STF_rtw_info_hook` mechanism has been replaced by the **Hardware Implementation** pane of the Configuration Parameters dialog box. Using this dialog box, you can specify the properties that were formerly specified in your `STF_rtw_info_hook` file.

For backward compatibility, existing `STF_rtw_info_hook` files are still available. However, you should convert your target and models to use the **Hardware Implementation** pane. See “Configure Run-Time Environment Options” (Simulink Coder).

**info.xml**

This file provides information to MATLAB software that specifies where to display the target toolbox in the MATLAB session environment. For more information, see “Display Custom Documentation” (MATLAB).

**mytarget_overview.html**

By convention, this file serves as home page for the target examples.

The `<description>` field in `demos.xml` should point to `mytarget_overview.html` (see “mytarget/blocks/demos.xml” on page 74-18).

**Example mytarget_overview.html File**

```html
<html>
<head><title>Embedded Target for MYTARGET</title></head>
<body>
<p style="color:#990000; font-weight:bold; font-size:x-large">Embedded Target for MYTARGET Example Model</p>
<p>This example provides a simple model that allows you to generate an executable for a supported target board. You can then download and run the executable and</p>
</body>
</html>
```
set breakpoints to study and monitor the execution behavior.</p> 

</body>

</html>

Additional Files for Externally Developed Targets

- “Introduction” on page 74-22

- “mytarget/mytarget/doc” on page 74-22

Introduction

If you are developing an embedded target that is not installed into the MATLAB tree, you should provide a target setup script and target documentation within mytarget/mytarget, for the convenience of your users. The following sections describe the required materials and where to place them.

mytarget/mytarget/mytarget_setup.m

This file script adds paths for your target to the MATLAB path. Your documentation should instruct users to run the script when installing the target.

You should include a call to the MATLAB function savepath in your mytarget_setup.m script. This function saves the added paths, so users need to run mytarget_setup.m only once.

The following code is an example mytarget_setup.m file.

```matlab
function mytarget_setup()
    curpath = pwd;
    tgtpath = curpath(1:end-length('mytarget'));
    addpath(fullfile(tgtpath, 'mytarget'));
    addpath(fullfile(tgtpath, 'dev_tool1'));
    addpath(fullfile(tgtpath, 'blocks'));
    addpath(fullfile(tgtpath, 'mytargetdemos'));
    savepath;
    disp('MYTARGET Target Path Setup Complete.');
end
```

mytarget/mytarget/doc

You should put the documentation related to your target in the folder mytarget/mytarget/doc.
Target Development and the Build Process

• “About the Build Process” on page 74-23
• “Build Process Phases and Information Passing” on page 74-23
• “Additional Information Passing Techniques” on page 74-24

About the Build Process

To develop an embedded target, you need a thorough understanding of the build process. Your embedded target uses the build process and may require you to modify or customize the process. A general overview of code generation and the build process is given in “Code Generation” (Simulink Coder) and “Build Process” (Simulink Coder).

This section supplements that overview with a description of the build process as customized by the Embedded Coder software. The emphasis is on points in the process where customization hooks are available and on passing information between different phases of the process.

This section concludes with “Additional Information Passing Techniques” on page 74-24, describing assorted tips and tricks for passing information during the build process.

Build Process Phases and Information Passing

It is important to understand where (and when) the build process obtains required information. Sources of information include

• The model.rtw file, which provides information about the generating model. The information in model.rtw is available to target TLC files.
• The code generation panes of the Configuration Parameters dialog box. Options (both general and target-specific) are provided through check boxes, menus, and edit fields. You can associate options with TLC variables in the rtwoptions data structure. Use the Configuration Parameters > Code Generation > Custom Code > Additional build information > Defines field to define makefile tokens.
• The selected toolchain (for toolchain approach builds) or selected template makefile.tmf (for template makefile approach builds); these generate the model-specific makefile.
• Environment variables on the host computer. Environment variables provide additional information about installed development tools.
• Other target-specific files such as target-related TLC files, linker command files, or project files.
It is also important to understand the several phases of the build process and how to pass information between the phases. The build process comprises several high-level phases:

- Execution of the top-level file (slbuild.m or rtwbuild.m) to sequence through the build process for a target
- Conversion of the model into the TLC input file (model.rtw)
- Generation of the target code by the TLC compiler
- Compilation of the generated code with make or other utilities
- Transmission of the final generated executable to the target hardware with a debugger or download utility

It is helpful to think of each phase of the process as a different “environment” that maintains its own data. These environments include

- MATLAB code execution environment (MATLAB)
- Simulink
- Target Language Compiler execution environment
- makefile
- Development environments such as an IDE or debugger

In each environment, you might get information from the various sources mentioned above. For example, during the TLC phase, execute MATLAB file might execute to obtain information from the MATLAB environment. Also, a given phase may generate information for a subsequent phase.

See “Key Files in Target Folder (mytarget/mytarget)” on page 74-19 for details on the available MATLAB file and TLC hooks for information passing, with code examples.

**Additional Information Passing Techniques**

This section describes a number of useful techniques for passing information among different phases of the build process.

**tlcvariable Field in rtwoptions Structure**

Parameters on the code generation panes of the Configuration Parameters dialog box can be associated with a TLC variable, and specified in the tlcvariable field of the option's entry in the rtwoptions structure. The variable value is passed on the command line when TLC is invoked. This provides a way to make code generation parameters and their values available in the TLC phase.
See “System Target File Structure” on page 74-29 for further information.

**makevariable Field in rtwoptions Structure**

You can associate code generation parameters with a template makefile token, that you specify in the `makevariable` field of the option's entry in the `rtwoptions` structure. If a token of the same name as the `makevariable` name exists in the TMF, the token is updated with the option value when the final makefile is created. If the token does not exist in the TMF, the `makevariable` is passed in on the command line when make is invoked. Thus, in either case, the `makevariable` is available to the makefile.

See “System Target File Structure” on page 74-29 for further information.

**Accessing Host Environment Variables**

You can access host shell environment variables at the MATLAB command line by entering the `getenv` command. For example:

```matlab
getenv ('MSDEVDIR')
```

```matlab
ans =
D:\Applications\Microsoft Visual Studio\Common\MSDev98
```

To access the same information from TLC, use the `FEVAL` directive to invoke `getenv`.

```matlab
%assign eVar = FEVAL("getenv","<varname>")
```

**Supplying Development Environment Information to Your Template Makefile**

An embedded target must tie the build process to target-specific development tools installed on a host computer. For the make process to run these tools, the TMF must be able to determine the name of the tools, the path to the compiler, linker, and other utilities, and possibly the host operating system environment variable settings.

Require the end user to modify the target TMF. The user enters path information (such as the location of a compiler executable), and possibly host operating system environment variables, as make variables. This allows the TMF to be tailored to specific needs.

**Using MATLAB Application Data**

Application data provides a way for applications to save and retrieve data stored with the GUI. This technique enables you to create what is essentially a user-defined property for an object, and use this property to store data for use in the build process. If you are
unfamiliar with this technique for creating graphical user interfaces, see “Store Data as Application Data” (MATLAB).

The following code examples illustrates the use of application data to pass information to TLC.

This file, `tlc2appdata.m`, stores the data passed in as application data under the name passed in (`appDataName`).

```matlab
function k = tlc2appdata(appDataName, data)
    disp([mfilename, ': ', appDataName, ' ', data]);
    setappdata(0, appDataName, data);
    k = 0;  % TLC expects a return value for FEVAL.
```

The following sample TLC file uses the `FEVAL` directive to invoke `tlc2appdata.m` to store arbitrary application data, under the name `z80`.

```markdown
%% test.tlc
%%
%assign myApp = "z80"
%assign myData = "314159"
%assign dummy = FEVAL("tlc2appdata", myApp, myData)
```

To test this technique:

1. Create the `tlc2appdata.m` file as shown. Check that `tlc2appdata.m` is stored in a folder on the MATLAB path.
2. Create the TLC file as shown. Save it as `test.tlc`.
3. Enter the following command at the MATLAB prompt to execute the TLC file:
   ```matlab
tlc test.tlc
```
4. Get the application data at the MATLAB prompt:
   ```matlab
   k = getappdata(0, 'z80')
   ``
   The function returns the value 314159.
5. Enter the following command.
   ```matlab
   who
   ``
   Note that application data is not stored in the MATLAB workspace. Also observe that the z80 data is not visible. Using application data in this way has the advantage that
it does not clutter the MATLAB workspace. Also, it helps prevent you from accidentally deleting your data, since it is not stored directly in your workspace.

A real-world use of application data might be to collect information from the model.rtw file and store it for use later in the build process.

**Adding Block-Specific Information to the Makefile**

The rtwmakecfg mechanism provides a method for inlined S-functions such as driver blocks to add information to the makefile. This mechanism is described in “Use rtwmakecfg.m API to Customize Generated Makefiles” (Simulink Coder).

**More About**

- “About Embedded Target Development” (Simulink Coder)
Customize System Target Files

This section provides information on the structure of the STF, guidelines for customizing an STF, and a basic tutorial that helps you get a skeletal STF up and running.

Control Code Generation With the System Target File

The system target file (STF) exerts overall control of the code generation stage of the build process. The STF also lets you control the presentation of your target to the end user. The STF provides

- Definitions of variables that are fundamental to the build process, such as the value for the `CodeFormat` TLC variable
- The main entry point to the top-level TLC program that generates code
- Target information for display in the System Target File Browser
- A mechanism for defining target-specific code generation options (and other parameters related to the build process) and for displaying them in the Configuration Parameters dialog box
- A mechanism for inheriting options from another target (such as the Embedded Real-Time (ERT) target)

Note that, although the STF is a Target Language Compiler (TLC) file, it contains embedded MATLAB code. Before creating or modifying an STF, you should acquire a working knowledge of TLC and of the MATLAB language. “Target Language Compiler” (Simulink Coder) and “Scripts vs. Functions” (MATLAB) describe the features and syntax of both the TLC and MATLAB languages.

While reading this section, you may want to refer to the STFs provided with the code generator. Most of these files are stored in the target-specific folders under `matlabroot/rtw/c` (open). Additional STFs are stored under `matlabroot/toolbox/rtw/targets` (open).

System Target File Naming and Location Conventions

An STF must be located in a folder on the MATLAB path for the target to be displayed in the System Target File Browser and invoked in the build process. Follow the location and naming conventions for STFs and related target files given in “Folder and File Naming Conventions” on page 74-11.
System Target File Structure

- “Overview” on page 74-29
- “Header Comments” on page 74-30
- “TLC Configuration Variables” on page 74-32
- “TLC Program Entry Point and Related %includes” on page 74-33
- “RTW_OPTIONS Section” on page 74-34
- “rtwgensettings Structure” on page 74-34
- “Additional Code Generation Options” on page 74-36
- “Model Reference Considerations” on page 74-36

Overview

This section is a guide to the structure and contents of an STF. The following listing shows the general structure of an STF. Note that this is not a complete code listing of an STF. The listing consists of excerpts from each of the sections that make up an STF.

```%
% Header Comments Section
%----------------------------
% SYSTLC: Example Real-Time Target
% TMF: my_target.tmf MAKE: make_rtw EXTMODE: ext_comm
% Initial comments contain directives for STF Browser.
% Documentation, date, copyright, and other info may follow.
%
%selectfile NULL_FILE
%
% TLC Configuration Variables Section
%----------------------------
% Assign code format, language, target type.
%
%assign CodeFormat = "Embedded-C"
%assign TargetType = "RT"
%assign Language   = "C"
%
% TLC Program Entry Point
%----------------------------
% Call entry point function.
%include "codegenentry.tlc"
%
% (OPTIONAL) Generate Files for Build Process
%----------------------------
%include "mytarget_genfiles.tlc"
%
```
% RTW_OPTIONS Section
%--------------------------------------------------------
/
BEGIN RTW_OPTIONS
% Define rtwoptions structure array. This array defines target-specific
% code generation variables, and controls how they are displayed.
rtwoptions(1).prompt = 'example code generation options';
...
rtwoptions(6).prompt = 'Show eliminated blocks';
rtwoptions(6).type = 'Checkbox';
...

% Configure RTW code generation settings %
%--------------------------------------------------------%

%-----------------------------------------------------------------
% rtwgensettings Structure
%-----------------------------------------------------------------
% Define suffix text for naming build folder here.
rtwgensettings.BuildDirSuffix = '_mytarget_rtw'
% Callback compatibility declaration
rtwgensettings.Version = '1';

% (OPTIONAL) target inheritance declaration
rtwgensettings.DerivedFrom = 'ert.tlc';
% (OPTIONAL) other rtwGenSettings fields...
...
_END_RTW_OPTIONS
%
%-----------------------------------------------------------------
% targetComponentClass - MATHWORKS INTERNAL USE ONLY
% REMOVE NEXT SECTION FROM USER_DEFINED CUSTOM TARGETS
%-----------------------------------------------------------------
/
BEGIN_CONFIGSET_TARGET_COMPONENT

targetComponentClass = 'Simulink.ERTTargetCC';
_END_CONFIGSET_TARGET_COMPONENT
%

If you are creating a custom target based on an existing STF, you must remove the
targetComponentClass section (bounded by the directives
BEGIN_CONFIGSET_TARGET_COMPONENT and END_CONFIGSET_TARGET_COMPONENT).
This section is reserved for the use of targets developed internally by MathWorks.

Header Comments

These lines at the head of the file are formatted as TLC comments. They provide required
information to the System Target File Browser and to the build process. Note that you
must place the browser comments at the head of the file, before other comments or TLC
statements.
The presence of the comments enables the code generator to detect STFs. When the System Target File Browser is opened, the code generator scans the MATLAB path for TLC files that have formatted header comments. The comments contain the following directives:

- **SYSTLC**: The descriptor that appears in the browser.
- **TMF**: Name of the template makefile (TMF) to use during build process. When the target is selected, this filename is displayed in the “Template makefile” (Simulink Coder) field of the **Code Generation** pane of the Configuration Parameters dialog box.
- **MAKE**: Make command to use during build process. When the target is selected, this command is displayed in the **Make command** field of the **Code Generation** pane of the Configuration Parameters dialog box.
- **EXTMODE**: Name of external mode interface file (if any) associated with your target. If your target does not support external mode, use **no_ext_comm**.

The following header comments are from **matlabroot/rtw/c/ert/ert.tlc**.

```matlab
%% SYSTLC: Embedded Coder TMF: ert_default_tmf MAKE: make_rtw 
%%   EXTMODE: ext_comm
%% SYSTLC: Create Visual C/C++ Solution File for Embedded Coder
%%   TMF: RTW.MSVCBuild MAKE: make_rtw EXTMODE: ext_comm
```

**Note**

- Limitation: Each comment can only contain a maximum of two lines, as shown in the preceding example.
- If you do not specify the TMF or EXTMODE fields in the system target file, the file is still valid. To change the values for the parameters **Template makefile** (TemplateMakefile) and **External mode** (ExtMode), you can instead use the callback function specified by `rtwgensettings.SelectCallback`.

Note that you can specify more than one group of directives in the header comments. Each such group is displayed as a different target configuration in the System Target File Browser. In the above example, the first two lines of code specify the default configuration of the ERT target. The next two lines specify a configuration that creates and builds a Microsoft Visual C++ Solution (.sln) file. The figure below shows how these configurations appear in the System Target File Browser.
See “Create a Custom Target Configuration” on page 74-48 for an example of customized header comments.

**TLC Configuration Variables**

This section of the STF assigns global TLC variables that relate to the overall code generation process.

For an embedded target, in most cases you should simply use the global TLC variable settings used by the ERT target (ert.tlc). It is especially important that your STF use the 'Embedded-C' value for the CodeFormat TLC variable and uses the corresponding rtwgensettings.DerivedFrom = 'ert.tlc' in the RTW_OPTIONS section of the TLC file. Verify that values are assigned to the following variables:

- **CodeFormat**: The CodeFormat TLC variable selects generated code features. The 'Embedded-C' value for this variable is used by the ERT target. Your ERT-based target should specify 'Embedded-C' as the value for CodeFormat. This selection is designed for production code, minimal memory usage, static memory allocation, and a simplified interface to generated code.

  For information on other values for the CodeFormat TLC variable, see “Compare System Target File Support” (Simulink Coder).

- **Language**: The only valid value is C, which enables support for C or C++ code generation as specified by the configuration parameter TargetLang.

- **TargetType**: The code generator defines the preprocessor symbols RT and NRT to distinguish simulation code from real-time code. These symbols are used in conditional compilation. The TargetType variable determines whether RT or NRT is defined.
Most targets are intended to generate real-time code. They assign `TargetType` as follows.

```plaintext
%assign TargetType = "RT"
```

Some targets, such as the model reference simulation target, accelerated simulation target, RSim target, and S-function target, generate code for use in nonreal time only. Such targets assign `TargetType` as follows.

```plaintext
%assign TargetType = "NRT"
```

**TLC Program Entry Point and Related %includes**

The code generation process normally begins with `codegenentry.tlc`. The STF invokes `codegenentry.tlc` as follows.

```plaintext
%include "codegenentry.tlc"
```

**Note** `codegenentry.tlc` and the lower-level TLC files assume that `CodeFormat`, `TargetType`, and `Language` have been assigned. Set these variables before including `codegenentry.tlc`.

If you need to implement target-specific code generation features, you should include the TLC file `mytarget_genfiles.tlc` in your STF. This file provides a mechanism for executing custom TLC code before and after invoking `codegenentry.tlc`. For information on this mechanism, see

- “Using `mytarget_genfiles.tlc`” on page 74-45 for an example of custom TLC code for execution after the main code generation entry point.
- “Target Development and the Build Process” on page 74-23 for general information on the build process, and for information on other build process customization hooks.

Another way to customize the code generation process is to call lower-level functions (normally invoked by `codegenentry.tlc`) directly, and include your own TLC functions at each stage of the process. This approach should be taken with caution. See “TLC Files” (Simulink Coder) for more information.

The lower-level functions called by `codegenentry.tlc` are

- `genmap.tlc`: maps block names to corresponding language-specific block target files.
• commonsetup.tlc: sets up global variables.
• commonentry.tlc: starts the process of generating code.

**RTW_OPTIONS Section**

The RTW_OPTIONS section is bounded by the directives:

```
/%
  BEGIN_RTW_OPTIONS
  .
  .
  END_RTW_OPTIONS
%/```

The first part of the RTW_OPTIONS section defines an array of rtwoptions structures. This structure is discussed in “Using rtwoptions to Display Custom Target Options” on page 74-37.

The second part of the RTW_OPTIONS section defines rtwgensettings, a structure defining the build folder name and other settings for the code generation process. See “rtwgensettings Structure” on page 74-34 for information about rtwgensettings.

**rtwgensettings Structure**

The final part of the STF defines the rtwgensettings structure. This structure stores information that is written to the model.rtw file and used by the build process. The rtwgensettings fields of most interest to target developers are

• rtwgensettings.Version: Use this property to enable rtwoptions callbacks and to use the Callback API in rtwgensettings.SelectCallback.

**Note** To use callbacks, you must set:

```
rtwgensettings.Version = '1';
```

Add the statement above to the Configure RTW code generation settings section of the system target file.
• **rtwgensettings.DerivedFrom**: This structure field defines the system target file from which options are to be inherited. See “Inheriting Target Options” on page 74-44.

• **rtwgensettings.SelectCallback**: This structure field specifies a SelectCallback function. You must set rtwgensettings.Version = '1'; or your callback will be ignored. SelectCallback is associated with the target rather than with any of its individual options. The SelectCallback function is triggered when the user selects a target with the System Target File browser.

The SelectCallback function is useful for setting up (or disabling) configuration parameters specific to the target.

The following code installs a SelectCallback function:

```matlab
rtwgensettings.SelectCallback = 'my_select_callback_handler(hDlg,hSrc)';
```

The arguments to the SelectCallback function (hDlg, hSrc) are handles to private data used by the callback API functions.

**Note** If you have developed a custom target and you want it to be compatible with model referencing, you must implement a SelectCallback function to declare model reference compatibility. See “Support Model Referencing” on page 74-84.

• **rtwgensettings.ActivateCallback**: this property specifies an ActivateCallback function. The ActivateCallback function is triggered when the active configuration set of the model changes. This could happen during model loading, and also when the user changes the active configuration set.

The following code installs an ActivateCallback function:

```matlab
rtwgensettings.ActivateCallback = 'my_activate_callback_handler(hDlg,hSrc)';
```

The arguments to the ActivateCallback function (hDlg, hSrc) are handles to private data used by the callback API functions.

• **rtwgensettings.PostApplyCallback**: this property specifies a PostApplyCallback function. The PostApplyCallback function is triggered when the user clicks the **Apply** or **OK** button after editing options in the Configuration Parameters dialog box. The PostApplyCallback function is called after the changes have been applied to the configuration set.

The following code installs an PostApplyCallback function:

```matlab
rtwgensettings.PostApplyCallback = 'my_postapply_callback_handler(hDlg,hSrc)';
```
The arguments to the `PostApplyCallback` function (hDlg, hSrc) are handles to private data used by the callback API functions.

- `rtwgensettings.BuildDirSuffix`: Most targets define a folder name suffix that identifies build folders created by the target. The build process appends the suffix defined in the `rtwgensettings.BuildDirSuffix` field to the model name to form the name of the build folder. For example, if you define `rtwgensettings.BuildDirSuffix` as follows

  ```
  rtwgensettings.BuildDirSuffix = '_mytarget_rtw'
  ```

  the build folders are named `model_mytarget_rtw`.

### Additional Code Generation Options

“Configure Generated Code with TLC” (Simulink Coder) describes additional TLC code generation variables. End users of a target can assign these variables by entering a MATLAB command of the form

```plaintext
set_param(modelName,'TLCOptions','-aVariable=val');
```

(For more information, see “Specify TLC for Code Generation” (Simulink Coder).)

However, the preferred approach is to assign these variables in the STF using statements of the form:

```plaintext
%assign Variable = val
```

For readability, we recommend that you add such assignments in the section of the STF after the comment `Configure RTW code generation settings`.

### Model Reference Considerations

See “Support Model Referencing“ on page 74-84 for important information on STF and other modifications you may need to make to support the code generator model referencing features.

### Define and Display Custom Target Options

- “Using rtwoptions to Display Custom Target Options“ on page 74-37
- “Example System Target File With Customized rtwoptions“ on page 74-42
- “Inheriting Target Options” on page 74-44
**Using rtwoptions to Display Custom Target Options**

You control the options to display in the **Code Generation** pane of the Configuration Parameters dialog box by customizing the `rtwoptions` structure in your system target file.

The fields of the `rtwoptions` structure define variables and associated user interface elements to be displayed in the Configuration Parameters dialog box. Using the `rtwoptions` structure array, you can define target-specific options displayed in the dialog box and organize options into categories. You can also write callback functions to specify how these options are processed.

When the **Code Generation** pane opens, the `rtwoptions` structure array is scanned and the listed options are displayed. Each option is represented by an assigned user interface element (check box, edit field, menu, or push button), which displays the current option value.

The user interface elements can be in an enabled or disabled (grayed-out) state. If an option is enabled, the user can change the option value.

You can also use the `rtwoptions` structure array to define special NonUI elements that cause callback functions to be executed, but that are not displayed in the **Code Generation** pane. See “NonUI Elements” on page 74-42 for details.

The elements of the `rtwoptions` structure array are organized into groups. Each group of items begins with a header element of type Category. The default field of a Category header must contain a count of the remaining elements in the category.

The Category header is followed by options to be displayed on the **Code Generation** pane. The header in each category is followed by one or more option definition elements.

Each category of target options corresponds to options listed under **Code Generation** in the Configuration Parameters dialog box.

The table `rtwoptions` Structure Fields Summary summarizes the fields of the `rtwoptions` structure.

**Example rtwoptions Structure**

The following `rtwoptions` structure is excerpted from an example system target file, `matlabroot/toolbox/rtw/rtwdemos/rtwoptions_demo/usertarget.tlc`. The code defines an `rtwoptions` structure array. The default field of the first (header) element is set to 4, indicating the number of elements that follow the header.
rtwoptions(1).prompt = 'userPreferred target options (I)';
rtwoptions(1).type  = 'Category';
rtwoptions(1).enable = 'on';
rtwoptions(1).default = 4; % number of items under this category
% excluding this one.
rtwoptions(1).popupstrings = ''; % At the first item, user has to
rtwoptions(1).tlcvariable = ''; % initialize all supported fields
rtwoptions(1).tooltip = ''; 
rtwoptions(1).callback = ''; 
rtwoptions(1).makevariable = '';

rtwoptions(2).prompt = 'Execution Mode';
rtwoptions(2).type  = 'Popup';
rtwoptions(2).default = 'Real-Time';
rtwoptions(2).popupstrings = 'Real-Time|UserDefined';
rtwoptions(2).tlcvariable = 'tlcvariable1';
rtwoptions(2).tooltip = ['See this text as tooltip'];

rtwoptions(3).prompt = 'Log Execution Time';
rtwoptions(3).type  = 'Checkbox';
rtwoptions(3).default = 'on';
rtwoptions(3).tlcvariable = 'RL32LogTETModifier';
rtwoptions(3).tooltip = ['']; % no tooltip

rtwoptions(4).prompt = 'Real-Time Interrupt Source';
rtwoptions(4).type  = 'Popup';
rtwoptions(4).default = 'Timer';
rtwoptions(4).popupstrings = 'Timer|5|6|7|8|9|10|11|12|13|14|15';
rtwoptions(4).tlcvariable = 'tlcvariable3';
rtwoptions(4).callback = 'usertargetcallback(hDlg, hSrc, ''tlcvariable3'')';
rtwoptions(4).tooltip = ['See TLC file for how to use reserved ...'
  ' keyword ''hDlg'', and ''hSrc''...'];

rtwoptions(5).prompt = 'Signal Logging Buffer Size in Doubles';
rtwoptions(5).type  = 'Edit';
rtwoptions(5).default = '100000';
rtwoptions(5).tlcvariable = 'tlcvariable2';
rtwoptions(5).tooltip = [''];

The first element adds a **userPreferred target options (I)** pane under **Code Generation** in the Configuration Parameters dialog box. The pane displays the options defined in rtwoptions(2), rtwoptions(3), rtwoptions(4), and rtwoptions(5).
If you want to define a large number of options, you can define multiple Category groups within a single system target file.

Note the rtwoptions structure and callbacks are written in MATLAB code, although they are embedded in a TLC file. To verify the syntax of your rtwoptions structure definitions and code, you can execute the commands at the MATLAB prompt by copying and pasting them to the MATLAB Command Window.

To learn more about usertarget.tlc and the example callback files provided with it, see “Example System Target File With Customized rtwoptions” on page 74-42. For more examples of target-specific rtwoptions definitions, see the target.tlc files under matlabroot/rtw/c (open).
rtwoptions Structure Fields Summary lists the fields of the `rtwoptions` structure.
rtwoptions Structure Fields Summary

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>callback</td>
<td>For examples of callback usage, see “Example System Target File With Customized rtwoptions” on page 74-42.</td>

<td>tooltip</td>
<td>Help text displayed when mouse is over the item.</td>
</tr>
<tr>
<td>type</td>
<td>Type of element: Checkbox, Edit, NonUI, Popup, Pushbutton, or Category.</td>
</tr>
</tbody>
</table>

**NonUI Elements**

Elements of the `rtwoptions` array that have type NonUI exist solely to invoke callbacks. A NonUI element is not displayed in the Configuration Parameters dialog box. You can use a NonUI element if you want to execute a callback that is not associated with a user interface element, when the dialog box opens or closes. See the next section, “Example System Target File With Customized rtwoptions” on page 74-42 for an example.

**Note** The default value of an element of type NonUI or Edit determines the set of values allowed for that element.

- If the default value is '0' or '1':
  - For type NonUI, the element stores a Boolean value.
  - For type Edit, the element stores a value of type int32.
- If the default value contains an integer other than '0' or '1', the element stores a value of type int32.
- If the default value does not contain an integer, the element is evaluated as a character vector.

**Example System Target File With Customized rtwoptions**

A working system target file, with MATLAB file callback functions, has been provided as an example of how to use the `rtwoptions` structure to display and process custom
options on the **Code Generation** pane. The examples are compatible with the callback API.

The example target files are in the folder (open):

```
matlabroot/toolbox/rtw/rtwdemos/rtwoptions_demo
```

The example target files include:

- **usertarget.tlc**: The example system target file. This file illustrates how to define custom menus, check boxes, and edit fields. The file also illustrates the use of callbacks.
- **usertargetcallback.m**: A MATLAB file callback invoked by a menu.

Refer to the example files while reading this section. The example system target file, **usertarget.tlc**: illustrates the use of **rtwoptions** to display the following custom target options:

- The **Execution Mode** menu.
- The **Log Execution Time** check box.
- The **Real-Time Interrupt Source** menu. The menu executes a callback defined in an external file, **usertargetcallback.m**. The TLC variable associated with the menu is passed in to the callback, which displays the menu's current value.
- The edit field **Signal Logging Buffer Size in Doubles**.

Try studying the example code while interacting with the example target options in the Configuration Parameters dialog box. To interact with the example target file,

1. Make `matlabroot/toolbox/rtw/rtwdemos/rtwoptions_demo` (open) your working folder.
2. Open a model of your choice.
3. Open the Configuration Parameters dialog box and select the **Code Generation** pane.
4. Click **Browse**. The System Target File Browser opens. Select `usertarget.tlc`. Then click **OK**.
5. Observe that the **Code Generation** pane contains a custom sub-tab: **userPreferred target options** (I).
6. As you interact with the options in this category and open and close the Configuration Parameters dialog box, observe the messages displayed in the MATLAB
Command Window. These messages are printed from code in the STF, or from callbacks invoked from the STF.

**Inheriting Target Options**

er.tlc provides a basic set of Embedded Coder code generation options. If your target is based on er.tlc, your STF should normally inherit the options defined in ERT.

Use the rtwgensettings.DerivedFrom field in the rtwgensettings structure to define the system target file from which options are to be inherited. You should convert your custom target to use this mechanism as follows.

Set the rtwgensettings.DerivedFrom field value as in the following example:

```matlab
rtwgensettings.DerivedFrom = 'stf.tlc';
```

where stf is the name of the system target file from which options are to be inherited. For example:

```matlab
rtwgensettings.DerivedFrom = 'ert.tlc';
```

When the Configuration Parameters dialog box executes this line of code, it includes the options from stf.tlc automatically. If stf.tlc is a MathWorks internal system target file that has been converted to a new layout, the dialog box displays the inherited options using the new layout.

**Handling Unsupported Options**

If your target does not support all of the options inherited from er.tlc, you should detect unsupported option settings and display a warning or error message. In some cases, if a user has selected an option your target does not support, you may need to abort the build process. For example, if your target does not support the **Generate an example main program** option, the build process should not be allowed to proceed if that option is selected.

Even though your target may not support all inherited ERT options, it is required that the ERT options are retained in the Code Generation pane of the Configuration Parameters dialog box. Do not simply remove unsupported options from the rtwoptions structure in the STF. Options must be in the dialog box to be scanned by the code generator when it performs optimizations.

For example, you may want to prevent users from turning off the **Single output/update function** option. It may seem reasonable to remove this option from the dialog box and
simply assign the TLC variable `CombineOutputUpdateFcns` to `on`. However, if the option is not included in the dialog box, the code generator assumes that output and update functions are `not` to be combined. Less efficient code is generated as a result.

**Tips and Techniques for Customizing Your STF**

- “Introduction” on page 74-45
- “Required and Recommended %includes” on page 74-45
- “Handling Aliases for Target Option Values” on page 74-46
- “Supporting Multiple Development Environments” on page 74-48

**Introduction**

The following sections include information on techniques for customizing your STF, including

- How to invoke custom TLC code from your STF
- Approaches to supporting multiple development environments

**Required and Recommended %includes**

If you need to implement target-specific code generation features, we recommend that your STF include the TLC file `mytarget_genfiles.tlc`.

Once your STF has set up the required TLC environment, you must include `codegenentry.tlc` to start the standard code generation process.

`mytarget_genfiles.tlc` provides a mechanism for executing custom TLC code after the main code generation entry point. See “Using `mytarget_genfiles.tlc`” on page 74-45.

**Using `mytarget_genfiles.tlc`**

`mytarget_genfiles.tlc` (optional) is useful as a central file from which to invoke target-specific TLC files that generate additional files as part of your target build process. For example, your target may create sub-makefiles or project files for a development environment, or command scripts for a debugger to do automatic downloads.

The build process can then invoke these generated files either directly from the make process, or after the executable is created. This is done with the `STF_make_rtw_hook.m` mechanism, as described in “Customize Build Process with STF_make_rtw_hook File” (Simulink Coder).
The following TLC code shows an example mytarget_genfiles.tlc file.

```tcl
%selectfile NULL_FILE

%assign ModelName = CompiledModel.Name

%%% Create Debugger script
%assign model_script_file = "%<ModelName>.cfg"
%assign script_file = "debugger_script_template.tlc"

%if RTWVerbose
   %selectfile STDOUT
   ### Creating %<model_script_file>
   %selectfile NULL_FILE
%endif

#include "%<script_file>"
%openfile bld_file = "%<model_script_file>"
%<CreateDebuggerScript()>
%closefile bld_file
```

**Handling Aliases for Target Option Values**

This section describes utility functions that can be used to detect and resolve alias values or legacy values when testing user-specified values for the target device type (ProdHWDeviceType) and the code replacement library (CodeReplacementLibrary).

**RTW.isHWDeviceTypeEq**

To test if two target device type values represent the same hardware device, invoke the following function:

```tcl
result = RTW.isHWDeviceTypeEq(type1,type2)
```

where `type1` and `type2` are character vectors containing target device type values or aliases.

The `RTW.isHWDeviceTypeEq` function returns true if `type1` and `type2` are character vectors representing the same hardware device. For example, the following call returns true:

```tcl
RTW.isHWDeviceTypeEq('Specified','Generic->Custom')
```
For a description of the target device type option `ProdHWDeviceType`, see the command-line information for the **Hardware Implementation** pane parameters “Device vendor” (Simulink) and “Device type” (Simulink).

**RTW.resolveHWDeviceType**

To return the device type value for a hardware device, given a value that might be an alias or legacy value, invoke the following function:

```
result = RTW.resolveHWDeviceType(type)
```

where `type` is a character vector containing a target device type value or alias.

The `RTW.resolveHWDeviceType` function returns the device type value of the device. For example, the following calls both return `'Generic->Custom'`:

```
RTW.resolveHWDeviceType('Specified')
RTW.resolveHWDeviceType('Generic->Custom')
```

For a description of the target device type option `ProdHWDeviceType`, see the command-line information for the **Hardware Implementation** pane parameters “Device vendor” (Simulink) and “Device type” (Simulink).

**RTW.isTflEq**

To test if two code replacement library (CRL) names represent the same CRL, invoke the following function:

```
result = RTW.isTflEq(name1,name2)
```

where `name1` and `name2` are character vectors containing CRL values or aliases.

The `RTW.isTflEq` function returns true if `name1` and `name2` are character vectors representing the same code replacement library. For example, the following call returns true:

```
RTW.isTflEq('GNU','GNU C99 extensions')
```

For a description of the `CodeReplacementLibrary` parameter, see “Code replacement library” (Simulink Coder).

**RTW.resolveTflName**

To return the CRL value for a code replacement library, given a value that might be an alias or legacy value, invoke the following function:
result = RTW.resolveTflName(name)

where name is a character vector containing a CRL value or alias.

The RTW.resolveTflName function returns the value of the referenced code replacement library. For example, the following calls both return 'GNU C99 extensions':

RTW.resolveTflName('GNU')
RTW.resolveTflName('GNU C99 extensions')

For a description of the CodeReplacementLibrary parameter, see “Code replacement library” (Simulink Coder).

Supporting Multiple Development Environments

Your target may require support for multiple development environments (for example, two or more cross-compilers) or multiple modes of code generation (for example, generating a binary executable versus generating a project file for your compiler).

One approach to this requirement is to implement multiple STFs. Each STF invokes a template makefile for the development environment. This amounts to providing two separate targets.

Create a Custom Target Configuration

- “my_ert_target Overview” on page 74-49
- “Creating Target Folders” on page 74-51
- “Create ERT-Based, Toolchain Compliant STF” on page 74-52
- “Create ERT-Based TMF” on page 74-58
- “Create Test Model and S-Function” on page 74-58
- “Verify Target Operation” on page 74-59

Introduction

This tutorial can supplement the example target guides described in “Sample Custom Targets” on page 74-9. For an introduction and example files, try the example targets first.
This tutorial guided you through the process of creating an ERT-based target, my_ert_target. This exercise illustrates several tasks, which are typical for creating a custom target:

- Setting up target folders and modifying the MATLAB path.
- Making modifications to a standard STF and TMF such that the custom target is visible in the System Target File Browser, inherits ERT options, displays target-specific options, and generates code with the default host-based compiler.
- Testing the build process with the custom target, using a simple model that incorporates an inlined S-function.

During this exercise, you implement an operational, but skeletal, ERT-based target. This target can be useful as a starting point in a complete implementation of a custom embedded target.

my_ert_target Overview

In the following sections, you create a skeletal target, my_ert_target. The target inherits and supports the standard options of the ERT target and displays additional target-specific options in the Configuration Parameters dialog box (see “Target-Specific Options for my_ert_target” on page 74-50).
Target-Specific Options for my_ert_target

my_ert_target supports a toolchain-based build, generating code and executables that run on the host system. my_ert_target uses the lcc compiler on a Microsoft Windows platform. The chosen compiler is readily available and is distributed with the code generator. On a Microsoft Windows platform, if you use a different compiler, you can set up lcc temporarily as your default compiler through the following MATLAB command:

```
mex -setup
```

The software displays links for supported compilers that are installed on your computer. Click the lcc link.
Note On Linux systems, make sure that you have an installed C compiler. If so, you can use Linux folder syntax to complete this exercise.

my_ert_target can also support template makefile-based builds. For more information about using this target with the template makefile approach, see “Create ERT-Based TMF” on page 74-58.

You can test my_ert_target with a model that is compatible with the ERT target (see “Configure a System Target File” on page 33-2). Generated programs operate identically to ERT generated programs.

To simplify the testing of your target, test with targetmodel, a very simple fixed-step model (see “Create Test Model and S-Function” on page 74-58). The S-Function block in targetmodel uses the source code from the timestwo example, and generates fully inlined code. See “S-Function Examples” (Simulink) and “Inline S-Functions with TLC” (Simulink Coder) for further discussion of the timestwo example S-function.

Creating Target Folders

Create folders to store the target files and add them to the MATLAB path, following the recommended conventions (see “Folder and File Naming Conventions” on page 74-11). You also create a folder to store the test model, S-function, and generated code.

This example assumes that your target and model folders are located within the folder c:/work. Do not place your target and model folders within the MATLAB folder tree (that is, in or under the matlabroot folder).

To create the folders and make them accessible:

1. Create a target root folder, my_ert_target. From the MATLAB Command Window on a Windows platform, enter:

   cd c:/work
   mkdir my_ert_target

2. Within the target root folder, create a subfolder to store your target files.

   mkdir my_ert_target/my_ert_target

3. Add these folders to your MATLAB path.

   addpath c:/work/my_ert_target
   addpath c:/work/my_ert_target/my_ert_target

4. Create a folder, my_targetmodel, to store the test model, S-function, and generated code.
Create ERT-Based, Toolchain Compliant STF

Create an STF for your target by copying and modifying the standard STF for the ERT target. Then, validate the STF by viewing the new target in the System Target File Browser and in the Configuration Parameters dialog box.

Editing the STF

To edit the STF, use these steps:

1. Change your working folder to the folder you created in “Creating Target Folders” on page 74-51.
   ```bash
cd c:/work/my_ert_target/my_ert_target
   ```

2. Place a copy of `matlabroot/rtw/c/ert/ert.tlc` in `c:/work/my_ert_target/my_ert_target` and rename it to `my_ert_target.tlc`. The file `ert.tlc` is the STF for the ERT target.

3. Open `my_ert_target.tlc` in a text editor of your choice.

4. Customize the STF, replacing the header comment lines with directives that make your STF visible in the System Target File Browser and define the associated TMF, make command, and external mode interface file (if any). For more information about these directives, see “Header Comments” on page 74-30.

Replace the header comments in `my_ert_target.tlc` with the following header comments.

```matlab
%% SYSTLC: My ERT-based Target TMF: my_ert_target_lcc.tmf MAKE: make_rtw \\
%%   EXTMODE: no_ext_comm
```

5. The file `my_ert_target.tlc` inherits the standard ERT options, using the mechanism described in “Inheriting Target Options” on page 74-44. Therefore, the existing `rtwoptions` structure definition is superfluous. Edit the `RTW_OPTIONS` section such that it includes only the following code.

```matlab
/%
BEGIN_RTW_OPTIONS
  %----------------------------------------%
  % Configure RTW code generation settings %
  %----------------------------------------%
  rtwgensettings.BuildDirSuffix = '\ert_rtw';
END_RTW_OPTIONS
/%
```
Delete the code after the end of the RTW_OPTIONS section, which is delimited by the directives BEGIN_CONFIGSET_TARGET_COMPONENT and END_CONFIGSET_TARGET_COMPONENT. This code is for use only by internal MathWorks developers.

Modify the build folder suffix in the rtwgenSettings structure in accordance with the conventions described in “rtwgensettings Structure” on page 74-34.

To set the suffix to a character vector for the _my_ert_target custom target, change the line

```matlab
rtwgensettings.BuildDirSuffix = '_ert_rtw'
```

to

```matlab
rtwgensettings.BuildDirSuffix = '_my_ert_target_rtw'
```

Modify the rtwgenSettings structure to inherit options from the ERT target and declare Release 14 or later compatibility as described in “rtwgensettings Structure” on page 74-34. Add the following code to the rtwgenSettings definition:

```matlab
rtwgensettings.DerivedFrom = 'ert.tlc';
rtwgensettings.Version = '1';
```

Add an rtwoptions structure that defines a target-specific options category with three check boxes just after the BEGIN_RTW_OPTIONS directive. The following code shows the complete RTW_OPTIONS section, including the previous rtwgenSettings changes.

```matlab
/*
BEIN_RTW_OPTIONS

rtwoptions(1).prompt = 'My Target Options';
rtwoptions(1).type = 'Category';
rtwoptions(1).enable = 'on';
rtwoptions(1).default = 3; % number of items under this category
rtwoptions(1).popupstrings = ''; % excluding this one.
rtwoptions(1).tlcvariable = '';
rtwoptions(1).tooltip = '';
rtwoptions(1).callback = '';
rtwoptions(1).makevariable = '';

rtwoptions(2).prompt = 'Demo option 1';
rtwoptions(2).type = 'Checkbox';
rtwoptions(2).default = 'off';
rtwoptions(2).tlcvariable = 'DummyOpt1';
rtwoptions(2).makevariable = ';
rtwoptions(2).tooltip = ['Demo opt1 (non-functional)'];
rtwoptions(2).callback = '';
*/
rtwoptions(3).prompt         = 'Demo option 2';
rtwoptions(3).type           = 'Checkbox';
rtwoptions(3).default        = 'off';
rtwoptions(3).tlcvariable    = 'DummyOpt2';
rtwoptions(3).makevariable   = '';
rtwoptions(3).tooltip        = ['Demo option2 (non-functional)'];
rtwoptions(3).callback       = '';

rtwoptions(4).prompt         = 'Demo option 3';
rtwoptions(4).type           = 'Checkbox';
rtwoptions(4).default        = 'off';
rtwoptions(4).tlcvariable    = 'DummyOpt3';
rtwoptions(4).makevariable   = '';
rtwoptions(4).tooltip        = ['Demo option3 (non-functional)'];
rtwoptions(4).callback       = '';

%----------------------------------------%
% Configure RTW code generation settings%
%----------------------------------------%

rtwgensettings.BuildDirSuffix = '_my_ert_target_rtw';
rtwgensettings.DerivedFrom   = 'ert.tlc';
rtwgensettings.Version       = '1';
rtwgensettings.SelectCallback = 'enableToolchainCompliant(hSrc, hDlg)';
%SelectCallback provides toolchain approach support, but requires custom function
%Omit this SelectCallback if using the template makefile approach

END_RTW_OPTIONS

10 Save your changes to my_ert_target.tlc and close the file.

Create ToolchainCompliant Function

To enable builds using the toolchain approach, you create a function that corresponds to the SelectCallback near the end of the custom STF. This function sets properties for toolchain compliance.

function enableToolchainCompliant(hSrc, hDlg)
    hCS = hSrc.getConfigSet();

    % The following parameters enable toolchain compliance.
    slConfigUISetVal(hDlg, hSrc, 'UseToolchainInfoCompliant', 'on');
    hCS.setProp('GenerateMakefile','on');

    % The following parameters are not required for toolchain compliance. % But, it is recommended practice to set these default values and % disable the parameters (as shown).
    hCS.setProp('RTWCompilerOptimization','off');
    hCS.setProp('MakeCommand','make_rtw');
    hCS.setPropEnabled('RTWCompilerOptimization',false);
    hCS.setPropEnabled('MakeCommand',false);
end
Note If you are using the template makefile approach, omit calling the function enabling toolchain-compliance from your STF file. Instead, use the information in “Create ERT-Based TMF” on page 74-58.

Viewing the STF

At this point, you can verify that the target inherits and displays ERT options as follows:

1 Create a new model.
2 Open the Model Explorer or the Configuration Parameters dialog box.
3 Select the Code Generation pane.
4 Click Browse to open the System Target File browser.
5 In the file browser, scroll through the list of targets to find the new target, my_ert_target.tlc. (This step assumes that your MATLAB path contains c:/work/my_ert_target/my_ert_target, as previously set in “Creating Target Folders” on page 74-51.)
6 Select My ERT-based Target and click OK.

7 The Code Generation pane now shows that the model is configured for the my_ert_target.tlc target. The System target file, Language, Toolchain, and Build configuration fields should appear:
Select the **My Target Options** pane. The target displays the three check box options defined in the `rtwoptions` structure.
Select the **Code Generation** pane and reopen the System Target File Browser.

Select the Embedded Coder target (**ert.tlc**). The target displays the standard ERT options.

Close the model. You do not need to save it.

The STF for the skeletal target is complete. If you are using the toolchain approach, you are ready to invoke the build process for your target.

If you prefer to use the template makefile approach, the reference to a TMF, **my_ert_target_lcc.tmf**, in the STF header comments prevents you from invoking the build process for your target until the TMF file is in place. First, you must create a **my_ert_target_lcc.tmf** file.
Create ERT-Based TMF

If you are using the toolchain makefile approach with a toolchain compliant custom target, omit the steps that apply to the template makefile approach. (Skip this section.)

If you are using the templated makefile approach, follow the steps applying to TMF and omit calling the function enabling toolchain-compliance from your STF file, which is described in “Create ERT-Based, Toolchain Compliant STF” on page 74-52.

Create a TMF for your target by copying and modifying the standard ERT TMF for the LCC compiler:

1. Make sure that your working folder is still set to the target file folder you created previously in “Creating Target Folders” on page 74-51.
   
   `c:/work/my_ert_target/my_ert_target`

2. Place a copy of `matlabroot/rtw/c/ert/ert_lcc.tmf` in `c:/work/my_ert_target/my_ert_target` and rename it `my_ert_target_lcc.tmf`. The file `ert_lcc.tmf` is the ERT compiler-specific template makefile for the LCC compiler.

3. Open `my_ert_target_lcc.tmf` in a text editor.

4. Change the `SYS_TARGET_FILE` parameter so that the file reference for your `.tlc` file is generated in the `make` file. Change the line

   ```
   SYS_TARGET_FILE = any
   ```

   to

   ```
   SYS_TARGET_FILE = my_ert_target.tlc
   ```

5. Save changes to `my_ert_target_lcc.tmf` and close the file.

Your target can now generate code and build a host-based executable. In the next sections, you create a test model and test the build process using `my_ert_target`.

Create Test Model and S-Function

In this section, you build a simple test model for later use in code generation:

1. Set your working folder to `c:/work/my_targetmodel`.
   
   ```
   cd c:/work/my_targetmodel
   ```

   For the remainder of this tutorial, `my_targetmodel` is assumed to be the working folder. Your target writes the output files of the code generation process into a build
folder within the working folder. When inlined code is generated for the \texttt{timestwo} S-function, the build process looks for the TLC implementation of the S-function in the working folder.

2 Copy the following C and TLC files for the \texttt{timestwo} S-function to your working folder:

   - \texttt{matlabroot/toolbox/simulink/simdemos/simfeatures/src/timestwo.c}
   - \texttt{matlabroot/toolbox/simulink/simdemos/simfeatures/tlc_c/timestwo.tlc}

3 Build the \texttt{timestwo} MEX-file in c:/work/my_targetmodel.
   
   \texttt{mex timestwo.c}

4 Create the following model, using an S-Function block from the Simulink User-Defined Functions library. Save the model in your working folder as \texttt{targetmodel}.

   \begin{center}
   \includegraphics[width=0.5\textwidth]{model.png}
   \end{center}

5 Double-click the S-Function block to open the Block Parameters dialog box. Enter the S-function name \texttt{timestwo}. Click \texttt{OK}. The block is now bound to the \texttt{timestwo} MEX-file.

6 Open Model Explorer or the Configuration Parameters dialog box and select the \texttt{Solver} pane.

7 Set the solver \texttt{Type} to \texttt{fixed-step} and click \texttt{Apply}.

8 Save the model.

9 Open the scope and run a simulation. Verify that the \texttt{timestwo} S-function multiplies its input by 2.0.

Keep the \texttt{targetmodel} model open for use in the next section, in which you generate code using the test model.

\section*{Verify Target Operation}

In this section you configure \texttt{targetmodel} for the \texttt{my_ert_target} custom target, and use the target to generate code and build an executable.
Open the Configuration Parameters dialog box and select the **Code Generation** pane.

Click **Browse** to open the System Target File Browser.

In the Browser, select **My ERT-based Target** and click **OK**.

The Configuration Parameters dialog box now displays the **Code Generation** pane for **my_ert_target**.

Select the **Code Generation > Report** pane and select the **Create code generation report** option.

Click **Apply** and save the model. The model is configured for **my_ert_target**.

Build the model. If the build succeeds, the MATLAB Command Window displays the message below.

```
### Created executable: ../targetmodel.exe
### Successful completion of build procedure for model: targetmodel
```

Your working folder contains the **targetmodel.exe** file and the build folder, **targetmodel_my_ert_target_rtw**, which contains generated code and other files. The working folder also contains an slprj folder, used internally by the build process.

The code generator also creates and displays a code generation report.

To view the generated model code, go to the code generation report window. In the **Contents** pane, click the **targetmodel.c** link.

In **targetmodel.c**, locate the model step function, **targetmodel_step**. Observe the following code.

```c
/* S-Function Block: <Root>/S-Function */
/* Multiply input by two */
targetmodel_B.SFunction = targetmodel_B.SineWave * 2.0;
```

The presence of this code confirms that the **my_ert_target** custom target has generated an inlined output computation for the S-Function block in the model.

Customize Template Makefiles

To configure or customize a template makefile (TMF), you should be familiar with how the make command works and how it processes makefiles. You should also understand makefile build rules. For information on these topics, refer to the documentation provided with the make utility you use.

Template Makefiles and Tokens

TMFs are made up of statements containing tokens. The build process expands tokens and creates a makefile, *model.mk*. TMFs are designed to generate makefiles for specific compilers on specific platforms. The generated *model.mk* file is tailored to compile and link code generated from your model, using commands specific to your development system.

Creation of *model.mk*

Template Makefile Tokens

The `make_rtw` command (or a different command provided with some targets) directs the process of generating *model.mk*. The `make_rtw` command processes the TMF specified on the Code Generation pane of the Configuration Parameters dialog box. `make_rtw` copies the TMF, line by line, expanding each token encountered. Template Makefile Tokens Expanded by `make_rtw` lists the tokens and their expansions.

These tokens are used in several ways by the expanded makefile:

- To control the conditional behavior in the makefile. The conditionals are used to control the source file lists, library names, target to be built, and other build-related information.
• To provide the macro definitions for compiling the files, for example, `-DINTEGRER_CODE=1`.

<td>MODELREF_LINK_LIBS&lt;</td>
</tr>
<tr>
<td>`</td>
<td>MODELREF_LINK_RSPFILE_NAME&lt;</td>
</tr>
</tbody>
</table>
| `|MODELREF_TARGET_TYPE<|` | Type of target being built. Possible values are:  
  - `NONE`: Standalone model or top model referencing other models  
  - `RTW`: Model reference target build  
  - `SIM`: Model reference simulation target build |
| `|RELATIVE_PATH_TO_ANCHOR<|` | Relative path, from the location of the generated makefile, to the MATLAB working folder. |
| `|START_DIR<|` | Current work folder (pwd) at the time the build started. This token is required for parallel builds. |
These tokens are expanded by substitution of parameter values known to the build process. For example, if the source model contains blocks with two different sample times, the TMF statement

NUMST = |>NUMST| 

expands to the following in model.mk.

NUMST = 2

In addition to the above, make_rtw expands tokens from other sources:

- Target-specific tokens defined in the target options of the Configuration Parameters dialog box
- Structures in the rtwoptions section of the system target file. Structures in the rtwoptions structure array that contain the field makevariable are expanded.

The following example is extracted from matlabroot/rtw/c/grt/grt.tlc. The section starting with BEGIN_RTW_OPTIONS contains MATLAB code that sets up rtwoptions. The following directive causes the |>EXT_MODE<| token to be expanded to 1 (on) or 0 (off), depending on how you set the external mode options.

rtwoptions(2).makevariable = 'EXT_MODE'
Invoke the make Utility

• “make Command” on page 74-70
• “make Utility Versions” on page 74-70

make Command

After creating model.mk from your TMF, the build process invokes a make command. To invoke make, the build process issues this command.

makecommand -f model.mk

makecommand is defined by the MAKECMD macro in your target’s TMF (see “Structure of the Template Makefile” on page 74-71). You can specify additional options to make in the Make command field of the Code Generation pane. (See the sections “Specify a Make Command” (Simulink Coder) and “Template Makefiles and Make Options” (Simulink Coder).)

For example, specifying OPT_OPTS=-O2 in the Make command field causes make_rtw to generate the following make command.

makecommand -f model.mk OPT_OPTS=-O2

A comment at the top of the TMF specifies the available make command options. If these options do not provide you with enough flexibility, you can configure your own TMF.

make Utility Versions

The make utility lets you control nearly every aspect of building your real-time program. There are several different versions of make available. The code generator provides the Free Software Foundation GNU make for both UNIX9 and PC platforms in platform-specific subfolders under

matlabroot/bin

It is possible to use other versions of make with the code generator, although GNU Make is recommended. To be compatible with the code generator, verify that your version of make supports the following command format.

makecommand -f model.mk

9. UNIX is a registered trademark of The Open Group in the United States and other countries.
Structure of the Template Makefile

A TMF has multiple sections, including the following:

- **Abstract** — Describes what the makefile targets. Here is a representative abstract from the GRT TMFs in `matlabroot/rtw/c/grt` (open):

  # File : grt_lcc.tmf
  #
  # Abstract:
  # Template makefile for building a PC-based stand-alone generic real-time
  # version of Simulink model using generated C code and LCC compiler
  # Version 2.4.
  #
  # This makefile attempts to conform to the guidelines specified in the
  # IEEE Std 1003.2-1992 (POSIX) standard. It is designed to be used
  # with GNU Make (gmake) which is located in matlabroot/bin/win32.
  #
  # Note that this template is automatically customized by the build
  # procedure to create "<model>.mk"
  #
  # The following defines can be used to modify the behavior of the
  # build:
  # OPT_OPTS       - Optimization options. Default is none. To enable
  #                  debugging specify as OPT_OPTS=-g4.
  # OPTS           - User specific compile options.
  # USER_SRCS      - Additional user sources, such as files needed by
  #                  S-functions.
  # USER_INCLUDES  - Additional include paths
  #                  (i.e. USER_INCLUDES="-Iwhere-ever -Iwhere-ever2")
  #                  (For Lcc, have a '/'as file seperator before the
  #                  file name instead of a '\'.
  #                  i.e., d:\work\proj1/myfile.c - reqd for 'gmake')
  #
  # This template makefile is designed to be used with a system target
  # file that contains 'rtwgensettings.BuildDirSuffix'. See grt.tlc.

- **Macros read by make_rtw section** — Defines macros that tell make_rtw how to process the TMF. Here is a representative Macros read by make_rtw section from the GRT TMFs in `matlabroot/rtw/c/grt` (open):

  # --- Macros read by make_rtw ---
  #
  # The following macros are read by the build procedure:
  #
  # MAKECMD       - The command that invokes the make utility
  # HOST         - The platform (for example, PC) for
  #                which this TMF is written
  # SHELL        - An operating system shell command
  #               (for example, cmd) for the platform
  # BUILD        - The flag that indicates whether to
  #               invoke make from the build procedure
# SYS_TARGET_FILE - Name of system target file.

MAKECMD = "%MATLAB%\bin\win32\gmake"
HOST = PC
SHELL = cmd
BUILD = yes
SYS_TARGET_FILE = grt.tlc
BUILD_SUCCESS = *** Created
COMPILER_TOOL_CHAIN = lcc

MAKEFILE_FILESEP = /

The macros in this section might include:

- **MAKECMD** — Specifies the command used to invoke the make utility. For example, if `MAKECMD = mymake`, then the make command invoked is
  
  mymake -f model.mk

- **HOST** — Specifies the platform targeted by this TMF. This can be PC, UNIX, `computer_name` (see the MATLAB `computer` command), or ANY.

- **SHELL** — Specifies an operating system shell command for the platform. For Windows, this can be `cmd`.

- **BUILD** — Instructs make_rtw whether or not it should invoke make from the build procedure. Specify `yes` or `no`.

- **SYS_TARGET_FILE** — Specifies the name of the system target file or the value `any`. This is used for consistency checking by make_rtw to verify the system target file specified in the **Target selection** panel of the **Code Generation** pane of the Configuration Parameters dialog box. If you specify `any`, you can use the TMF with any system target file.

- **BUILD_SUCCESS** — Optional macro that specifies the build success message to be displayed for make completion on the PC. For example,

  BUILD_SUCCESS = ### Successful creation of

  The `BUILD_SUCCESS` macro, if used, replaces the standard build success message found in the TMFs distributed with the bundled code generator targets (such as GRT):

  @echo ### Created executable $(MODEL).exe

  Your TMF must include either the standard build success message, or use the `BUILD_SUCCESS` macro. For an example of the use of `BUILD_SUCCESS`, see `matlabroot/rtw/c/grt/grt_lcc.tmf` or the code example above this list of macros.
• **BUILD_ERROR** — Optional macro that specifies the build error message to be displayed when an error is encountered during the make procedure. For example,

`BUILD_ERROR = ['Error while building ', modelName]`

• **VERBOSE_BUILD_OFF_TREATMENT = PRINT_OUTPUT_ALWAYS** — Optional macro to include if you want the makefile output to be displayed regardless of the setting of the **Verbose build** option in the **Code Generation > Debug** pane.

• **COMPILER_TOOL_CHAIN** — For builds on Windows systems, specifies which compiler setup file — located in `matlabroot/toolbox/rtw/rtw` (open) — to use:
  - lcc selects `setup_for_lcc.m`
  - vc selects `setup_for_visual.m`
  - vcx64 selects `setup_for_visual_x64.m`
  - default selects `setup_for_default.m`

For builds on UNIX systems, specify `unix`. Other values are flagged as unknown and `make_rtw` uses `setup_for_default.m`.

**Note** Do not omit **COMPILER_TOOL_CHAIN** or leave it unspecified in your TMF. If your compiler is not the host compiler, specify `COMPILER_TOOL_CHAIN = default`.

• **DOWNLOAD** — An optional macro that you can specify as yes or no. If specified as yes (and **BUILD**=yes), then `make` is invoked a second time with the download target.

`make -f model.mk download`

• **DOWNLOAD_SUCCESS** — An optional macro that you can use to specify the download success message to be used when looking for a completed download. For example,

`DOWNLOAD_SUCCESS = ### Downloaded`

• **DOWNLOAD_ERROR** — An optional macro that you can use to specify the download error message to be displayed when an error is encountered during the download. For example,

`DOWNLOAD_ERROR = ['Error while downloading ', modelName]`
• **Tokens expanded by make_rtw section** — Defines the tokens that make_rtw expands. Here is a brief excerpt from a representative Tokens expanded by make_rtw section from the GRT TMFs in `matlabroot/rtw/c/grt` (open):

```makefile
#---------------------- Tokens expanded by make_rtw ----------------------------
#
# The following tokens, when wrapped with "|>" and "<|" are expanded by the
# build procedure.
#
# MODEL_NAME          - Name of the Simulink block diagram
# MODEL_MODULES       - Any additional generated source modules
# MAKEFILE_NAME       - Name of makefile created from template makefile <model>.mk
# MATLAB_ROOT         - Path to where MATLAB is installed.
...

MODEL = |>MODEL_NAME<|
MODULES = |>MODEL_MODULES<|
MAKEFILE = |>MAKEFILE_NAME<|
MATLAB_ROOT = |>MATLAB_ROOT<|
...
```

For more information about TMF tokens, see Template Makefile Tokens Expanded by make_rtw.

• Subsequent sections vary based on compiler, host, and target. Some common sections include Model and reference models, External mode, Tool Specifications or Tool Definitions, Include Path, C Flags, Additional Libraries, and Source Files.

• **Rules section** — Contains the make rules used in building an executable from the generated source code. The build rules are typically specific to your version of make. The Rules section might be followed by related sections such as Dependencies.

### Customize and Create Template Makefiles

- “Introduction” on page 74-75
- “Setting Up a Template Makefile” on page 74-75
- “Using Macros and Pattern Matching Expressions in a Template Makefile” on page 74-75
- “Customizing Generated Makefiles with rtwmakecfg” on page 74-77
- “Supporting Continuous Time in Custom Targets” on page 74-78
- “Model Reference Considerations” on page 74-79
**Introduction**

This section describes the mechanics of setting up a custom template makefile (TMF) and incorporating it into the build process. It also discusses techniques for modifying a TMF and MATLAB file mechanisms associated with the TMF.

Before creating a custom TMF, you should read “Folder and File Naming Conventions” on page 74-11 to understand the folder structure and MATLAB path requirements for custom targets.

**Setting Up a Template Makefile**

To customize or create a new TMF, you should copy an existing GRT or ERT TMF from one of the following locations:

```
matlabroot/rtw/c/grt (open)
matlabroot/rtw/c/ert (open)
```

Place the copy in the same folder as the associated system target file (STF). Usually, this is the `mytarget/mytarget` folder within the target folder structure. Then, rename your TMF (for example, `mytarget.tmf`) and modify it.

To allow the build process to locate and select your TMF, you must provide information in the STF file header (see “System Target File Structure” on page 74-29). For a target that implements a single TMF, the standard way to specify the TMF to be used in the build process is to use the TMF directive of the STF file header.

```
TMF: mytarget.tmf
```

**Using Macros and Pattern Matching Expressions in a Template Makefile**

This section shows, through an example, how to use macros and file-pattern-matching expressions in a TMF to generate commands in the `model.mk` file.

The make utility processes the `model.mk` makefile and generates a set of commands based upon dependency rules defined in `model.mk`. After make generates the set of commands for building or rebuilding `test`, make executes them.

For example, to build a program called `test`, make must link the object files. However, if the object files don't exist or are out of date, make must compile the source code. Thus there is a dependency between source and object files.
Each version of make differs slightly in its features and how rules are defined. For example, consider a program called test that gets created from two sources, file1.c and file2.c. Using most versions of make, the dependency rules would be

```
test: file1.o file2.o
    cc -o test file1.o file2.o

file1.o: file1.c
    cc -c file1.c

file2.o: file2.c
    cc -c file2.c
```

In this example, a UNIX\textsuperscript{10} environment is assumed. In a PC environment the file extensions and compile and link commands are different.

In processing the first rule

```
test: file1.o file2.o
```

make sees that to build test, it needs to build file1.o and file2.o. To build file1.o, make processes the rule

```
file1.o: file1.c
    cc -c file1.c
```

If file1.o doesn't exist, or if file1.o is older than file1.c, make compiles file1.c.

The format of TMFs follows the above example. Our TMFs use additional features of make such as macros and file-pattern-matching expressions. In most versions of make, a macro is defined with

```
MACRO_NAME = value
```

References to macros are made with $(MACRO_NAME). When make sees this form of expression, it substitutes value for $(MACRO_NAME).

You can use pattern matching expressions to make the dependency rules more general. For example, using GNU\textsuperscript{11} Make, you could replace the two “file1.o: file1.c” and “file2.o: file2.c” rules with the single rule

```
%.o : %.c
    cc -c $<
```

\textsuperscript{10} UNIX is a registered trademark of The Open Group in the United States and other countries.

\textsuperscript{11} GNU is a registered trademark of the Free Software Foundation.
Note that $<$ in the previous example is a special macro that equates to the dependency file (that is, file1.c or file2.c). Thus, using macros and the "%" pattern matching character, the previous example can be reduced to

```plaintext
SRCS = file1.c file2.c
OBJS = $(SRCS:.c=.o)
```

test: $(OBJS)
  cc -o $@ $(OBJS)

%.o : %.c
  cc -c $<
```

Note that the $@ macro above is another special macro that equates to the name of the current dependency target, in this case test.

This example generates the list of objects (OBJS) from the list of sources (SRCS) by using the text substitution feature for macro expansion. It replaces the source file extension (for example, .c) with the object file extension (.o). This example also generalized the build rule for the program, test, to use the special "$@$" macro.

**Customizing Generated Makefiles with rtwmakecfg**

TMFs provide tokens that let you add the following items to generated makefiles:

- Source folders
- Include folders
- Run-time library names
- Run-time module objects

S-functions can add this information to the makefile by using an rtwmakecfg.m file function. This function is particularly useful when building a model that contains one or more of your S-Function blocks, such as device driver blocks.

To add information pertaining to an S-function to the makefile,

1. Create the function rtwmakecfg in file rtwmakecfg.m. The code generator associates this file with your S-function based on its folder location.
2. Modify your target's TMF such that it supports macro expansion for the information returned by rtwmakecfg functions.

After the TLC phase of the build process, when generating a makefile from the TMF, the build process searches for an rtwmakecfg.m file in the folder that contains the S-
function component. If it finds the file, the build process calls the `rtwmakecfg` function. For more information, see “Use `rtwmakecfg.m` API to Customize Generated Makefiles” (Simulink Coder).

**Supporting Continuous Time in Custom Targets**

If you want your custom ERT-based target to support continuous time, you must update your template makefile (TMF) and the static main program module (for example, `mytarget_main.c`) for your target.

**Template Makefile Modifications**

Add the `NCSTATES` token expansion after the `NUMST` token expansion, as follows:

```plaintext
NUMST = |NUMST<|
NCSTATES = |NCSTATES<|
```

In addition, add `NCSTATES` to the `CPP_REQ_DEFINES` macro, as in the following example:

```plaintext
CPP_REQ_DEFINES = -DMODEL=$(MODEL) -DNUMST=$(NUMST) -DNCSTATES=$(NCSTATES) \
-DMAT_FILE=$(MAT_FILE) \
-DINTEGER_CODE=$(INTEGER_CODE) \ 
-DONESTEPFCN=$(ONESTEPFCN) -DTERMFCN=$(TERMFCN) \ 
-DHAVESTDIO  \ 
-DMULTI_INSTANCE_CODE=$(MULTI_INSTANCE_CODE) \ 
```

**Modifications to Main Program Module**

The main program module defines a static main function that manages task scheduling for the supported tasking modes of single- and multiple-rate models. `NUMST` (the number of sample times in the model) determines whether the main function calls multirate or single-rate code. However, when a model uses continuous time, do not rely on `NUMST` directly.

When the model has continuous time and the flag `TID01EQ` is true, both continuous time and the fastest discrete time are treated as one rate in generated code. The code associated with the fastest discrete rate is guarded by a major time step check. When the model has only two rates, and `TID01EQ` is true, the generated code has a single-rate call interface.

To support models that have continuous time, update the static main module to take `TID01EQ` into account, as follows:

1. Before `NUMST` is referenced in the file, add the following code:
#if defined(TID01EQ) && TID01EQ == 1 && NCSTATES == 0
#define DISC_NUMST (NUMST - 1)
#else
#define DISC_NUMST NUMST
#endif

2 Replace instances of NUMST in the file by DISC_NUMST.

Model Reference Considerations

See “Support Model Referencing” on page 74-84 for important information on TMF modifications you may need to make to support the code generator model referencing features.

Note If you are using a TMF without the variables SHARED_SRC or MODELREFS, the file might have been used with a previous release of Simulink software. If you want your TMF to support model referencing, add either variable SHARED_SRC or MODELREFS to the make file.

</tr>
</tbody>
</table>

The required configuration changes are modifications to your system target file (STF), and in some cases also modifications to your template makefile (TMF) or your custom static main program.
The API for STF callbacks provides a function `SelectCallback` for use in STFs. `SelectCallback` is associated with the target rather than with its individual options. If you implement a `SelectCallback` function for a target, it is triggered whenever the user selects the target in the System Target File Browser.

The API provides the functions `slConfigUIGetVal`, `slConfigUISetEnabled`, and `slConfigUISetVal` for controlling custom target configuration options from a user-written `SelectCallback` function. (For function descriptions and examples, see the function reference pages.)

The general requirements for supporting one of the optional features include:

- To support model referencing or compiler optimization level control, the target must be derived from the GRT or the ERT target. To support C function prototype control or C++ class interface control, the target must be derived from the ERT target.
- The system target file (STF) must declare feature compliance by including one of the target configuration parameters listed above in a `SelectCallback` function call.
- Additional changes such as TMF modifications or static main program modifications may be required, depending on the feature. See the detailed steps in the subsections for individual features.

For an example that shows how to configure custom target optional features, see “Customize System Target Files” (Simulink Coder).

Support Toolchain Approach with Custom Target

This section describes how to configure a custom system target file to support builds with the toolchain approach.

In the Configuration Parameters dialog box, on the Code Generation pane of, you can present either the build controls for the toolchain approach or the template makefile approach. The model parameters that contribute to determining which build controls appear include these parameters.

<table>
<thead>
<tr>
<th>Model Parameter</th>
<th>Value</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>UseToolchainInfoCompliant</td>
<td>on</td>
<td>For toolchain approach, set this parameter to 'on'. For TMF approach, set this parameter to 'off'.</td>
</tr>
<tr>
<td>GenerateMakefile</td>
<td>on</td>
<td>For toolchain approach, set this parameter to 'on'.</td>
</tr>
</tbody>
</table>

When the dialog box detects that the selected target has these properties, the dialog box recognizes the target as toolchain-compliant and displays the build controls for the toolchain approach.

Because the custom target file cannot set these properties directly, use a SelectCallback function in the custom target file to set the properties. The SelectCallback function call in the RTW_OPTION section of the TLC file can take the form:

```plaintext
rtwgensettings.SelectCallback = 'enableToolchainCompliant(hSrc, hDlg)';
```

A corresponding callback function can contain:

```plaintext
function enableToolchainCompliant(hSrc, hDlg)
    hCS = hSrc.getConfigSet();
    % The following parameters enable toolchain compliance.
    % But, it is recommended practice to set these default values and
    % disable the parameters (as shown).
    hCS.setProp('RTWCompilerOptimization','off');
    hCS.setProp('MakeCommand','make_rtw');
    hCS.setPropEnabled('RTWCompilerOptimization',false);```

```plaintext
hCS.setProp('UseToolchainInfoCompliant','on');
hCS.setProp('GenerateMakefile','on');```

```plaintext
% The following parameters are not required for toolchain compliance.
```
When you select your custom target, the configuration parameters dialog box displays the toolchain approach build controls. For an example, see “Create a Custom Target Configuration” on page 74-48.

For an example that shows how to configure custom target optional features, see “Customize System Target Files” (Simulink Coder).

Support Model Referencing

This section describes how to configure a custom embedded target to support model referencing. Without the described modifications, you will not be able to use the custom target when building a model that includes referenced models. If you do not intend to use referenced models with your target, you can skip this section. If you later find that you need to use referenced models, you can upgrade your target then.

About Model Referencing with a Custom Target

The requirements for supporting model referencing are as follows:

- The target must be derived from the GRT target or the ERT target.
- The system target file (STF) must declare model reference compliance, as described in “Declaring Model Referencing Compliance” on page 74-85.
- The template makefile (TMF) must define some entities that support model referencing, as described in “Providing Model Referencing Support in the TMF” on page 74-85.
- The TMF must support using the Shared Utilities folder, as described in “Supporting the Shared Utilities Folder” on page 74-89.

Optionally, you can provide additional capabilities that support model referencing:

- You can configure a target to support parallel builds for large model reference hierarchies (see “Reduce Build Time for Referenced Models” (Simulink Coder)). To do this, you must modify the STF and TMF for parallel builds as described in “Declaring Model Referencing Compliance” on page 74-85 and “Providing Model Referencing Support in the TMF” on page 74-85.
- If your target supports parallel builds for large model reference hierarchies, you can additionally set up automatic verification of MATLAB Distributed Computing Server workers, as described in “Verifying Worker Configuration for Parallel Builds of Model Reference Hierarchies (Optional)” on page 74-93.
- You can modify hook files to handle referenced models differently than top models to prevent resource conflicts, as described in “Preventing Resource Conflicts (Optional)” on page 74-95.

See “Overview of Model Referencing” (Simulink) for information about model referencing in Simulink models, and “Generate Code for Referenced Models” (Simulink Coder) for information about model referencing in generated code.
For an example that shows how to configure custom target optional features, see “Customize System Target Files” (Simulink Coder).

**Declaring Model Referencing Compliance**

To declare model reference compliance for your target, you must implement a callback function that sets the `ModelReferenceCompliant` flag, and then install the callback function in the `SelectCallback` field of the `rtwgensettings` structure in your STF. The callback function is triggered whenever the user selects the target in the System Target File Browser. For example, the following STF code installs a `SelectCallback` function named `custom_select_callback_handler`:

```
rtwgensettings.SelectCallback = 'custom_select_callback_handler(hDlg,hSrc)';
```

The arguments to the `SelectCallback` function (`hDlg`, `hSrc`) are handles to private data used by the callback API functions. These handles are restricted to use in STF callback functions. They should be passed in without alteration.

Your callback function should set the `ModelReferenceCompliant` flag as follows:

```
slConfigUISetVal(hDlg,hSrc,'ModelReferenceCompliant','on');
slConfigUISetEnabled(hDlg,hSrc,'ModelReferenceCompliant',false);
```

If you might use the target to build models containing large model reference hierarchies, consider configuring the target to support parallel builds, as discussed in “Reduce Build Time for Referenced Models” (Simulink Coder).

To configure a target for parallel builds, your callback function must also set the `ParMdlRefBuildCompliant` flag as follows:

```
slConfigUISetVal(hDlg,hSrc,'ParMdlRefBuildCompliant','on');
slConfigUISetEnabled(hDlg,hSrc,'ParMdlRefBuildCompliant',false);
```

For more information about the STF callback API, see the `slConfigUIGetVal`, `slConfigUISetEnabled`, and `slConfigUISetVal` function reference pages.

**Providing Model Referencing Support in the TMF**

Do the following to configure the template makefile (TMF) to support model referencing:

1. Add the following make variables and tokens to be expanded when the makefile is generated:

   ```
   MODELREFS = \$MODELREFS
   MODELLIB = \$MODELLIB
   ```
The following code excerpt shows how makefile tokens are expanded for a referenced model.

```
MODELREFS                 =
MODELLIB                  = engine3200cc_rtwlib.a
MODELREF_LINK_LIBS       =
MODELREF_LINK_RSPFILE     =
MODELREF_INC_PATH        =
RELATIVE_PATH_TO_ANCHOR  = ../../..
MODELREF_TARGET_TYPE     = RTW
```

The following code excerpt shows how makefile tokens are expanded for the top model that references the referenced model.

```
MODELREFS                 = engine3200cc transmission
MODELLIB                  = archlib.a
MODELREF_LINK_LIBS       = engine3200cc_rtwlib.a transmission_rtwlib.a
MODELREF_LINK_RSPFILE     =
MODELREF_INC_PATH        = -I../slprj/ert/engine3200cc -I../slprj/ert/transmission
RELATIVE_PATH_TO_ANCHOR  = ..
MODELREF_TARGET_TYPE     = NONE
```

<table>
<thead>
<tr>
<th>Token</th>
<th>Expands to</th>
</tr>
</thead>
<tbody>
<tr>
<td>MODELREFS for the top model</td>
<td>List of referenced model names.</td>
</tr>
<tr>
<td>MODELLIB</td>
<td>Name of the library generated for the model.</td>
</tr>
<tr>
<td>MODELREF_LINK_LIBS token for the top model</td>
<td>List of referenced model libraries that the top model links against.</td>
</tr>
<tr>
<td>MODELREF_LINK_RSPFILE token for the top model</td>
<td>Name of a response file that the top model links against. This token is valid only for build environments that support linker response files. For an example of its use, see <code>matlabroot/rtw/c/grt/grt_vc.tmf</code>.</td>
</tr>
<tr>
<td>MODELREF_INC_PATH token for the top model</td>
<td>Include path to the referenced models.</td>
</tr>
<tr>
<td>Token</td>
<td>Expands to</td>
</tr>
<tr>
<td>-----------------------------------</td>
<td>---------------------------------------------------------------------------</td>
</tr>
<tr>
<td>RELATIVE_PATH_TO_ANCHOR</td>
<td>Relative path, from the location of the generated makefile, to the MATLAB working folder.</td>
</tr>
<tr>
<td>MODELREF_TARGET_TYPE</td>
<td>Signifies the type of target being built. Possible values are</td>
</tr>
<tr>
<td></td>
<td>• NONE: Standalone model or top model referencing other models</td>
</tr>
<tr>
<td></td>
<td>• RTW: Model reference target build</td>
</tr>
<tr>
<td></td>
<td>• SIM: Model reference simulation target build</td>
</tr>
</tbody>
</table>

If you are configuring your target to support parallel builds, as discussed in “Reduce Build Time for Referenced Models” (Simulink Coder), you must also add the following token definitions to your TMF:

```plaintext
START_DIR = |START_DIR<|  
MASTER_ANCHOR_DIR = |MASTER_ANCHOR_DIR<|
```

<table>
<thead>
<tr>
<th>Token</th>
<th>Expands to</th>
</tr>
</thead>
<tbody>
<tr>
<td>START_DIR</td>
<td>Current work folder (pwd) at the time the build started.</td>
</tr>
<tr>
<td>MASTER_ANCHOR_DIR</td>
<td>Current work folder (pwd) at the time the build started.</td>
</tr>
</tbody>
</table>

2. Add RELATIVE_PATH_TO_ANCHOR and MODELREF_INC_PATH include paths to the overall INCLUDES variable.

```plaintext
INCLUDES = -I. -I$(RELATIVE_PATH_TO_ANCHOR) $(MATLAB_INCLUDES) $(ADD_INCLUDES) \ $(USER_INCLUDES) $(MODELREF_INC_PATH) $(SHARED_INCLUDES)
```

3. Change the SRCS variable in your TMF so that it initially lists only common modules. Additional modules are then appended conditionally, as described in the next step. For example, change

```plaintext
SRCS = $(MODEL).c $(MODULES) ert_main.c $(ADD_SRCS) $(EXT_SRC)
```

to

```plaintext
SRCS = $(MODULES) $(S_FUNCTIONS)
```
4 Create variables to define the final target of the makefile. You can remove variables that may have existed for defining the final target. For example, remove

```
PROGRAM    = ..$/$(MODEL)
```

and replace it with

```
ifeq ($(MODELREF_TARGET_TYPE), NONE)
  # Top model for RTW
  PRODUCT   = $(RELATIVE_PATH_TO_ANCHOR)/$(MODEL)
  BIN_SETTING = $(LD) $(LDFLAGS) -o $(PRODUCT) $(SYSLIBS)
  BUILD_PRODUCT_TYPE = "executable"
  # ERT based targets
  SRCS += $(MODEL).c ert_main.c $(EXT_SRC)
  # GRT based targets
  # SRCS += $(MODEL).c grt_main.c rt_sim.c $(EXT_SRC) $(SOLVER)
else
  # sub-model for RTW
  PRODUCT = $(MODELLIB)
  BUILD_PRODUCT_TYPE = "library"
endif
```

5 Create rules for the final target of the makefile (replace existing final target rules). For example:

```
ifeq ($(MODELREF_TARGET_TYPE), NONE)
  # Top model for RTW
  $(PRODUCT) : $(OBJS) $(SHARED_LIB) $(LIBS) $(MODELREF_LINK_LIBS)
    $(BIN_SETTING) $(LINK_OBJS) $(MODELREF_LINK_LIBS)
    $(SHARED_LIB) $(LIBS)
    @echo "### Created $(BUILD_PRODUCT_TYPE): $@"
else
  # sub-model for RTW
  $(PRODUCT) : $(OBJS) $(SHARED_LIB) $(LIBS)
    $(ar) ruvs $(MODELLIB) $(LINK_OBJS)
    @echo "### Created $(MODELLIB)"
    @echo "### Created $(BUILD_PRODUCT_TYPE): $@"
endif
```

6 Create a rule to allow referenced models to compile files that reside in the MATLAB working folder (pwd).

```
%.o : $(RELATIVE_PATH_TO_ANCHOR)/%.c
   $(CC) -c $(CFLAGS) <$
```

**Note** If you are using a TMF without the variables SHARED_SRC or MODELREFS, the file might have been used with a previous release of Simulink software. If you want your TMF to support model referencing, add either variable SHARED_SRC or MODELREFS to the make file.
Controlling Configuration Option Value Agreement

By default, the value of a configuration option defined in the system target file for a TLC-based custom target must be the same in any referenced model and its parent model. To relax this requirement, include the `modelReferenceParameterCheck` field in the `rtwoptions` structure element that defines the configuration option, and set the value of the field to 'off'. For example:

```plaintext
rtwoptions(2).prompt         = 'My Custom Parameter';
rtwoptions(2).type           = 'Checkbox';
rtwoptions(2).default        = 'on';
rtwoptions(2).modelReferenceParameterCheck  = 'on';
rtwoptions(2).tlcvariable    = 'mytlcvariable';
...```

The configuration option **My Custom Parameter** can differ in a referenced model and its parent model. See “Customize System Target Files” on page 74-28 for information about TLC-based system target files, and `rtwoptions` Structure Fields Summary for a list of `rtwoptions` fields.

Supporting the Shared Utilities Folder

- “Overview” on page 74-89
- “Implementing Shared Utilities Folder Support” on page 74-91

Overview

The `makefile` used by the build process must support compiling and creating libraries, and so on, from the locations in which the code is generated. Therefore, you need to update your `makefile` and the model reference build process to support the shared utilities location. The **Shared code placement** options have the following requirements:

- **Auto**
  - Standalone model build — Build files go to the build folder; `makefile` is not updated.
  - Referenced model or top model build — Use shared utilities folder; `makefile` requires full model reference support.

- **Shared location**
  - Standalone model build — Use shared utilities folder; `makefile` requires shared location support.
• Referenced model or top model build — Use shared utilities folder; makefile requires full model reference support.

The shared utilities folder (`slprj/target/_sharedutils`) typically stores generated utility code that is common between a top model and the models it references. You can also force the build process to use a shared utilities folder for a standalone model. See “Manage Build Process Folders” (Simulink Coder) for details.

If you want your target to support compilation of code generated in the shared utilities folder, several updates to your template makefile (TMF) are required. Support for Model Reference builds requires the shared utilities folder. See the preceding sections to learn about additional updates for supporting Model Reference builds.

The exact syntax of the changes can vary due to differences in the make utility and compiler/archiver tools used by your target. The examples below are based on the GNU\textsuperscript{12} make utility. You can find the following updated TMF examples for GNU and Microsoft Visual C++ make utilities in the GRT and ERT target folders:

• GRT: `matlabroot/rtw/c/grt` (open)
  • `grt_lcc.tmf`
  • `grt_vc.tmf`
  • `grt_unix.tmf`

• ERT: `matlabroot/rtw/c/ert` (open)
  • `ert_lcc.tmf`
  • `ert_vc64.tmf`
  • `ert_unix.tmf`

Use the GRT or ERT examples as a guide to the location, within the TMF, of the changes and additions described below.

**Note** The ERT-based TMFs contain extra code to handle generation of ERT S-functions and Model Reference simulation targets. Your target does not need to handle these cases.

---

\textsuperscript{12} GNU is a registered trademark of the Free Software Foundation.
Implementing Shared Utilities Folder Support

Make the following changes to your TMF to support the shared utilities folder:

1. Add the following make variables and tokens to be expanded when the makefile is generated:

   ```
   SHARED_SRC      = |>SHARED_SRC<|
   SHARED_SRC_DIR  = |>SHARED_SRC_DIR<|
   SHARED_BIN_DIR  = |>SHARED_BIN_DIR<|
   SHARED_LIB      = |>SHARED_LIB<|
   ```

   `SHARED_SRC` specifies the shared utilities folder location and the source files in it. A typical expansion in a makefile is

   ```
   SHARED_SRC = ../slprj/ert/_sharedutils/*.c
   ```

   `SHARED_LIB` specifies the library file built from the shared source files, as in the following expansion.

   ```
   SHARED_LIB = ../slprj/ert/_sharedutils/rtwshared.lib
   ```

   `SHARED_SRC_DIR` and `SHARED_BIN_DIR` allow specification of separate folders for shared source files and the library compiled from the source files. In the current release, the TMFs use the same path, as in the following expansions.

   ```
   SHARED_SRC_DIR = ../slprj/ert/_sharedutils
   SHARED_BIN_DIR = ../slprj/ert/_sharedutils
   ```

2. Set the `SHARED_INCLUDES` variable according to whether shared utilities are in use. Then append it to the overall `INCLUDES` variable.

   ```
   SHARED_INCLUDES =
   ifndef $(SHARED_SRC_DIR),
   SHARED_INCLUDES = -I$(SHARED_SRC_DIR)
   endif

   INCLUDES = -I, $(MATLAB_INCLUDES) $(ADD_INCLUDES) \ $(USER_INCLUDES) $(SHARED_INCLUDES)
   ```

3. Update the `SHARED_SRC` variable to list shared files explicitly.

   ```
   SHARED_SRC := $(wildcard $(SHARED_SRC))
   ```

4. Create a `SHARED_OBJS` variable based on `SHARED_SRC`.

   ```
   SHARED_OBJS = $(addsuffix .o, $(basename $(SHARED_SRC)))
   ```
5 Create an OPTS (options) variable for compilation of shared utilities.

```
SHARED_OUTPUT_OPTS = -o $@
```

6 Provide a rule to compile the shared utility source files.

```
$(SHARED_OBJC) : $(SHARED_BIN_DIR)/%.o : $(SHARED_SRC_DIR)/%.c
  $(CC) -c $(CFLAGS) $(SHARED_OUTPUT_OPTS) $<
```

7 Provide a rule to create a library of the shared utilities. The following example is based on UNIX\(^{13}\).

```
$(SHARED_LIB) : $(SHARED_OBJC)
  @echo "### Creating $@"
  ar r $@ $(SHARED_OBJC)
  @echo "### Created $@"
```

**Note** Depending on your make utility, you may be able to combine Steps 6 and 7 into one rule. For example, gmake (used with ert_unix.tmf) uses:

```
$(SHARED_LIB) : $(SHARED_SRC)
  @echo "### Creating $@"
  cd $(SHARED_BIN_DIR); $(CC) -c $(CFLAGS) $(GCC_WALL_FLAG_MAX) $(notdir $?)
  ar ruvs $@ $(SHARED_OBJC)
  @echo "### $@ Created"
```

See this and other examples in the files ert_vcx64.tmf, ert_lcc.tmf, and ert_unix.tmf located at `matlabroot/rtw/c/ert` (open).

8 Add SHARED_LIB to the rule that creates the final executable.

```
$(PROGRAM) : $(OBJS) $(LIBS) $(SHARED_LIB)
  $(LD) $(LDFLAGS) -o $@ $(LINK_OBJC) $(LIBS)
  $(SHARED_LIB) $(SYSLIBS)
  @echo "### Created executable: $(MODEL)"
```

9 Remove explicit references to rt_nonfinite.c from your TMF. For example, change

```
ADD_SRCS = $(RTWLOG) rt_nonfinite.c
```

to

```
ADD_SRCS = $(RTWLOG)
```

\(^{13}\) UNIX is a registered trademark of The Open Group in the United States and other countries.
Note: If your target interfaces to a development environment that is not makefile based, you must make equivalent changes to provide information to your target compilation environment.

Verifying Worker Configuration for Parallel Builds of Model Reference Hierarchies (Optional)

If your target supports parallel builds for large model reference hierarchies, you can additionally set up automatic verification of MATLAB Distributed Computing Server workers. This addresses the possibility that parallel workers might have different configurations, some of which might not be compatible with a specific target build. For example, the required compiler might not be installed on a worker system.

The code generator provides a programming interface that you can use to automatically check the configuration of parallel workers. If parallel workers are not set up as expected, take action, such as reverting to sequential builds or throwing an error.

To set up automatic verification of workers, you must define a parallel configuration check function named `STF_par_cfg_chk`, where `STF` designates your system target file name. For example, the parallel configuration check function for `ert.tlc` is `ert_par_cfg_chk`.

The general syntax for the function is:

```matlab
function varargout = STF_par_cfg_chk(action,varargin)
```

The number of output and input arguments vary according to the `action` specified, and according to the types of information you choose to coordinate between the client and the workers. The function should support the following general sequence of parallel configuration setup calls, differentiated by the first argument passed in:

<table>
<thead>
<tr>
<th>Call Syntax</th>
<th>Called on:</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>cfg = STF_par_cfg_chk('getPreferredCfg');</code></td>
<td>Client</td>
<td>Return a structure representing the preferred configuration for MATLAB Distributed Computing Server workers.</td>
</tr>
<tr>
<td>Call Syntax</td>
<td>Called on:</td>
<td>Action</td>
</tr>
<tr>
<td>------------</td>
<td>------------</td>
<td>--------</td>
</tr>
<tr>
<td><code>[tf, cfg] = STF_par_cfg_chk ('getWorkerCfg', cfg);</code></td>
<td>Workers</td>
<td>Each worker is passed the MATLAB Distributed Computing Server client’s preferred configuration. Return true if the worker can support the preferred configuration; otherwise return false along with a structure representing a configuration the worker can support. Information returned by each worker is added to a cell array of configurations.</td>
</tr>
<tr>
<td><code>[tf, cfg] = STF_par_cfg_chk ('getCommonCfg', cfgs);</code></td>
<td>Client</td>
<td>The client is passed the cell array of worker configurations. If a usable common configuration exists, return true, and return the common configuration to set for all systems. If a common configuration cannot be established, return false or take some action, such as reverting to sequential builds or throwing an error.</td>
</tr>
<tr>
<td><code>tf = STF_par_cfg_chk ('setCommonCfg', cfg);</code></td>
<td>Workers and client</td>
<td>Each system is passed the common configuration to use. Set up the common configuration and, if successful, return true. If errors or issues occur, return false or take some action, such as reverting to sequential builds or throwing an error.</td>
</tr>
<tr>
<td><code>STF_par_cfg_chk ('clearCfg');</code></td>
<td>Workers and client</td>
<td>Clean up after completion of the parallel build.</td>
</tr>
</tbody>
</table>

The parallel configuration check functions for MathWorks provided targets are implemented as wrapper functions that call a function named `parallelMdlRefHostConfigCheckFcn`. For example, see the ERT parallel configuration check function in the file `matlabroot/toolbox/rtw/rtw/ert_par_cfg_chk.m`, and the function it calls in the file `matlabroot/toolbox/simulink/simulink/+Simulink/parallelMdlRefHostConfigCheckFcn.m`. The `parallelMdlRefHostConfigCheckFcn` function tries to establish a common compiler across the MATLAB Distributed Computing Server client and workers.

For more information about parallel builds, see “Reduce Build Time for Referenced Models” (Simulink Coder).
Preventing Resource Conflicts (Optional)

Hook files are optional TLC and MATLAB program files that are invoked at well-defined stages of the build process. Hook files let you customize the build process and communicate information between various phases of the process.

If you are adapting your custom target for code generation compatibility with model reference features, consider adding checks to your hook files for handling referenced models differently than top models to prevent resource conflicts.

For example, consider adding the following check to your STF_make_rtw_hook.m file:

```matlab
% Check if this is a referenced model
mdlRefTargetType = get_param(codeGenModelName,'ModelReferenceTargetType');
isNotModelRefTarget = strcmp(mdlRefTargetType, 'NONE'); % NONE, SIM, or RTW
if isNotModelRefTarget
    % code that is specific to the top model
else
    % code that is specific to the referenced model
end
```

You may need to do a similar check in your TLC code.

```matlab
%if !IsModelReferenceTarget()
    % code that is specific to the top model
%else
    % code that is specific to the referenced model
%endif
```

- “Sample Custom Targets” (Simulink Coder)
- “Customize System Target Files” (Simulink Coder)
Support Compiler Optimization Level Control

This section describes how to configure a custom embedded target to support compiler optimization level control. Without the described modifications, you cannot use the Configuration Parameters > Code Generation > Build process > Compiler optimization level parameter to control the compiler optimization level for building generated code. For more information about compiler optimization level control, see “Compiler optimization level” (Simulink Coder).

About Compiler Optimization Level Control and Custom Targets

The requirements for supporting compiler optimization level control are as follows:

- The target must be derived from the GRT target or the ERT target.
- The system target file (STF) must declare compiler optimization level control compliance, as described in “Declaring Compiler Optimization Level Control Compliance” on page 74-96.
- The target makefile must honor the setting for **Compiler optimization level**, as described in “Providing Compiler Optimization Level Control Support in the Target Makefile” on page 74-97.

For an example that shows how to configure custom target optional features, see “Customize System Target Files” (Simulink Coder).

Declaring Compiler Optimization Level Control Compliance

To declare compiler optimization level control compliance for your target, you must implement a callback function that sets the CompOptLevelCompliant flag, and then install the callback function in the SelectCallback field of the rtwgensettings structure in your STF. The callback function is triggered whenever the user selects the target in the System Target File Browser. For example, the following STF code installs a SelectCallback function named custom_select_callback_handler:

```
rtwgensettings.SelectCallback = 'custom_select_callback_handler(hDlg,hSrc)';
```

The arguments to the SelectCallback function (hDlg, hSrc) are handles to private data used by the callback API functions. These handles are restricted to use in STF callback functions. They should be passed in without alteration.
Your callback function should set the CompOptLevelCompliant flag as follows:

```matlab
slConfigUISetVal(hDlg,hSrc,'CompOptLevelCompliant','on');
slConfigUISetEnabled(hDlg,hSrc,'CompOptLevelCompliant',false);
```

For more information about the STF callback API, see the `slConfigUIGetVal`, `slConfigUISetEnabled`, and `slConfigUISetVal` function reference pages.

When the CompOptLevelCompliant target configuration parameter is set to on, the Compiler optimization level parameter is displayed in the Code Generation pane of the Configuration Parameters dialog box for your model.

**Providing Compiler Optimization Level Control Support in the Target Makefile**

As part of supporting compiler optimization level control for your target, you must modify the target makefile to honor the setting for Compiler optimization level. Use a GRT or ERT target provided by MathWorks as a model for making the modifications.

**See Also**

**More About**

- “About Embedded Target Development” (Simulink Coder)
- “Sample Custom Targets” (Simulink Coder)
- “Customize System Target Files” (Simulink Coder)
Support C Function Prototype Control

This section describes how to configure a custom embedded target to support C function prototype control. Without the described modifications, you will not be able to use the Configure Model Functions button on the Interface pane of the Configuration Parameters dialog box to control the function prototypes of initialize and step functions that are generated for your model. For more information about C function prototype control, see “Customize Generated C Function Interfaces” on page 29-2.

About C Function Prototype Control and Custom Targets

The requirements for supporting C function prototype control are as follows:

- The target must be derived from the ERT target.
- The system target file (STF) must declare C function prototype control compliance, as described in “Declaring C Function Prototype Control Compliance” on page 74-98.
- If your target uses a custom static main program, and if a nondefault function prototype control configuration is associated with a model, the static main program must call the function prototype controlled initialize and step functions, as described in “Providing C Function Prototype Control Support in the Custom Static Main Program” on page 74-99.

For an example that shows how to configure custom target optional features, see “Customize System Target Files” (Simulink Coder).

Declaring C Function Prototype Control Compliance

To declare C function prototype control compliance for your target, you must implement a callback function that sets the ModelStepFunctionPrototypeControlCompliant flag, and then install the callback function in the SelectCallback field of the rtwgensettings structure in your STF. The callback function is triggered whenever the user selects the target in the System Target File Browser. For example, the following STF code installs a SelectCallback function named custom_select_callback_handler:

```matlab
rtwgensettings.SelectCallback = 'custom_select_callback_handler(hDlg,hSrc)';
```

The arguments to the SelectCallback function (hDlg, hSrc) are handles to private data used by the callback API functions. These handles are restricted to use in STF callback functions. They should be passed in without alteration.
Your callback function should set the `ModelStepFunctionPrototypeControlCompliant` flag as follows:

```matlab
slConfigUISetVal(hDlg,hSrc,'ModelStepFunctionPrototypeControlCompliant','on');
slConfigUISetEnabled(hDlg,hSrc,'ModelStepFunctionPrototypeControlCompliant',false);
```

For more information about the STF callback API, see the `slConfigUIGetVal`, `slConfigUISetEnabled`, and `slConfigUISetVal` function reference pages.

When the `ModelStepFunctionPrototypeControlCompliant` target configuration parameter is set to on, you can use the **Configure Model Functions** button on the **Interface** pane of the Configuration Parameters dialog box to control the function prototypes of initialize and step functions that are generated for your model.

### Providing C Function Prototype Control Support in the Custom Static Main Program

If your target uses a custom static main program, and if a nondefault function prototype control configuration is associated with a model, you must update the static main program to call the function prototype controlled initialize and step functions. You can do this in either of the following ways:

1. Manually adapt your static main program to declare model data and call the function prototype controlled initialize and step functions.

2. Generate your main program using **Generate an example main program** on the **Templates** pane of the Configuration Parameters dialog box. The generated main program declares model data and calls the function prototype controlled initialize and step function.

Support C++ Class Interface Control

This section describes how to configure a custom embedded target to support C++ class interface control. Without the described modifications, you will not be able to use C++ class code interface packaging and the Configure C++ Class Interface button on the Interface pane of the Configuration Parameters dialog box to generate and configure C++ class interfaces to model code. For more information about C++ class interface control, see “Customize Generated C++ Class Interfaces” on page 29-36.

About C++ Class Interface Control and Custom Targets

The requirements for supporting C++ class interface control are as follows:

- The target must be derived from the ERT target.
- The system target file (STF) must declare C++ class interface control compliance, as described in “Declaring C++ Class Interface Control Compliance” on page 74-100.

For an example that shows how to configure custom target optional features, see “Customize System Target Files” (Simulink Coder).

Declaring C++ Class Interface Control Compliance

To declare C++ class interface control compliance for your target, you must implement a callback function that sets the CPPClassGenCompliant flag, and then install the callback function in the SelectCallback field of the rtwgensettings structure in your STF. The callback function is triggered whenever the user selects the target in the System Target File Browser. For example, the following STF code installs a SelectCallback function named custom_select_callback_handler:

```
rtwgensettings.SelectCallback = 'custom_select_callback_handler(hDlg,hSrc)';
```

The arguments to the SelectCallback function (hDlg, hSrc) are handles to private data used by the callback API functions. These handles are restricted to use in STF callback functions. They should be passed in without alteration.

Your callback function should set the CPPClassGenCompliant flag as follows:

```
slConfigUISetVal(hDlg,hSrc,'CPPClassGenCompliant','on');
slConfigUISetEnabled(hDlg,hSrc,'CPPClassGenCompliant',false);
```

For more information about the STF callback API, see the slConfigUIGetVal, slConfigUISetEnabled, and slConfigUISetVal function reference pages.
When the `CPPClassGenCompliant` target configuration parameter is set to `on`, you can use the C++ class code interface packaging and the **Configure C++ Class Interface** button on the Interface pane of the Configuration Parameters dialog box to generate and configure C++ class interfaces to model code.

### Providing C++ Class Interface Control Support in the Custom Static Main Program

Selecting C++ class code interface packaging for your model turns on the model option **Generate an example main program**. With this option on, code generation generates an example main program, `ert_main.cpp`. The generated example main program declares model data and calls the C++ class interface configured model step method, and illustrates how the generated code can be deployed.

To customize the build process and disable generation and inclusion of an example main program, see the `setTargetProvidesMain` function. Disabling example main generation permits including a custom main program.

Support Concurrent Execution of Multiple Tasks

If a custom embedded target must support concurrent execution of multiple tasks on a multicore platform, the target must declare support for concurrent execution by setting the target configuration option ConcurrentExecutionCompliant. Otherwise, you will not be able to configure a multicore target model for concurrent execution.

If ConcurrentExecutionCompliant is not already configured for your custom target, you can set the option in the following ways:

- Include the following code directly in your system target file (mytarget.tlc):
  ```matlab
  rtwgensettings.SelectCallback = 'slConfigUISetVal(hDlg,hSrc,...
  'ConcurrentExecutionCompliant','on');';
  rtwgensettings.ActivateCallback = 'slConfigUISetVal(hDlg,hSrc,...
  'ConcurrentExecutionCompliant','on');';
  ``

- Implement a callback function that sets the ConcurrentExecutionCompliant option, and then install the callback function in the SelectCallback field of the rtwgensettings structure in your STF. The callback function is triggered whenever the user selects the target in the System Target File Browser. For example, the following STF code installs a SelectCallback function named custom_select_callback_handler:
  ```matlab
  rtwgensettings.SelectCallback = 'custom_select_callback_handler(hDlg,hSrc)';
  ``

  The arguments to the SelectCallback function (hDlg, hSrc) are handles to private data used by the callback API functions. These handles are restricted to use in STF callback functions. They should be passed in without alteration.

  Your callback function should set the ConcurrentExecutionCompliant option as follows:
  ```matlab
  slConfigUISetVal(hDlg,hSrc,'ConcurrentExecutionCompliant','on');
  slConfigUISetEnabled(hDlg,hSrc,'ConcurrentExecutionCompliant',false);
  ``

  For more information about the STF callback API, see the slConfigUIGetVal, slConfigUISetEnabled, and slConfigUISetVal function reference pages.

  When the ConcurrentExecutionCompliant target configuration option is set to 'on', you can select the custom target and configure your multicore target model for concurrent execution.

  For an example that shows how to configure custom target optional features, see “Customize System Target Files” (Simulink Coder).

Interface to Development Tools

Unless you are developing a target purely for code generation purposes, you will want your embedded target to support a complete build process. A full post-code generation build process includes

- Compilation of generated code
- Linking of compiled code and runtime libraries into an executable program module (or some intermediate representation of the executable code, such as S-Rec format)
- Downloading the executable to target hardware with a debugger or other utility
- Initiating execution of the downloaded program

Supporting a complete build process is inherently a complex task, because it involves interfacing to cross-development tools and utilities that are external to the code generator.

If your development tools can be controlled with traditional makefiles and a make utility such as `gmake`, it may be relatively simple for you to adapt existing target files (such as the `ert.tlc` and `ert.tmf` files provided by the Embedded Coder software) to your requirements. This approach is discussed in “Template Makefile Approach” on page 74-104.

About Interfacing to Development Tools

Automating your build process through a modern integrated development environment (IDE) presents a different set of challenges. Each IDE has its own way of representing the set of source files and libraries for a project and for specifying build arguments. Interfacing to an IDE may require generation of specialized file formats required by the IDE (for example, project files) and, and also may require the use of inter-application communication (IAC) techniques to run the IDE. One such approach to build automation is discussed in “Interface to an Integrated Development Environment” on page 74-105.

Template Makefile Approach

A template makefile provides information about your model and your development system. The build process uses this information to create a makefile (.mk file) to build an executable program. The code generator provides a number of template makefiles suitable for development computer compilers, such as LCC (`ert_lcc.tmf`) and Microsoft Visual C++ (`ert_vcx64.tmf`).

74-104
Adapting one of the existing template makefiles to your cross-compiler’s make utility may require little more than copying and renaming the template makefile in accordance with the conventions of your project.

If you need to make more extensive modifications, you need to understand template makefiles in detail. For a detailed description of the structure of template makefiles and of the tokens used in template makefiles, see “Customize Template Makefiles” on page 74-62.

The following topics supplement the basic template makefile information:

- “Supporting Multiple Development Environments” on page 74-48
- “Supplying Development Environment Information to Your Template Makefile” on page 74-25

**Interface to an Integrated Development Environment**

This section describes techniques that have been used to integrate embedded targets with integrated development environment (IDEs), including:

- How to generate a header file containing directives to define variables (and their values) required by a non-makefile based build.
- Some problems and solutions specific to interfacing embedded targets with the Freescale Semiconductor CodeWarrior IDE. The examples provided should help you to deal with similar interfacing problems with your particular IDE.
- “Generating a CPP_REQ_DEFINES Header File” on page 74-105
- “Interfacing to the Freescale CodeWarrior IDE” on page 74-106

**Generating a CPP_REQ_DEFINES Header File**

In template makefiles, the token CPP_REQ_DEFINES is expanded and replaced with a list of parameter settings entered with various dialog boxes. This variable often contains information such as MODEL (name of generating model), NUMST (number of sample times in the model), MT (model is multitasking or not), and numerous other parameters (see “Template Makefiles and Tokens” on page 74-62).

The makefile mechanism handles the CPP_REQ_DEFINES token automatically. If your target requires use of a project file, rather than the traditional makefile approach, you can generate a header file containing directives to define these variables and provide their values.
The following TLC file, gen_rtw_req_defines.tlc, provides an example. The code generates a C header file, cpp_req_defines.h. The information required to generate each #define directive is derived either from information in the model.rtw file (e.g., CompiledModel.NumSynchronousSampleTimes), or from make variables from the rtwoptions structure (for example, PurelyIntegerCode).

```tcl
%% File: gen_rtw_req_defines_h.tlc
%openfile CPP_DEFINES = "cpp_req_defines.h"
#ifndef _CPP_REQ_DEFINES_
#define _CPP_REQ_DEFINES_
#define MODEL %<CompiledModel.Name>
#define ERT  1
#define NUMST %<CompiledModel.NumSynchronousSampleTimes>
#define TID01EQ %<CompiledModel.FixedStepOpts.TID01EQ>
%%
%if CompiledModel.FixedStepOpts.SolverMode == "MultiTasking"
#define MT  1
#define MULTITASKING  1
#else
#define MT  0
#define MULTITASKING  0
%endif
%%
#define MAT_FILE  0
#define INTEGER_CODE %<PurelyIntegerCode>
#define ONESTEPFCN %<CombineOutputUpdateFcns>
#define TERMFCN %<IncludeMdlTerminateFcn>
%%
#define MULTI_INSTANCE_CODE  0
#define HAVESTDIO  0
%endif
%closefile CPP_DEFINES
```

**Interfacing to the Freescale CodeWarrior IDE**

Interfacing an embedded target's build process to the CodeWarrior IDE requires that two problems must be dealt with:

- The build process must generate a CodeWarrior compatible project file. This problem, and a solution, is discussed in “XML Project Import” on page 74-107. The solution described is applicable to ASCII project file formats.
- During code generation, the target must automate a CodeWarrior session that opens a project file and builds an executable. This task is described in “Build Process
Automation” on page 74-110. The solution described is applicable to IDEs that can be controlled with Microsoft Component Object Model (COM) automation.

**XML Project Import**

This section illustrates how to use the Target Language Compiler (TLC) to generate an eXtensible Markup Language (XML) file, suitable for import into the CodeWarrior IDE, that contains information about the source code generated by an embedded target.

The choice of XML format is dictated by the fact that the CodeWarrior IDE supports project export and import with XML files. As of this writing, native CodeWarrior project files are in a proprietary binary format.

Note that if your target needs to support some other compiler's project file format, you can apply the techniques shown here to other ASCII file formats (see “Generating a CPP_REQ_DEFINES Header File” on page 74-105).

To illustrate the basic concept, consider a hypothetical XML file exported from a CodeWarrior stationery project. The following is a partial listing:

```xml
<target>
    <settings>
        ...
        <settings>
        <file><name>foo.c</name>
        <file>
        ...
        <file><name>foobar.c</name>
        <file>
        <fileref><name>foo.c</name>
        <fileref>
        ...
        <fileref><name>foobar.c</name>
        <fileref>
    <target>
```

Insert this XML code into an `%openfile%/closefile` block within a TLC file, `test.tlc`, as shown below.

```plaintext
%% test.tlc
%% This code will generate a file model_project.xml,
%% where model is the generating model name specified in
%% the CompiledModel.Name field of the model.rtw file.
%openfile XMLFileContents = %<CompiledModel.Name>_project.xml
```

74-107
Note the use of the TLC token `CompiledModel.Name`. The token is resolved and the resulting filename is included in the output stream. You can specify other information, such as paths and libraries, in the output stream by specifying other tokens defined in `model.rtw`. For example, `System.Name` may be defined as `<Root>/Subsystem1`.

Now suppose that `test.tlc` is invoked during a target's build process, where the generating model is `mymodel`. This should be done after the `codegenentry` statement. For example, `test.tlc` could be included directly in the system target file:

```tcl
%include "codegenentry.tlc"
%include "test.tlc"
```

Alternatively, the `%include "test.tlc"` directive could be inserted into the `mytarget_genfiles.tlc` hook file, if present.

TLC tokens such as

```tcl
<file><name>%<CompiledModel.Name>.c</name>
```

are expanded, with the `CompiledModel` record in the `mymodel.rtw` file, as in

```tcl
<file><name>mymodel.c</name>
```

test.tlc generates an XML file, file `model_project.xml`, from a model. `model_project.xml` contains references to generated code files. `model_project.xml` can be imported into the CodeWarrior IDE as a project.
The following flowchart summarizes this process.

proj.mcp: CodeWarrior project binary stationery file

Code Warrior (manual): Export to XML.

proj.xml: XML project file

Text editor (manual): Add TLC tokens to generate references to model files, MATLAB and other paths, and other settings. Embed the XML code marked with tokens in openfile/closefile block. Save as proj_gen.tlc.

proj_gen.tlc: TLC file for generating XML file

TLC: During code generation, expand TLC tokens and generate XML project file, model_project.xml.

model_project.xml: Generated XML project file with generated file references and target-specific information

Code Warrior (manual or with script): Import from XML.

model_project.mcp: CodeWarrior project binary file

Code Warrior (manual or with script): Build project as indicated in "Build Process Automation".

Interface to Development Tools
**Note** This process has drawbacks. First, manually editing an XML file exported from a CodeWarrior stationery project can be a laborious task, involving modification of a few dozen lines embedded within several thousand lines of XML code. Second, if you make changes to the CodeWarrior project after importing the generated XML file, the XML file must be exported and manually edited once again.

**Build Process Automation**

An application that supports COM automation can control other applications that include a COM interface. Using MATLAB COM automation functions, a MATLAB file can command a COM-compatible development system to execute tasks required by the build process.

The MATLAB COM automation functions described in this section are documented in “Call COM Objects” (MATLAB).

For information about automation commands supported by the CodeWarrior IDE, see your CodeWarrior documentation.

COM automation is used by some embedded targets to automate the CodeWarrior IDE to execute tasks such as:

- Opening a new CodeWarrior session
- Configure a project
- Loading a CodeWarrior project file
- Removing object code from the project
- Building or rebuilding the project
- Debug an application

COM technology automates certain repetitive tasks and allows the user to interact directly with the external application. For example, when the end user of the embedded targets capability initiates a build, the target quickly invokes CodeWarrior actions and leaves a project built and ready to run with the IDE.

**Example COM Automation Functions**

The functions below use the MATLAB `actxserver` command to invoke COM functions for controlling the CodeWarrior IDE from a MATLAB file:
• **CreateCWComObject**: Create a COM connection to the CodeWarrior IDE.
• **OpenCW**: Open the CodeWarrior IDE without opening a project.
• **OpenMCP**: Open the CodeWarrior project file (.mcp file) specified by the input argument.
• **BuildCW**: Open the specified .mcp file, remove object code, and build project.

These functions are examples; they do not constitute a full implementation of a COM automation interface. If your target creates the project file during code generation, the top-level BuildCW function should be called after the code generation process is completed. Normally BuildCW would be called from the exit method of your `STF_make_rtw_hook.m` file (see “STF_make_rtw_hook.m” on page 74-20).

In the code examples, the variable `in_qualifiedMCP` is assumed to store a fully qualified path to a CodeWarrior project file (for example, path, filename, and extension). For example:

```matlab
in_qualifiedMCP = 'd:\work\myproject.mcp';
```

In actual practice, your code is responsible for determining the conventions used for the project filename and location. One simple convention would be to default to a project file `model.mcp`, located in your target's build folder.

```matlab
%======================================================================
% Function: CreateCWComObject
% Abstract: Creates the COM connection to CodeWarrior
% function ICodeWarriorApp = CreateCWComObject
% vprint([mfilename ': creating CW com object']);
% try
%  ICodeWarriorApp = actxserver('CodeWarrior.CodeWarriorApp');
% catch
%  error(['Error creating COM connection to ' ComObj ...'
%       '. Verify that CodeWarrior is installed. Verify COM access to
% CodeWarrior outside of MATLAB.']);
% end
% return;
%
%======================================================================
% Function: OpenCW
% Abstract: Opens CodeWarrior without opening a project. Returns the
% handle ICodeWarriorApp.
% function ICodeWarriorApp = OpenCW()
%  ICodeWarriorApp = CreateCWComObject;
%  CloseAll;
%  OpenMCP(in_qualifiedMCP);
```

%======================================================================
% Function: OpenCW
% Abstract: Opens CodeWarrior without opening a project. Returns the
% handle ICodeWarriorApp.
% function ICodeWarriorApp = OpenCW()
%  ICodeWarriorApp = CreateCWComObject;
%  CloseAll;
%  OpenMCP(in_qualifiedMCP);
% Function: OpenMCP
% Abstract: open an MCP project file

function OpenMCP(in_qualifiedMCP)
    % Argument checking. This method requires valid project file.
    if ~exist(in_qualifiedMCP)
        error([mfilename ': Missing or empty project file argument']);
    end
    if isempty(in_qualifiedMCP)
        error([mfilename ': Missing or empty project file argument']);
    end
    ICodeWarriorApp = CreateCWComObject;
    vprint([mfilename ': Importing']);
    try
        ICodeWarriorProject = ...  
        invoke(ICodeWarriorApp.Application,...
            'OpenProject', in_qualifiedMCP,...
            1,0,0);
        catch
            error(['Error using COM connection to import project. ' ...
                'Verify that CodeWarrior is installed. Verify COM access to
                CodeWarrior outside of MATLAB.']);
        end
    end

% Function: BuildCW
% Abstract: Opens CodeWarrior.
%           Opens the specified CodeWarrior project.
%           Deletes objects.
%           Builds.

function ICodeWarriorApp = BuildCW(in_qualifiedMCP)
    % ICodeWarriorApp = BuildCW;
    ICodeWarriorApp = CreateCWComObject;
    CloseAll;
    OpenMCP(in_qualifiedMCP);
    try
        invoke(ICodeWarriorApp.DefaultProject,'RemoveObjectCode', 0, 1);
        catch
            error(['Error using COM connection to remove objects of current project. ' ... 
                'Verify that CodeWarrior is installed. Verify COM access to
                CodeWarrior outside of MATLAB.']);
        end
        try
            invoke(ICodeWarriorApp.DefaultProject,'BuildAndWaitToComplete');
        catch
            error(['Error using COM connection to build current project. ' ... 
                'Verify that CodeWarrior is installed. Verify COM access to
                CodeWarrior outside of MATLAB.']);
        end
    end

Device Drivers

Device drivers that communicate with target hardware are essential to many real-time development projects.

You can integrate existing C (or C++) device driver functions into Simulink models by using the Legacy Code Tool. When you use the code generator to generate code from a model, the Legacy Code Tool can insert a call to your C function into the generated code. For details, see “Import Calls to External Code into Generated Code with Legacy Code Tool” (Simulink Coder) and “Integrate C Functions into Simulink Models with Legacy Code Tool” (Simulink).

Block Selection

You can create models for targeting the same way you create other Simulink models—by combining standard blocks and C-MEX S-functions.

You can use blocks from the following sources:

- The Embedded Coder Support Packages.
- The Embedded Targets library (embeddedtargetslib) in the Embedded Coder product.
- Blocks from the System Toolboxes products
- Custom blocks

Avoid using blocks that do not generate code, including the following blocks.

<table>
<thead>
<tr>
<th>Block Name/Category</th>
<th>Library</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Simulink, DSP System Toolbox software</td>
<td>Provides oscilloscope view of your output. Do not use the <strong>Save data to workspace</strong> option on the Data history pane in the Scope Parameters dialog.</td>
</tr>
<tr>
<td>To Workspace</td>
<td>Simulink</td>
<td>Return data to your MATLAB workspace.</td>
</tr>
<tr>
<td>From Workspace</td>
<td>Simulink</td>
<td>Send data to your model from your MATLAB workspace.</td>

**Configure Target Hardware Resources**

This topic contains the following subtopics:

- “About Supported IDEs” on page 75-3
- “Configure Parameters Under the Target Hardware Resources Tab” on page 75-4

**About Supported IDEs**

This “Configure Target Hardware Resources” on page 75-3 section applies to the following IDEs:

- Analog Devices VisualDSP++®
- Wind River Diab/GCC (makefile generation only)
Configure Parameters Under the Target Hardware Resources Tab

Configure the parameters under the Target Hardware Resources tab of your Simulink model for a specific tool chain and target hardware. Doing so updates other parameters in the Configuration Parameters dialog to the default values for the software build tool chain and target hardware you are using.

**Note** The Target Preferences (Removed) block has been removed from the Simulink block libraries for the Embedded Coder and Simulink Coder products. Parameters in the Target Preferences block have been moved to the Target Hardware Resources tab.

To configure your Simulink model for a specific tool chain and target hardware:

1. In a Simulink model, open the model Configuration Parameters by:
   - Clicking the gear icon,
   - Pressing Ctrl+E on your keyboard
   - Selecting the Simulation > Model Configuration Parameters menu items

2. In the Configuration Parameters dialog, click Code Generation, and then click “+” next to Code Generation. This action displays the sub-panes under Code Generation.

3. On the Code Generation pane, change System target file to idelink_ert.tlc or idelink_grt.tlc.

   The dialog displays a Coder Target pane under the Code Generation pane.

4. Select the Coder Target pane.
5. Select the Target Hardware Resources tab.
6. Set the following parameters to match the tool chain and target hardware you are using:
   - IDE/Tool Chain
   - Board
   - Processor
Review the other parameters under the **Target Hardware Resources** tab.

Click **Apply**, and save the changes to your model.

**Configuration Parameters**

- “What are Configuration Parameters?” on page 75-5
- “Setting Model Configuration Parameters” on page 75-5

**What are Configuration Parameters?**

To see the model Configuration Parameters, open the **Configuration Parameters** dialog. You can do this in the model editor by selecting **Simulation > Model Configuration Parameters**, or by pressing **Ctrl+E** on your keyboard.

The **Configuration Parameters** dialog specifies the values for a model’s active configuration set. These parameters determine the type of solver used, the import and export settings, and other values that determine how the model runs.

**Setting Model Configuration Parameters**

To set the Configuration Parameters to the right values for you to generate code from your model, see “Configure Parameters Under the Target Hardware Resources Tab” on page 75-4. This action initializes the model Configuration Parameters to the right default values for you to generate code. You can then use the Configuration Parameters dialog to make further modifications to the values. You can generate buildable code using these default values.

The following subsections provide a quick overview of the panes and parameters with which you are most likely to interact.

**Code Generation Pane**

When you set **System target file** to `idelink_ert.tlc` or `idelink_grt.tlc`, the dialog adds an **Coder Target** pane to the list of panes under **Code Generation**.

Leave **Language** set to C. The `idelink_ert.tlc` and `idelink_grt.tlc` system target files do not support C++ code generation.

For more information, see “Model Configuration Parameters: Code Generation” (Simulink Coder).
The Coder Target entry provides options in these areas:

- **Run-Time** — Set options for run-time operations, like the build action
- **Vendor Tool Chain** — Set compiler, linker, and system stack size options
- **Code Generation** — Configure your code generation requirements
- **Link Automation** — Export an IDE link handle object, such as `IDE_Obj`, to your MATLAB workspace
- **Diagnostics** — Determine how the code generation process responds when you use source code replacement in the **Custom Code** pane.
For more information, see Code Generation Pane: Coder Target.

**Model Reference**

The `ert.tlc` system target files provide support for generating code from models that use Model Reference. A referenced model will generate an archive library.

To enable Model Reference builds:

1. Open your referenced model.
2. Select Simulation > Model Configuration Parameters from the model menus.
3. From the list of panes under **Code Generation**, choose **Coder Target**.
4. In the right pane, under Run-Time, select **Archive_library** from the **Build action** list.

If your top-model uses a reference model that does not have the **Build action** set to **Archive_library**, the build process automatically changes the **Build action** to **Archive_library** and issues a warning about the change.

**Configuration Parameters in Reference Models**

Use the same Coder Target pane settings in Configuration Parameters for the models in the model hierarchy.
XMakefiles for Software Build Tool Chains

</table>

What is the XMakefile Feature

- “Overview” on page 75-8
- “Available XMakefile Configurations” on page 75-9
- “Feature Support” on page 75-10

Overview

You can use makefiles instead of IDE projects during the automated software build process. This approach is described in “Using Makefiles to Generate and Build Software” on page 75-10.

The XMakefile feature lets you choose the configuration of a specific software build tool chain to use during the automated build process. The configuration contains paths and settings for your make utility, compiler, linker, archiver, pre-build, post-build, and execute tools.

You can also create a new configuration for a new tool chain, as described in “Creating a New XMakefile Configuration” on page 75-13.

Your requirements for specific features may determine whether you choose makefiles or IDE projects. See “Feature Support” on page 75-10.

Note The XMakefile feature is an older build process that uses extended template makefiles. For new code generation projects, use the toolchain approach build process. See “Choose Build Approach and Configure Build Process” on page 43-14.
Available XMakefile Configurations

The following list describes the configurations in the XMakefile dialog that this product supports:

- **adivdsp_blackfin**: Analog Devices VisualDSP++ & Analog Devices Blackfin®
- **adivdsp_sharc**: Analog Devices VisualDSP++ & Analog Devices SHARC®
- **adivdsp_tigersharc**: Analog Devices VisualDSP++ & Analog Devices TigerSHARC®
- **gcc_target**: GNU Compiler Collection & Host Operating System or Embedded Operating System
- **wrsdiab_arm9_vxworks67_rtp**: Wind River Systems DIAB Compiler & ARM 9 & VxWorks 6.7 & real-time process applications
- **wrsdiab_arm9_vxworks67_rtp_so**: Wind River Systems DIAB Compiler & ARM 9 & VxWorks 6.7 & real-time process applications with shared object
- **wrsdiab_hostsim_vxworks67_rtp**: Wind River Systems DIAB Compiler & VxWorks Host Simulator & VxWorks 6.7 & real-time process applications
- **wrsdiab_hostsim_vxworks67_rtp_so**: Wind River Systems DIAB Compiler & VxWorks Host Simulator & VxWorks 6.7 & real-time process applications with shared object
- **wrsdiab_hostsim_vxworks68_rtp**: Wind River Systems DIAB Compiler & VxWorks Host Simulator & VxWorks 6.8 & real-time process applications
- **wrsdiab_hostsim_vxworks68_rtp_so**: Wind River Systems DIAB Compiler & VxWorks Host Simulator & VxWorks 6.8 & real-time process applications with shared object
- **wrsgnu_arm9_vxworks67_rtp**: Wind River Systems GNU Compiler & VxWorks Host Simulator & VxWorks 6.7 & real-time process applications
- **wrsgnu_hostsim_vxworks67_rtp**: Wind River Systems GNU Compiler & VxWorks Host Simulator & VxWorks 6.7 & real-time process applications with shared object
- **wrsgnu_hostsim_vxworks68_rtp**: Wind River Systems GNU Compiler & VxWorks Host Simulator & VxWorks 6.8 & real-time process applications with shared object
- **xilinx_ise_14_x**: Xilinx ISE Design Suite & ARM Cortex-A9 running Linux on Xilinx Zynq-7000 platform
Feature Support

With makefiles, you cannot use features that rely on direct communications between your MathWorks software and third-party IDEs.

You cannot use the following features with makefiles:

- IDE Project Generation
- IDE Automation Interface
- IDE debugger communications during Processor-in-the-loop (PIL) simulation

Using Makefiles to Generate and Build Software

Configuring Your Model to Use Makefiles

Update your model Configuration Parameters to use a makefile instead of an IDE when you build software from the model:

1. Configure your model for your IDE, tool chain, and target hardware, as described in “Configure Target Hardware Resources” on page 75-3.
2. In the Configuration Parameters dialog, under the Code Generation tab, select Coder Target.
3. Set Build format to Makefile. For more information, see “Build format”.
4. Set Build action to Build_and_execute. For more information, see “Build action”.

Choosing an XMakefile Configuration

Configure how to generate makefiles:

1. Enter xmakefilesetup on the MATLAB Command Window. The software opens an XMakefile User Configuration dialog.
2 Set the **Template** parameter to the option that matches the **Configuration** parameter.

**Note** In most cases, the only option for **Template** is `gmake`. However, if you have installed a Support Package, **Template** can have multiple options.

3 For **Configuration**, select the option that describes your software build toolchain and target platform. Click **Apply**.

**Note** Changing some elements of the XMakefile dialog disables other elements until you apply the changes. Click **Apply** or **OK** after changing:

- **Template**
- **Configurations**
- **User Templates**
- **User Configurations**
- **Tool Directories**

**Note** With the XMakefile User Configuration dialog, if you have an Embedded Coder license and do not have a Simulink Coder license, the **Configuration** list includes two unsupported options: `gcc_target` or `msvs_host`. Disregard those two configurations. Choose one of the other configurations.
Things to consider while setting **Configuration**:

- Selecting **Display operational configurations only** hides configurations that contain incomplete or invalid information. For a configuration to be operational, the vendor tool chain must be installed, and the configuration must have the valid paths for each component of the vendor tool chain. For more information, see “Making an XMakefile Configuration Operational” on page 75-12.
- To display the configurations, including non-operational configurations, clear **Display operational configurations only**.
- The list of configurations can include non-editable configurations defined in the software and editable configurations defined by you.
- To create a new editable configuration, use the **New** button.
- For more information, see “XMakefile User Configuration dialog” on page 75-19.

**Building Your Model**

In your model, click **Build Model**.

![Build Model](image)

This action creates a makefile and performs the other actions you specified in **Build action**.

By default, this process outputs files in the `<builddir>/<buildconfiguration>` folder. For example, in `model_name/CustomMW`.

**Making an XMakefile Configuration Operational**

When the XMakefile utility starts, it checks each configuration file to verify that the specified paths for the vendor tool chain are valid. If the paths are not valid, the configuration is non-operational. Typically, the cause of this problem is a difference between the path in the configuration and the actual path of the vendor toolchain.

To make a configuration operational:

1. Clear **Display operational configurations only** to display non-operational configurations.
2 Select the non-operational configuration from the Configuration options.

3 When you click Apply, a new dialog prompts you for the folder path of the missing resources the configuration requires.

Use mapped network drives instead of UNC paths to specify directory locations. Using UNC paths with compilers that do not support them causes build errors.

Creating a New XMakefile Configuration

- “Overview” on page 75-13
- “Create a Configuration” on page 75-13
- “Modify the Configuration” on page 75-15
- “Test the Configuration” on page 75-17

Overview

This example shows you how to add support for a software development toolchain to the XMakefile utility. This example uses the Intel Compiler and an IDE.

Note To specify directory locations, use mapped network drives instead of UNC paths. UNC paths cause build errors with compilers that do not support them.

Create a Configuration

When you click New, the new configuration inherits values and behavior from the current configuration. To create a configuration for the Intel Compiler, clone a configuration from one of these configurations: montavista_arm and gcc_target.

Open the XMakefile User Configuration UI by typing xmakefilesetup at the MATLAB prompt. This action displays the following dialog.
Select an existing configuration, such as montavista_arm or gcc_target. Click the New button.

A pop-up dialog prompts you for the name of the new configuration. Enter intel_compiler and click OK.

The dialog displays a new configuration called intel_compiler, based on the previous configuration.
Modify the Configuration

Adjust the compiler, linker, and archiver settings of the newly created configuration. This example assumes the location of the Intel compiler is C:\Program Files\Intel\Compiler\.

Make Utility

You do not need to make changes. This configuration uses the gmake tool that ships with MATLAB.

Compiler

For Compiler, enter the location of icl.exe in the Intel installation.
Linker

For **Linker**, enter the location of the linker executable, xilink.exe. For **Arguments**, add the /LIBPATH path to the Intel libraries.

Archiver

For **Archiver**, enter the location of the archiver, xilib.exe. Confirm that **File extensions for library files** includes .lib.
Other tabs

For this example, ignore the remaining tabs. In other circumstances, you can use them to configure additional build actions. In a later step of this example, you will configure the software to automatically build and run the generated code.

Test the Configuration

Open the “sumdiff” model by entering sumdiff on the MATLAB prompt.
Configure the summdiff model for use with an IDE. Follow the steps in “Configure Target Hardware Resources” on page 75-3, set the IDE/Tool Chain parameter, set Board to Custom, and Processor to Intel x86/Pentium.

On the Tool Chain Automation page, set Operating System to None or select Windows. Click OK.

Open the Configuration Parameters for the sumdiff model by pressing Ctrl+E. Set Build format to Makefile and Build action to Build_and_execute.

Save the model to a temporary location, such as C:\Temp\IntelTest\. Set that location as a Current Folder by typing cd C:\temp\IntelTest\ at the MATLAB prompt.

Build the model by pressing Ctrl+B. The MATLAB Command Window displays something like:

```bash
### TLC code generation complete.
### Creating HTML report file sumdiff_codegen_rpt.html
### Creating project: c:\temp\IntelTest\sumdiff_idenameide\sumdiff.mk
### Project creation done.
### Building project...
### Build done.
### Downloading program: c:\temp\IntelTest\sumdiff_idenameide\sumdiff
### Download done.
```
A command window comes up showing the running model. Terminate the generated executable by pressing **Ctrl+C**.

**XMakefile User Configuration dialog**

- “Active” on page 75-19
- “Make Utility” on page 75-21
- “Compiler” on page 75-21
- “Linker” on page 75-22
- “Archiver” on page 75-23
- “Pre-build” on page 75-23
- “Post-build” on page 75-24
- “Execute” on page 75-24
- “Tool Directories” on page 75-25

**Active**

![XMakefile User Configuration dialog](image)

**Template**

Set the **Template** parameter to the option that matches the **Configuration** parameter.

**Note** In most cases, the only option for **Template** is gmake. However, if you have installed a Support Package, **Template** can have multiple options.
The template defines the syntax rules for writing the contents of the makefile or buildfile. The default template is `gmake`, which works with the GNU make utility.

To add templates to this parameter, save them as `.mkt` files to the location specified by the **User Templates** parameter. For more information, see “User Templates” on page 75-21.

**Configuration**

Select the configuration that best describes your toolchain and target hardware.

You cannot edit or delete the configurations provided by MathWorks. You can, however, edit and delete the configurations that you create.

Use the **New** button to create an editable copy of the currently selected configuration.

Use the **Delete** button to delete a configuration you created.

**Note** You cannot edit or delete the configurations provided by MathWorks.

**Note** Use mapped network drives instead of UNC paths to specify directory locations. Using UNC paths with compilers that do not support them causes build errors.

**Display operational configurations only**

When you open the XMakefile User Configuration dialog, the software verifies that each configuration provided by MathWorks contains valid paths to the executable files it uses. If the paths are valid, the configuration is operational. If the paths are not valid, the configuration is not operational.

This setting only applies to configurations provided by MathWorks, not configurations you create.

To display valid configurations, select **Display operational configurations only**.

To display the configurations, including non-operational configurations, clear **Display operational configurations only**.

For more information, see “Making an XMakefile Configuration Operational” on page 75-12.
**User Templates**

Set the path of the folder to which you can add template files. Saving templates files with the .mkt extension to this folder adds them to the Templates options.

**User Configurations**

Set the location of configuration files you create with the New button.

**Make Utility**

Set the path and filename of the make utility executable.

**Arguments**

Define the command-line arguments to pass to the make utility. For more information, consult the third-party documentation for your make utility.

**Optional include**

Set the path and file name of an optional makefile to include.

**Compiler**

Set the path and file name of the compiler executable.
**Arguments**

Define the command-line arguments to pass to the compiler. For more information, consult the third-party documentation for your compiler.

**Source**

Define the file name extension for the source files. Use commas to separate multiple file extensions.

**Header**

Define the file name extension for the header files. Use commas to separate multiple file extensions.

**Object**

Define the file name extension for the object files.

**Linker**

Set the path and file name of the linker executable.

**Arguments**

Define the command-line arguments to pass to the linker. For more information, consult the third-party documentation for your linker.

**File extensions for library files**

Define the file name extension for the file library files. Use commas to separate multiple file extensions.

**Generated output file extension**

Define the file name extension for the generated libraries or executables.
**Archiver**

Set the path and file name of the archiver executable.

**Arguments**

Define the command-line arguments to pass to the archiver. For more information, consult the third-party documentation for your archiver.

**Generated output file extension**

Define the file name extension for the generated libraries.

**Pre-build**

**Enable Prebuild Step**

Select this check box to define a prebuild tool that runs before the compiler.

**Prebuild tool**

Set the path and file name of the prebuild tool executable.

**Arguments**

Define the command-line arguments to pass to the prebuild tool. For more information, consult the third-party documentation for your prebuild tool.
Post-build

Enable Postbuild Step

Select this check box to define a postbuild tool that runs after the compiler or linker.

Postbuild tool

Set the path and file name of the postbuild tool executable.

Arguments

Define the command-line arguments to pass to the postbuild tool. For more information, consult the third-party documentation for your postbuild tool.

Execute

Use Default Execute Tool

Select this check box to use the generated derivative as the execute tool when the build process is complete. Uncheck it to specify a different tool. The default value, echo, simply displays a message that the build process is complete.

Note

On the Linux operating system, multirate multitasking executables require root privileges to schedule POSIX threads with real-time priority. If you are using makefiles to build multirate multitasking executables on your Linux development system, you cannot use Execute tool to run the executable. Instead, use the Linux command, sudo, to run the executable.
**Execute tool**

Set the path and file name of the execute tool executable or built-in command.

**Arguments**

Define the command-line arguments to pass to the execute tool. For more information, consult the third-party documentation for your execute tool.

**Tool Directories**

Use the Tool Directories tab to change the toolchain path of an operational configuration.

For example, if you installed two versions of a vendor build tool in separate folders, you can use the **Installation** path to change which one the configuration uses.
Verification and Profiling Generated Code in Embedded Coder

Overview

Verification consists broadly of running generated code on a processor and verifying that the code does what you intend. Embedded Coder provides processor-in-the-loop (PIL) simulation to meet this need. PIL compares the numeric output of your model under simulation with the numeric output of your model running as an executable on a target hardware.

With PIL, you run your generated code on a target hardware or instruction set simulator. To verify your generated code, you compare the output of model simulation modes, such as Normal or Accelerator, with the output of the generated code running on the processor. You can switch between simulation and PIL modes. This flexibility allows you to verify the generated code by executing the model as compiled code in the target environment. You can model and test your embedded software component in Simulink and then reuse your regression test suites across simulation and compiled object code. This process avoids the time-consuming process of leaving the Simulink software environment to run tests again on object code compiled for the production hardware.

Embedded Coder supports the following PIL approaches:

- Model block PIL
- Top-model PIL
- PIL block

When you use makefiles with PIL, use the “model block PIL” approach. With makefiles, the other two approaches, “top-model PIL” and “PIL block”, and are not supported.
PIL Approaches

- “Model Block PIL” on page 76-3
- “Top-Model PIL” on page 76-4
- “PIL Block” on page 76-5

Model Block PIL

Use model block PIL to:

- Verify code generated for referenced models (model reference code interface).
- Provide a test harness model (or a system model) to generate test vector or stimulus inputs.
- Switch a model block between normal, SIL, or PIL simulation modes.

To perform a model block PIL simulation, start with a top-model that contains a model block. The top-model serves as a test harness, providing inputs and outputs for the model block. The model block references the model you plan to run on target hardware. During PIL simulation, the referenced model runs on the target hardware.

For more information about using the model block, see Model and “Model Referencing” (Simulink).

By default, your MathWorks software uses the IDE debugger for PIL communications with the target hardware. To achieve faster communications, consider using one of the alternatives presented in “Communications” on page 76-7.

To use model block PIL:

1. Create and share a configuration reference between the top model and the referenced model, as described in “Share a Configuration for Multiple Models” (Simulink).
2. Right-click the Model block, and select **ModelReference Parameters**.
3. When the software displays the **Function Block Parameters: Model** dialog box, set **Simulation mode** to **Processor-in-the-loop** (PIL) and click **OK**.
4. Open the model block.
5. In the referenced model (model block) Configuration Parameters (Ctrl+E), under **Code Generation > Coder Target**, set **Build action** set to **Archive_library**. This action avoids a warning when you start the simulation.
6 Save the changes to both models.
7 In the top-model menu bar, select **Simulation > Run**. This action builds the referenced model in the model block, downloads it to your target hardware, and runs the PIL simulation.

**Note** In the top-model Configuration Parameters (Ctrl+E), under **Code Generation > Coder Target**, leave **Build action** set to **Build_and_execute**. Do not change **Build action** to **Create_Processor_In_the_Loop_Project**.

---

**Top-Model PIL**

Use top-model PIL to:

- Verify code generated for a top-model (standalone code interface).
- Load test vectors or stimulus inputs from the MATLAB workspace.
- Switch the entire model between normal and SIL or PIL simulation modes.

**Setting Model Configuration Parameters to Generate the PIL Application**

Configure your model to generate the PIL executable from your model:

1 Configure your model to run on target hardware, as described in “Configure Target Hardware Resources” on page 75-3.
2 From the model toolstrip, select **Simulation > Model Configuration Parameters**.
3 In Configuration Parameters, select **Code Generation**.
4 Set **System Target File** to **idelink_ert.tlc**.
5 From the list of panes under **Code Generation**, choose **Coder Target**.
6 Set **Build format** to **Project**.
7 Set **Build action** to **Create_processor_in_the_loop_project**.
8 Click **OK** to close the Configuration Parameters dialog box.

For more information, see “Code Generation: Coder Target Pane”.

**Running the Top-Model PIL Application**

To create a PIL block, perform the following steps:
1 In the model toolstrip, set the Simulation mode to Processor-in-the-loop.

2 In the model toolstrip, click Run.

A new Simulink Editor opens with the new PIL model block in it. The third-party IDE compiles and links the PIL executable file. Follow the progress of the build process in the MATLAB Command Window.

**PIL Block**

Use the PIL block to:

- Verify code generated for a top-model (standalone code interface) or subsystem (right-click build standalone code interface).
- Represent a component running in SIL or PIL mode. The test harness model or a system model provides test vector or stimulus inputs.

**Preparing Your Model to Generate a PIL Block**

Start with a model that contains the algorithm blocks you want to verify on the processor as compiled object code. To create a PIL application and PIL block from your algorithm subsystem, follow these steps:

1 Identify the algorithm blocks to cosimulate.
2 Convert those blocks into an unmasked subsystem in your model.

For information about how to convert your process to a subsystem, refer to Creating Subsystems (Simulink) in *Using Simulink* or in the online Help system.

3 Open the newly created subsystem.
4 Configure your subsystem to run on target hardware, as described in “Configure Target Hardware Resources” on page 75-3.
Setting Model Configuration Parameters to Generate the PIL Application

After you create your subsystem, set the Configuration Parameters for your model to enable the model to generate a PIL block.

Configure your model to enable it to generate PIL algorithm code and a PIL block from your subsystem:

1. From the model menu bar, select Simulation > Model Configuration Parameters. This action opens the Configuration Parameters dialog box.
2. In the Configuration Parameters dialog box, select Code Generation.
3. Set System Target File to idelink_ert.tlc.
4. From the list of panes under Code Generation, choose Coder Target.
5. Set Build format to Project.
6. Set Build action to Create_processor_in_the_loop_project.
7. Click OK to close the Configuration Parameters dialog box.

For more information, see “Code Generation: Coder Target Pane”.

Creating the PIL Block from a Subsystem

To create a PIL block, perform the following steps:

1. Right-click the masked subsystem in your model and select C/C++ Code > Build This Subsystem from the context menu.

A new Simulink Editor opens and the new PIL block appears in it. The third-party IDE compiles and links the PIL executable file.

This step builds the PIL algorithm object code and a PIL block that corresponds to the subsystem, with the same inputs and outputs. Follow the progress of the build process in the MATLAB Command Window.

2. Copy the new PIL block from the new model to your model. To simulate the subsystem processes concurrently, place it parallel to your masked subsystem. Otherwise, replace the subsystem with the PIL block.

To see a PIL block in a parallel masked subsystem, search the product help for Getting Started with Application Development and select the example that matches your IDE.
**Note** Models can have multiple PIL blocks for different subsystems. They cannot have more than one PIL block for the same subsystem. Including multiple PIL blocks for the same subsystem causes errors and inaccurate results.

**Communications**

- “TCP/IP” on page 76-7
- “IDE Debugger” on page 76-9

Choose one of the following communication methods for transferring code and data during PIL simulations:

<table>
<thead>
<tr>
<th>Method</th>
<th>Speed</th>
<th>Comments</th>
</tr>
</thead>
</table>
| IDE Debugger | Slow  | • Supports PIL communications with an executable running an embedded target hardware.  
• Supports the largest number of targets.  
• Requires a physical connection between host and target hardware.  
• Only works with builds from IDE projects. Does not work with builds from makefiles. |
| TCP/IP     | Fast  | • Supports PIL communications with an executable running on a Linux or Windows host.  
• Supports embedded targets running Linux, TI DSP/BIOS, and Wind River VxWorks.  
• Requires network connection between host and target hardware.  
• Works with builds from IDE projects and from makefiles. |

**TCP/IP**

You can use TCP/IP for PIL communications with target hardware running:
Using TCP/IP for PIL communications is typically faster than using a debugger, particularly for large data sets, such as with video and audio applications.

It also works well when you build an application on a remote Linux target using the remoteBuild function.

You can use TCP/IP with the following PIL approaches:

- Top-model PIL
- Model block PIL

TCP/IP does not work with the Subsystem PIL approach.

To enable and configure TCP/IP with PIL:

1. Set up a PIL simulation according to the PIL approach you have chosen.
2. In the MATLAB Command Window, use `setpref` to specify the IP address of the PIL server (`servername`).

   If you are running the PIL server on a remote target, specify the IP address of the target hardware. For example:
   ```matlab```
   ```
   setpref('MathWorks_Embedded IDE Link PIL Preferences', 'servername', '144.212.109.114');
   ```
   ```
   If you are running PIL server locally, on your host Windows or Linux system, enter 'localhost' instead of an IP address:
   ```matlab```
   ```
   setpref('MathWorks_Embedded IDE Link PIL Preferences', 'servername', 'localhost');
   ```
   ```
   3. Specify the TCP/IP port number to use for PIL data communication. Use one of the free ports in your system. For example:
      ```matlab```
      ```
      setpref('MathWorks_Embedded IDE Link PIL Preferences', 'portnum', 17025);
      ```
      ```
   4. Enable PIL communications over TCP/IP:
      ```matlab```
      ```
      setpref('MathWorks_Embedded IDE Link PIL Preferences', 'enabletcpip', true);
      ```
      ```
   To disable PIL communications over TCP/IP, change the value to `false`. This action automatically enables PIL communications over an IDE debugger, if an IDE is available.
Open the Configuration Parameters in your model. On the Coder Target pane, set the Operating System parameter to the operating system your target hardware is running.

**Note** You cannot use TCP/IP for PIL when the value of Operating System is None.

Regenerate the code or PIL block.

To disable PIL communications over TCP/IP, enter:

```matlab
setpref('MathWorks_Embedded_IDE_Link_PIL_Preferences','enabletcpip', false);
```

**IDE Debugger**

To enable PIL communications over an IDE debugger, disable PIL communications over TCP/IP and SCI by entering the following commands:

```matlab
setpref('MathWorks_Embedded_IDE_Link_PIL_Preferences','enabletcpip',false);
setpref('MathWorks_Embedded_IDE_Link_PIL_Preferences','enableserial',false);
```

Then regenerate the code or PIL block.

Using IDE debugger for PIL communication only works when you build your code from IDE projects. Using IDE debugger for PIL communication does not work with builds from makefiles.

**Configuring Breakpoints**

You can use the `setStartApplicationPause` API to set breakpoints in the PIL application on the first PIL block simulation. If you do not use the `setStartApplicationPause` API, you can configure breakpoints after the initial run. The breakpoints remain active for subsequent runs.

You can enter the following static API method to pause after loading the application and manually configure breakpoints:

```matlab
rtw.connectivity.Launcher.setStartApplicationPause(pauseAmount)
```

About this method:

- This method tells the MATLAB session to pause immediately after the PIL launcher starts the PIL application.
- `pauseAmount` is a pause time in seconds. To disable the pause, enter 0.

When you do not specify a pause, the software displays the following message:
### To pause during PIL application start, run: >> rtw.connectivity.Launcher.
setStartApplicationPause(120)

The default pause is 120 sec. You can change this value.

When you specify a pause, a Start PIL Application Pause message box appears and displays following message:

Pausing during PIL application start for 120s (click OK to continue).
To disable this pause, see the hyperlink in the MATLAB command window.

- The MATLAB Command Window shows the following text:

  ### To remove the pause during PIL application start,
  run: >> rtw.connectivity.Launcher. setStartApplicationPause(0)

  where rtw.connectivity.Launcher. setStartApplicationPause(0) is a hyperlink.
- The pause times out, or you can clear it early by closing the message box.
- During the pause, you cannot access MATLAB and thus cannot configure breakpoints programmatically via the IDE Automation Interface API.
- For the PIL block, the debugger stays open between simulation runs. When you perform an initial simulation run, you can automatically configure breakpoints via the IDE Automation Interface API before starting the second simulation.

## Running Your PIL Application to Perform Simulation and Verification

After you add PIL block to your model, add the required pause in seconds, using the following command in the MATLAB command prompt:

rtw.connectivity.Launcher.setStartApplicationPause(120)

Then click **Simulation > Run** or press **Ctrl+T** to run the PIL simulation and view the results.

**Note** The pause command is to make sure that the automatic download of PIL completes, before the model starts executing.
Definitions

PIL Algorithm

The algorithmic code, which corresponds to a subsystem or portion of a model, to test during the PIL simulation. The PIL algorithm is in compiled object form to enable verification at the object level.

PIL Application

The executable application that runs on the processor platform. The code generator produces code for a PIL application by augmenting your algorithmic code with the PIL execution framework. The PIL execution framework code compiles as part of your embedded application.

The PIL execution framework code includes the string.h header file so that the PIL application can use the memcpy function. The PIL application uses memcpy to exchange data between the Simulink model and the simulation processor.

PIL Block

When you build a subsystem from a model for PIL, the process creates a PIL block optimized for PIL simulation. When you run the simulation, the PIL block acts as the interface between the model and the PIL application running on the processor. The PIL block inherits the signal names and shape from the source subsystem in your model. Inheritance is convenient for copying the PIL block into the model to replace the original subsystem for simulation.

PIL Issues and Limitations

Consider the following issues when you work with PIL blocks.

Constraints

When using PIL in your models, keep in mind the following constraints:

- Models can have multiple PIL blocks for different subsystems. They cannot have more than one PIL block for the same subsystem. Including multiple PIL blocks for the same subsystem causes errors and inaccurate results.
- A model can contain a single model block running PIL mode.
• A model can contain a subsystem PIL block or a model block in PIL mode, but not both.

**Generic PIL Issues**

Refer to PIL Feature Support and Limitations on page 67-68 for general information about using the PIL block with embedded link products.

**Simulink Coder grt.tlc-Based Targets Not Supported**

PIL does not support grt.tlc system target files.

To use PIL, set **System target file** in the Configuration Parameters > Code Generation pane to idelink_ert.tlc.
Code Execution Profiling for IDE and Toolchain Targets

In this section...

| “Execution-Time Profiling” on page 76-13 |
| “Stack Profiling” on page 76-13 |

Execution-Time Profiling

You can measure the execution times during a standalone execution or processor-in-the-loop (PIL) simulation. You can generate execution time profiles for synchronous tasks, asynchronous tasks, and atomic subsystems. Use this feature to check whether your code runs in real time on your target hardware. For details, see “Perform Execution-Time Profiling for IDE and Toolchain Targets” on page 76-16.

You can use this profiling for generated code in the following cases:

- **Code Generation > System target file** is ert.tlc and **Code Generation > Target hardware** is not None, for example, ARM Cortex-A9 (QEMU) or ARM Cortex-M3 (QEMU).
- **Code Generation > System target file** is idelink_ert.tlc

The following table provides execution time profiling support information.

<table>
<thead>
<tr>
<th>Mode</th>
<th>Coder Target &gt; Tool Chain Automation &gt; Build format parameter value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Standalone execution or PIL simulation</td>
<td>Project</td>

Stack Profiling

With stack profiling, you can determine how generated code uses the processor system stack. Using the profile method, you can initialize and test the size and usage of the stack. See “Perform Stack Profiling with IDE and Toolchain Targets” on page 76-22. This information can help you optimize both the size of the stack and how your code uses the stack.

You can use this profiling for generated code in the following cases:
• **Code Generation > System target file** is `ert.tlc` and **Code Generation > Target hardware** is not None, for example, ARM Cortex–A9 (QEMU) or ARM Cortex–M3 (QEMU).

• **Code Generation > System target file** is `idelink_ert.tlc`

**Note** Stack profiling is not supported on embedded targets that run an operating system or RTOS.

To provide stack profiling, `profile` writes a known pattern to the addresses in the stack. After you run your application for a while, and then stop your application, `profile` examines the contents of the stack addresses. `profile` counts each address that does not contain the known pattern. The total number of addresses that have been used, compared to the total number of addresses that you allocated, becomes the stack usage profile. This profile process does not determine how often your application changes an address.

You can profile the stack with the manually written code in a project and the code that you generate from a model.

When you use `profile` to initialize and test the stack operation, the software returns a report that contains information about stack size, usage, addresses, and direction. With this information, you can modify your code to use the stack efficiently. The following program listing shows the stack usage results from running an application on a simulator.

```matlab
profile(IDE_Obj,'stack','report')

Maximum stack usage:

System Stack: 532/1024 (51.95%) MAUs used.

| name: System Stack | startAddress: [512 0] | endAddress: [1535 0] | stackSize: 1024 MAUs | growthDirection: ascending |

The following table describes the entries in the report.
<table>
<thead>
<tr>
<th>Report Entry</th>
<th>Units</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Stack</td>
<td>Minimum Addressable Unit (MAU)</td>
<td>Maximum number of MAUs used and the total MAUs allocated for the stack.</td>
</tr>
<tr>
<td>name</td>
<td>Character vector for the stack name</td>
<td>Lists the name assigned to the stack.</td>
</tr>
<tr>
<td>startAddress</td>
<td>Decimal address and page</td>
<td>Lists the address of the stack start and the memory page.</td>
</tr>
<tr>
<td>endAddress</td>
<td>Decimal address and page</td>
<td>Lists the address of the end of the stack and the memory page.</td>
</tr>
<tr>
<td>stackSize</td>
<td>Addresses</td>
<td>Reports number of address locations, in MAUs, allocated for the stack.</td>
</tr>
<tr>
<td>growthDirection</td>
<td>Not applicable</td>
<td>Reports whether the stack grows from the lower address to the higher address (ascending) or from higher to lower (descending).</td>
</tr>
</tbody>
</table>

Perform Execution-Time Profiling for IDE and Toolchain Targets

In this section...

| “Execution-Time Profiling During Standalone Execution” on page 76-16 |
| “Execution-Time Profiling During PIL Simulation” on page 76-19 |

Execution-Time Profiling During Standalone Execution

During standalone execution, instrumentation in the generated code collects execution-time samples, which are stored in target hardware memory. After halting target hardware execution, you can use the profile function to transfer the execution data from target hardware memory to the MATLAB workspace for viewing and analysis.

You can perform profiling by task or subsystem. A profiling sample represents a task or subsystem execution instance. Each sample requires two memory locations, one for the start time and one for the end time. Therefore, you must specify a buffer size that is twice the number of required profiling samples. Sample collection begins with the start of code execution and ends when the buffer is full.

Task Profiling

To configure a model for task execution profiling:

1. In your model, select Simulation > Model Configuration Parameters.
2. Select the Code Generation > Coder Target pane.
3. Set Build format to Project and set Build action to Build_and_execute.
4. Select Profile real-time execution.
5. In the Profile by list, select Tasks.
6. Specify Number of profiling samples to collect, the size of the buffer that stores execution data. Enter a value that is twice the number of profiling samples you require.
7. Click OK.

To view the execution profile for your model:
1 Click **Build Model** on the model toolstrip. This action builds, loads, and runs your code on the processor.

2 To stop the running program, select **Debug > Halt** in the IDE or use `IDE_obj.halt` from the MATLAB command line. Gathering profiling data from a running program can yield inaccurate results.

3 At the MATLAB command prompt, enter

   ```matlab
   profile(IDE_Obj,'execution','report')
   ```

   to view the MATLAB software graphic of the execution report and the HTML execution report.

   For more information about other reporting options, see the product help for the `profile` function.

The following profiling plot is from an application that runs with three rates — the base rate and two slower rates. Gaps in the **Sub-Rate 2** task bars indicate preempted operations.

**Subsystem Profiling**

To configure a model for subsystem execution profiling:
1  Configure your model for your IDE, tool chain, and target hardware, as described in “Configure Target Hardware Resources” on page 75-3.

2  On the Coder Target pane, set Build format to Project and set Build action to Build_and_execute.

3  Select Profile real-time execution.

4  In the Profile by list, select Atomic subsystems.

5  Specify Number of profiling samples to collect, the size of the buffer that stores execution data. Enter a value that is twice the number of profiling samples you require.

6  Click OK.

To view the execution profile for your model:

1  Click Build Model on the model toolstrip. This action builds, loads, and runs your code on the processor.

2  To stop the running program, select Debug > Halt in the IDE or use IDE_obj.halt from the MATLAB command line. Gathering profiling data from a running program can yield inaccurate results.

3  At the MATLAB command prompt, enter:

   profile(IDE_Obj, 'execution', 'report')

   to view the MATLAB software graphic of the execution report and the HTML execution report.

The following profiling plot is from an application with three subsystems — For Iterator Subsystem, For Iterator Subsystem1, and Idle Task Subsystem.
Execution-Time Profiling During PIL Simulation

During a processor-in-the-loop (PIL) simulation, you can profile execution times of synchronous tasks. The software stores the profile data in a `coder.profile.ExecutionTime` object, located in the MATLAB workspace. After halting the PIL simulation, you can view and analyze the data.

**Gathering Execution Profile Data**

1. Configure a model for PIL simulation, as described in “PIL Simulation for IDE and Toolchain Targets” on page 76-2.
2. In your model, select **Simulation > Model Configuration Parameters**.
3. In the Configuration Parameters dialog box, select **Code Generation**, and then **Verification**.
4. Select the **Measure task execution time** check box.
5. Provide a valid MATLAB variable name in the **Workspace** edit box. The software uses this name when it creates the `coder.profile.ExecutionTime` object.
6. Click **OK** to close the Configuration Parameters dialog box.
Run the PIL simulation, as described in “PIL Simulation for IDE and Toolchain Targets” on page 76-2.

The software creates the `coder.profile.ExecutionTime` object and stores the execution profile data in it.

Halt the PIL simulation.

**Analyzing the Execution Profile Data**

After halting the PIL simulation, you can view or analyze the data in the `coder.profile.ExecutionTime` object. For more information, see:

- “View and Compare Code Execution Times” on page 61-7
- “Analyze Code Execution Data” on page 61-16

Depending on the target, the execution profile data is measured in seconds or timer ticks.

<table>
<thead>
<tr>
<th>Targets</th>
<th>Units</th>
</tr>
</thead>
<tbody>
<tr>
<td>Analogue Devices Blackfin, SHARC, and TigerSHARC processors with VisualDSP++ IDE</td>
<td>Timer Ticks</td>
</tr>
<tr>
<td>ARM processors running Wind River VxWorks</td>
<td>Timer Ticks</td>
</tr>
</tbody>
</table>

The `coder.profile.ExecutionTime` class has property `TimerTicksPerSecond` for getting and setting the data units. You can use this property on the execution profile data object after halting the PIL simulation. When the data unit is timer ticks, using the `TimerTicksPerSecond` property converts the data units to seconds.

**See Also**

`TimerTicksPerSecond`, `profile`

Perform Stack Profiling with IDE and Toolchain Targets

To profile the system stack operation:

1. Load an application.
2. Set up the stack to enable profiling.
3. Run your application.
4. Request the stack profile information.

Follow these steps to profile the stack as your application interacts with it. This particular example uses Texas Instruments Code Composer Studio™ 3.3. However, you can generalize from this example to another supported IDE.

1. Load the application to profile.
2. Use the `profile` method with the `setup` input keyword to initialize the stack to a known state.

   ```matlab
   profile(IDE_Obj,'stack','setup')
   ```

   With the `setup` input argument, `profile` writes a known pattern into the addresses that compose the stack.

3. Run your application.
4. Stop your running application. Stack use results gathered from an application that is running may be inaccurate.
5. Use the `profile` method to capture and view the results of profiling the stack.

   ```matlab
   profile(IDE_Obj,'stack','report')
   ```

The following example shows how to set up and profile the stack. The IDE link handle object, `IDE_Obj`, must exist in your MATLAB workspace and your application must be loaded on your processor. This example comes from a TI C6713 simulator.

```matlab
profile(IDE_Obj,'stack','setup')  % Set up processor stack
% by write A5 to the stack addresses.
```

Maximum stack usage:

System Stack: 0/1024 (0%) MAUs used.

```plaintext
name: System Stack
startAddress: [512 0]
endAddress: [1535 0]
```
stackSize: 1024 MAUs
growthDirection: ascending

run(IDE_Obj)
halt(IDE_Obj)
profile(IDE_Obj,'stack','report') % Request stack use report.

Maximum stack usage:

System Stack: 356/1024 (34.77%) MAUs used.

name: System Stack
startAddress: [512  0]
endAddress: [1535  0]
stackSize: 1024 MAUs
growthDirection: ascending

<tbody>
<tr>
<td>“Using a Processor-Specific Code Replacement Library to Optimize Code” on page 77-2</td>
</tr>
</tbody>
</table>

Using a Processor-Specific Code Replacement Library to Optimize Code

You can optimize the code the code generator produces for a specific processor by configuring the code generator to use a code replacement library (CRL) during code generation. If you have an Embedded Coder license, you can develop and apply custom code replacement libraries.

For more information about replacing code, using code replacement libraries that MathWorks provides, see “What Is Code Replacement?” on page 41-2 and “Replace Code Generated from Simulink Models” on page 41-10. For information about developing code replacement libraries, see “What Is Code Replacement Customization?” on page 54-3 and “Develop a Code Replacement Library” on page 54-27.

Process of Determining Optimization Effects Using Real-Time Profiling Capability

You can use the real-time profiling capability to examine the results of applying the processor-specific library functions and operators to your generated code. After you select a processor-specific code replacement library, use the real-time execution profiling capability to examine the change in program execution time.

Use the following process to evaluate the effects of applying a processor-specific code replacement library when you generate code:

1. Enable real-time profiling in your model. Refer to “Code Execution Profiling”.
2. Generate code for your project without specifying a code replacement library (the default Code replacement library setting is None).
3. Profile the code, and save the report.
4 Rebuild your project using a processor-specific code replacement library.
5 Profile the code, and save the second report.
6 Compare the profile report from running your application with the processor-specific library selected to the profile results in the first report with no code replacement library selected.

For an example of verifying the code optimization, search help for "Optimizing Embedded Code via Code Replacement Library" and select the example that matches your IDE.
Code Generation from MATLAB Code
Build Configuration for Code Generation from MATLAB Code

Specify Comment Style for C/C++ Code

In this section...

“Specify Comment Style Using the MATLAB Coder App” on page 78-2
“Specify Comment Style Using the Command-Line Interface” on page 78-3

If you have an Embedded Coder, you can specify the comment style for C/C++ code generated from MATLAB code. Specify single-line style to generate single-line comments preceded by //. Specify multiline style to generate single-line or multiline comments delimited by /* and */. Single-line style is the default for C++ code generation. Multiline style is the default for C code generation. For C code generation, select single-line comment style only if your compiler supports it.

Specify Comment Style Using the MATLAB Coder App

1 On the Generate Code page, to open the Generate dialog box, click the Generate arrow.
2 Set Build type to one of the following:
   - Source Code
   - Static Library (.lib)
   - Dynamic Library (.dll)
   - Executable (.exe)
3 Click More Settings.
4 On the Code Appearance tab, select the Include comments check box if it is not already selected. By default, the Include comments check box is selected.
5 Set Comment Style to one of the following options.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Auto(Use standard comment style of the target language)</td>
<td>For C, generate multiline comments. For C++, generate single-line comments. (default)</td>
</tr>
<tr>
<td>Single-line (Use C++-style comments)</td>
<td>Generate single-line comments preceded by //.</td>
</tr>
<tr>
<td>Multi-line (Use C-style comments)</td>
<td>Generate single-line or multiline comments delimited by /* and */.</td>
</tr>
</tbody>
</table>
Specify Comment Style Using the Command-Line Interface

1. Create a code configuration object for C/C++ code generation. For example, create a configuration object for C/C++ static library generation:

```matlab
cfg = coder.config('lib','ecoder',true);
```

2. Set the CommentStyle property to one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'Auto'</td>
<td>For C, generate multiline comments. For C++, generate single-line comments. (default)</td>
</tr>
<tr>
<td>'Single-line'</td>
<td>Generate single-line comments preceded by <code>//</code>.</td>
</tr>
<tr>
<td>'Multi-line'</td>
<td>Generate single-line or multiline comments delimited by <code>/*</code> and <code>*/</code>.</td>
</tr>
</tbody>
</table>

For example, this code sets the comment style to single-line style:

```matlab
cfg.CommentStyle='Single-line';
```

coder.EmbeddedCodeConfig

**More About**
- “Configure Build Settings” (MATLAB Coder)
Specify Indent Style for C/C++ Code

If you have an Embedded Coder license, you can control the indent style and indent size in C/C++ code generated from MATLAB code. Indent style controls the placement of braces. Indent size controls the number of characters per indentation level.

You can specify the K&R indent style or the Allman indent style. Both styles:

- Place the function opening and closing braces on their own lines at the same indentation level as the function header.
- Indent code within the function according to the indent size.
- For blocks within a function, place closing braces on a new line at the same indentation level as the control statement.
- Indent code within a block according to the indent size.

The K&R style and the Allman style differ in their placement of the opening brace for a control statement. If you want the opening brace on the same line as its control statement, select the K&R style. Here is code that has the K&R indent style:

```c
void addone(const double x[6], double z[6])
{
    int i0;
    for (i0 = 0; i0 < 6; i0++) {
        z[i0] = x[i0] + 1.0;
    }
}
```

If you want the opening brace on its own line, select the Allman style. Here is code that has the Allman indent style:

```c
void addone(const double x[6], double z[6])
{
    int i0;
    for (i0 = 0; i0 < 6; i0++)
    {
        z[i0] = x[i0] + 1.0;
    }
}
Specify Indent Style Using the MATLAB Coder App

1. On the Generate Code page, to open the Generate dialog box, click the Generate arrow.
2. Set Build type to one of the following:
   • Source Code
   • Static Library (.lib)
   • Dynamic Library (.dll)
   • Executable (.exe)
3. Click More Settings.
4. On the All Settings tab, under Advanced, set Indent style to K&R or Allman.
5. On the All Settings tab, under Advanced, set Indent size to an integer from 2 to 8.

Specify Indent Style Using the Command-Line Interface

1. Create a code configuration object for 'lib', 'dll', or 'exe'. For example:
   ```matlab
cfg = coder.config('lib','ecoder',true); % or dll or exe
```
2. Set the IndentStyle property to 'K&R' or 'Allman'. For example:
   ```matlab
cfg.IndentStyle = 'Allman';
```
3. Set the IndentSize property to an integer from 2 to 8. For example:
   ```matlab
cfg.IndentSize = 4;
```

More About
• “Configure Build Settings” (MATLAB Coder)
Generate Custom File and Function Banners for C/C++ Code

When you generate C and C++ code from MATLAB code, you can use a code generation template (CGT) file to specify custom:

- File banners
- Function Banners
- File trailers
- Comments before code sections

This example shows how you can create your own CGT file and customize it to generate your own file and function banners.

1. Create a local copy of the default CGT file for MATLAB Coder and rename it. The default CGT file is `matlabcoder_default_template.cgt` in the `matlabroot/toolbox/coder/matlabcoder/templates/` folder.

2. Store the copy in a folder that is outside of the MATLAB folder structure, but on the MATLAB path. If necessary, add the folder to the MATLAB path. If you intend to use the CGT file with a custom target, locate the CGT file in a folder under your target root folder. If the file is not on the MATLAB path, specify a full path to the file when adding the file to your configuration.

3. View the default template and generated output. For example, here is the default File Banner section:

```plaintext
%% Custom File Banner section (optional)
%% Customize File banners by using either custom tokens or the following predefined tokens:
%% %<FileName>, %<MATLABCoderVersion>, %<EmbeddedCoderVersion>
%% %<SourceGeneratedOn>, %<HardwareSelection>, %<OutputType>
%%
%% You can also use "custom tokens" in all of the sections below. See the documentation center for more details.
%%
<FileBanner style="classic">
File: %<FileName>
MATLAB Coder version : %<MATLABCoderVersion>
C/C++ source code generated on : %<SourceGeneratedOn>
</FileBanner>
```

When you generate code using this default, the file banner looks similar to this file banner:
/*
 * File: coderand.c
 *
 * MATLAB Coder version : 2.7
 * C/C++ source code generated on : 06-Apr-2014 14:34:15
 */

4 Edit your local copy of the CGT file. You can change the default values and add your own custom tokens. For example, here is the File Banner section with the style changed to box and a custom token myCustomToken:

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
%% Custom File Banner section (optional)
%% Customize File banners by using either custom tokens or the following
%% predefined tokens:
%% %<FileName>, %<MATLABCoderVersion>, %<EmbeddedCoderVersion>
%% %<SourceGeneratedOn>, %<HardwareSelection>, %<OutputType>
%%
%% You can also use "custom tokens" in all of the sections below. See the
%% documentation center for more details.
%%
%%<FileBanner style="box">
File: %<FileName>
My custom token                : %<myCustomToken>
MATLAB Coder version           : %<MATLABCoderVersion>
C/C++ source code generated on : %<SourceGeneratedOn>
</FileBanner>

For more information, see “Code Generation Template Files for MATLAB Code” on page 78-9.

5 Create a configuration object for generation of a C static library for an embedded target.

% Create configuration object for an embedded target
cfgObj = coder.config('lib','ecoder',true);

6 Create a MATLABCodeTemplate object from your CGT file and add it to the configuration object.

% Specify the custom CGT file
CGTFile = 'myCGTFile.cgt';
% Use custom template
cfgObj.CodeTemplate = coder.MATLABCodeTemplate(CGTFile);

7 Assign values for custom tokens that you added to the template. For example, assign the value 'myValue' to the myCustomToken token that you added in a previous step.

cfgObj.CodeTemplate.setTokenValue('myCustomToken','myValue');
8 Make sure that generation of comments is enabled. Otherwise, the code generator does not produce file or function banners.

   cfgObj.GenerateComments=true;

9 Generate code using the configuration object that you created.

   codegen -config cfgObj coderand

10 View the changes to the generated file banner. For example, here is the file banner for coderand.c using the customized CGT file:

   /******************************************************************************/
   /* File: coderand.c                                                           */
   /*                                                                            */
   /* My custom token                : myValue                                   */
   /*                                                                            */
   /* MATLAB Coder version           : 2.7                                       */
   /* C/C++ source code generated on : 06-Apr-2014 14:42:55                      */
   /******************************************************************************/

Changes to a CGT file do not affect the generated code unless you create a MATLABCodeTemplate object from the modified CGT file, and then add it to the configuration object. If you modify the CGT File, myCGTFile.cgt, used in the previous example, you must repeat these steps:

1 Create a MATLABCodeTemplate object from myCGTFile.cgt and add it to the configuration object.

   CGTFile = 'myCGTFile.cgt';
   cfgObj.CodeTemplate = coder.MATLABCodeTemplate(CGTFile);

2 Assign the value 'myValue' to the myCustomToken token.

   cfgObj.CodeTemplate.setTokenValue('myCustomToken','myValue');

3 Generate code.

   codegen -config cfgObj coderand

coder.MATLABCodeTemplate

More About
• “Code Generation Template Files for MATLAB Code” on page 78-9
A code generation template (CGT) file defines the sections in generated code that you can customize using comments and tokens. Using a code generation template (CGT) file for the generation of C and C++ code from MATLAB code, you can specify custom file banners and function banners for generated code. File banners are comment sections in the header and trailer sections of a generated file. Function banners are comment sections for each function in the generated code. You can also customize comments before code sections. Use these banners to:

- Add a company copyright statement.
- Specify a special version symbol for your configuration management system.
- Remove timestamps.
- Add other custom information to your generated files.

For information on creating, customizing, and using a CGT file, see “Generate Custom File and Function Banners for C/C++ Code” on page 78-6.

**Default CGT File**

You can base your custom template on the default CGT file, `matlabcoder_default_template.cgt`, in the `matlabroot/toolbox/coder/matlabcoder/templates/` folder.

**Note** If you choose not to customize banners for your generated code, the default template is used for code generation.

**CGT File Structure**

A CGT file consists of 13 optional sections.
**File Banner Section**
Contains comments and tokens for use in generating a custom file banner.

**Function Banner Section**
Contains comments and tokens for use in generating a custom function banner.

**Shared Utility Function Banner**
Contains comments and tokens for use in generating custom banners for shared utility functions.

**File Trailer Section**
Contains comments for use in generating a custom trailer banner.

**Include Files Banner**
Contains comments for use in generating a custom banner for the include files section.

**Type Definitions**
Contains comments for use in generating a custom banner for the type definitions section.

**Named Constants**
Contains comments for use in generating a custom banner for the named constants section.

**Variable Declarations**
Contains comments for use in generating a custom banner for the variable declarations section.

**Variable Definitions**
Contains comments for use in generating a custom banner for the variable definitions section.

**Function Declarations**
Contains comments for use in generating a custom banner for the function declarations section.
Function Definitions

Contains comments for use in generating a custom banner for the function definitions section.

Custom Source Code

Contains comments for use in generating a custom banner for the custom source code section.

Custom Header Code

Contains comments for use in generating a custom banner for the custom header code section.

Components of the CGT File Sections

Each CGT file section is defined by open and close tags.

<table>
<thead>
<tr>
<th>CGT File Section</th>
<th>Open Tag</th>
<th>Close Tag</th>
</tr>
</thead>
<tbody>
<tr>
<td>“File Banner” on page 78-14</td>
<td><code>&lt;FileBanner&gt;</code></td>
<td><code>&lt;/FileBanner&gt;</code></td>
</tr>
<tr>
<td>“Function Banner Section” on page 78-10</td>
<td><code>&lt;FunctionBanner&gt;</code></td>
<td><code>&lt;/FunctionBanner&gt;</code></td>
</tr>
<tr>
<td>“Shared Utility Function Banner” on page 78-10</td>
<td><code>&lt;SharedUtilityBanner&gt;</code></td>
<td><code>&lt;/SharedUtilityBanner&gt;</code></td>
</tr>
<tr>
<td>“File Trailer Section” on page 78-10</td>
<td><code>&lt;FileTrailer&gt;</code></td>
<td><code>&lt;/FileTrailer&gt;</code></td>
</tr>
<tr>
<td>“Include Files Banner” on page 78-10</td>
<td><code>&lt;IncludeFilesBanner&gt;</code></td>
<td><code>&lt;/IncludeFilesBanner&gt;</code></td>
</tr>
<tr>
<td>“Type Definitions” on page 78-10</td>
<td><code>&lt;TypeDefinitionsBanner&gt;</code></td>
<td><code>&lt;/TypeDefinitionsBanner&gt;</code></td>
</tr>
<tr>
<td>“Named Constants” on page 78-10</td>
<td><code>&lt;NamedConstantsBanner&gt;</code></td>
<td><code>&lt;/NamedConstantsBanner&gt;</code></td>
</tr>
<tr>
<td>“Variable Declarations” on page 78-10</td>
<td><code>&lt;VariableDeclarationsBanner&gt;</code></td>
<td><code>&lt;/VariableDeclarationsBanner&gt;</code></td>
</tr>
</tbody>
</table>
You can customize your banners by including tokens and comments between the open and close tags for each section. Tokens are replaced with values in the generated code. The following rules apply to tokens in your CGT file:

- You can have only one token per line.
- Token values must not contain a ‘\t’ for formatting.

**Note** In the contents of your banner, C comment indicators, ‘/*’ or ‘*/’, can introduce an error in the generated code.

An open tag includes tag attributes. Enclose the value of the attribute in double quotes. The attributes available for an open tag are:

- **width**: specifies the width of the file or function banner comments in the generated code. The default value is 80.
- **style**: specifies the boundary for the file or function banner comments in the generated code.

The open tag syntax is:

```xml
<OpenTag style = “style_value” width = “num_width”>
```

There are five options for the banner style. The CommentStyle and TargetLang configuration object properties determine the use of C or C++ comment style. The built-in style options for the style attribute are:

<table>
<thead>

** File Banner **

This section contains comments and tokens for use in generating a custom file banner that precedes the generated C and C++ code. If you omit the file banner section from the CGT file, the code generator does not generate a file banner in the generated code. The file banner section provided in the default CGT file is:
Summary of Tokens for File Banner Generation

<table>
<thead>
<tr>
<th>Token</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FileName</td>
<td>Name of the generated file (for example, &quot;kalman.c&quot;)</td>
</tr>
<tr>
<td>SourceGeneratedOn</td>
<td>Timestamp of generated file</td>
</tr>
<tr>
<td>MATLABCoderVersion</td>
<td>Version of MATLAB Coder</td>
</tr>
<tr>
<td>EmbeddedCoderVersion</td>
<td>Version of Embedded Coder</td>
</tr>
<tr>
<td>HardwareSelection</td>
<td>Selected target</td>
</tr>
<tr>
<td>OutputType</td>
<td>Type of output (for example, lib, exe, or dll)</td>
</tr>
</tbody>
</table>

Function Banner

This section contains comments and tokens for use in generating a custom function banner that precedes a generated C or C++ function. If you omit the function banner section from the CGT file, the code generator does not generate function banners. The function banner section provided in the default CGT file is:

<!-- Custom Function Banner section (optional) -->
<!-- Customize function banners by using the following predefined tokens: -->
<!-- %<FunctionName>, %<FunctionDescription>, %<FunctionPrototype> -->
<!-- %<Arguments>, %<ReturnType> -->
<!-- -->
<!-- <FunctionBanner style="classic"> -->
<!-- %<FunctionPrototype> -->
<!-- %<FunctionDescription> -->
<!-- Arguments : %<Arguments> -->
<!-- Return Type : %<ReturnType> -->
<!-- </FunctionBanner> -->
### Summary of Tokens for Function Banner Generation

<table>
<thead>
<tr>
<th>Table Entry</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FunctionName</td>
<td>Name of function</td>
</tr>
<tr>
<td>FunctionDescription</td>
<td>Short abstract about the function</td>
</tr>
<tr>
<td></td>
<td>If the configuration parameter MATLABFcnDesc is true, the function description appears in the function banner. Otherwise, the code generator treats the function description as user comments.</td>
</tr>
<tr>
<td>FunctionPrototype</td>
<td>MATLAB function prototype</td>
</tr>
<tr>
<td></td>
<td>The function prototype appears in the function banner only if the MATLABSourceComments configuration parameter is true.</td>
</tr>
<tr>
<td>Arguments</td>
<td>List of function arguments</td>
</tr>
<tr>
<td>ReturnType</td>
<td>Return type of function</td>
</tr>
</tbody>
</table>

### Shared Utility Banner

This section contains comments and tokens for use in generating a custom shared utility function banner that precedes a generated C or C++ shared utility function. If you omit the shared utility function banner section from the CGT file, the code generator does not generate shared utility function banners. The shared utility function banner section provided in the default CGT file is:

```matlab
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
%% Custom Shared Utility Function Banner section (optional)
%% Customize shared utility function banners by using the following
%% predefined tokens:
%% %<FunctionName>, %<FunctionDescription>
%% %<Arguments>, %<ReturnType>
%%<SharedUtilityBanner style="classic">
Arguments : %<Arguments>
Return Type : %<ReturnType>
</SharedUtilityBanner>
```
Summary of Tokens for Shared Utility Function Banner Generation

<table>
<thead>
<tr>
<th>Token Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FunctionName</td>
<td>Name of function</td>
</tr>
<tr>
<td>FunctionDescription</td>
<td>Short abstract about the function</td>
</tr>
<tr>
<td>Arguments</td>
<td>List of function arguments</td>
</tr>
<tr>
<td>ReturnType</td>
<td>Return type of function</td>
</tr>
</tbody>
</table>

**File Trailer**

The file trailer section contains comments for generating a custom file trailer that follows the generated C or C++ code. If you omit the file trailer section from the CGT file, the code generator does not generate a file trailer. The file trailer section provided in the default CGT file is:

```matlab
<
%% Custom file trailer section (optional)
%% You can use any of the predefined tokens used for File Banner
%%
<FileTrailer style="classic"> File trailer for %<FileName>

[EOF]
</FileTrailer>
```

Tokens for the file banner are available for the file trailer. See Summary of Tokens for File Banner Generation.

**Include Files Banner**

The include files banner section contains comments for generating a custom banner that precedes the include files section in the generated code. If you omit the include files banner section from the CGT file, the code generator does not generate a banner for this section. The include files banner section provided in the default CGT file is:

```matlab
<IncludeFilesBanner  style="classic"> Include Files
</IncludeFilesBanner>
```

**Type Definitions Banner**

The type definitions banner section contains comments for generating a custom banner that precedes the type definitions section in the generated code. If you omit the type definitions banner section from the CGT file, the code generator does not generate a
banner for this section. The type definitions banner section provided in the default CGT file is:

<TypeDefinitionsBanner style="classic"> Type Definitions </TypeDefinitionsBanner>

**Named Constants Banner**

The named constants banner section contains comments for generating a custom banner that precedes the named constants section in the generated code. If you omit the named constants banner section from the CGT file, the code generator does not generate a banner for this section. The named constants banner section provided in the default CGT file is:

<NamedConstantsBanner style="classic"> Named Constants </NamedConstantsBanner>

**Variable Declarations**

The variable declarations banner section contains comments for generating a custom banner that precedes the variable declarations section in the generated code. If you omit the variable declarations banner section from the CGT file, the code generator does not generate a banner for this section. The variable declarations banner section provided in the default CGT file is:

<VariableDeclarationsBanner style="classic"> Variable Declarations </VariableDeclarationsBanner>

**Variable Definitions**

The variable definitions banner section contains comments for generating a custom banner that precedes the variable definitions section in the generated code. If you omit the variable definitions banner section from the CGT file, the code generator does not generate a banner for this section. The variable definitions banner section provided in the default CGT file is:

<VariableDefinitionsBanner style="classic"> Variable Definitions </VariableDefinitionsBanner>
**Function Declarations**

The function declarations banner section contains comments for generating a custom banner that precedes the function declarations section in the generated code. If you omit the function declarations banner section from the CGT file, the code generator does not generate a banner for this section. The function declarations banner section provided in the default CGT file is:

```xml
<functionDeclarationsBanner style="classic">
    Function Declarations
</functionDeclarationsBanner>
```

**Function Definitions**

The function definitions banner section contains comments for generating a custom banner that precedes the function definitions section in the generated code. If you omit the function definitions banner section from the CGT file, the code generator does not generate a banner for this section. The function definitions banner section provided in the default CGT file is:

```xml
<FunctionDefinitionsBanner style="classic">
    Function Definitions
</FunctionDefinitionsBanner>
```

**Custom Source Code**

The custom source code banner section contains comments for generating a custom banner that precedes the custom source code section in the generated code. If you omit the custom source code banner section from the CGT file, the code generator does not generate a banner for this section. The custom source code banner section provided in the default CGT file is:

```xml
<CustomSourceCodeBanner style="classic">
    Custom Source Code
</CustomSourceCodeBanner>
```

**Custom Header Code**

The custom header code banner section contains comments for generating a custom banner that precedes the custom header code section in the generated code. If you omit the custom header code banner section from the CGT file, the code generator does not generate a banner for this section. The custom header code banner section provided in the default CGT file is:

More About
• “Generate Custom File and Function Banners for C/C++ Code” on page 78-6
Customize Generated Identifiers

If you have Embedded Coder, you can customize the identifiers in C/C++ code generated from MATLAB code. For each kind of identifier that you want to customize, set the appropriate identifier format parameter to a macro that specifies the format of the generated identifiers. The macro can include:

- Valid C or C++ language identifiers (a-z, A-Z, _, 0-9).
- The tokens listed in the following table. $M$ is required.

<table>
<thead>
<tr>
<th>Token</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$M$</td>
<td>Code generator inserts name mangling text to avoid naming collisions. Required.</td>
</tr>
<tr>
<td>$N$</td>
<td>Code generator inserts the name of the object (global variable, global type, local function, local temporary variable, or constant macro) for which the identifier is generated. Improves readability of generated code.</td>
</tr>
<tr>
<td>$R$</td>
<td>Code generator inserts the root project name into identifier, replacing unsupported characters with the underscore (_) character.</td>
</tr>
</tbody>
</table>

**Customize Identifiers by Using the MATLAB Coder App**

1. On the Generate Code page, to open the Generate dialog box, click the Generate arrow ▼.
2. Set Build type to one of the following:
   - Source Code
   - Static Library
• Dynamic Library
• Executable

3 Click More Settings.

4 On the Code Appearance tab, under Identifier Format, for each kind of identifier that you want to customize, enter the macro.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default Macro</th>
</tr>
</thead>
<tbody>
<tr>
<td>Global variables</td>
<td>$M$N</td>
</tr>
<tr>
<td>Global types</td>
<td>$M$N</td>
</tr>
<tr>
<td>Field name of global types</td>
<td>$M$N</td>
</tr>
<tr>
<td>Local functions</td>
<td>$M$N</td>
</tr>
<tr>
<td>Local temporary variables</td>
<td>$M$N</td>
</tr>
<tr>
<td>Constant macros</td>
<td>$M$N</td>
</tr>
<tr>
<td>EMX Array Types</td>
<td>emxArray$_M$N</td>
</tr>
<tr>
<td>EMX Array Utility Functions</td>
<td>emx$_M$N</td>
</tr>
</tbody>
</table>

For example, suppose that Global variables has the value glob$_M$N. For a global variable named g, when name mangling is not required, the generated identifier is glob_g. If name mangling is required, the generated identifier includes the name mangling text.

**Customize Generated Identifiers by Using the Command-Line Interface**

1 Create a code configuration object for a library or executable program. For example:

    cfg = coder.config('lib','ecoder',true);

2 For each kind of identifier that you want to customize, specify the macro as a character vector.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Default Macro</th>
</tr>
</thead>
<tbody>
<tr>
<td>CustomSymbolStrGlobalVar</td>
<td>Global variables</td>
<td>'M$N'</td>
</tr>
<tr>
<td>CustomSymbolStrType</td>
<td>Global types</td>
<td>'M$N'</td>
</tr>
<tr>
<td>CustomSymbolStrField</td>
<td>Field name of global types</td>
<td>'M$N'</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Default Macro</td>
</tr>
<tr>
<td>---------------------------</td>
<td>------------------------</td>
<td>---------------------------</td>
</tr>
<tr>
<td>CustomSymbolStrFcn</td>
<td>Local functions</td>
<td>'$M$N'</td>
</tr>
<tr>
<td>CustomSymbolStrTmpVar</td>
<td>Local temporary variables</td>
<td>'$M$N'</td>
</tr>
<tr>
<td>CustomSymbolStrMacro</td>
<td>Constant macros</td>
<td>'$M$N'</td>
</tr>
<tr>
<td>CustomSymbolStrEMXArray</td>
<td>EMX Array Types</td>
<td>'emxArray_$M$N'</td>
</tr>
<tr>
<td>CustomSymbolStrEMXArrayFcn</td>
<td>EMX Array Utility Functions</td>
<td>'emx$M$N'</td>
</tr>
</tbody>
</table>

For example:

```matlab
cfg.CustomSymbolStrGlobalVar = 'glob_$M$N';
```

For a global variable named g, when name mangling is not required, the generated identifier is glob_g. If name mangling is required, the generated identifier includes the name mangling text.

- “Configure Build Settings” (MATLAB Coder)
Control Signed Left Shifts in Generated Code

If you have an Embedded Coder license, you can control whether MATLAB Coder replaces multiplications by powers of two with signed left bitwise shifts. Some coding standards, such as MISRA, do not allow bitwise operations on signed integers.

By default, MATLAB Coder replaces multiplication by powers of two with signed left shifts. Here is an example of generated C code that uses a signed left shift for multiplication by eight:

\[ i \ll 3; \]

To increase the likelihood of generating MISRA C:2012 compliant code, disable the replacement of multiplication by powers of two with signed left shifts. Here is an example of generated C code that does not use a signed left shift for multiplication by eight:

\[ i = i \times 8; \]

Control Signed Left Shifts Using the MATLAB Coder App

1. On the Generate Code page, to open the Generate dialog box, click the Generate arrow.
2. Set Build type to one of the following:
   - Source Code
   - Static Library (.lib)
   - Dynamic Library (.dll)
   - Executable (.exe)
3. Click More Settings.
4. On the Code Appearance tab, select or clear the Use signed shift left for fixed-point operations and multiplication by powers of 2 check box.
Control Signed Left Shifts Using the Command-Line Interface

1. Create a code configuration object for 'lib', 'dll', or 'exe'. For example:
   ```matlab
cfg = coder.config('lib','ecoder',true); % or dll or exe
```

2. Set the `EnableSignedLeftShifts` property to true or false. For example:
   ```matlab
cfg.EnableSignedLeftShifts = false;
```

More About

- “Configure Build Settings” (MATLAB Coder)
Control Data Type Casts in Generated Code

If you have an Embedded Coder license, you can control data type casts in C/C++ code generated from MATLAB code. You can specify one of the following casting modes.

<table>
<thead>
<tr>
<th>Casting Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Nominal</td>
<td>Nominal casting mode is the default casting mode. Generated C/C++ code uses the default C compiler data type casting. When you do not have special data type information requirements, choose this option. Here is an example of code generated using nominal casting mode:</td>
</tr>
</tbody>
</table>

```matlab
short addone(short x)
{
    int i0;
    i0 = x + 1;
    if (i0 > 32767) {
        i0 = 32767;
    }
    return (short)i0;
}
```
<table>
<thead>
<tr>
<th>Casting Mode</th>
<th>Description</th>
</tr>
</thead>
</table>
| Standards Compliant  | Generated C/C++ code has data type casts that conform to MISRA standards. The MISRA data type casting eliminates common MISRA standard violations, including address arithmetic and assignment. It reduces 10.1, 10.2, 10.3, and 10.4 violations. Here is an example of code generated using standards-compliant casting mode:  
  ```c
  short addone(short x)  
  {  
    int i0;  
    i0 = (int)x + (int)1;  
    if (i0 > (int)32767)  
      {  
        i0 = (int)32767;  
      }  
    return (short)i0;  
  }  
  ``` |
| Explicit             | Generated C/C++ code has explicit data type casts. Explicit data type casts provide information about the amount of memory that the variable uses and the level of precision for calculations using the variable. Here is an example of code generated using explicit casting mode:  
  ```c
  short addone(short x)  
  {  
    int i0;  
    i0 = (int)x + 1;  
    if (i0 > 32767)  
      {  
        i0 = 32767;  
      }  
    return (short)i0;  
  }  
  ``` |
Specify Casting Mode Using the MATLAB Coder App

1. On the Generate Code page, to open the Generate dialog box, click the Generate arrow.
2. Set Build type to one of the following:
   - Source Code
   - Static Library (.lib)
   - Dynamic Library (.dll)
   - Executable (.exe)
3. Click More Settings.
4. On the All Settings tab, under Advanced, set Casting mode to one of the following values:
   - Nominal
   - Standards Compliant
   - Explicit

Specify Casting Mode Using the Command-Line Interface

1. Create a code configuration object for 'lib', 'dll', or 'exe'. For example:
   
   ```matlab
cfg = coder.config('lib','ecoder',true); % or dll or exe
```
2. Set the CastingMode property to one of the following values:
   - 'Nominal'
   - 'Standards'
   - 'Explicit'

   For example:

   ```matlab
cfg.CastingMode = 'Standards';
```

More About

- “Configure Build Settings” (MATLAB Coder)
Simplify Multiply Operations for Array Indexing in Loops

If you use Embedded Coder to generate C/C++ code from MATLAB code, you can enable an optimization that simplifies array indexing in loops in the generated code. When possible, for array indices in loops, this optimization replaces multiply operations with add operations. Multiply operations can be expensive. This optimization, referred to as strength reduction, is useful when the C/C++ compiler on the target platform does not optimize the array indexing.

Here is code generated without the optimization:

```c
for (i = 0; i < 10; i++) {
    z[5 * (1 + i) - 1] = x[5 * (1 + i)];
}
```

Here is code generated with the optimization:

```c
for (b_i = 0; b_i < 10; b_i++) {
    z[i + 4] = x[i + 5];
    i += 5;
}
```

By default, the strength reduction optimization is disabled. To enable it:

- At the command line, set the configuration object parameter `EnableStrengthReduction` to `true`.
- In the MATLAB Coder app, project build settings, on the **All Settings** tab, set **Simplify array indexing** to **Yes**.

Even when the optimization replaces the multiply operations in the generated code, it is possible that the C/C++ compiler can generate multiply instructions.

Increase Likelihood of Generating MISRA C Compliant Code from MATLAB Code

The Motor Industry Software Reliability Association (MISRA)\(^{14}\) has established “Guidelines for the Use of the C Language in Critical Systems” (MISRA C). When you generate code from MATLAB code, if you have Embedded Coder, you can configure certain code generation parameters to increase the likelihood of generating code that complies with the MISRA C:2012 guidelines.

**Configure Code Generation Configuration Object Properties to Increase Likelihood of MISRA C Compliant Code**

1. Create an Embedded Coder code generation configuration object.

   ```matlab
cfg = coder.config('lib', 'ecoder', true);
```

2. Set the properties listed in the table to the values for increased MISRA C compliance.

<table>
<thead>
<tr>
<th>Property</th>
<th>Value for Increased MISRA C Compliance</th>
</tr>
</thead>
<tbody>
<tr>
<td>CastingMode</td>
<td>'Standards'</td>
</tr>
<tr>
<td>DataTypeReplacement</td>
<td>'CoderTypedefs'</td>
</tr>
<tr>
<td>DynamicMemoryAllocation</td>
<td>'Off'</td>
</tr>
<tr>
<td>EnableRuntimeRecursion</td>
<td>false</td>
</tr>
<tr>
<td>EnableSignedLeftShifts</td>
<td>false</td>
</tr>
<tr>
<td>EnableSignedRightShifts</td>
<td>false</td>
</tr>
<tr>
<td>GenerateDefaultInSwitch</td>
<td>true</td>
</tr>
<tr>
<td>ParenthesesLevel</td>
<td>'Maximum'</td>
</tr>
<tr>
<td>TargetLangStandard</td>
<td>'C99 (ISO)' for C, 'C++03 (ISO)' for C++</td>
</tr>
</tbody>
</table>

To set these properties in one step, use `coder.setupMISRAConfig`.

```matlab
coder.setupMISRAConfig(cfg);
```

---

\(^{14}\) MISRA and MISRA C are registered trademarks of MIRA Ltd., held on behalf of the MISRA Consortium.
Alternatively, set properties individually. For example:

```matlab
cfg.CastingMode = 'Standards';
3 Pass the configuration object to codegen by using the -config option.
codegen myFunction -config cfg ...
```

**Configure MATLAB Coder App Settings to Increase Likelihood of MISRA C Compliant Code**

1. On the Generate Code page, set **Build type** to Source Code, Static Library, Dynamic Library, or Executable.
2. Click **More Settings**.
3. Click **MISRA Compliance**.

The app displays the settings that might impact MISRA C compliance.

The following settings can be used to improve MISRA compliance of generated code:

<table>
<thead>
<tr>
<th>Setting</th>
<th>Current Value</th>
<th>Recommended Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic memory allocation</td>
<td>For arrays with max size at or above thres...</td>
<td><strong>Never</strong></td>
</tr>
<tr>
<td>Enable run-time recursion</td>
<td>Yes</td>
<td><strong>No</strong></td>
</tr>
<tr>
<td>Use signed shift left for fixed-point ...</td>
<td>Yes</td>
<td><strong>No</strong></td>
</tr>
<tr>
<td>Allow right shifts on signed integers</td>
<td>Yes</td>
<td><strong>No</strong></td>
</tr>
<tr>
<td>Casting mode</td>
<td>Nominal</td>
<td><strong>Standards Compliant</strong></td>
</tr>
<tr>
<td>Data Type Replacement</td>
<td>Use built-in C data types in the generated ...</td>
<td>Use MathWorks typedefs in the generated ...</td>
</tr>
<tr>
<td>Parentheses</td>
<td>Nominal (Optimize for readability)</td>
<td>Maximum (Specify precedence with paren...</td>
</tr>
<tr>
<td>Always generate a default case for s...</td>
<td>No</td>
<td><strong>Yes</strong></td>
</tr>
</tbody>
</table>

4. To set all of these settings to the recommended values, click **Set to Recommended Values**.

To modify an individual setting, click **All Settings**, and then search for the setting.

Code Replacement for MATLAB Code

- “Choose a Code Replacement Library” on page 79-8
- “Replace Code Generated from MATLAB Code” on page 79-10
What Is Code Replacement?

Code replacement is a technique to change the code that the code generator produces for functions and operators to meet application code requirements. For example, you can replace generated code to meet requirements such as:

- Optimization for a specific run-time environment, including, but not limited to, specific target hardware.
- Integration with existing application code.
- Compliance with a standard, such as AUTOSAR.
- Modification of code behavior, such as enabling or disabling nonfinite or inline support.
- Application- or project-specific code requirements, such as:
  - Elimination of math.h.
  - Elimination of system header files.
  - Elimination of calls to memcpy or memset.
  - Use of BLAS.
  - Use of a specific BLAS.

To apply this technique, configure the code generator to apply a code replacement library (CRL) during code generation. By default, the code generator does not apply a code replacement library. You can choose from libraries that MathWorks provides and that you create and register by using the Embedded Coder product. The list of available libraries depends on:

- Installed support packages.
- System target file, language, standard math library, and device vendor configuration.
- Whether you have created and registered libraries, using the Embedded Coder product.

Libraries that include GNU99 extensions are intended for use with the GCC compiler. If you use one of those libraries with another compiler, generated code might not compile.

Code Replacement Libraries

A code replacement library consists of one or more code replacement tables that specify application-specific implementations of functions and operators. For example, a library for
a specific embedded processor specifies function and operator replacements that optimize generated code for that processor.

A code replacement table contains one or more code replacement entries, with each entry representing a potential replacement for a function or operator. Each entry maps a conceptual representation of a function or operator to an implementation representation and priority.

<table>
<thead>
<tr>
<th>Table Entry Component</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Conceptual representation</td>
<td>Identifies the table entry and contains match criteria for the code generator. Consists of:</td>
</tr>
<tr>
<td></td>
<td>• Function name or a key. The function name identifies most functions. For operators and some functions, a series of characters, called a key identifies a function or operator. For example, function name 'cos' and operator key 'RTW_OP_ADD'.</td>
</tr>
<tr>
<td></td>
<td>• Conceptual arguments that observe code generator naming ('y1', 'u1', 'u2', ...), with corresponding I/O types (output or input) and data types.</td>
</tr>
<tr>
<td></td>
<td>• Other attributes, such as an algorithm, fixed-point saturation, and rounding modes, which identify matching criteria for the function or operator.</td>
</tr>
<tr>
<td>Table Entry Component</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| Implementation representation | Specifies replacement code. Consists of:  
  • Function name. For example, 'cos_dbl' or 'u8_add_u8_u8'.  
  • Implementation arguments, with corresponding I/O types (output or input) and data types.  
  • Parameters that provide additional implementation details, such as header and source file names and paths of build resources. |
| Priority | Defines the entry priority relative to other entries in the table. The value can range from 0 to 100, with 0 being the highest priority. If multiple entries have the same priority, the code generator uses the first match with that priority. |

When the code generator looks for a match in a code replacement library, it creates and populates a call site object with the function or operator conceptual representation. If a match exists, the code generator uses the matched code replacement entry populated with the implementation representation and uses it to generate code.

The code generator searches the tables in a code replacement library for a match in the order that the tables appear in the library. If the code generator finds multiple matches within a table, the priority determines the match. The code generator uses a higher-priority entry over a similar entry with a lower priority.

**Code Replacement Terminology**

<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cache hit</td>
<td>A code replacement entry for a function or operator, defined in the specified code replacement library, for which the code generator finds a match.</td>
</tr>
<tr>
<td>Cache miss</td>
<td>A conceptual representation of a function or operator for which the code generator does not find a match.</td>
</tr>
<tr>
<td>Term</td>
<td>Definition</td>
</tr>
<tr>
<td>----------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Call site object</td>
<td>Conceptual representation of a function or operator that the code generator uses when it encounters a call site for a function or operator. The code generator uses the object to query the code replacement library for a conceptual representation match. If a match exists, the code generator returns a code replacement object, fully populated with the conceptual representation, implementation representation, and priority, and uses that object to generate replacement code.</td>
</tr>
<tr>
<td>Code replacement library</td>
<td>One or more code replacement tables that specify application-specific implementations of functions and operators. When configured to use a code replacement library, the code generator uses criteria defined in the library to search for matches. If a match is found, the code generator replaces code that it generates by default with application-specific code defined in the library.</td>
</tr>
<tr>
<td>Code replacement table</td>
<td>One or more code replacement table entries. Provides a way to group related or shared entries for use in different libraries.</td>
</tr>
<tr>
<td>Code replacement entry</td>
<td>Represents a potential replacement for a function or operator. Maps a conceptual representation of a function or operator to an implementation representation and priority.</td>
</tr>
<tr>
<td>Conceptual argument</td>
<td>Represents an input or output argument for a function or operator being replaced. Conceptual arguments observe naming conventions ('y1', 'u1', 'u2', ...) and data types familiar to the code generator.</td>

<td>Defines the match priority for a code replacement entry relative to other entries, which have the same name and conceptual argument list, within a code replacement library. The priority can range from 0 to 100, with 0 being the highest priority. The default is 100. If a library provides two implementations for a function or operator, the implementation with the higher priority shadows the one with the lower priority.</td>
</tr>
</tbody>
</table>

**Code Replacement Limitations**

Code replacement verification — It is possible that code replacement behaves differently than you expect. For example, data types that you observe in code generator input might not match what the code generator uses as intermediate data types during an operation. Verify code replacements by examining generated code.

### About Choosing a Code Replacement Library

By default, the code generator does not use a code replacement library.

If you are considering using a code replacement library:

1. Explore available libraries. Identify one that best meets your application needs.
   - Consider the lists of application code replacement requirements and libraries that MathWorks provides in “What Is Code Replacement?” on page 79-2.

If you do not find a suitable library and you have an Embedded Coder license, you can create a custom code replacement library.

### Explore Available Code Replacement Libraries

You can select the code replacement library to use for code generation in a project, on the Custom Code tab, by setting the Code replacement library parameter. Alternatively, in a code configuration object, set the CodeReplacementLibrary parameter.

### Explore Code Replacement Library Contents

Use the Code Replacement Viewer to explore the content of a code replacement library.

1. At the command prompt, type `crviewer`.

   ```
   >> crviewer
   ```
The viewer opens. To view the content of a specific library, specify the name of the library as an argument in single quotes. For example:

```
>> crviewer('GNU C99 extensions')
```

2 In the left pane, select the name of a library. The viewer displays information about the library in the right pane.

3 In the left pane, expand the library, explore the list of tables it contains, and select a table from the list. In the middle pane, the viewer displays the function and operator entries that are in that table, along with abbreviated information for each entry.

4 In the middle pane, select a function or operator. The viewer displays information from the table entry in the right pane.

If you select an operator entry that specifies net slope fixed-point parameters (instantiated from entry class `RTW.TflCOperationEntryGenerator` or `RTW.TflCOperationEntryGenerator_NetSlope`), the viewer displays an additional tab that shows fixed-point settings.

See **Code Replacement Viewer** for details on what the viewer displays.

Replace Code Generated from MATLAB Code

This example shows how to replace generated code using a code replacement library. Code replacement is a technique for changing the code that the code generator produces for functions and operators to meet application code requirements.

Prepare for Code Replacement

1. Make sure that you have installed required software. Required software is:
   - MATLAB
   - MATLAB Coder
   - C compiler

   Some code replacement libraries available in your development environment require Embedded Coder.

   For instructions on installing MathWorks products, see the MATLAB installation documentation. If you have installed MATLAB and want to see which other MathWorks products are installed, in the MATLAB Command Window, enter `ver`.

2. Identify an existing MATLAB function or create a new MATLAB function for which you want the code generator to replace code.

Choose a Code Replacement Library

If you are not sure which library to use, explore available libraries.

Configure Code Generator To Use Code Replacement Library

1. Configure the code generator to apply a code replacement library during code generation for the MATLAB function. Do one of the following:
   - In a project, on the Custom Code tab, set the Code replacement library parameter.
   - In a code configuration object, set the CodeReplacementLibrary parameter.

2. Configure the code generator to produce only code. Before you build an executable, verify your code replacements. Do one of the following:
   - In a project, in the Generate dialog box, select the Generate code only check box.
• In a code configuration object, set the GenCodeOnly parameter.

**Include Code Replacement Information In Code Generation Report**

If you have an Embedded Coder license, you can configure the code generator to include a code replacement section in the code generation report. The additional information helps you verify code replacements.

1  Configure the code generator to generate a report.
   • In a project, on the **Debugging** tab, set the **Always create a code generation report** parameter.
   • In a code configuration object, set the GenerateReport parameter.

2  Include the code replacement section in the report.
   • In a project, on the **Debugging** tab, select the **Code replacements** check box.
   • In a code configuration object, set the GenerateCodeReplacementReport parameter.

**Generate Replacement Code**

Generate C/C++ code from the MATLAB code. If you configured the code generator to produce a report, generate a code generation report. For example, in the MATLAB Coder app, on the **Generate Code** page, click **Generate**. Or, at the command prompt, enter:

```
codegen -report myFunction -args {5} -config cfg
```

The code generator produces the code and displays the report.

**Verify Code Replacements**

Verify code replacements by examining the generated code. Code replacement can sometimes behave differently than you expect. For example, data types that you observe
in the code generator input might not match what the code generator uses as intermediate data types during an operation.

Storage Classes for Code Generation from MATLAB Code

- “Storage Classes for Code Generation from MATLAB Code” on page 80-2
- “Control Declarations and Definitions of Global Variables in Code Generated from MATLAB Code” on page 80-5
If you have an Embedded Coder license, you can use storage classes to control the declaration and definition of a global variable in the generated C/C++ code.

In the context of code generation, a storage class is a specification that determines the declaration and definition of a variable in the generated code. For code generation, the term storage class is not the same as the C language term storage class specifier.

Storage classes help you to integrate generated code with external code. You can make a generated variable visible to external code. You can also make variables declared in the external code visible to the generated code. For code generation from MATLAB code, you can use storage classes with global variables only. The storage class determines:

- The file placement of a global variable declaration and definition.
- Whether the global variable is imported from external code or exported for use by external code.

To assign a storage class to a global variable, in your MATLAB code, use the `coder.storageClass` function. Only when you use an Embedded Coder project or configuration object for generation of C/C++ libraries or executables does the code generator recognize `coder.storageClass` calls.

The syntax for `coder.storageClass` is:

```plaintext```
```
coder.storageClass(global_name, storage_class)
```
```
```
`global_name` is the name of a global variable, specified as a character vector. `global_name` must be a compile-time constant.

`storage_class` can be one of the following values.
<table>
<thead>
<tr>
<th>Storage Class</th>
<th>Description</th>
</tr>
</thead>
</table>
| 'ExportedGlobal'      | • Defines the variable in the Variable Definitions section of the C file `entry_point_name.c`.  
|                       | • Declares the variable as an extern in the Variable Declarations section of the header file `entry_point_name.h`.  
|                       | • Initializes the variable in the function `entry_point_name_initialize.h`.                                                                  |
| 'ExportedDefine'      | Declares the variable with a #define directive in the Exported data define section of the header file `entry_point_name.h`.                |
| 'ImportedExtern'      | Declares the variable as an extern in the Variable Declarations section of the header file `entry_point_name_data.h`. The external code must supply the variable definition. |
| 'ImportedExternPointer'| Declares the variable as an extern pointer in the Variable Declarations section of the header file `entry_point_name_data.h`. The external code must define a valid pointer variable. |

Storage classes have these requirements and limitations:

- Assign the storage class to a global variable in a function that declares the global variable. You do not have to assign the storage class in more than one function.
- After you assign a storage class to a global variable, you cannot assign a different storage class to that global variable.
- You cannot assign a storage class to a constant global variable.
- A global variable with an ExportedDefine storage class must be a scalar but not a complex or multi-word scalar. The global variable must only be read and not written to in the code.
If you do not assign a storage class to a global variable, except for the declaration location, the variable behaves like it has an 'ExportedGlobal' storage class. For an 'ExportedGlobal' storage class, the global variable is declared in the file `entry_point_name.h`. When the global variable does not have a storage class, the variable is declared in the file `entry_point_name_data.h`.

Control Declarations and Definitions of Global Variables in Code Generated from MATLAB Code

This example uses storage classes to control the declarations and definitions of global variables in C/C++ code generated from MATLAB code. Using storage classes helps you to interface generated code with external code.

This example requires an Embedded Coder license.

Write a function `adddglobals` that adds four global variables. Declare the global variables in the function.

```matlab
function y = adddglobals
% Define the global variables.
global u;
global v;
global x;
global z;

% Assign the storage classes.
coder.storageClass('u','ExportedGlobal');
coder.storageClass('v','ImportedExtern');
coder.storageClass('x','ImportedExternPointer');
coder.storageClass('z','ExportedDefine');
y = u + v + x + z;
end
```

Create a file `c:\myfiles\myfile.c` that defines and initializes the imported global variables `u` and `v`.

```c
#include <stdio.h>

/* Variable definitions for imported variables */
double v = 1.0;
double *x = &v;
```

Create a code configuration object. Configure the code generation parameters to include `myfile.c`. For output type 'lib', or if you generate source code only, you can generate code without providing this file. Otherwise, you must provide this file.
cfg = coder.config('dll', 'ecoder', true);
cfg.CustomSource = 'myfile.c';
cfg.CustomInclude = 'c:\myfiles';

Generate the code. This example uses the -globals argument to specify the types and initial values of the global variables u, v, x, and z. Alternatively, you can define global variables in the MATLAB global workspace. For the imported global variables v and x, the code generator uses the initial values only to determine the type.

codegen -config cfg -globals {'u', 1, 'v', 2, 'x', 3, 'z', 4} addglobals -report

From the initial values 1, 2, 3, and 4 codegen determines that u, v, x and z have type double. codegen defines and declares the exported global variables u and z. It generates code that initializes u to 1.0 and z to 4.0. codegen declares the imported global variables v and x. It does not define these variables or generate code that initializes them. myfile.c provides the code that defines and initializes v and x.

To view the code generated for the global variables, open the report. Click the View report link.

View the definition for the exported global z in the Exported data define section in addglobals.h.

/* Definition for custom storage class: ExportedDefine */
#define z 4.0

View the definition and declaration for the exported global u.

- u is defined in the Variable Definitions section in addglobals.c.

  /* Variable Definitions */
  /* Definition for custom storage class: ExportedGlobal */
  double u;

- u is declared as extern in the Variable Declarations section in addglobals.h.

  /* Variable Declarations */
  /* Declaration for custom storage class: ExportedGlobal */
  extern double u;

- u is initialized in addglobals_initialize.c.

  /* Include Files */
  #include "rt_nonfinite.h"
  #include "addglobals.h"
#include "addglobals_initialize.h"

/* Named Constants */
#define b_u  (1.0)

/* Function Definitions */

/*
 * Arguments : void
 * Return Type : void
 */
void addglobals_initialize(void)
{
    rt_InitInfAndNaN(8U);
    u = b_u;
}

View the definition and declaration for the imported external global v and the imported external global pointer x.

v and x are declared as extern in the Variable Declarations section in addglobals_data.h.

/* Variable Declarations */
/* Declaration for custom storage class: ImportedExtern */
extern double v;

/* Declaration for custom storage class: ImportedExternPointer */
extern double *x;

Highlight Potential Data Type Issues in a Report

<table>
<thead>
<tr>
<th>In this section...</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Enable Highlight Option Using the MATLAB Coder App” on page 81-2</td>
</tr>
<tr>
<td>“Enable Highlight Option Using the Command Line Interface” on page 81-3</td>
</tr>
</tbody>
</table>

If you have Embedded Coder, you have the option to highlight potential data types issues in the code generation report for standalone code generated from MATLAB code. If you enable this option, on the Code Insights tab, the report identifies single-precision and double-precision operations in the generated C/C++ code. If you have Fixed-Point Designer, the report also identifies expensive fixed-point operations.

To view potential data type issues in a code generation report:

1. Click the Code Insights tab.
2. Expand the Potential data type issues section.
3. Expand the data type issues section that you want to see.

For example, this report identifies MATLAB code that results in double-precision operations in the generated code.

The option to highlight potential data type issues is disabled by default.

Enable Highlight Option Using the MATLAB Coder App

1. On the Generate Code page, to open the Generate dialog box, click the Generate arrow.
2. Set Build type to one of the following:
   - Source Code
   - Static Library (.lib)
• Dynamic Library (.dll)
• Executable (.exe)

3 Click More Settings.

4 On the Debugging tab, select the Always create a code generation report and Highlight potential data type issues check boxes.

Enable Highlight Option Using the Command Line Interface

1 Create an embedded code configuration object for 'lib', 'dll', or 'exe':

   ```matlab
cfg = coder.config('lib','ecoder',true); % or dll or exe
   ```

2 Set the GenerateReport and HighlightPotentialDataTypeIssues configuration object properties to true:

   ```matlab
cfg.GenerateReport = true;
cfg.HighlightPotentialDataTypeIssues = true;
   ```

Data Type Issues Overview

When you generate C code from MATLAB code, you can highlight potential data type issues in the C code generation report. The report highlights MATLAB code that requires single-precision, double-precision, or expensive fixed-point operations. The expensive fixed-point operations checks require a Fixed-Point Designer.

- The double-precision check highlights expressions that result in a double-precision operation. When trying to achieve a strict-single or fixed-point design, manual inspection of code can be time-consuming and error prone.

  For a strict-single precision design, specify a standard math library that supports single-precision implementations. To change the library for a project, during the Generate Code step, in the project settings dialog box, on the Custom Code tab, set the Standard math library to C99 (ISO).

- The single-precision check highlights expressions that result in a single operation.

- The expensive fixed-point operations check identifies optimization opportunities for fixed-point code. It highlights expressions in the MATLAB code that require cumbersome multiplication or division, expensive rounding, expensive comparison, or multiword operations. For more information on optimizing generated fixed-point code, see “Tips for Making Generated Code More Efficient” (Fixed-Point Designer).
Enable Highlighting of Potential Data Type Issues

Enable the highlight option using the MATLAB Coder app

1. On the Generate Code page, to open the Generate dialog box, click the Generate arrow.
2. Set Build type to one of the following:
   - Source Code
   - Static Library (.lib)
   - Dynamic Library (.dll)
   - Executable (.exe)
3. Click More Settings.
4. On the Debugging tab, select the Always create a code generation report and Highlight potential data type issues check boxes.

Enable the highlight option using the command-line interface

1. Create an embedded code configuration object for 'lib', 'dll', or 'exe':
   ```matlab
cfg = coder.config('lib','ecoder',true); % or dll or exe
```
2. Set the GenerateReport and HighlightPotentialDataTypeIssues configuration object properties to true:
   ```matlab
cfg.GenerateReport = true;
cfg.HighlightPotentialDataTypeIssues = true;
```

Find and Address Cumbersome Operations

Cumbersome operations usually occur due to an insufficient range of output. Avoid inputs to a multiply or divide operation that have word lengths larger than the base integer type of your processor. Software can process operations with larger word lengths, but this approach requires more code and runs slower.

This example requires Embedded Coder and Fixed-Point Designer. The target word length for the processor in this example is 64.

1. Create the function `myMul`. 
function out = myMul(in1, in2)
    out = fi(in1*in2, 1, 64, 0);
end

2  Generate code for myMul.

cfg = coder.config('lib');
cfg.GenerateReport = true;
cfg.HighlightPotentialDataTypeIssues = true;
fm = fimath('ProductMode', 'SpecifyPrecision', 'ProductWordLength', 64);
codegen -config cfg myMul -args {fi(1, 1, 64, 4, fm), fi(1, 1, 64, 4, fm)}

3  Click View report.
4  In the code generation report, click the Code Insights tab.
5  Expand the Potential data type issues section. Then, expand the Expensive fixed-point operations section.

The report flags the expression in1 * in2. To resolve the issue, modify the data types of in1 and in2 so that the word length of the product does not exceed the target word length of 64.

Find and Address Expensive Rounding

Traditional handwritten code, especially for control applications, almost always uses "no effort" rounding. For example, for unsigned integers and two's complement signed integers, shifting right and dropping the bits is equivalent to rounding to floor. To get results comparable to, or better than, what you expect from traditional handwritten code, use the floor rounding method.

This example requires Embedded Coder and Fixed-Point Designer.

1  Create the function myRounding.

    function [quot] = myRounding(in1, in2)
        quot = in1 / in2;
    end

2  Generate code for myRounding.

    cfg = coder.config('lib');
    cfg.GenerateReport = true;
cfg.HighlightPotentialDataTypeIssues = true;
codegen -config cfg myRounding -args {fi(1, 1, 16, 2), fi(1, 1, 16, 4)}

3 Click View report.
4 In the code generation report, click the Code Insights tab.
5 Expand the Potential data type issues section. Then, expand the Expensive fixed-point operations section.

The division operation \( \text{in1/in2} \) uses the default rounding method, nearest. Changing the rounding method to Floor provides a more efficient implementation.

**Find and Address Expensive Comparison Operations**

Comparison operations generate extra code when a casting operation is required to do the comparison. For example, before comparing an unsigned integer to a signed integer, one of the inputs must be cast to the signedness of the other. Consider optimizing the data types of the input arguments so that a cast is not required in the generated code.

This example requires Embedded Coder and Fixed-Point Designer.

1 Create the function myRelop.

```matlab
function out = myRelop(in1, in2)
    out = in1 > in2;
end
```

2 Generate code for myRelop.

```bash
cfg = coder.config('lib');
cfg.GenerateReport = true;
cfg.HighlightPotentialDataTypeIssues = true;
codegen -config cfg myRelop -args {fi(1, 1, 14, 3, 1), fi(1, 0, 14, 3, 1)}
```

3 Click View report.
4 In the code generation report, click the Code Insights tab.
5 Expand the Potential data type issues section. Then, expand the Expensive fixed-point operations section.
The first input argument, \( \text{in1} \), is signed, while \( \text{in2} \) is unsigned. Extra code is generated because a cast must occur before the two inputs can be compared.

Change the signedness and scaling of one of the inputs to generate more efficient code.

**Find and Address Multiword Operations**

Multiword operations can be inefficient on hardware. When an operation has an input or output data type larger than the largest word size of your processor, the generated code contains multiword operations. You can avoid multiword operations in the generated code by specifying local \text{fi}math properties for variables. You can also manually specify input and output word lengths of operations that generate multiword code.

This example requires Embedded Coder and Fixed-Point Designer. In this example, the target word length is 64.

1. Create the function \text{myMul}.

   ```matlab
   function \text{out} = \text{myMul}(\text{in1}, \text{in2})
   \text{out} = \text{in1} \times \text{in2};
   \end```

2. Generate code for \text{myMul}.

   ```matlab
   \text{cfg} = \text{coder.config(}'lib'\text{);};
   \text{cfg.GenerateReport} = \text{true};
   \text{cfg.HighlightPotentialDataTypeIssues} = \text{true};
   \text{codegen -config cfg myMul -args \{fi(1, 1, 33, 4), fi(1, 1, 32, 4)\}}
   ```

3. Click **View report**.

4. In the code generation report, click the **Code Insights** tab.

5. Expand the **Potential data type issues** section. Then, expand the **Expensive fixed-point operations** section.
The report flags the \texttt{in1 * in2} operation in line 2 of \texttt{myMul}.

In the code pane, pause over \texttt{in1}, \texttt{in2}, and the expression \texttt{in1 * in2}. You see that:

- The word length of \texttt{in1} is 33 bits and the word length of \texttt{in2} is 32 bits.
- The word length of the expression \texttt{in1 * in2} is 65 bits.

The software detects a multiword operation because the word length 65 is larger than the target word length of 64.

To resolve this issue, modify the data types of \texttt{in1} and \texttt{in2} so that the word length of the product does not exceed the target word length. Alternatively, specify the \texttt{ProductMode} property of the local \texttt{fimath} object.

PIL Execution with ARM Cortex-A at the Command Line

This example shows how to set up a PIL execution to verify generated code at the command line.

You can use processor-in-the-loop (PIL) executions to verify generated code that you deploy to target hardware by using a MATLAB Coder procedure. You can profile algorithm performance and speed for your generated code. To verify generated code with the MATLAB Coder app, you must have an Embedded Coder license.

This PIL execution is available with these hardware support packages. To use the PIL execution, install one of these support packages.

- Embedded Coder Support Package for BeagleBone® Black Hardware
- Embedded Coder Support Package for ARM Cortex-A Processors

In the Command Window, select the hardware for PIL execution.

```matlab
hw = coder.hardware('ARM Cortex-A9 (QEMU)')
```

```matlab
hw =

Hardware with properties:

    Name: 'ARM Cortex-A9 (QEMU)'
    CPUClockRate: 1000
```

When using the BeagleBone hardware, more hardware properties are supported (Username, Password, and DeviceAddress). Set these properties based on your specific hardware or application.

```matlab
hw = coder.hardware('BeagleBone Black')
```

```matlab
hw =

Hardware with properties:

    Name: 'BeagleBone Black'
    CPUClockRate: 1000
    Password: 'root'
    Username: 'admin'
    DeviceAddress: '192.168.1.10'
```

Add the hardware to the MATLAB Coder configuration object.
cfg = coder.config('lib','ecoder',true);
cfg.VerificationMode = 'PIL';
cfg.Hardware = hw;

Generate PIL code for a function, averaging_filter.

codegen -config cfg averaging_filter -args {zeros(1,16)}

For more information on the averaging_filter function, see the “Averaging Filter” example in “MATLAB Coder Examples” (MATLAB Coder).

For another example of PIL verification, see the "Processor-in-the-Loop Verification of MATLAB Functions" page in the documentation of the Embedded Coder Support Package for ARM Cortex-A Processors. To install the Embedded Coder Support Package for ARM Cortex-A Processors, see “Supported Hardware”.

PIL Execution with ARM Cortex-A by Using the MATLAB Coder App

You can use processor-in-the-loop (PIL) executions to verify generated code that you deploy to target hardware by using a MATLAB Coder procedure. You can profile algorithm performance and speed for your generated code. To verify generated code with the MATLAB Coder app, you must have an Embedded Coder license.

This PIL execution is available with these hardware support packages. To use the PIL execution, install one of these support packages.

- Embedded Coder Support Package for BeagleBone Black Hardware
- Embedded Coder Support Package for ARM Cortex-A Processors

You can set up PIL execution with the MATLAB Coder app.

To configure the build type and hardware board:

1. On the Generate Code page, in the Generate dialog box:
   - Set the Build type to Static Library.
   - Clear the Generate code only check box.
   - Set the Hardware Board to BeagleBone Black or ARM Cortex-A9 (QEMU).
2. If necessary, modify the settings for your board. To modify the settings, click More Settings, and then click Hardware.
3. To generate the library, click Generate.
4. Set up your PIL execution. Click Verify Code to open the Verify Code dialog box.
   
   Because the hardware board is not MATLAB Host Computer, the Verify Code dialog box is configured for PIL execution.
   
   In the Verify Code dialog box:
   - Enter the name of the test file to use for PIL execution.
   - Select Generated code.
5. To start the PIL execution, click Run Generated Code.
6. To stop the PIL execution, click Stop.
For another example of PIL verification, see the "Processor-in-the-Loop Verification of MATLAB Functions" page in the documentation of the Embedded Coder Support Package for ARM Cortex-A Processors. Install the support package to view the documentation.
Interactively Trace Between MATLAB Code and Generated C/C++ Code

This example shows how to trace between MATLAB source code and the generated C/C++ code. Tracing between source code and generated code helps you to:

• Understand how the code generator implemented your algorithm.
• Debug issues in the generated code.
• Evaluate the quality of the generated code.

If you have Embedded Coder and enable production of a code generation report with traceability, you can view MATLAB source code and generated C/C++ code next to each other. As you move your pointer over code, you can follow highlighted traces to the corresponding generated code or source MATLAB code.

Create the MATLAB Source Code

To illustrate interactive traceability, this example produces a report for generation of a C static library for a MATLAB function `lpsolve` that solves the linear program:

• maximize \( y = c^x \)
• subject to \( A^x \leq b \)
• where \( x \geq 0 \) and \( b \geq 0 \)

`lpsolve`

%Attempts to solve the linear program:
% maximize \( y = c^x \)
% subject to: \( A^x \leq b \),
% where \( x \geq 0 \) and \( b \geq 0 \)
% using the dictionary form of the simplex algorithm.
% c must be a double, real row vector.
% b must be a double, real column vector.
% A must be a double, real, non-empty matrix with
% size(A) = [length(b),length(c)].
% Compare to
% x = linprog(-c(:,),A,b,[],[],zeros(length(c),1))
% y = c*x
%
% Copyright 2011-2018 The MathWorks, Inc.

function [x,y] = lpsolve(c,A,b)
 %#codegen
 narginchk(3,3);
 m = int32(size(A,1));
 n = int32(size(A,2));
 if ~validInputs(c,A,b)
   % Something is wrong with the inputs. Return NaNs.
   x = nan(n,1);
   y = nan;
   return
 end
 cn = c;
 nIdx = 1:n; % indices of non-basic variables
 bIdx = n + (1:m); % indices of basic variables
 % Perform iterations.
 j = findPivotColumn(cn,nIdx);
 unbounded = false;
 while j > 0 && ~unbounded
   [i,r] = findPivotRow(j,A,b);
   if i == 0 || isinf(r)
     unbounded = true;
   else
     b(i) = r;
     % Take account of the variables entering and leaving the basis.
     entering = nIdx(j);
     leaving = bIdx(i);
     bIdx(i) = entering;
     nIdx(j) = leaving;
     [cn,A,b] = pivot(cn,A,b,i,j);
     j = findPivotColumn(cn,nIdx);
   end
 end
 % Construct the solution.
 if unbounded
   x = nan(n,1);
   y = inf;
 else
   x = zeros(n,1);
   y = 0;
 end
for k = 1:m
  j = bIdx(k);
  if j <= n
    x(j) = b(k);
    y = y + c(j)*x(j);
  end
end

%-------------------------------------------------------------------------------
function p = validInputs(c,A,b)
coder.inline('never');
% All inputs must be double.
p = isa(c,'double') && isa(A,'double') && isa(b,'double');
% All inputs must be real.
p = p && isreal(c) && isreal(A) && isreal(b);
% A must be a non-empty matrix.
p = p && ismatrix(A) && ~isempty(A);
% c must be a row-vector with length = size(A,2).
p = p && isrow(c) && size(c,2) == size(A,2);
% b must be a column-vector with length = size(A,1).
p = p && iscolumn(b) && size(b,1) == size(A,1);
% The elements of b must be non-negative.
p = p && all(b(:) >= 0);
%-------------------------------------------------------------------------------
function [c,A,b] = pivot(c,A,b,i,j)
% Pivot on element i,j.
coder.inline('never');
m = int32(size(A,1));
aij = A(i,j);
A(i,j) = 1;
A(i,:) = A(i,:)/aij;
for k = 1:m
  if k ~= i
    akj = A(k,j);
    A(k,j) = 0;
    A(k,:) = A(k,:) - akj*A(i,:);
    b(k) = b(k) - akj*b(i);
  end
end
cj = c(j);
c(j) = 0;
c = c - cj*A(i,:);

%-------------------------------------------------------------------------------
function j = findPivotColumn(c,idx)
% Find a suitable variable to enter the basis using the smallest
% subscript rule to prevent cycling.
coder.inline('never');
j = int32(0);
nc = int32(numel(c));
lastidx = int32(0);
for k = 1:nc
    if c(k) > 0 && (lastidx < 1 || idx(k) < lastidx)
        j = k;
        lastidx = idx(k);
    end
end

%-------------------------------------------------------------------------------
function [i,r] = findPivotRow(j,A,b)
% Find the pivot row in column j of A and also return r = b(i)/A(i,j).
coder.inline('never');
r = inf;
i = int32(0);
b = int32(numel(b));
for k = 1:nb
    if A(k,j) > 0
        rtmp = b(k)/A(k,j);
        if rtmp < r
            r = rtmp;
            i = k;
        end
    end
end

%-------------------------------------------------------------------------------

The example also uses a test function lpsolve_test that calls lpsolve with representative input values.
lpsolve_test

% Test function for lpsolve
%   Copyright 2011-2018 The MathWorks, Inc.

function lpsolve_test()
c = [2 3 1 1];
A = [2 3 1 -1;1 0 2 1;0 2 1 1];
b = [27;9;18];
[x,y] = lpsolve(c,A,b);
x % display x
y % display y

Copy lpsolve.m and lpsolve_test.m to a writable folder.

copyfile(fullfile(docroot, 'toolbox', 'ecoder', 'examples', 'lpsolve.m'))
copyfile(fullfile(docroot, 'toolbox', 'ecoder', 'examples', 'lpsolve_test.m'))

Prepare for Code Generation

Before you generate C/C++ code, it is a best practice to screen your MATLAB code for code generation readiness.

coder.screener('lpsolve')

The code generation readiness report indicates that lpsolve is suitable for code generation.

It is also a best practice to check for run-time issues by generating and testing a MEX function.

• To specify the types of the inputs arguments, pass representative input values to the codegen -args option. Alternatively, because you have a test function, you can use coder.getArgTypes to determine the types.
• To generate and test a MEX function, use the -test option.

c = [2 3 1 1];
A = [2 3 1 -1;1 0 2 1;0 2 1 1];
b = [27;9;18];
codegen lpsolve -args {c A b} -test lpsolve_test

Running test file: 'lpsolve_test' with MEX function 'lpsolve_mex'.

81-18
codegen successfully generates and runs the MEX function.

**Produce a Code Generation Report with Traceability**

To generate a report that has interactive traceability:

- Create a `coder.EmbeddedCodeConfig` object. The `EnableTraceability` property controls traceability. By default, the `EnableTraceability` property is `true`.
- Specify the types of the input arguments by passing representative input values to the `-args` option.
- Enable production of a code generation report by using the `-report` option.

```matlab
cfg = coder.config('lib', 'ecoder', true);
codegen -config cfg lpsolve -args {c A b} -report
```

**Access Trace Mode in the Report**

To open the code generation report, click **View report**.

In the code pane, you see `lpsolve.m`.

To enable tracing, on the **Report** tab, click **Trace Code**.
You see the MATLAB source code and the generated C code next to each other.

Trace Code

You can trace from the MATLAB code to the C code or from the C code to the MATLAB code. Traceable code is marked with blue on the side that you are tracing from and with orange on the side that you are tracing to. As you move your pointer over traceable code, the code is highlighted in purple and you see the traces to the corresponding code on the
other side. When you select highlighted code by clicking it, the code becomes yellow and you can see the traces even when you move your pointer away from the selection. The code remains selected until you press \texttt{Esc} or select different code. To change the side that you are tracing from, select code on the other side.

Explore tracing in the example report.

1. In the MATLAB code, point to the \texttt{while}-loop that starts at line 38 and scroll down until the entire \texttt{while}-loop is in view.

You see this symbol that tells you that the highlighted MATLAB code has one trace that is not in view.

You see the corresponding C code in a separate window in the C code pane.

2. In the C code pane, scroll down until you see the C code that corresponds to the \texttt{while} loop.
In the MATLAB code, move your pointer over different syntax elements in the while loop. Highlight variables, expressions, and code blocks.

When you move your pointer over expressions that are part of larger expressions, different shades of purple help you to find the relevant expression in the corresponding C code. For example, at line 43, pause over i.

In the MATLAB code, move your pointer back to the while-loop that starts at line 38. When the entire loop is highlighted in purple, select it by clicking. When you move your pointer outside of the trace, the yellow highlighting identifies the selected trace.

To clear the selection, press Esc or select different code.
View Multiple Traces

When code traces to more than one place in the corresponding source or generated code:

- If you pause over the code that you are tracing, at the top of the code pane, you see the number of traces.
- If some traces are not in view, you see a symbol that tells you how many traces are out of view.

- In the code pane, if you select the code that you want to trace, at the top of the code pane, you can select the trace that you want to see.

In the report for `lpsolve`, view multiple traces.

1  Pause over line 36.
   At the top of the code pane, you see that line 36 has two traces.

2  Select line 36.
   At the top of the code pane, you see the location of the first trace.

3  To list all traces, click the arrow to the right of the traces.

View Traces to Different Files

In the code generation report for `lpsolve`, all traces from the MATLAB code go to one C file `lpsolve.c`. If MATLAB code traces to multiple C files, above the C code, you see a symbol such as `†` that provides the number of additional files in which you can find a trace. If you click the symbol, you can select the file that you want to see. If you select the MATLAB code, then you can select the trace that you want to see.
Likewise, above the MATLAB source code, a symbol such as indicates that the highlighted C code traces to multiple MATLAB files.

**Switch the Locations of the Source and Generated Code**

1. To view lpsolve.c on the left side of the code pane, in the list of generated files, click lpsolve.c.

2. To view the MATLAB code on the left side of the code pane, click a MATLAB function, for example, lpsolve.

**Enable Code Tooltips and Links**

When you are not in trace mode:

- In the MATLAB code, if you point to a variable or expression, a tooltip provides information such as the type.
- In the C code, links go to other parts of the code such as type or function definitions.

When you are in trace mode, to enable MATLAB code tooltips and C code links, hold down **Ctrl**. MATLAB code tooltips are available only for a selected MATLAB function.

In the report for lpsolve, view type information for a variable.

1. In the **MATLAB Source** pane, select pivot.
2 In the code pane, hold down Ctrl and pause over the input argument i.

![Code pane with variable i](image)

**Note** On a Macintosh platform, use the Command key instead of Ctrl.

### Disable Traceability

To produce a code generation report that does not include traceability:

- In a `coder.EmbeddedCodeConfig` object, set the `EnableTraceability` property to `false`.
- In the MATLAB Coder app, set **Enable code traceability** to No.

Polyspace Verification of C/C++ Code Generated by MATLAB Coder

To check for run-time errors in C/C++ code generated from MATLAB code, you can use Polyspace Code Prover. To check for defects, you can use Polyspace Bug Finder. If you have Polyspace and Embedded Coder, Polyspace is integrated into the MATLAB Coder workflow.

- In the MATLAB Coder app, you can run Polyspace analysis without additional setup.
- At the command line, after code generation with `codegen`, you can run Polyspace analysis on the generated code by providing the code generation output folder to `pslinkrun`.

Run Polyspace Analysis in the MATLAB Coder App

1. Generate standalone C/C++ code (a static library, dynamically linked library, or executable program).
2. On the Generate Code page, click Polyspace.
4. Click Run.

The app logs the analysis output on the Polyspace Log tab and opens the Polyspace user interface.

Run Polyspace Analysis on Code Generated by codegen

1. Create a `pslinkoptions` object for verification of code generated by MATLAB Coder.
2. As needed, change object properties:
   - In the `ResultDir` property, specify the name of the folder for the Polyspace results.
   - In the `VerificationMode` property, specify the Polyspace verification product.
3. Run the verification by using `pslinkrun`. Provide the `pslinkoptions` object and the folder that contains the generated code.
4. To view verification results, open the Polyspace user interface.
For example, suppose that you generated a static library for the MATLAB function `myFunction` and that the code generation output folder is `codegen/lib/myFunction`. To run Polyspace Code Prover on the generated code, use this code:

```matlab
generate = pslinkoptions('codegen');
generate.ResultDir = 'polyspace';
generate.VerificationMode = 'CodeProver';
pslinkrun('-codegenfolder', 'codegen/lib/myFunction', generate);
polyspaceCodeProver('polyspace/myFunction.psprj');
```

You can also set the `VerificationMode` property to 'BugFinder' and view verification results by using `polyspaceBugFinder`.

**Review Analysis Results**

In the **Results List** pane of the Polyspace user interface, review the run-time checks. See whether you can trace the issues back to the original MATLAB code. See “Interactively Trace Between MATLAB Code and Generated C/C++ Code” on page 81-14.

For example, an operation in the C code might overflow because Polyspace assumes an unbounded range for a function input. Consider specifying a constraint on the input and reanalyzing the code with Polyspace. See “Run Polyspace on C/C++ Code Generated from MATLAB Code” (Polyspace Code Prover).
